Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles - Phase 2

Response to Comments for Joint Rulemaking
Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles - Phase 2

Response to Comments for Joint Rulemaking

Office of Transportation and Air Quality
U.S. Environmental Protection Agency

And

National Highway Traffic Safety Administration
U.S. Department of Transportation

EPA-420-R-16-901
August 2016
Introduction

On June 19, 2015, the Administrator of the U.S. Environmental Protection Agency (EPA) and the Secretary of the Department of Transportation (DOT) jointly signed a Notice of Proposed Rulemaking (NPRM) to propose a national program that would establish the next phase of greenhouse gas (GHG) emissions and fuel efficiency standards for medium- and heavy-duty vehicles. This “Phase 2 program” would significantly reduce carbon emissions and improve the fuel efficiency of heavy-duty vehicles, helping to address the challenges of global climate change and energy security. On July 13, 2015, the NPRM was published in the Federal Register, and following an extension, the public comment period closed on October 1, 2015. During this time EPA and the National Highway Traffic Safety Administration (NHTSA) held two public hearings, one in Chicago, IL on August 6, 2015 and one in Long Beach, CA on August 18, 2015. EPA and NHTSA later issued a Notice of Data Availability (NODA) on March 2, 2016 to provide an opportunity to comment on new information being made available by EPA and by NHTSA related to the proposed Phase 2 program. The comment period for the NODA closed on April 1, 2016. This joint Response to Comments (RTC) document addresses written comments and testimony received during both public comment periods. In the spirit of our commitment to meaningful collaboration with stakeholders and the public to identify and understand the opportunities and challenges involved with this next level of fuel-saving technology, we address late comments (i.e., comments received after the comment periods were closed) to the extent that they were received in time to include in this document.

We received over 230,000 comments written comments on the proposed Phase 2 rules. The comments and responses are organized by topic (see Table of Contents) to help the reader find comments and responses of interest. The general layout of each RTC subsection is organized such that excerpts of comments based on a particular topic are first provided, and then our responses to either individual excerpts or groups of comments represented by the excerpts follows. Whether responding to a single comment or a group, the agencies’ responses are separated from the comments with the following section header:

Response

The excerpts include either portions of a commenter’s submission on a particular topic, or the entirety of the commenter’s submission if the breadth of the comments were narrow enough. In general, we have associated comments with a specific commenter in responding to comments. However, due to the large number of comments that addressed similar issues, as well as the volume of the comments received, we do not claim to have identified for each response every comment or commenter addressed by the response. A complete list of organizations and individuals that provided comments is contained in this document below. This RTC addresses citizen comments that raised unique substantive issues. Tens of thousands of citizens also commented through mass e-mail campaigns; these comments are not included individually, but rather examples are provided.
Table of Contents

1 General Comments................................................................................................................1
  1.1 General Comments on the Proposed Phase 2 Program.................................................... 1
  1.2 Support for a National Program....................................................................................... 5
  1.3 EPA and NHTSA Statutory Authorities........................................................................... 6
    1.3.1 EPA Authority ....................................................................................................... 20
    1.3.2 NHTSA Authority ................................................................................................. 67
  1.4 General Compliance Provisions..................................................................................... 76
    1.4.1 Advanced Technology Credits and Multipliers ..................................................... 88
    1.4.2 Innovative and Off-Cycle Technologies................................................................. 119
    1.4.3 Selective enforcement audits and confirmatory testing........................................ 133
    1.4.4 Delegated assembly (dividing responsibility among manufacturers).................... 147
    1.4.5 Labeling ............................................................................................................... 172
    1.4.6 CBI and Compliance Data .................................................................................... 185
    1.4.7 General ABT issues .............................................................................................. 197
    1.4.8 Global Warming Potential Comments ................................................................ 211
  1.5 Lead Time .................................................................................................................... 216
  1.6 Alternative Refrigerants............................................................................................... 250
    1.6.1 Requests for Credit/Incentive for Alternative Refrigerants .................................... 250
    1.6.2 Requests for EPA Action on Status of Current or Alternative Refrigerant ............ 253
    1.6.3 Comments Relating to Alternative Refrigerants and Compliance with Leakage Standards .......................................................................................................................... 257
    1.6.4 Additional Issues.................................................................................................. 261
  1.7 General Comments on Regulatory Framework and Rule Principles ........................... 265
  1.8 Basing Standards on Life Cycle Analysis .................................................................... 283

2 Vehicle Simulation Model ................................................................................................298
  2.1 General Comments....................................................................................................... 298
  2.2 Proposed Modifications to GEM.................................................................................. 307
  2.3 Validation of GEM ....................................................................................................... 369
  2.4 Supplements to GEM Simulation............................................................................... 371
    2.4.1 Technology Test Procedures ............................................................................... 373
    2.4.2 Powertrain Testing ............................................................................................... 410
  2.5 Production Vehicle Testing for Comparison to GEM.................................................. 442
6.1 General Comments ..................................................................................................... 1102
  6.1.1 NOx from Idling Emissions .................................................................................. 1102
  6.1.2 Comments Generally Supporting Stronger Standards .......................................... 1103
  6.1.3 Other General Comments .................................................................................... 1107
  6.1.4 Framework: Duty Cycles ..................................................................................... 1117
  6.1.5 Framework: Regulatory Subcategories ................................................................. 1133
6.2 Vocational Vehicle Standards for CO2 and Fuel Consumption ................................. 1142
  6.2.1 Baselines ............................................................................................................. 1142
  6.2.2 Comments on the Standard-Setting Process ......................................................... 1146
  6.2.3 General Comments on Custom Chassis Standards ............................................... 1151
6.3 Projected Vocational Vehicle Technologies, Effectiveness, and Cost ....................... 1168
  6.3.1 General Comments about Vocational Technologies ............................................. 1168
  6.3.2 SI Vehicle Standards .......................................................................................... 1173
  6.3.3 Transmission Technologies .................................................................................. 1173
  6.3.4 Workday Idle Reduction Technologies ............................................................... 1201
  6.3.5 Lower Rolling Resistance Tires ............................................................................ 1219
  6.3.6 Electrification ...................................................................................................... 1227
  6.3.7 Tire Pressure Systems ......................................................................................... 1246
  6.3.8 Axle Technologies .............................................................................................. 1249
  6.3.9 Weight Reduction ............................................................................................... 1251
  6.3.10 Other Technologies .......................................................................................... 1261
6.4 Exemptions and Exclusions ....................................................................................... 1273
  6.4.1 Small Businesses and Small Volume Producers ................................................... 1273
  6.4.2 Off-Road/Low Speed Vehicles ......................................................................... 1296
6.5 Compliance Provisions and Flexibilities for Vocational Vehicle Standards .......... 1301
  6.5.1 Selection of Subcategory for Certification ......................................................... 1302
  6.5.2 Test Procedures .................................................................................................. 1309
6.6 HFC Leakage Standards for Vocational Vehicles ...................................................... 1310
  6.6.1 Feasibility of Applying HFC Leakage Technologies for Vocational Vehicles ... 1310
  6.6.2 HFC Compliance Provisions for Vocational Vehicles ......................................... 1312
  6.6.3 Program-Wide HFC Compliance Provisions ...................................................... 1313
7 Pickups and Vans ........................................................................................................ 1315
  7.1 General Comments .................................................................................................. 1315
  7.2 Proposed Pickup and Van Standards for CO2 and Fuel Consumption ................. 1315
11.2 Vehicle-Related Costs ................................................................. 1518
11.3 Changes in Fuel Consumption and Expenditures ...................... 1549
11.4 Maintenance Expenditures ....................................................... 1564
11.5 Analysis of the Rebound Effect .................................................. 1566
  11.5.1 General Rebound .............................................................. 1566
  11.5.2 Response to POP Diesel ..................................................... 1578
11.6 Impact on Class Shifting, Fleet Turnover, and Sales ................... 1582
  11.6.1 Impact on Class Shifting & Other Concerns ....................... 1582
  11.6.2 Impact on Fleet Turnover and Sales ..................................... 1587
11.7 Monetized GHG Impacts ............................................................ 1595
11.8 Monetized Non-GHG Health Impacts ........................................ 1658
11.9 Energy Security Impacts ............................................................ 1660
11.10 Other Impacts ............................................................................ 1669
11.11 Employment Impacts ............................................................... 1670
11.12 Cost of Ownership and Payback Analysis ................................. 1683
11.13 Safety Impacts ........................................................................... 1697
11.14 Consumer Impacts ................................................................. 1699
12 Natural Gas Vehicles and Engines ..................................................1713
  12.1 General Comments on Natural Gas ........................................... 1713
  12.2 Natural Gas Engine and Vehicle Technology ........................... 1721
    12.2.1 General Technology Comments ....................................... 1721
    12.2.2 Natural Gas Emission Control Measures ......................... 1726
    12.2.3 Crankcase ....................................................................... 1730
    12.2.4 Emerging Technologies/OBD .......................................... 1735
    12.2.5 Aerodynamic Performance of Natural Gas Vehicles .......... 1739
  12.3 GHG Lifecycle Analysis for Natural Gas Vehicles ...................... 1739
    12.3.1 Methane GWP .................................................................. 1739
  12.4 Other Lifecycle Comments ........................................................ 1744
  12.5 Projected Use of LNG and CNG .............................................. 1770
    12.5.1 Applying Standards to Natural Gas Vehicles ................... 1774
    12.5.2 Converters and Dual-Fuel Conversions ............................. 1776
13 Amendments to Phase 1 Standards ................................................ 1780
  13.1 General Comments ............................................................... 1780
  13.2 EPA Amendments ............................................................... 1780
13.2.1 Pickups and Vans ................................................................................................ 1780
13.2.2 Differentiating Spark-Ignition and Compression-Ignition Engines ............. 1781
13.2.3 Evaporative Emission Testing for LNG Vehicles ........................................ 1788
13.2.4 Additional LNG Technology Considerations .............................................. 1796
13.2.5 Stockpiling Provisions for Heavy-Duty Highway Engines ....................... 1800
13.2.6 Compliance and Other General Provisions ............................................. 1811
13.2.7 Compliance Provisions for Tires .............................................................. 1814
13.3 Other Compliance Provisions for NHTSA ..................................................... 1821
13.3.1 Standards and Credit Alignment ............................................................... 1821
14 Other Regulatory Provisions ........................................................................... 1822
14.1 General Comments ....................................................................................... 1822
14.2 Amendments Affecting Gliders and Glider Kits .......................................... 1823
14.3 Technical Amendments - Heavy-Duty Vehicles Other than GHG ................ 1886
14.3.1 Alternate Emission Standards for Specialty Heavy-Duty Vehicles ............ 1887
14.3.2 Chassis Certification of Class 4 Heavy-Duty Vehicles ................................ 1900
14.3.3 On-Board Diagnostics for Heavy-Duty Vehicles .................................. 1902
14.3.4 Nonconformance Penalties (NCPs) for Heavy-Duty Vehicles .................. 1908
14.3.5 Modifying Certified Vehicles for Competition ........................................ 1910
14.4 Additional Technical Amendments ............................................................. 1915
14.4.1 Miscellaneous Amendments to 40 CFR Parts 85, 86 and 600 ...................... 1915
14.4.2 Applying 40 CFR part 1068 to Heavy-Duty Highway Engines and Vehicles 1916
14.4.3 Applying 40 CFR part 1068 to Light-Duty Vehicles, Light-Duty Trucks, Chassis-certified Class 2B and 3 Heavy-Duty Vehicles and Highway Motorcycles .......... 1918
14.4.4 Amendments to General Compliance Provisions in 40 CFR part 1068 ........ 1920
14.4.5 Amendments to Light-Duty Greenhouse Gas Program Requirements .... 1926
14.4.6 Testing with Aftertreatment Devices Involving Infrequent Regeneration .... 1931
14.4.7 Additional Test Procedure Amendments .................................................. 1934
14.4.8 Amendments Related to Nonroad Diesel Engines in 40 CFR Part 1039 ........ 1939
14.4.9 Amendments Related to Marine Diesel Engines in 40 CFR part 1042 and 10431946
14.4.10 Amendments Related to Locomotives in 40 CFR Part 1033 ...................... 1950

Appendix A to Section 14 - Sensitivity Analysis of Glider Impacts ...................... 1960

15 Other Comments ............................................................................................. 1969
15.1 General Other Comments ............................................................................ 1969
15.2 Comments on International Harmonization................................................ 1971
15.3 NAS Recommendations ................................................................................ 1973

1 General Comments

1.1 General Comments on the Proposed Phase 2 Program

The following comments relate in general to the Notice of Proposed Rulemaking (NPRM). The comments in this chapter are not on any specific aspect of the proposed rule; rather, they are directed to the general substance of the proposal. Responses to more detailed comments on specific provisions of the proposal can be found in later chapters of this joint Response to Comments (RTC), as well as the FRM Preamble, and the Regulatory Impact Analysis (RIA). For more information on the proposed rule, see the Federal Register at 80 FR 40138, published on July 13, 2015. The public comments submitted on this rule can be viewed online at www.regulations.gov (the public docket for this rulemaking are docket number EPA-HQ-OAR-2014-0827 and NHTSA-2014-0132).

We received a large number of comments on the Phase 2 NPRM, and even in their general comments many stakeholders expressed concerns with very specific aspects of the program. In responding comments about the general substance of the program below, we have categorized these comments into four broad categories: comments that generally support the Phase 2 program, comments that support the goals of the Phase 2 program but with concerns about specific aspects of the proposal, comments that generally call for stronger standards, and comments that generally call for no regulation or that question the need for Phase 2 GHG/fuel efficiency standards. While some comments are applicable to more than one category, we considered each comment’s overall message in associating one commenter per category. Comments made on specific aspects of the Phase 2 program are responded to according to topic in the later chapters of this document.

Comments that Generally Call for No Regulation or Question the Need for Phase 2 GHG/Fuel Efficiency Standards 4
National Automobile Dealers Association (NADA)
North American Die Casting Association (NADCA)
Owner-Operator Independent Drivers Association (OOIDA)
Schneider National Inc.

Response:

The Phase 2 program builds on our commitment to robust collaboration with stakeholders and the public, following an expansive and thorough outreach effort in which the agencies gathered input, data and views from heavy-duty vehicle and engine manufacturers, technology suppliers, trucking fleets, truck drivers, dealerships, environmental organizations, and state agencies. We appreciate the time and effort taken by the commenters in developing these comments.

Many commenters generally supported the Phase 2 program or the goals of the proposal. The detailed comments on specific aspects of the proposal submitted by many commenters that supported overall program goals covered a range of positions – from support for standards that are less stringent than the proposed alternative (Alternative 3) to support for standards that are stronger than the more stringent alternative considered (Alternative 4). Similarly, we received general comments that call for a stronger program and those that call for no regulation or questions the need for further GHG/fuel efficiency reductions from the heavy-duty vehicle sector.

The agencies have revised the proposed standards and related requirements to address issues raised in these comments, resulting in an improved final program. While fundamentally similar to the proposed rules, the final program will achieve greater GHG and fuel consumption savings. Responding to the President’s Climate Action Plan and his February 18, 2014 directive, as well as our statutory obligations, the final Phase 2 program includes technology-advancing standards that will phase in over the long-term (through model year 2027) to result in an ambitious, yet achievable program that will significantly reduce GHG emissions and fuel consumption from new on-road medium- and heavy-duty vehicles. Phase 2 will maintain the underlying regulatory structure developed in the Phase 1 program, such as the general categorization of Heavy-Duty Vehicles HDVs (including vehicles considered Medium-Duty Vehicles or MDVs under NHTSA regulations) and the separate standards for vehicles and engines. The final standards are almost entirely performance based, allowing manufacturers to meet standards through a mix of different technologies at reasonable cost. As described in the Preamble, EPA and NHTSA believe the final standards best fulfill our respective statutory authorities when
considered in the context of available technology, feasible reductions of emissions and fuel consumption, costs, lead time, safety, and other relevant factors.

For responses to specific issues raised these comments, please see the separate chapters of this joint Response to Comment document.

1.2 Support for a National Program

Many commenters expressed support for a single, national set of standards, i.e., a program harmonized between the two agencies and across all 50 states. These commenters include:

- American Automotive Policy Council
- American Trucking Associations (ATA)
- California Trucking Association
- Caterpillar, Daimler, Navistar, PACCAR, and the Volvo Group
- Chemours Company FC, LLC
- Cummins, Inc
- Diesel Technology Forum
- Eaton Vehicle Group
- Electric Drive Transportation Association (EDTA)
- FCA US, LLC
- FedEx Corporation
- Ford Motor Company
- General Motors
- International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)
- Motor & Equipment Manufacturers Association (MEMA)
- North American Die Casting Association (NADCA)
- National Association of Manufacturers (NAM)
- Navistar, Inc.
- Nissan
- Truck & Engine Manufacturers Association (EMA)
- Truck Renting and Leasing Association
- Volvo Group
- Isuzu Motors Limited
- United Parcel Service (UPS)
- Walmart Transportation

Response:

Finalizing federal standards that would help manufacturers continue to build a single fleet of vehicles and engines is an important goal of the Phase 2 program. The agencies have made significant efforts to coordinate the Phase 2 standards between EPA and NHTSA and with the California Air Resources Board (CARB). The agencies have consulted frequently with CARB staff during the development of this rule, given California’s unique ability among the states to adopt their own GHG standards for on-highway engines and vehicles (assuming criteria of CAA section 209 (b) are satisfied). As discussed in the NPRM, the agencies’ technical staffs have shared information on technology cost, technology effectiveness, and feasibility with the CARB staff prior to the proposal. See 80 FR 40150. We also received information from CARB on these same topics. EPA and NHTSA have also shared preliminary results from several of our modeling exercises with CARB as we examined different potential levels of
stringency for the Phase 2 program. In addition, CARB staff and managers have also participated with EPA and NHTSA in meetings with many external stakeholders, in particular with vehicle OEMs and technology suppliers. We have also had additional discussions with CARB, as documented in the agencies’ dockets. Through this close coordination, the agencies are finalizing a Phase 2 program that will be fully aligned between EPA and NHTSA, while providing CARB with the opportunity to adopt a Phase 2 program that will allow manufacturers to continue to build a single fleet of vehicles and engines.

1.3 EPA and NHTSA Statutory Authorities

Organization: California Air Resources Board (CARB)

Legal Authority

Organization: Center for Biological Diversity

THE PROPOSED STANDARDS DO NOT MEET THE TECHNOLOGY-FORCING REQUIREMENTS OF THE GOVERNING STATUTES

The applicable statutes require that the Proposed Rule implement fuel efficiency standards that achieve the maximum feasible improvement in HD Vehicle fuel efficiency and are technology-forcing. The Proposed Rule fails to fulfill this mandate. [EPA-HQ-OAR-2014-0827-1460-A1 p.4]

Statutory Overview

The purposes of the Energy Policy Conversation Act (“EPCA”) are to decrease the nation’s dependence on foreign imports, to enhance national security and to achieve the efficient utilization of scarce resources. To achieve these goals, EPCA, as amended by the Energy Independence and Security Act of 2007 (“EISA”), expressly demands that NHTSA set maximum feasible fuel economy standards. In the case of HD Vehicles, Section 32902(k) of EPCA requires NHTSA to set standards and implement a HD Vehicle “fuel efficiency improvement program designed to achieve the maximum feasible improvement.” The requisite standards shall be “appropriate, cost-effective, and technologically feasible for commercial medium-and heavy-duty on-highway vehicles and work trucks.” In fulfilling its duties under Section 32902(a), NHTSA “cannot set fuel economy standards that are contrary to Congress’s purpose in enacting the EPCA – energy conservation,” it cannot act arbitrarily and capriciously; it cannot advance conclusions unsupported by the evidence; if it conducts cost-benefit analyses, it may not assign values of zero to benefits that can be ascertained within a range; and it cannot bias its cost-benefit analysis. Section 32902(k) imposes the same requirements. In addition, fuel efficiency standards under EPCA and EISA must be technology-forcing. [EPA-HQ-OAR-2014-0827-1460-A1 p.4]

While the Agencies may have discretion, as noted in the Proposed Rule, to balance the factors related to maximum feasible improvements and technology-forcing, this discretion is not unlimited. The Agencies may not make arbitrary and capricious determinations that ignore the statutory limits upon that
discretion. As discussed below, the Proposed Rule fails to achieve the statutory mandates of setting maximum feasible fuel efficiency improvements and of forcing technological innovation by purposefully limiting itself to the application of technology that is either commercially available today or mere steps from market-ready, by permitting manufacturers to exclude even some of this technology, and by failing to present an alternative that truly presents the “maximum feasible” emission reductions. The Agencies should revise the Proposed Rule and adopt standards that meet their respective statutory obligations. [EPA-HQ-OAR-2014-0827-1460-A1 p.5]

An Additional 30 Percent Fuel Savings and Greenhouse Gas Reduction is Possible Through Reasonable Technology Forcing and an Accelerated Implementation Schedule

The technologies upon which the Agencies based the proposed standards are largely already in use or else very close to market ready. Yet, as discussed above, by statute the Agencies must consider all innovative technologies as well. Doing so to the maximum reasonable level would bring additional significant benefits and remain feasible in both cost and manufacturing logistics. Furthermore, as the Agencies repeatedly acknowledge, there are substantial benefits to a faster implementation schedule: this is both feasible and necessary to comply with the statutory requirement for maximally feasible reductions. [EPA-HQ-OAR-2014-0827-1460-A1 p.6]

1. Additional Technology Options

In several instances, the Agencies present a “suite” of presently available and feasible technologies, but expressly do not require that each technology within the “suite” be applied. In other words, the Agencies make adoption of some proven, available, feasible and efficient technologies optional. However, in every instance where such “optional” technologies would add to a vehicle’s fuel efficiency, the failure to require their implementation constitutes a violation of the mandates of EISA to produce the “maximum feasible” fuel efficiency improvements. We urge the Agencies instead to adopt efficiency standards that include every one of the technologies now allocated to an optional technology “suite”, excepting only those that provide no additional benefit. [EPA-HQ-OAR-2014-0827-1460-A1 p.6]

The Proposed Rule represents an unreasonable balancing of factors related to technology-forcing. As noted above, the NHTSA may balance cost, appropriateness and technological feasibility when determining maximal feasible reductions under the EISA. Similarly, the EPA may balance a number of factors, also including cost and technological effectiveness. But here, the Phase 2 standards as proposed would result in not only zero net operating costs (in contrast to the Phase 1 rules), but would even result in net benefit to operators in the form of fuel savings. Though this seems laudable, these savings have come at a health and environmental cost that cannot be borne by U.S. citizens. Here, the benefit to truck operators is far greater than the technologically feasible reductions that would benefit public health and the environment, and consequently violate the statutory requirements. [EPA-HQ-OAR-2014-0827-1460-A1 p.6]

The Proposed Rule neglects a wide range of technologies that could significantly reduce fuel use and emissions. For instance, one analysis indicates that up to 30 percent greater reductions in emissions are technologically feasible in the timeframe of the Proposed Rule. The areas of the Proposed Rule that should be strengthened are briefly reviewed below. [EPA-HQ-OAR-2014-0827-1460-A1 p.6]

CONCLUSION
The Proposed Rule must be strengthened to fulfill the technology forcing nature of the Clean Air Act and to meet the requirement of maximal feasible reductions required by EPCA/EISA. Specifically, the Phase 2 standards should: (1) reflect all potential technologies; (2) assume more aggressive penetration rates and reduction potential; and (3) occur over a shorter implementation period. Furthermore, we urge the EPA to revisit the treatment of methane emissions from natural gas engines and vehicles to ensure that the climate benefits of the Phase 2 standards are not compromised. Finally, the Center requests that EPA require adequate after-treatment of APU exhaust to ensure that nationwide particulate matter emissions do not increase as a result of the Phase 2 standards. [EPA-HQ-OAR-2014-0827-1460-A1 p.21]

13 Center for Biological Diversity v. NHTSA, 538 F.3d 1172, 1182 (9th Cir. 2007).

16 Id.

17 Center for Biological Diversity v. NHTSA, supra note 13, 538 F.3d at 1197, 1200, and passim.

18 EPCA and EISA are meant to encourage technological innovation in the field, not simply promote the wider adoption of existing technologies. See, e.g., Center for Auto Safety v. Thomas, 847 F.2d 843, 847 (D.C. Cir. 1988) (overruled on other grounds) (“[t]he experience of a decade leaves little doubt that the congressional scheme in fact induced manufacturers to achieve major technological breakthroughs as they advanced towards the mandated goal”); Green Mt. Chrysler Plymouth Dodge Jeep v. Crombie, 508 F. Supp. 2d 295, 358-359 (D. Vt. 2007) (discussing technology-forcing character of EPCA and the use of increased fuel efficiency to augment performance rather than mileage); Kennecott Greens Creek Min. Co. v. Mine Safety and Health Admin., 476 F.3d 946, 957 (D.C. Cir. 2007) (“when a statute is technology forcing, the agency can impose a standard which only the most technologically advanced plants in an industry have been able to achieve – even if only in some of their operations some of the time”). The Clean Air Act is similarly technology-forcing. Legislative history indicates that the primary purpose of the Act was not “to be limited by what is or appears to be technologically or economically feasible,” which may mean that “industries will be asked to do what seems impossible at the present time.” 116 Cong. Rec. 32901-32902 (1970), Legislative History of the Clean Air Amendments of 1970 (Committee Print compiled for the Senate Committee on Public Works by the Library of Congress), Ser. No. 93-18, p. 227 (1974); see also Whitman v. American Trucking Association, 531 U.S. 457, 491 (2001).

Organization: National Automobile Dealers Association (NADA)

NON-REGULATORY STRATEGIES
In its 2014 report, the NAS discussed numerous non-regulatory approaches to increasing FE, including comprehensive driver training, the use of higher productivity vehicles (e.g., longer combinations), congestion mitigation, more efficient vehicle deployment and routing, and rigorous maintenance practices. NADA/ATD recognizes the limited authority EPA and NHTSA have to regulate vehicles in-use. Nonetheless, EPA and NHTSA are uniquely situated to partner with key government, industry and other interested stakeholders to promote non-regulatory but effective FE improvement strategies. [EPA-HQ-OAR-2014-0827-1309-A1 p.12]

**Organization:** North American Die Casting Association (NADCA)

**Nationwide Standard as a Ceiling, not Floor**

Regardless of whether regulators move forward with Phase II, manufacturers and consumers need a single nationwide standard. This applies not only to overall efficiency reduction targets but also to types of permissible vehicles and weight loads transported across state lines. Manufacturers and shippers face major hurdles meeting the regulations of various states, often causing transportation delays, rerouting, and confusion. [EPA-HQ-OAR-2014-0827-1283-A1 p.2]

In this instance, we strongly encourage regulators to establish these rules as a ceiling rather than a floor for states to follow. Manufacturers are concerned certain states may take steps to go beyond the federal rule and create more stringent regulations. This not only creates significant confusion throughout the industry, it effectively forces manufacturers to go beyond federal guidelines, particularly in the case of a state as large and economically significant as California. It is simply not feasible to expect manufacturers to invest heavily to meet the federal standard only to have the bar moved again by each state. [EPA-HQ-OAR-2014-0827-1283-A1 p.2]

However, should the Administration move forward with the Phase II standards, we encourage regulators to adopt a nationwide ceiling with achievable standards rejecting Alternative 4. [EPA-HQ-OAR-2014-0827-1283-A1 p.3]

**Organization:** Plant Oil Powered Diesel Fuel Systems

The Truck Rule 2 is inconsistent with law; both the Congressional intent underlying the truck fuel efficiency statute, 49 U.S.C. § 32902(k) (‘Truck Rule statute’), and the mandate of the Supreme Court to ‘take steps to slow or reduce [global warming].’ Massachusetts v. EPA, 549 U.S. 497, 525 (2007) (emphasis supplied) (interpreting Clean Air Act sections 202(a)(1) and (a)(2), 42 U.S.C. §§ 7521(a)(1) and (a)(2)). A way to make them consistent with law, and, if the two agencies so desired, although they are not required to, to harmonize them, would be to define 'fuel' as 'fossil fuel.’ The two agencies have not considered this solution, even though it would simply and elegantly address the putative statutory purposes in far more effective manner than does the proposed Truck Rule 2. [EPA-HQ-OAR-2014-0827-1125-A1 p.3]

If the two agencies do not adopt this definitional change, but adhere, instead, to the proposed Truck Rule 2, then this Rule will automatically disqualify a new engine fueled by 100 percent ordinary plant oil from ever winning the two agencies' certification for sale in the United States. This anomaly is due to the Truck Rule 2’s calculation of both GHG emissions and fuel consumption as an incorrect surrogate for 'fuel efficiency' based solely on tailpipe emissions. For the reason stated below, having to do with the composition of plant oil, the proposed Truck Rule 2's utilizing tailpipe emissions as the sole determinant of 'fuel efficiency' and GHG emissions unduly penalizes a plant oil-enabled engine; it
would pass either if the two agencies defined 'fuel' to be 'fossil fuel' or if this Rule were changed to adhere, as POP Diesel points out below, to the lawfully mandated measurement of 'fuel efficiency' as energy input to the engine (instead of fuel consumed) per unit of work performed and greenhouse gas emissions as net life cycle emissions (instead of exclusively tailpipe emissions). [EPA-HQ-OAR-2014-0827-1125-A1 p.3]

Since the two agencies have approved of the Clean Air Act criteria emissions from select, retrofitted plant oil-enabled engines' and EPA has approved of beneficial 100 percent plant oil from the inedible fruit seeds of the jatropha tree's supplying these engines, this prejudice that the Truck Rule 2 wreaks on a new POP Diesel-equipped engine prevents 100 percent plant oil fuel from ever coming on to the market in new engines, without the two agencies' adopting either a waiver or variance from the proposed Standards for such engines. Since the economics of generating a supply of jatropha plant oil do not lend themselves to the high cost of POP Diesel's retrofitting older engines that are not subject to the Truck Rule 2 or its predecessor Truck Rule 1, which took effect in 2011, the viability of this economically and environmentally-beneficial fuel's coming on to the market in more than just esoteric applications depends on introduction, following the two agencies' certification, of new engines equipped from the factory to run on this fuel. [EPA-HQ-OAR-2014-0827-1125-A1 p.4]

A. The Fuel Efficiency Standards are inconsistent with law because they measure fuel consumption, rather than fuel efficiency, and thereby are inconsistent with the plain meaning of the statutory law codified at 49 U.S.C. § 32902(k) and Congressional intent evident therein. [EPA-HQ-OAR-2014-0827-1125-A1 p.4]

B. The GHG Standards are inconsistent with the law laid down by the U.S. Supreme Court in Massachusetts v. EPA that following an endangerment finding, which the courts have upheld, EPA must 'take steps to slow or reduce [global warming].' 549 U.S. at 525 (Emphasis supplied). [EPA-HQ-OAR-2014-0827-1125-A1 p.4]

1. They measure emissions only coming from the tailpipe, rather than net, life cycle greenhouse gas emissions, which is the only way to calibrate penalties and rewards so as to bring about effective change in product offerings and consumer choice in the marketplace. [EPA-HQ-OAR-2014-0827-1125-A1 p.4]

C. Although the two agencies are not under any obligation to harmonize the GHG Emissions and Fuel Efficiency Standards, the two agencies have not considered crafting a viable, unified regulation that would be consistent with the Congressional intent underlying both the GHG Emissions and Fuel Efficiency Standards: to define 'fuel' as the quantity of fossil fuel supplying an engine, according to its carbon content, for the purposes of calculating both fuel efficiency and GHG emissions. Since the statutes involved do not define 'fuel,' the two agencies have the discretion to utilize any definition that is 'reasonable.' Chevron, USA, Inc. v. Natural Resources Defense Council, 467 U.S. 837 (1984). Defining 'fuel' as 'fossil fuel' would satisfy Congressional intent by proportionally penalizing those engines that consume more fossil fuel than others, and within the realm of fossil fuels, penalizing a fossil fuel such as petroleum that has a higher mole weight of carbon than does another fossil fuel, such as natural gas. Thus, NHTSA is in error in believing that converting tailpipe carbon emissions into fuel consumption is 'necessarily' the only way to gauge 'fuel efficiency' and equating tailpipe emissions with the sum total of GHG emissions the only way to harmonize the two sets of Standards. Proposed Truck Rule 2, 80 Fed. Reg. 40137, 40159. EPA's taking the additional step of basing the merit determination for an engine under the GHG Emissions Standards fully according to the net life cycle greenhouse gas emissions of the fuel powering the engine would bring these Standards into full compliance with the Supreme Court's mandate. [EPA-HQ-OAR-2014-0827-1125-A1 p.4-5]
A. The Fuel Efficiency Standards Are Inconsistent with Law

1. Fuel Efficiency Standards' Fail to Abide by the Plain Meaning of Fuel 'Efficiency'

The Tailpipe Rule is the Truck Rule 2's moniker for measuring tailpipe carbon emissions as the sum total of engine and vehicle 'greenhouse gas emissions' and converting these carbon emissions into fuel consumed in erroneous satisfaction of Congress's 'fuel efficiency' mandate. The Tailpipe Rule is contrary to the plain meaning of the term 'fuel efficiency' used in statute codified in 42 U.S.C. § 32902(k)(2).

Dictionaries customarily define 'efficiency' to mean a measurement of the energy input to, rather than the fuel consumed by, a machine or engine to perform a unit of work or travel a certain distance. For example, efficiency is:

3. Efficient operation as measured by a comparison of actual results with those that could be achieved with the same expenditure of energy: as [EPA-HQ-OAR-2014-0827-1125-A1 p.6]

a. the ratio of the useful energy delivered by a dynamic system (as a machine, engine, or motor) to the energy supplied to it over the same period or cycle of operation. [EPA-HQ-OAR-2014-0827-1125-A1 p.6]

the ratio of the useful work performed by a machine or in a process to the total energy expended or heat taken in.

3. the ratio of the work done or energy developed by a machine, engine, etc., to the energy supplied to it, usually expressed as a percentage.

2b. The ratio of the energy delivered by a machine to the energy supplied for its operation.

In sum, all dictionaries define the word 'efficiency' to be energy input to an engine per unit of work performed, not fuel consumed. That the Fuel Efficiency Standards fail to define 'fuel efficiency' by its only common definition defies the plain meaning of the statute. [EPA-HQ-OAR-2014-0827-1125-A1 p.7]

2. The Fuel Efficiency Standards Fail to Give Meaning to the Statutory Term 'Fuel Economy'; As a Matter of Truck Statutory Construction, the Only Feasible Meaning with Respect to Trucks Is 'Fuel Efficiency' (i.e., Energy Input to the Engine)
To consider the two agencies' statutory basis for anchoring the two sets of Standards on tailpipe emissions, because the preamble to the proposed Truck Rule 2 does not go into as much detail, POP Diesel refers to excerpts from the preamble to the Final Rule for these Standards that took effect in 2011 ('Final Truck Rule 1'), on which the proposed Truck Rule 2 is based. These excerpts appear as Exhibit 4 [exhibit 4 can be found on p.25 of docket number EPA-HQ-OAR-2014-0827-1125-A1].[EPA-HQ-OAR-2014-0827-1125-A1 p.7]

As a matter of statutory construction, POP Diesel agrees with NHTSA that Congress has expressly defined 'fuel economy' with regards to light duty vehicles to mean 'miles per gallon,' but that this metric is unsuitable for the commercial trucking sector because of the substantial and variable weight that trucks haul over distance. Final Truck Rule 1, 76 Fed. Reg. 57,106, 57,133 / 1-2 (Sept. 15, 2011). See, e.g., 49 U.S.C. § 32912(b) (authorizing penalties on car manufacturers per 0.1 mile-per-gallon excess). [EPA-HQ-OAR-2014-0827-1125-A1 p.7]

However, NHTSA's selection of 'fuel consumption' to govern the Truck Rule 2, instead of the measure of 'fuel efficiency' that accords with its plain, dictionary meaning,' fails to give any meaning in the Truck Rule 2 to the term 'fuel economy' that Congress included in a subsidiary clause in 49 U.S.C. § 32902(k)(2), 49 U.S.C. § 32902(k)(2) ('and [DOT and EPA] shall adopt and implement ... [truck] fuel economy standards'). Since Congress is presumed to have intended to give meaning to every word and phrase it includes in statute, the failure by NHTSA's adoption of a 'fuel consumption' metric to give any meaning to the term 'fuel economy,' as that term is stated in Congress's directive for NHTSA's development of truck 'fuel efficiency' standards,' raises a further question about the validity of the 'fuel consumption' metric itself. [EPA-HQ-OAR-2014-0827-1125-A1 p.7]

POP Diesel agrees with NHTSA's position that there is and must be a difference between 'fuel economy' and 'fuel consumption' with regards to trucks and the Truck Rule 2. As NHTSA stated, 'the [heavy duty] program is built around a fuel consumption metric,' versus a 'fuel economy' metric. 76 Fed. Reg. at 57,133 / 1. [EPA-HQ-OAR-2014-0827-1125-A1 p.8]

Since, as NHTSA stated, 'fuel economy' does not mean 'fuel consumption' with regards to the Truck Rule statute, one must give a different meaning to 'fuel economy' in this context. In conclusion, the plain, dictionary meaning of 'fuel efficiency' set forth above means that Congress must have intended both 'fuel efficiency' and the subsidiary term 'fuel economy' stated in 42 U.S.C. § 32909(k)(2) to mean, with respect to trucks (and not light duty vehicles subject to 42 U.S.C. § 32912(b)), the exact same thing: fuel energy supplied to the engine per unit of work performed by the engine, and not fuel consumed by the engine. [EPA-HQ-OAR-2014-0827-1125-A1 p.8]

3. The Legislative History Supports the View That the Fuel Efficiency and Greenhouse Gas Emissions Standards Need Not Both Turn on the Same Measure of Tailpipe Emissions

Recapping, the Tailpipe Rule's measure of 'fuel efficiency' by the rate of carbon coming out the tailpipe is contrary to the plain meaning of the term 'fuel efficiency' used in Congress's mandate to NHTSA, codified in 49 U.S.C. § 32902(k)(2), to adopt a 'commercial [] truck fuel efficiency program' that 'achieve[s] the maximum feasible improvement.' POP Diesel submits that the term 'fuel efficiency' means the amount of fuel energy going into a truck engine per unit of work performed, not the amount of carbon emissions coming out the tailpipe, which the Fuel Efficiency Standards convert to a measure of fuel consumption. [EPA-HQ-OAR-2014-0827-1125-A1 p.8]

The legislative commentary, from the Senate debate, on adoption of the provision now codified as 49 U.S.C. § 32902(k)(2) is included in the Senate Congressional Record for December 13, 2007, at pages
S15385-S15389 and S15421-S15432, attached hereto as Exhibit 5 [exhibit 5 can be found on p.34 of docket number EPA-HQ-OAR-2014-0827-1125-A1]. Senator Diane Feinstein's unopposed comments therein support POP Diesel's position that Congress did not intend that the Fuel Efficiency and the Greenhouse Gas Standards rely on the same measure of tailpipe emissions. [EPA-HQ-OAR-2014-0827-1125-A1 p.8]

While agreeing with Senators Carl Levin and Daniel Inouye that there was no reason why the two sets of standards could not, generally speaking, be 'consistent' with each other, Senator Feinstein stated, at page S15386, 'Congress resisted all efforts to add legislative language requiring 'harmonization' of the[ ] EPA and NHTSA standards.' Exhibit 5. On information and belief, Sen. Feinstein made this statement to preserve California's life cycle greenhouse gas emissions standards ('the California standards') that were then under development or in effect. These were different from fuel efficiency standards and were more stringent than the tailpipe measurement of GHG emissions included in the subsequent federal Truck Rule 1 adopted in 2011. [EPA-HQ-OAR-2014-0827-1125-A1 p.8-9]

A federal court in California later struck down the California standards as being violative of the Constitution's Commerce Clause because, measuring and comparing the entire life cycle emissions of different fuels, they penalized, for instance, biodiesel made from soy that came all the way from the Midwest, as compared to biodiesel that came from soy grown locally in California. As a result of this decision, California later abandoned its net life cycle greenhouse gas emissions standards and for the sake of nationwide conformity, made them identical to the federal Truck Rule's Tailpipe Rule that forms the heart of the Truck Rule 1 and proposed Truck Rule 2. [EPA-HQ-OAR-2014-0827-1125-A1 p.9]

The point that Sen. Feinstein was making in the Senate floor debate was that federal greenhouse emissions standards need not be identical to federal fuel efficiency standards because Congress resisted including language that would have made them so. Even so, EPA and NHTSA went ahead made them identical by using the measure of tailpipe carbon emissions as an (incorrect) surrogate for 'fuel efficiency' and (incomplete) surrogate for 'greenhouse gas emissions.' POP Diesel suggests in part C below a simple way that the two sets of standards could be harmonized in keeping with the statutory purposes. [EPA-HQ-OAR-2014-0827-1125-A1 p.9]

B. The Greenhouse Gas Emissions Standards Are Inconsistent with Law

1. The GHG Standards Are Legally Inadequate for Measuring Only Tailpipe Emissions, and Not Net Life Cycle Emissions

The U.S. Court of Appeals for the D.C. Circuit determined in Center for Biological Diversity v. EPA, a 2013 decision, that EPA was not exempt from basing its penalty and merits assessments with respect to stationary source GHG emissions on an assessment of full life cycle emissions. Although the Court has not had occasion to extend this holding to 42 U.S.C. §§ 7521(a)(1) and (a)(2)) requiring Greenhouse Gas Emissions Standards for trucks, logically, the Clean Air Act should compel assessment of net life cycle greenhouse gas emissions in every instance, since that is the only way to penalize and reward engine technologies and the fuels they enable so as to cause market players to make effective decisions. [EPA-HQ-OAR-2014-0827-1125-A1 p.9]

For instance, a study conducted by the National Renewable Energy Laboratory and a literature review commissioned by EPA both concluded that 100% plant oil embodies approximately half the energy in its manufacture, including planting the oil-bearing plants, harvesting, extracting the oil, and in transport, as does its biodiesel-processed derivative. Exhibits 6 and 7 [exhibit 6 can be found on p.41 and exhibit 7 can be found on p.44 of docket number EPA-HQ-OAR-2014-0827-1125-A1]. The process to make
HEFA's out of plant oil is similarly energy intensive: hydro-processing plant oil and then running this through a petroleum refinery. Therefore, per unit of fuel used, plant oil has far superior greenhouse gas-mitigating potential than do biodiesel or HEFA's. Yet the Renewable Fuel Standard (RFS), as EPA has implemented it, is only concerned with life cycle greenhouse gas emissions insofar as a fuel crosses either the 20% threshold in GHG reduction, compared to the petroleum base, to qualify as a 'renewable fuel' or the 50% threshold GHG reduction to qualify as an 'advanced biofuel.' EPA has not yet factored into the Renewable Fuel Standard any life cycle analysis that would differentiate in the award of tradable credits as between fuels passing either of these thresholds that have markedly different global warming-mitigation value. Since EPA has already determined that biodiesel and HEFA's qualify as 'advanced biofuels,' the RFS, as presently constructed, would not award the use of ordinary plant oil any more tradable credits per gallon than EPA has already awarded biodiesel or HEFA's, were EPA to approve POP Diesel's pending petitions for a pathway for tradable RFS credits for ordinary jatropha plant oil used as fuel. POP Diesel's petitions to EPA to award ordinary plant oil higher or double the tradeable credits of biodiesel have been pending since February 2012, July 2012 and May 2014. [EPA-HQ-OAR-2014-0827-1125-A1 p.9-10]

A POP Diesel-equipped new engine running on 100% plant oil except for the brief startup and shutdown periods on petroleum diesel magnifies the superior global warming-mitigation value of ordinary plant oil fuel because, in comparison, biodiesel and HEFA's ordinarily blend in subordination to petroleum diesel. Nationwide standards adopted by the Petroleum Products Committee of ASTM International and incorporated by law in most states limit biodiesel for most applications, including on-highway use, to at most a 5% to 20% blend, with the remainder being 80% to 95% petroleum diesel. While ASTM Standard Specification D-975 no longer distinguishes between the source of the fuel, whether petroleum hydrocarbons or plant oil hydrocarbons turned into HEFA's, as a practical matter, the 80% to 95% balance of 5% to 20% biodiesel or HEFA's will be petroleum, and not a processed derivative of plant oil.' Therefore, these other diesel engine biofuels, while having inferior greenhouse gas-mitigating value, do not run at close to the 100% concentration that POP Diesel Fuel comprised of 100% jatropha plant oil operates at in a POP Diesel-equipped engine. [EPA-HQ-OAR-2014-0827-1125-A1 p.10]

Once EPA acts on POP Diesel's petitions for a pathway to receive tradable credits under the Renewable Fuel Standard for jatropha plant oil, POP Diesel will be disadvantaged in comparison to these other derivative fuels from plant oil, unless EPA concurrently proposes a level of credits commensurate with plant oil's superior net life cycle emissions value, in comparison to biodiesel's and HEFA's'. Given the need for modest expenditure of an additional $1,500 to $3,000 per new semi truck engine specially equipped to run from the factory on this fuel with modified fuel tank, heaters and valve set comprising the patented and EPA- and NHTSA-approved POP Diesel Fuel System, there would not be any governmental incentive for private investment to finance POP Diesel's business, and the broader distribution and sale of its global warming-preferred fuel, unless EPA simultaneously awards tradable credits per gallon of 100% jatropha plant oil worth well more than those for the more highly processed and energy intensive fuels deriving from this oil. Without these correspondingly more valuable tradable credits per volume equivalent of POP Diesel Fuel, private financiers may conclude to eschew POP Diesel's products in favor of the alternatives which are not as beneficial to the cause of fighting global warming. [EPA-HQ-OAR-2014-0827-1125-A1 p.10-11]

While the proposed Truck Rule 2 relies without change on the Truck Rule 1's assessment of different alternative fuels and their corresponding engine technologies, this assessment, on which basis EPA decides to focus on solely tailpipe emissions in measuring GHG emissions, is more deeply flawed, given the passage of time, than it was at the time of the 2011 publication of the Truck Rule 1. Regardless of the fact that the majority of the electricity generated in the United States continues to
derive from the combustion of fossil fuels, battery-powered electric engines are unsuitable for the trucking market because they cannot produce the torque necessary. There are no hydrogen-powered trucks on the market, and none planned, as far as POP Diesel is aware. As set forth in the news release that is Exhibit 8 [exhibit 8 can be found on p.49 of docket number EPA-HQ-OAR-2014-0827-1125-A1], the two semi truck engine manufacturers which had started to develop such new engines to run on natural gas halted this development in 2014. Since the proposed Truck Rule 2 disqualifies an engine from certification running on 100% plant oil, the only kind of engine left for the trucking market is a petroleum diesel engine certified to run on 5% to 20% biodiesel, which will not suffice to satisfy EPA's mandate to 'slow or reduce' global warming from trucks, since these trucks will continue to combust 80% to 95% fossil fuel petroleum. [EPA-HQ-OAR-2014-0827-1125-A1 p.11]

As is set forth in comments submitted to the proposed Truck Rule 1 docket, Exhibit 9 (page 16-155 therein) [exhibit 9 can be found on p.52 of docket number EPA-HQ-OAR-2014-0827-1125-A1], the California Air Resources Board has already done significant work to determine and compare life cycle GHG emissions from different engine-enabled fuels. This approach is very feasible. [EPA-HQ-OAR-2014-0827-1125-A1 p.11]

If they want to, the two agencies can achieve 'harmonization' of the Fuel Efficiency and Greenhouse Gas Emissions Standards in the following way, fully in keeping with the two sets of statutory mandates, as interpreted by the Supreme Court in Massachusetts v. EPA: [EPA-HQ-OAR-2014-0827-1125-A1 p.12]

1. Define 'fuel' as 'fossil fuel.' ('Fuel' is not defined in the statute; therefore, the agencies can use any 'reasonable' definition, according the Supreme Court case Chevron v. Natural Resources Defense Council., 467 U.S. 837 ). [EPA-HQ-OAR-2014-0827-1125-A1 p.13]

Therefore, by definition, those engines that have less fossil fuel going into them will have better 'fuel efficiency' and also lower net, life cycle greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1125-A1 p.13]

Since POP Diesel expects that by the time of publication of the final Truck Rule 2, it will have an agreement with an original diesel engine manufacturer to manufacture POP Diesel-equipped engines for the medium- and heavy-duty market for sale ready from the factory to run on 100% jatropha plant oil, POP Diesel would like to be able to introduce these engines to the diesel engine U.S. market. However, since the existing Truck Rule 1 and Truck Rule 2, as presently written, would not permit such a new engine to win certification for the reasons stated above, there is no point in POP Diesel's even submitting such an engine for certification testing. POP Diesel prays that if the two agencies do not agree in full with POP Diesel's comments and amend the proposed Truck Rule 2 accordingly, they will grant it such relief as will allow its engines fairly to become certification on the merits of their true fuel efficiency and net life cycle GHG emissions performance, so that it will be able to sell its engines in the United States market. [EPA-HQ-OAR-2014-0827-1125-A1 p.14]

[The following comments are from a supplemental comment with a correction to the original comments in docket number EPA-HQ-OAR-2014-0827-1467-A2]
I write on behalf of the above-named corporation, which goes by the short name POP Diesel, to make one correction and amplify one point for your consideration in addition to the comments submitted on September 11, 2015 (“Comments”). These supplemental and amended comments give details on and concern matters that your two agencies have not heretofore considered. Because of the novelty and profundity of its Comments, POP Diesel had been unable to formulate these details by the deadline of its September 11 submission. Therefore, I respectfully request that the agencies give this statement full consideration at this time. [EPA-HQ-OAR-2014-0827-1467-A2 p.1]

The amplification is to Part IV, Section (C), Point (1) of the Comments, as to the details of how POP Diesel proposes that the agencies measure fossil fuel going into a truck engine. The Comments and Exhibit 3 thereto explained that a medium- or heavy-duty compression ignition engine demands a quantity of energy input to it from the fuel according to the throttle position commanded by the operator. The quantity of fuel that the engine consumes at any particular throttle position will vary according to the fuel’s energy or heat content. [EPA-HQ-OAR-2014-0827-1467-A2 p.2-3]

The measurement of “fuel efficiency” by fossil fuel going into an engine for the purpose of final Standards should be determined by the carbon content, or carbon as a fraction of the molecular weight, per unit of energy of the fossil fuel. Fuels such as jatropha plant oil which do not derive from fossilized matter should count as contributing zero energy in the “fuel efficiency” calculation of total energy consumed per unit of work performed under the final Standards for the portion of an emissions test cycle in which the engine runs on the non-fossil fuel. [EPA-HQ-OAR-2014-0827-1467-A2 p.3]

In this way, engines that consume a fossil fuel that has a higher carbon content per unit of the fuel’s energy, such as petroleum, will have worse “fuel efficiency” than fossil fuels with lower carbon content, such as natural gas. In addition, non-fossil fuel jatropha plant oil, run in a POP Diesel-equipped engine, would not contribute any fossil fuel energy consumed towards the calculation of the engine’s “fuel efficiency.” The agencies would have to establish milestone measurements of an engine’s energy efficiency, its efficiency in consuming energy, corresponding to the brake power of the engine, to be able to ratchet down over a period of years the amount of energy consumed per unit of power generated, thereby improving “fuel efficiency” of any particular power-output engine. [EPA-HQ-OAR-2014-0827-1467-A2 p.3]

In the alternative, the agencies may choose to not ratchet down “fuel efficiency” of particular power-output engines, but instead, to calculate and ratchet down the manufacturer’s fleet average of “fuel efficiency” and pursuant to Point (2) of Part IV, Section C of the Comments, net life cycle greenhouse gas emissions, thereby encouraging engine manufacturers to include engines that run on non-fossil fuels within their portfolio of engines certified and sold to the market. The price of the non-fossil fuel may then play a part in determining market adoption of the engine powered in part or all by non-fossil fuel. If EPA changes the proposed Standards to not automatically disqualify a POP Diesel-equipped engine from ever winning certification running on 100 percent jatropha plant oil, POP Diesel will be able to sell 100 percent jatropha plant oil in the United States at a fifty (50) cent per gallon discount below petroleum diesel, even at today’s low petroleum prices and taking into account the engine’s consumption of 10 percent more plant oil to perform the same amount of work as it would running on petroleum diesel fuel. [EPA-HQ-OAR-2014-0827-1467-A2 p.3-4]

1 Although EPA grants formal certification that emissions are compliant with the Clean Air Act, NHTSA must give its approval as part of the certification process.
2 A POP Diesel-equipped engine's first such approval, which took place in July 2013, is listed in the EPA spreadsheet excerpted as Exhibit 1, which is available at http://www.epa.gov/otaq/consumer/fuels/altfuels/altfuels.htm (scroll down the page to find the link titled 'Outside Useful Life Clean Alternative Fuel Conversion Systems') (last checked Sept. 8, 2015); Exhibit 1 can be found on p.15 of docket number EPA-HQ-OAR-2014-0827-1125-A1

3 This mandate is to adopt a 'commercial [] truck fuel efficiency program' that 'achieve[s] the maximum feasible improvement.' 49 U.S.C. § 32902(k)(2).

4 Energy input to an engine, rather than fuel consumed by the engine, per unit of work performed.

5 42 U.S.C. § 32902(k)(2).

6 As there are not any Committee reports on this legislative provision in either Chamber, this Senate legislative commentary from the Congressional Record constitutes the complete legislative history of the truck fuel efficiency mandate, 42 U.S.C. § 32902(k)(2). Apparently, this provision was never subject to any hearings, but found its way into the final floor version that the Senate, and then passed the House without comment from the House floor.

7 POP Diesel expects to equip, initially, a new semi-truck engine from the factory to run on 100% ordinary plant oil. Such engines will run for almost their entire daily drive cycle on 100% plant oil fuel, with only the first 15 minutes and the last 5 minutes on petroleum diesel.

Organization: Union of Concerned Scientists (UCS)

Freight is the one section of the transportation sector in which fuel use is projected to rise over the next 20 years, with increases in truck fuel consumption being the primary cause. EIA projects that fuel use will increase 37 percent, from 2.4 million barrels of oil a day (mbd) to 3.3 mbd from 2010 to 2035. The Phase 1 heavy-duty standards mitigated the growth in fuel use to some extent but do not change the overall trajectory. The long lead-time and duration of the Phase 2 standards offer both the opportunity and responsibility to make real reductions in fuel consumption. We believe that the proposed rule is an important step forward; however, the proposal does not go far enough. It is insufficient to bring oil use down to 2010 levels, let alone put us on a trajectory towards the emissions reductions needed to reach an 80 percent reduction below 1990 levels by mid-century, a level necessary to prevent the worst consequences of climate change. The agencies should strengthen the rule to ensure that they are reducing truck fuel consumption and associated greenhouse gas emissions to the maximum extent that is technically achievable and cost-effective. [EPA-HQ-OAR-2014-0827-1329-A2 p.4]

UCS, in collaboration with researchers, has shown that reducing fuel consumption 40 percent over 2010 levels by 2025 is both technically achievable and cost effective (Khan et al. 2015). We strongly urge the agencies to adopt a level of stringency that is in line with this analysis to maximize the potential reductions in fuel use. The attached analysis shows that this is an achievable goal while relying predominantly on incremental increases in conventional technologies, with advanced technologies only entering the market slowly in the later years of the proposed regulatory period. With the long lead time proposed by the agencies (more than a decade after the rule is slated to be finalized), it is important to take a complete view of the technologies that will be available to reduce fuel use that far into the future. Under the Clean Air Act, EPA has the authority to set “technology-forcing” standards to achieve emissions reductions. NHTSA, under the Energy Independence and Security Act, has an obligation to set “maximum feasible” standards. Thus, it is appropriate for the standard to include promising
technologies that are not yet market-ready but are expected to be available in a decade in setting the stringency of the standard. [EPA-HQ-OAR-2014-0827-1329-A2 p.4]

Our comments touch on many aspects of the proposed rule, but are nearly all directed at ways in which the stringency of the standard can and should be increased. Compared to our target of 40 percent fuel use reduction from new trucks by 2025 compared to 2010, we calculate that this standard achieves a 36% decrease in fuel use and emissions by 2027. Although the benefits cited by the agencies are significant—saving 550,000 barrels of oil a day and reducing greenhouse gas emissions by 120 million metric tons in 2035—they would be significantly higher if the agencies proposal mirrored our analysis. Achieving a 40-percent reduction from new trucks would save an additional 200,000 barrels of oil a day and avoid 40 million metric tons of greenhouse gas emissions in 2035. From our perspective, this proposal leaves too much on the table. [EPA-HQ-OAR-2014-0827-1329-A2 p.4]

There are numerous analyses from independent institutions such as the National Academies of Science and Southwest Research Institute as well as data from industry and the Department of Energy’s SuperTruck program that show that the 40-percent target by 2025 is feasible and cost-effective, indicating that waiting until 2027 to implement the stringency in the preferred alternative (Alternative 3) is unnecessary. Thus, we believe that the timing and stringency of Alternative 4 is more appropriate, as it pulls the 36-percent reduction of Alternative 3 forward to 2024. However, many of the concerns we articulate in these comments also apply to Alternative 4 and is therefore not an approach that we would fully endorse. If the final rule extends to 2027, we urge the agencies to increase the stringency beyond a 40-percent reduction, recognizing the broader array of technologies available with longer lead-time. [EPA-HQ-OAR-2014-0827-1329-A2 p.4]

We appreciate the work that the agencies have done to work with stakeholders and integrate data into their analysis of the issues involved in this rule. We have included detailed analysis on many parts of the rule in these comments and look forward to continued engagement with the agencies. [EPA-HQ-OAR-2014-0827-1329-A2 p.5]

**Response:**

CARB stated that Alternative 4 is consistent with each agencies’ respective statutory authorities to promulgate GHG and fuel efficiency standards. The agencies would not disagree with that assertion if we had determined Alternative 4 to be feasible. However, due to concerns over the risks associated with the rapid pace of technology implementation required under the proposal’s Alternative 4 (in particular, risk of unreliability due to the shorter lead time to bring technologies to market or to apply existing technologies to unfamiliar market segments), and the unquantified costs associated with those risks, we have determined that it is likely that Alternative 4, as set out in the NPRM, is infeasible.

The Center for Biological Diversity argues that the proposed standards are insufficiently stringent and are inconsistent with the “technology-forcing” mandate of the Clean Air Act. CBD is correct that certain CAA provisions are technology forcing (any provision, for example, requiring standards to be based on some type of best performing technology, e.g. CAA section 112 (d)(2) and (3), or 213(a)(3) and (4), but neither section 202 (a) (1) nor (2) is one of those provisions. See 77 FR 62673/1
(explaining why section 202 (a) (1) and (2) allow but do not compel technology forcing standards; see also id. column 2 correcting this same commenter’s erroneous characterization). However, the final Phase 2 standards are technology-forcing, in that they are premised in part on performance of technologies not presently commercialized, but which the agencies show can be brought reliably to market in the lead time afforded by the rule. A notable example is waste heat recovery as part of the basis for the tractor engine standards. Certain aerodynamic technologies projected to be available for trailers are another example.

NADA encouraged the agencies to pursue non-regulatory strategies to improve fuel efficiency. However, such non-regulatory strategies would not necessarily fulfill the agencies’ respective statutory obligations.

NADCA encouraged the agencies “to establish these rules as a ceiling rather than a floor for states to follow.” However, it is not within the scope of this rulemaking to establish limits on state actions. In addition, EPA notes that the CAA provisions preempting state actions, explicitly allow more stringent requirements under certain circumstances.

POP Diesel submitted comments which largely reiterate its comments in the Phase 1 rulemaking. With respect to the greenhouse gas standards, POP Diesel maintains that the standards should not be established on a fuel neutral/tailpipe emission basis, but rather should be established on a lifecycle basis. POP Diesel takes this position because the fuel additive it produces actually results in increased CO2 emissions at the tailpipe, so if there is any CO2 benefit, it could only come from some earlier point in the fuel’s lifecycle. EPA has already rejected these comments, and we incorporate that entire response here. See 77 FR 51704-705 (Aug. 27, 2012). In sum, EPA is well within its discretion not to turn a vehicular emission standard into a motor fuel program, particularly when there is an entire separate statutory program (the section 211 renewable fuels program) respecting life-cycle implications of vehicular fuel use.1 EPA is also well within its discretion in adopting a fuel neutral, tailpipe – based program in order to harmonize the program with fuel consumption rules of NHTSA. POP Diesel cites Center for Biological Diversity v. EPA, 722 F. 3d 401 (D.C. Cir. 2013) for the proposition that “EPA was not exempt from basing its penalty and merits assessments with respect to stationary source GHG emissions on an assessment of full life cycle emissions.” The commenter is mistaken. The court quite pointedly did not address the merits of EPA’s action, but found that the agency had failed to provide a reasoned justification, and hence had acted arbitrarily. 722 F. 3d at 412.

POP Diesel’s comments related to EISA are addressed in section I.E.1 of the Preamble to the final rule.

1 See in particular: “Even if EPA were to assume that POP Diesel’s claim of lifecycle emissions reductions are valid, and considered setting a vehicle emissions standard that assumed or required use of the POP Diesel technology and fuel, POP Diesel admits this would in fact lead to an increase in the actual GHG emissions from the vehicle. The only decrease in emissions would come from the claimed reduction in lifecycle GHG emissions that POP Diesel says would occur with use of their fuel. That would amount to adopting a vehicle emissions standard to promote a vehicle technology that does not reduce but instead increases the GHG emissions of the vehicle. The vehicle emissions standard would take that approach solely as a mechanism to mandate the use of a certain diesel fuel -based on emissions impacts associated with the fuel, not the vehicle. This would dramatically distort the purpose and structure of the vehicle emissions standard program, largely turning it into a de facto fuel program. There is no good reason to consider such a result here, especially where there already is a separate fuel based program, the RFS program, that is directly aimed at achieving the result POP Diesel seeks—a fuel program that achieves a reduction in lifecycle GHG emissions associated with the diesel fuel used by motor vehicles, through a mandate to use certain renewable diesel fuels”
1.3.1 **EPA Authority**

**Organization:** California Air Resources Board (CARB)

**Alternative 4 is Consistent with U.S. EPA’s Statutory Authority**

U.S. EPA is promulgating the proposed Phase 2 greenhouse gas emission standards pursuant to the statutory authority of Title II of the federal CAA, and specifically sections 202(a)(1) and (2), sections 202(d), 203-209, 216, and 301 (42 U.S.C. 7521 (a)(1) and (2), 7521(d), 7522-7543, 7550, and 7601). [EPA-HQ-OAR-2014-0827-1265-A1 p.24]

Alternative 4 is consistent with the statutory provisions applicable to U.S. EPA’s determination of the requisite lead time requirements associated with the proposed greenhouse gas emission standards. CAA section 202(a)(2) [42 U.S.C.§ 7521(a)(2)] provides that “[a]ny regulation prescribed under paragraph (1) of this subsection (and any revision thereof) shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” [EPA-HQ-OAR-2014-0827-1265-A1 p.24]

Courts interpreting section 202(a) of the CAA have recognized that Congress intended U.S. EPA to rely upon projected future developments and advances in pollution control technology in establishing emission standards, and expected U.S. EPA to “press for the development and application of improved technology rather than be limited by that which exists today.” Natural Resources Defense Council v. U.S. EPA, 655 F.2d 318, 328 (D.C. Cir. 1981) (NRDC). The NRDC court noted that a longer lead time “gives the U.S. EPA greater scope for confidence that theoretical solutions will be translated successfully into mechanical realizations”, and further stated that “the presence of substantial lead time for development before manufacturers will have to commit themselves to mass production of a chosen prototype gives the agency greater leeway to modify its standards if the actual future course of technology diverges from expectation.” (Id.). The court concluded: [EPA-HQ-OAR-2014-0827-1265-A1 p.24]

“We think that the U.S. EPA will have demonstrated the reasonableness of its basis for prediction if it answers any theoretical objections to the [projected control technology], identifies the major steps necessary in refinement of the [projected control technology], and offers plausible reasons for believing that each of those steps can be completed in the time available.” [EPA-HQ-OAR-2014-0827-1265-A1 p.25]

11 Id. at 329.

**Organization:** Center for Biological Diversity

EPA’s authority to regulate greenhouse gas emissions from Heavy Duty (“HD”) Vehicles is codified in section 202(a) of the Clean Air Act (“CAA”). The Act’s pollution emission reduction goals are technology-forcing: [EPA-HQ-OAR-2014-0827-1460-A1 p.5]
Case and statutory law support the broad authority of EPA to force substantial change on the status quo on an industry-wide basis. The 'technology-forcing goals' of Subchapter 11, the portion of the Clean Air Act that establishes emissions standards for moving vehicles, are well recognized. See Whitman v. American Trucking Ass'ns, 531 U.S. 457, 491-492, 121 S. Ct. 903, 149 L. Ed. 2d 1 (2001) (Breyer, J. dissenting). The technology-forcing authority of the Clean Air Act is embodied in the language of the Act that directs EPA to promulgate standards 'that reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which the standards apply, ...' 42 U.S.C. § 7521(a)(3)(A)(i). EPA is thus empowered to set standards for future model years based on reasonable projections of technology that may not be available currently. NRDC v. Thomas, 256 U.S. App. D.C. 310, 805 F.2d 410, 429 (D.C. Cir. 1986). [EPA-HQ-OAR-2014-0827-1460-A1 p.5]

Most importantly, when directly comparing the Proposed Rule 2027 standards and what SuperTruck partners have already achieved, the proposed standards for tractors-trailers would achieve only about three-quarters of the fuel savings that have been demonstrated by SuperTruck partners.50 The Proposed Rule takes SuperTruck research and development into account when calculating the dynamic baseline, or reference truck, but fails to properly employ the demonstrated improvements from the SuperTruck program when determining what technology is maximally feasible. In fact, the Draft Regulatory Impact Analysis ("RIA") explicitly acknowledges that there are likely to be more advanced aerodynamics options by 2027.52 Since the Agencies already predict such advances, the technology-forcing nature of the governing statutes requires that they be included in the standards, especially when the proposed time horizon is within the range of tractor redesign cycles.53 [EPA-HQ-OAR-2014-0827-1460-A1 p.11]

Although the Proposed Rule assumes a wide range of technologies, the penetration rates assumed by the Agencies and potential improvements appear to be underestimated.54 The technology forcing nature of Clean Air Act § 202 and EPCA/EISA requires more aggressive assumptions regarding technology adoption. The Agencies are proposing standards that are either already attained or easily attainable, and then hoping that manufacturers will explore and continue to improve technologies of their free will.55 This is contrary to the specific language, structure, and intent of the statutes: a clear regulatory signal is necessary and intended to drive innovation, ensuring that technology improvements occur as rapidly as possible. [EPA-HQ-OAR-2014-0827-1460-A1 p.11]

In sum, the total reductions of greenhouse gas emissions and fuel usage could be significantly greater if the Agencies adopt standards that represent true maximum efficiency improvements, even while remaining economically feasible and safe. The NHTSA may not adopt standards that undermine the purpose of the EPCA/EISA – energy conservation. Yet, the proposed fuel use reductions for tractor-trailers would provide only about one-third of the maximal feasible benefits. This constitutes an arbitrary and capricious balancing of factors that significantly impedes the congressional mandate to promote energy conservation. Likewise, these minimal reductions fail the Clean Air Act’s technology-forcing requirement. [EPA-HQ-OAR-2014-0827-1460-A1 p.11-12]

50 ICCT SuperTruck blog, supra note 46.

52 Draft RIA at 2-18.

53 Id. at 2-16 ("tractor model lifecycle of up to 10 years").

54 For example, dual clutch systems are assumed to provide only up to 2% improvement (Proposed Rule at Table III-7), but the stakeholder workshop assigned this technology approximately 5.5 (+ 2) % improvement (ICCT Tractor-Trailer report, supra note 44); the Proposed Rule omits weight reduction in setting stringency assigning an improvement of 0.3 % (Proposed Rule at 40223), while the stakeholder workshop found over 3 (+ 1) % improvements from weight reduction (ICCT Tractor-Trailer report, supra note 44).

55 See, e.g., Draft RIA, supra note 43 at 2-16 (“we anticipate manufacturers would continue to apply these techniques [sealing gaps] across their models and continue to explore refinements and re-designs in other areas of the tractor”). But note that the Agencies are also fully aware that a regulatory signal is necessary to correct private market failures and “provide regulatory certainty and thus generate important economic benefits in addition to reducing externalities.” Id. at 8-5.

Organization: Daimler Trucks North America LLC

Legal Issues with Glider Provisions

As DTNA expressed in its comments to the Phase 2 Proposed Rule, DTNA has concerns with EPA's proposed regulation of 'glider kits' and 'glider vehicles,' including EPA's legal authority for regulating them. EPA's Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act ('CAA'), which does not provide EPA authority to regulate the sale of motor vehicle components. The CAA only provides EPA with authority to regulate 'new motor vehicles' and their engines, defined as 'self-propelled' vehicles 'the equitable or legal title to which has never been transferred to the ultimate purchaser'—not non-motorized frames, cabs, and axles. 42 U.S.C. §§ 7522(a), 7550(3). In turn, any regulation of glider kits is beyond the agency's authority. Further, glider vehicles when constructed retain the identity of the donor vehicle, such that the title has already been exchanged, making the vehicles not 'new' under the CAA. Thus, EPA lacks authority to regulate glider vehicles. And even if the EPA had authority to regulate, the CAA requires 4-years' lead-time for new or revised NOx and PM requirements and for regulations governing engine rebuilding practices, which has not been met under the proposed regulations. [EPA-HQ-OAR-2014-0827-1926-A1 p.2]

B. EPA Lacks Authority to Regulate 'Glider Kits' and 'Glider Vehicles'

The distinction between 'glider kits' and 'glider vehicles' is important because EPA lacks authority to regulate vehicle parts, including assemblages of parts (without an engine) such as glider kits. EPA's Phase 2 Proposed Rule is being carried out under the authority of the CAA, and the CAA does not provide EPA authority to regulate the sale of motor vehicle components, which is all that glider kits are. The CAA only authorizes EPA to set emission standards for 'new motor vehicles' and 'new motor vehicle engines,' 42 U.S.C. § 7521(a)(1), and to prohibit the sale of uncertified 'new motor vehicles' and 'new motor vehicle engines,' see 42 U.S.C. § 7522(a)(1). 'New motor vehicles' are defined under the CAA as 'self-propelled' vehicles 'the equitable or legal title to which has never been transferred to an ultimate purchaser'—not non-motorized frames, cabs, and axles. 42 U.S.C. § 7550(2), (3). Because glider kits do not contain engines, transmissions, and drive axles, and have no motive power, the CAA does not authorize EPA to regulate the sale of glider kits. [EPA-HQ-OAR-2014-0827-1926-A1 p.2-3]
EPA's examples of CAA provisions that address certain vehicle components are inapplicable. EPA cites to three CAA provisions granting it authority to regulate evaporative emissions, including from certain components, and concludes from those specific provisions that it has authority to regulate all vehicle components, whether or not they produce emissions in any form. Specifically, EPA cites to 'CAA section 202(a)(6) (standards for onboard vapor recovery systems on 'new light-duty vehicles,' and requiring installation of such systems); section 202(a)(5)(A) (standards to control emissions from refueling motor vehicles, and requiring consideration of, and possible design standards for, fueling system components), 202(k) (standards to control evaporative emissions from gasoline-fueled motor vehicles).’ EPA Legal Memo, at 3. From these examples, EPA concludes that it has authority to regulate all vehicle components, a conclusion that is not justified under the language, of the Act. First, the fact that the CAA lists specific components that EPA may regulate suggests that EPA lacks authority to regulate other components that are not specifically listed, particularly given the broader dictate that EPA may set emission standards only for 'new motor vehicles' and 'new motor vehicle engines,' 42 U.S.C. § 7521(a)(1), and may prohibit only the sale of uncertified 'new motor vehicles' and 'new motor vehicle engines,' 42 U.S.C. § 7522(a)(1). Second, all of the examples cited by EPA relate to evaporative emissions. Although EPA might be able to argue that it has authority to regulate evaporative emissions from those specific components, and exhaust emissions from 'new motor vehicles' and 'new motor vehicle engines,' it is a stretch to say that EPA has authority to regulate all motor vehicle components. This is particularly true where, as with glider kits, the components do not produce emissions on their own. EPA itself recognizes that it cannot extend its argument to the smallest vehicle component—This is not to say that the Act authorizes emission standards for any part of a motor vehicle, however small,' EPA Legal Memo, at 3—but nonetheless believes it has the authority to draw the line to include glider kits and trailers. In fact, Congress drew the line in the CAA at 'new motor vehicles' and 'new motor vehicle engines,' and EPA may not extend its authority further than Congress allowed. [EPA-HQ-OAR-2014-0827-1926-A1 p.3]

EPA also lacks authority to regulate glider vehicles. When constructed, glider vehicles retain the identity of the donor vehicle, such that the title has already been exchanged, making the vehicles not 'new' under the CAA and not subject to EPA's regulatory authority. EPA's argument that glider assemblers market their finished products as 'new trucks' is unavailing. A company's marketing materials have no bearing on the statutory definition that governs EPA's authority. Although the CAA may not reference Vehicle Identification Numbers as determinative of new motor vehicle status, the Act does contain an express definition of 'new motor vehicles'—'self-propelled' vehicles 'the equitable or legal title to which has never been transferred to an ultimate purchaser,' 42 U.S.C. § 7550(2), (3)—which EPA is not free to disregard. Glider vehicles incorporate not just a used engine, as EPA suggests, but the engine, transmission, and rear axle—the entire powertrain that comprises a significant portion of a vehicle's cost and identity—from a previously owned vehicle. The glider kit, which may be considered to be 'new' vehicle parts, is not self-propelled. The glider becomes self-propelled only when the powertrain components are added, but cannot be a 'new motor vehicle' because the equitable or legal title of those powertrain components has previously been transferred to an ultimate purchaser. [EPA-HQ-OAR-2014-0827-1926-A1 p.3-4]

- EPA Lacks Authority to Regulate 'Glider Kits' - The distinction between “glider kits” and “glider vehicles” is important because EPA lacks authority to regulate vehicle parts, including assemblages of parts (without an engine) such as glider kits. EPA’s Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act (“CAA”), and the CAA does not provide EPA authority to regulate the sale of motor vehicle components, which is all that glider kits are. The CAA only authorizes EPA to prohibit the sale of uncertified “new motor vehicles” and “new motor vehicle engines.” See 42 U.S.C. § 7522(a)(1). “New motor vehicles” are defined under the CAA as “self-propelled” vehicles “the equitable or legal title to which has never been transferred to an ultimate purchaser”—not non-motorized frames, cabs, and axles. 42 U.S.C. § 7550(2), (3). Because glider kits do not contain engines,
and have no motive power, the CAA does not authorize EPA to regulate the sale of glider kits. [EPA-HQ-OAR-2014-0827-1164-A1 p.122-123]

**Regulation of 'Glider Vehicles' Targets NOx / PM Emissions and Must Meet Statutory Lead Time Requirement** - In addition, the proposed regulation of “glider vehicles” actually targets NOx/PM emissions rather than GHG emissions, as EPA concedes, and is therefore inappropriate for inclusion in a GHG rule. Glider sales actually create the potential to reduce GHG emissions by incorporating used and rebuilt engines in newer, more aerodynamic vehicles. Rebuilt engines used in glider vehicles emit fewer GHGs, and new cabs and low rolling resistance tires are more efficient than what they replace. Because regulation of glider vehicles targets NOx/PM emissions, it should be done only in a separate rulemaking, if at all. [EPA-HQ-OAR-2014-0827-1164-A1 p.123][This comment can also be found in section 14.2 of this comment document]

In addition, this separate rulemaking should be carefully drafted to meet statutory lead-time requirements for NOx and PM regulations as required by statute. NOx and PM emissions standards are subject to an express CAA lead-time requirement under which new or revised NOx and PM requirements cannot take effect sooner than the model year commencing 4 years after new or revised standard is promulgated. 42 U.S.C. § 7521(a)(3)(C). As currently proposed, with an effective date of January 1, 2018, the proposed glider regulations violate the 4-year lead-time requirement under the CAA. Assuming the Phase 2 rule is finalized in early 2016, the earliest that the regulations governing glider vehicles could take effect would be 2020, in compliance with the CAA lead-time requirement. [EPA-HQ-OAR-2014-0827-1164-A1 p.123]

For its proposed glider provisions, EPA purports to rely on its authority to regulate the “practice of rebuilding heavy-duty engines.” 42 U.S.C. § 7521(a)(3)(D). However, EPA is not regulating engine rebuilding practices, as evidenced by the lack of relevant proposed amendments to its engine rebuilding regulations (40 C.F.R. §§ 86.004-40, 1068.120). Instead, EPA is attempting to regulate vehicle rebuilding, which it clearly does not have the authority to do under the CAA. Congress granted EPA authority to regulate “new motor vehicles” and “new motor vehicle engines” only, and while Congress granted EPA authority to regulate engine rebuilding, it did not grant EPA similar authority to regulate vehicle rebuilding. EPA’s reliance on (3)(D) is misplaced with respect to its proposed regulation of glider vehicles. [EPA-HQ-OAR-2014-0827-1164-A1 p.123]

Even if EPA were properly regulating heavy-duty engine rebuilding practices with its proposed glider provisions, it would be subject to the same four-year statutory lead-time requirement. The four-year lead-time and three-year stability requirements of 42 U.S.C. § 7521(a)(3)(C) are applicable to all of paragraph 3, which includes the engine rebuilding provision contained in (3)(D). It is not enough for EPA to opine that the January 1, 2018 implementation date for the glider provisions allows “sufficient time to ‘permit the development and application of the requisite control measures’” under 42 U.S.C. § 7521(a)(3)(D). The four-year lead-time and three-year stability requirements of (3)(C) provide an absolute minimum, even for engine rebuilding regulations, and then EPA must determine whether additional time is required above and beyond that based on its determination under the standard contained in (3)(D). [EPA-HQ-OAR-2014-0827-1164-A1 p.123]

As currently proposed, EPA is attempting to regulate NOx and PM in the GHG rule in a way it could not undertake in a proper NOx and PM rulemaking. Under the CAA, EPA must allow four years of lead time, at a minimum, before its proposed glider provisions would take effect. [EPA-HQ-OAR-2014-0827-1164-A1 p.124]
Delegated Assembly, EPA’s lack of authority - DTNA has a concern about the EPA creating a large paperwork burden, requiring contracts with and instructions to body builders, that creates no benefit to the environment beyond our current business practice of supplying an Incomplete Vehicle Document (IVD) to final stage manufacturers. This concern drives us to comment that the EPA lacks the authority for delegated assembly regulations any more expansive than those in 40 C.F.R. § 1037.620 today. EPA bases its delegated assembly regulations on the authority to regulate the “introduction into commerce” and a claim that the sale of a partially complete vehicle or engine from the primary manufacturer to the secondary manufacturer is within the scope of this “commerce.” 42 U.S.C. §7522(a)(1) (authorizing regulation at the introduction into commerce) and 75 Fed. Reg. 74152 at 74362 (Nov. 30, 2010) (citing EPA authority for Part 1037 delegated assembly regulations). But the EPA incorrectly interprets what “commerce” is. [EPA-HQ-OAR-2014-0827-1164-A1 p.105-106]

Unlike Congress’s authority over commerce, which extends down to matters within a manufacturing plant located entirely within one state (see, e.g., National Labor Relations Board v. Jones & Laughlin Steel, 301 U.S. 1 (1937)), Congress defined the scope of the EPA’s “commerce” more narrowly than its own. If Congress intended for the EPA to regulate manufacturing processes or to consider “introduction into commerce” to include the manufacturing process, Congress knew how to specify so. Within the CAA itself, Congress commanded the EPA to regulate the manufacture of consumer or commercial products (prohibiting “the manufacture or introduction into commerce...”), the manufacture of aftermarket motor vehicle components (prohibiting any person to “manufacture or sell...”), and the manufacture of fuel (prohibiting “the manufacture, introduction into commerce, offering for sale, or sale...”). 42 U.S.C. §§ 7511b (e)(3)(A), 7522(a)(3)(B), and 7545(c)(1) (emphases added). Moreover, the text of the Air Quality Act of 1967, the predecessor to the CAA, contained a prohibition against the “manufacture for sale” of noncompliant vehicles and engines, but Congress explicitly struck “manufacture for sale” from the law relating to vehicles during the 1970 amendment process. Air Quality Act, P.L. 90-148 (Nov. 21, 1967), §203(a)(1), formerly 42 U.S.C. §1857f-2(a)(1); CAA, P.L. 91-604, §203(a)(1) (Dec. 31, 1970) (enacting H.R. 17255). Following the canons of statutory interpretation, one might logically presume that Congress intended for manufacture of vehicles and engines not to be regulated from the fact that (1) Congress omitted manufacturing from the regulated activities while including it elsewhere and (2) it actively struck manufacturing from the list of such activities. Stated another way, if Congress considered “introduction into commerce” to include manufacturing, then the “manufacture for sale” is surplusage in the sections of the CAA where it sits alongside mention of sale or introduction into commerce. In summary, Congress’s vehicle and engine regulations provide for regulation at the “introduction into commerce” but not for regulation of manufacture, as do (e.g.) the fuel regulations. [EPA-HQ-OAR-2014-0827-1164-A1 p.106]

So what is “introduction into commerce”? Congress gives an indication through its regulation of vehicles and engines over their “useful life.” 42 U.S.C. §7521(a)(1). Useful life is defined in the CAA and in the EPA’s regulations to be “a period of use” of some number of years or thousands of miles, depending on the type of vehicle. See, e.g., 42 U.S.C. §7521(d)(1) (defining useful life for light-duty vehicles and light-duty trucks as “a period of use of five years or of fifty thousand miles ..., whichever first occurs”) and 40 C.F.R. §86.004-2 (defining the useful life for Class 8 heavy-duty vehicles as “a period of use” of 10 years or 435,000 miles). It strains credulity to argue that the useful life, defined as “a period of use,” also includes periods prior to the engines or vehicles first use. In other words, the most logical inference to draw from both Congress’s and the EPA’s own definition of the useful lives is that the period over which an engine or vehicle can be regulated is only a period beginning with initial use. By contrast, regulation of an engine or vehicle’s emissions prior the first use or prior to completion of manufacturing is beyond the EPA’s authority. In turn, because regulation of an engine or vehicle’s emissions prior to its being used is beyond the EPA’s authority, the most reasonable interpretation of “introduction into commerce,” the point at which the EPA can begin to regulate, is not a sale part way through the manufacturing process (as in a sale from an original-stage manufacturer to a later-stage
manufacturer) but the sale to the ultimate purchaser (at which point the vehicle begins its period of use).

Even if the EPA could regulate prior to the first use of an engine or vehicle, Congress authorized only test-based standards, not regulations over how vehicles or engines are manufactured. In particular, Congress (first) mandated the EPA to create “standards that shall be applicable to such vehicles and engines for their useful life.” 42 U.S.C. §7521(a)(1). Second, “to determine whether [a] vehicle or engine conforms with regulations prescribed under section 202 [§7521] of [the CAA],” the EPA “shall test, or require to be tested in such manner as [the EPA Administrator] deems appropriate,” such vehicles or engines. 42 U.S.C. §7525(a)(1) (emphases added). That is, “testing” of vehicles or engines is the means by which the EPA determines the compliance that is necessary for a vehicle or engine’s introduction into commerce. Prescribing procedures relating to contracts between manufacturers is not “testing.”

The CAA’s legislative history bears out the above interpretation of the EPA’s authority. A Senate report shows Congressional intent that “[e]very manufacturer must provide, at the time of delivery, dealers and the ultimate purchaser a certificate that the vessel, vehicle, aircraft, or engine conforms to the regulations.” Sen. Rpt. 91-1196, at 62 (1970) (emphasis added). Similarly, a House report authorized “test[ing] ... any new motor vehicle or motor vehicle engine as it comes off the assembly line in order to determine whether the vehicle or engine conforms with the applicable emission standards” but not a requirement for contracts between manufacturers. H.R. Rpt. 91-1146, at 5358-5359 (1970) (emphasis added). Further during a discussion between then-Vice President of Ford Motor Company Herbert Misch and Senator Robert Dole, Mr. Misch stated that one act proposed to be prohibited in Section 203 of the CAA goes too far: “the requirement that ‘manufacture for sale’ cease upon revocation of certification. We do not feel that production should cease in order to remedy whatever defects may be found through sampling.” 2 Clean Air Act Amendments of 1970 1015 (U.S. Government Printing Office 1970) (quoting Joint Hearings before the Subcommittee on Air and Water Pollution of the Committee on Public Works and the Committee on Commerce, United States Senate, March 24 and 25, 1970). Senator Dole responded “[A]s long as we prohibit the sale of the defective vehicle it should not be necessary to stop production.” That is, Mr. Misch and Senator Dole spoke in favor of allowing the manufacturing of vehicles and engines whose compliance certificate has been revoked, as long as the manufacturer did not sell them. And, as discussed above, in the final CAA text Congress struck “manufacture for sale” from the list of acts prohibited “unless [a] vehicle or engine is covered by a certificate of conformity.” 42 U.S.C. §7522(a)(1). In short, the legislative history is replete with statements like those above voicing a desire for test-based standards and for end of assembly line testing that will reflect in-use emissions, but not for compliance prior to completion of the vehicle nor formal written requests or other such mandatory documents.

In summary, the text and history of the CAA show that regulation of assembly processes and the requirement for delegated assembly contracts are beyond the EPA’s authority under the CAA. DTNA respectfully suggests that the EPA work with us to develop text that we could add to the industry’s current IVD to instruct second stage manufacturers what remains to be completed in order to bring the vehicle into compliance.

Organization:  Environmental Defense Fund (EDF)

Legal Authority

EPA has manifest legal authority to adopt greenhouse gas emission standards for new medium-and heavy-duty vehicles. Below, we discuss two particular features of this authority: the technology-
forcing nature of section 202 of the Clean Air Act (“CAA”) and EPA’s authority to address trailers. [EPA-HQ-OAR-2014-0827-1312-A1 p.19]

A. EPA has clear authority to establish technology-forcing standards

EPA has clear authority to establish technology-forcing emission standards under section 202(a) of the CAA, which provides that standards established under section 202(a)(1) “shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology.”86 [EPA-HQ-OAR-2014-0827-1312-A1 p.19]

Related provisions of section 202—including those governing heavy-duty vehicle criteria pollutant emissions—are expressly technology forcing, providing that regulations “shall contain standards which reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available for the model year to which such standards apply . . .”87 [EPA-HQ-OAR-2014-0827-1312-A1 p.19]

As the nation’s highest court has recognized, the legislative history of the CAA underscores that Congress did not intend for EPA to be “‘limited by what is or appears to be technologically or economically feasible,’ but ‘to establish what the public interest requires to protect the health of persons,’ even if that means that ‘industries will be asked to do what seems to be impossible at the present time.’”88 With respect to section 202(a)(1) and (a)(2), Congress intended that EPA “press for the development and application of improved technology rather than be limited by that which exists today.”89 [EPA-HQ-OAR-2014-0827-1312-A1 p.19-20]

EPA has a long history of establishing technology-forcing emission standards that have driven innovation and secured pollution reductions. For instance, EPA standards under section 202 resulted in the development and proliferation of the catalytic converter in 1975 and the three-way catalyst in 1981.90 Particulate standards for heavy-duty vehicles also resulted in the development of the diesel particulate filter.91 [EPA-HQ-OAR-2014-0827-1312-A1 p.20]

Courts have consistently affirmed EPA’s authority to establish technology-forcing standards under section 202, in some cases holding that only a technology-forcing standard would be compliant with the statute.92 In adopting such standards, EPA is empowered to make projections about future technology “subject” only “to the restraints of reasonableness.”93 [EPA-HQ-OAR-2014-0827-1312-A1 p.20]

In 1980, for example, EPA promulgated PM emission standards for light-duty diesel vehicles and trucks, requiring that emissions decrease to 0.20 grams per mile in the 1985 model year. EPA determined that the standard would be achievable in 1985 with the perfection of a particle trapping device, which at the time, had achieved only partial success in a prototype stage.94 The D.C. Circuit affirmed these standards, holding that EPA “will have demonstrated the reasonableness of its basis for prediction if it answers any theoretical objections to the . . .method, identifies the major steps necessary in refinement of the device, and offers plausible reasons for believing that each of those steps can be completed in the time available.”95 [EPA-HQ-OAR-2014-0827-1312-A1 p.20-21]

Likewise, in 2001, EPA established diesel PM and NOx emissions standards for heavy-duty trucks and buses that required substantial reductions and relied on studies suggesting that technologies currently being tested could collectively overcome then-existing obstacles.96 The D.C. Circuit upheld these standards, affirming EPA’s technological predictions and noting that “the rule could stand so long as there was one solution as to which EPA’s prediction was not arbitrary.”97 [EPA-HQ-OAR-2014-0827-1312-A1 p.21]
EPA describes its Phase 2 proposal as technology forcing, in line with this long and successful history. As we set forth more fully below, however, certain key aspects of the agency’s proposal—including the engine standards—are based almost entirely on today’s technologies and conservative assumptions about the development of those technologies. EPA must strengthen these provisions to be consistent with the technology-forcing history of section 202 and the agency’s own stated intention in the Phase 2 proposal. [EPA-HQ-OAR-2014-0827-1312-A1 p.21]

B. EPA has clear authority to regulate trailers

EPA and NHTSA have proposed standards for trailers that are used in combination with two different classes of tractors. EPA’s authority to adopt these proposed standards rests on firm legal footing, reflects a reasonable interpretation of the relevant Clean Air Act provisions, and is consistent with the agency’s past regulatory practice. [EPA-HQ-OAR-2014-0827-1312-A1 p.21]

Section 202(a)(1) of the Act authorizes EPA to regulate “the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines . . .”100 ‘Motor vehicle,’ as it is used in Section 202(a)(1), is defined under Section 216 as “any self-propelled vehicle designed for transporting persons or property on a street or highway.”101 [EPA-HQ-OAR-2014-0827-1312-A1 p.21]

EPA has interpreted this statutory definition to enable the agency to adopt standards addressing emissions from the Class 7 and 8 combination tractor-trailers, which “consist of a cab and engine (tractor or combination tractor) and a detachable trailer.” The statutory definition of ‘motor vehicle’ in section 216 expressly defines that term in light of the vehicle’s intended use; “transporting persons or property on a road or highway.” EPA has reasonably interpreted ‘motor vehicle’ to encompass all of the components of Class 7 and 8 tractor-trailers (including the trailer), which are needed to accomplish that objective. [EPA-HQ-OAR-2014-0827-1312-A1 p.21-22]

In particular, Class 7 and 8 tractor-trailers are designed and used to transport large quantities of goods. To perform this task, the vehicle must have three components: an engine, a tractor, and a trailer. These three components are inextricably linked; no one part can successfully transport goods without the other two. And the trailers addressed in the proposal are designed and engineered to operate in tandem with tractors. [EPA-HQ-OAR-2014-0827-1312-A1 p.22]

As their design features would suggest, these tractors and trailers are operated together almost exclusively.104 The height of the tractor is designed to correspond to the height of the trailer, achieving optimal aerodynamic performance and minimal air-resistance only when the two are coordinated.105 Moreover, as the primary load-carrying device, trailers account for a substantial percentage of the engine load and therefore contribute significantly to the vehicle’s emissions. Accordingly, the use of improved aerodynamic and tire technologies on the trailer will reduce the vehicle’s emissions.106,107 EPA’s interpretation of ‘motor vehicle’ as consisting of the engine, tractor, and trailer in the heavy-duty context is therefore a reasonable interpretation of the statute.108 [EPA-HQ-OAR-2014-0827-1312-A1 p.22]

EPA’s interpretation is likewise consistent with other provisions of the CAA and EPA implementing regulations addressing heavy-duty vehicles. Section 202(b), which authorizes EPA to adopt criteria pollutant standards for heavy-duty vehicles, defines a ‘heavy duty vehicle’ as, among other things, having “a gross vehicle weight (as determined under regulations promulgated by the Administrator) in excess of six thousand pounds.”109 EPA regulations confirm that a vehicle’s ‘gross vehicle weight’ can be measured by “the maximum weight of a loaded vehicle and trailer,” or by “the maximum design loaded weight of a single vehicle.”110 These provisions are both tied to the way in which the vehicles are
operated and contemplate the load carried by the trailer. As EPA notes in the proposal, its determination of its authority as to trailers is also consistent with a prior interpretation of the heavy-duty vehicle as being incomplete unless a trailer is attached.\footnote{111} EPA must strengthen these provisions to be consistent with its delegated responsibility to establish technology-forcing standards under section 202 and the Agency’s own stated intention in the Phase 2 proposal. [EPA-HQ-OAR-2014-0827-1312-A1 p.23]

104 Trucking companies do not provide insurance protection for truckers when operating a truck-tractor without an attached trailer; it is considered a non-business activity. Truckers must separately purchase ‘bobtail insurance’ to be covered between dropping off one trailer load and picking up the next one. See, e.g. Insure My Rig, http://www.insuremyrig.com/what-is-bobtail-insurance.html (last visited Sept. 29, 2015); Understanding the Difference Between Bobtail and Non-Trucking Liability Insurance.

106 EPA notes in the proposed rule that the trailers that are pulled by Class 7 and 8 tractors account for two-thirds of the heavy-duty sector’s total CO2 emissions and fuel consumption. 80 Fed. Reg. 40253.

107 As a result of studies undertaken as part of initiatives such as the Department of Energy’s SuperTruck program and EPA’s SmartWay program, design and operational practices have already been developed to cost-effectively reduce those emissions.

108 The fact that the trailer does not itself ‘emit,’ does not exclude it from EPA’s regulatory authority. Section 202(a)(1) authorizes EPA to adopt standards “applicable to the emission of any air pollutant” from new motor vehicles and motor vehicle engines. This statutory grant of authority clearly encompasses standards like those EPA has previously adopted for vehicle attributes that effect emissions, including low-rolling-resistance tires, low-drag brakes, and more aerodynamic vehicle shapes. 75 Fed. Reg. 25374 (2010 Light Duty Vehicle Greenhouse Gas Emission Standards). EPA has likewise interpreted this authority to allow the agency to adopt compliance approaches that reflect upstream emissions. See id. See also Response to Comments (“[Section 202(a)] does not directly address what the ‘standards applicable to’ the emissions must be, or how those standards are to be measured. It does not specify how or what mechanisms EPA may reasonably use in applying a standard to vehicle emissions. This leaves EPA with discretion to develop both elements of the standards and the means of measuring compliance with them.”).

110 40 CFR 86.1803-01.

111 40 CFR 86.1803–01 defines a ‘complete heavy-duty vehicle’ as a heavy-duty vehicle “that has the primary load carrying device or container attached,” while a heavy-duty truck without a load-carrying device is considered an ‘incomplete vehicle.’ Because trailers are ‘load carrying devices,’ they are implicitly part of the vehicle.
EPA Lacks Authority to Regulate “Glider Kits”

The distinction between “glider kits” and “glider vehicles” is important because EPA lacks authority to regulate vehicle parts, including assemblages of parts (without an engine) such as glider kits. EPA’s Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act (“CAA”), and the CAA does not provide EPA authority to regulate the sale of motor vehicle components, which is all that glider kits are. The CAA only authorizes EPA to prohibit the sale of uncertified “new motor vehicles” and “new motor vehicle engines.” See 42 U.S.C. § 7522(a)(1). Because glider kits do not contain engines, and have no motive power, regulation of the sale of glider kits is not authorized by the CAA. EPA has been aware of the use of glider kits for over 35 years, and has not attempted to regulate them because they are not “new motor vehicles” or “new motor vehicle engines” under the CAA. [EPA-HQ-OAR-2014-0827-1134-A1 p.4]

Organization: Navistar, Inc.

Title II of the Clean Air Act (“CAA”) governs regulation of on-highway medium- and heavy-duty engines and vehicles. According to EPA, the Proposed GHG Rule implements Section 202(a) of Title II of the CAA. That section requires the EPA Administrator to “prescribe (and from time to time revise) . . . standards applicable to the emission of any air pollutant from any class of classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipate to endanger public health and welfare.” 42 U.S.C. § 7521(a)(1). [EPA-HQ-OAR-2014-0827-1199-A1 p.3-4]

The agencies acknowledge in the NPRM that the Proposed Rule is technology-forcing. That is, manufacturers must develop new technologies or significantly improve existing technologies to meet the standards. In that case, the agencies must demonstrate that their predictions are reasonable, that they have answered any theoretical objection to the identified technologies, identified the steps needed for the technology to be completed in the available time and offer reasons that those steps can be completed. Thus EPA bears the burden of laying out the pathway to the predicted technology in order to make its demonstration that a Proposed Rule is feasible. [EPA-HQ-OAR-2014-0827-1199-A1 p.4]

engines, and have no motive power, regulation of the sale of glider kits is not authorized by the CAA. EPA has been aware of the use of glider kits for over 35 years, and has not attempted to regulate them because they are not “new motor vehicles” or “new motor vehicle engines” under the CAA. [EPA-HQ-OAR-2014-0827-1134-A1 p.4]

b. Consistency can be achieved by exempting motorhomes from the Phase 2 Regulation

Under Phase 1, NHTSA and EPA plainly differed on their regulation of motorhomes. While NHTSA exempted such vehicles from fuel efficiency standards for the reasons discussed above, EPA exercised regulatory authority over these vehicles under the Clean Air Act. Such divergent treatment may not be ideal from the regulator’s perspective, but harmonization can be worse for the regulated entity where fuel efficiency standards may impose undue costs or require impractical reduction with little fuel savings as they would here. [EPA-HQ-OAR-2014-0827-1261-A1 p.12]

We recognize the importance of regulatory consistency. Executive Order (EO) 13563 requires agencies to tailor its regulations to impose the least burden on society, consistent with obtaining regulatory objectives, taking into account, among other things, and to the extent practicable, the costs of cumulative regulations. The EO seeks to promote such coordination, simplification, and harmonization as will reduce redundancy, inconsistency, and costs of multiple regulatory requirements. [EPA-HQ-OAR-2014-0827-1261-A1 p.12]

The only fair and lawful way to ensure consistency, harmony and cost-effective regulation is for EPA to exclude motorhomes from its regulations as NHTSA is required to do by EISA. The goal of harmonization cannot be used to create legal authority where there is none. NHTSA’s authority under EISA is limited to commercial vehicles. EPA should exercise its discretion to follow NHTSA’s congressionally mandated course and exclude motorhomes from its Phase 2 regulations. This approach takes into account both legal authority and disproportionate costs on the motorhome sector. [EPA-HQ-OAR-2014-0827-1261-A1 p.12-13]

In order to maintain regulatory consistency, harmony and cost-effectiveness, EPA should also exempt motorhomes entirely from its Phase 2 standards. [EPA-HQ-OAR-2014-0827-1261-A1 p.27]

**Organization:** Truck Renting and Leasing Association

The context for these comments is President Obama’s January 18, 2011 executive order on regulatory review, which states that “[w]here relevant, feasible, and consistent with regulatory objectives, and to the extent permitted by law, each agency ... shall consider regulatory approaches that reduce burdens and maintain flexibility and freedom of choice for the public” (Executive Order, “Improving Regulation and Regulatory Review,” § 4 (White House, Jan. 18, 2011)). [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

**Organization:** Truck Trailer Manufacturers Association (TTMA)

EPA lacks statutory authority.

In our “Authority Objections” section (3), we will discuss the legal rationale the agencies are putting forward for regulating trailers, why that rationale is flawed, and that the agencies should focus their
efforts on end users, which they actually do have authority to regulate. [EPA-HQ-OAR-2014-0827-1172-A1 p.2]

EPA and NHTSA do not have statutory authority to adopt GHG emission and fuel efficiency standards applicable to trailers. [EPA-HQ-OAR-2014-0827-1172-A1 p.3]

Trailers themselves fail to meet the definition of a “motor vehicle” which states: [EPA-HQ-OAR-2014-0827-1172-A1 p.3]

(2) The term “motor vehicle” means any self-propelled vehicle designed for transporting persons or property on a street or highway. [EPA-HQ-OAR-2014-0827-1172-A1 p.3]

Trailers are not self-propelled, do not burn fuel or exhaust “Greenhouse Gasses.” A vehicle is defined as something used for conveyance having a frame, a suspension, and a braking system. A motorized vehicle is a vehicle (such as a car, truck, or motorcycle) that is powered by a motor. A trailer is a vehicle that is not motorized and therefore does not fall under the jurisdiction of the Clean Air Act. [EPA-HQ-OAR-2014-0827-1172-A1 p.3]

EPA acknowledges this in its claim to authority and then attempts to dismiss it by claiming that the tractor, when combined with the trailer, together creates the motor vehicle that they are allowed to regulate under the CAA. “Connected together, a tractor and trailer constitute “a self-propelled vehicle designed for transporting . . . property on a street or highway,” and thus meets the definition of “motor vehicle” under Section 216(2) of the CAA.” [EPA-HQ-OAR-2014-0827-1172-A1 p.3]

Trucks and trailers are legally recognized by the U.S. federal and state governments as two different vehicles, each possessing its own DOT vehicle identification number (VIN), state license plate, registration, regulations, and ownership. The EPA cannot legally declare one vehicle part of the other or the two vehicles to be the same or treated as the same vehicle to enable a new regulation. If they do, then it is not the trailer manufacturer who is creating a new motor vehicle. The CAA directs the EPA Administrator to regulate “new motor vehicles.” The trailer is not a motor vehicle under CAA statute until it is “connected” making it possibly subject to EPA authority not at the time the trailer was constructed, but at the time an operator connects it to a tractor and completes the “Self-propelled motor vehicle” that EPA is claiming meets the definition provided under 216(2) of the CAA. At connection, the combination could then be said to meet the definition for “new motor vehicle” in 216(3) since the combination has not yet had its title transferred to the ultimate purchaser, defined in 216(5) as “the first person who in good faith purchases such new motor vehicle.” [EPA-HQ-OAR-2014-0827-1172-A1 p.3-4]

Any given trailer is not intended to be permanently connected to any truck by the trailer OEM for the useful life of the trailer. This is the distinction that makes the trailer different from any other part or component of the truck. The truck has a device that engages the trailer’s king pin and traps it within the truck’s fifth wheel. It is a third party that engages and disengages this truck device, not the trailer, and not the trailer OEM. Specifically, trailer manufacturers do not sell new “tractor-trailers.” As such, the tractor and trailer cannot be considered a single motor vehicle (indeed, a single trailer is likely to be hauled by multiple tractors during its lifetime, and, conversely, a single tractor is likely to haul multiple trailers). [EPA-HQ-OAR-2014-0827-1172-A1 p.4]

Therefore, if the Agency wants to claim, for practical reasons, that the trailer and tractor are a regulated motor vehicle, it can only regulate the party that joined the trailer to the tractor. EPA has been claiming that they cannot regulate end users of trailers, and so must aim their regulations at trailer manufacturers,
but this exposes EPA’s lack of authority to regulate, for these trailer manufacturers do not create the vehicles that EPA claims authority to regulate. Under the laws given in the CAA and the usual industry practice of creating new combinations of tractors and trailers to be used briefly and then separating the tractor from the trailer to create a new combination, all without transferring the titles of the combination or even of any of the individual components of the combination, it is those end users who are routinely manufacturing motor vehicles and are thus possibly subject to regulation under the laws of the CAA. It is these very end users who could and possibly should be directed to select certain trailer-based GHG-Reduction/Fuel-Economy devices based on how they ultimately use the vehicle they alone assemble. [EPA-HQ-OAR-2014-0827-1172-A1 p.4]

Since a trailer is built for customer specifications and not an intended truck, trailer OEMs cannot be regulated by the EPA GHG-2 regulations. At the time of trailer manufacture, there is no defined or intended truck and the trailer is still a non-motor vehicle. Upon completion and the trailer title is passed from the trailer OEM to the trailer dealer, or end user, there is still no motorized truck that can be associated with the trailer. The trailer can be pulled by a gas, diesel, natural gas, or electric truck in the future with unknown, varying aerodynamic characteristics. When title of the trailer passes, the trailer OEM has no legal ownership of the trailer vehicle and the trailer is not a part of any truck or other motorized vehicle. The trailer at this point is a separate product yet to be put into commerce. The EPA’s definition of a trailer being a part of a motorized vehicle has not been met and the OEM no longer has a legal basis to alter the vehicle. [EPA-HQ-OAR-2014-0827-1172-A1 p.4]

The language and structure of the Clean Air Act requirements and prohibitions for new motor vehicles and engines also contradict EPA’s interpretation. Those provisions contemplate a single manufacturer of each new motor vehicle or each new motor vehicle engine. For example, Section 206(a)(1) requires EPA to require testing of “any new motor vehicle . . . submitted by a manufacturer” to determine whether the vehicle may be certified as conforming to emissions regulations. Section 206(b) authorizes EPA to conduct emissions testing to determine whether new motor vehicles “manufactured by a manufacturer do in fact conform” after being certified. Section 207 requires “the manufacturer of each new motor vehicle” to provide an emissions warranty to the ultimate purchaser to certify that the vehicle conforms to the emissions regulations and is free of defects for its useful life. And Section 203(a) prohibits “a manufacturer of new motor vehicles or new motor vehicle engines” from selling or importing such vehicles or engines unless covered by a certificate of conformity. The language of these provisions plainly contemplates a single manufacturer that is responsible for each motor vehicle, not multiple manufacturers of “two detachable parts” that together constitute the single motor vehicle, and are mixed and matched in different pairs throughout their lifetime. Moreover, these provisions on their face do not work as applied to “two detachable parts” of a single motor vehicle that are mixed and matched. In the case of separate manufacturers of the tractor and various trailers that might be hauled by that tractor, the requirements to test, certify, and warrant “the motor vehicle” cannot on their face apply as written, since there is no single manufacturer of “the motor vehicle.” And responsibility for violations, such as by selling an uncertified new motor vehicle, is unspecified. [EPA-HQ-OAR-2014-0827-1172-A1 p.4-5]

EPA also contends that the tractor minus the engine constitutes a “motor vehicle,” even though such a chassis cannot move without the engine. We are skeptical of this assertion. We are aware of no instance in which EPA has sought to regulate a “motor vehicle” that does not contain an engine, for the obvious reason that such a “vehicle” is not self-propelled and thus does not fall within EPA’s jurisdiction. In short, Congress authorized EPA to regulate both engines and complete motor vehicles (containing engines), but did not authorize EPA to regulate a trailer, which is not self-propelled, even if that trailer might be regarded as essential to the purpose of a tractor to transport property. [EPA-HQ-OAR-2014-0827-1172-A1 p.5]
Therefore, as the legal basis of the proposal from the EPA perspective is flawed, all parts of the proposal suggesting expansion of regulation of EPA to trailers should be struck. NHTSA regulation should remove requirements that, by extension, require trailer manufacturers to be regulated by EPA by directing compliance with regulations in 40CFR. [EPA-HQ-OAR-2014-0827-1172-A1 p.5]

The legal basis for including trailers in this rulemaking is flawed and as such it should remove trailers from consideration. If the agencies are set on working to reduce greenhouse gas emissions and fuel consumption as a result of trailer use, they would be better served by regulating that use directly. Drivers and fleets are the ones in control of trailer use, from specification thru disposal; they create new tractor-trailer combinations every day and are the ones who purchase fuel and emit greenhouse gas as a result. [EPA-HQ-OAR-2014-0827-1172-A1 p.18]

**Organization:** American Council for an Energy-Efficient Economy (ACEEE) et al.

**EPA’s Clean Air Act Authority**

*Reducing Emissions through Trailer Improvements*

We support EPA’s interpretation of its authority to regulate trailer manufacturers, namely, that the trailer manufacturer is a motor vehicle manufacturer subject to compliance with emission standards under section 202 of the Clean Air Act. EPA’s prior regulations affecting the manufacturers of major components of the motor vehicle demonstrate the agency’s tradition of addressing mobile sources as systems of components that contribute to vehicle emissions. The trailer manufacturer is the entity with control over the design of the trailer -the load-carrying component of the heavy-duty vehicle, and thus a major contributor to that vehicle’s emissions. As such, it is eminently reasonable for EPA to devise standards that harness the emissions-reducing opportunities inherent in trailer design. [EPA-HQ-OAR-2014-0827-1896-A1 p.7]

**Organization:** Environmental Defense Fund (EDF)

Along with the NODA, EPA has provided a legal memorandum responding to certain claims made by TTMA that further explicates its legal authority to establish standards for trailers. We support EPA’s reasonable interpretation that a combined tractor-trailer is a motor vehicle within the meaning of section 202(a) and agree that EPA has permissibly required trailer manufactures to demonstrate compliance with these requirements. We also support NHTSA’s separate statutory authority to adopt standards for trailers. [EPA-HQ-OAR-2014-0827-1886-A1 p.6-7]

a. EPA reasonably determined the combined tractor-trailer constitutes a “new motor vehicle” within the meaning of section 202(a) and has permissibly established standards for trailers on that basis.

Section 202(a)(1) of the Act directs the Administrator to:

by regulation prescribe . . . standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare. [EPA-HQ-OAR-2014-0827-1886-A1 p.7]

The Act further defines “motor vehicle” to mean “any self-propelled vehicle designed for transporting persons or property on a street or highway.” EPA reasonably explained that a combined tractor-trailer
meets the statutory definition for motor vehicle, noting “Class 7/8 heavy-duty vehicles are composed of three major components:—The engine, the cab-chassis (i.e. the tractor), and the trailer,” and “[c]onnected together, a tractor and trailer constitute ‘a self-propelled vehicle designed for transporting . . . property on a street or highway,’ and thus meet the definition of ‘motor vehicle’ under Section 216(2) of the CAA.”19 [EPA-HQ-OAR-2014-0827-1886-A1 p.7]

TTMA argues that, for purposes of regulating trailer manufacturers, the agency must separately consider the tractor and trailer, but later, once physically connected, TTMA seems to concede that the combined tractor-trailer would meet the statutory definition of “motor vehicle.”20 That conclusion certainly does not flow inextricably from the statute; nor is it reasonable. Indeed, TTMA’s preferred interpretation—which creates artificial limitations on the agency’s ability to establish standards for a “new motor vehicle”—ignores the realities of how these vehicles are designed and used, and would frustrate EPA’s statutory mandate to regulate “the emission of any air pollutant from any class or classes of new motor vehicles.”21 [EPA-HQ-OAR-2014-0827-1886-A1 p.7-8]

In any event, EPA is tasked with interpreting ambiguous statutory provisions and has done so reasonably here, concluding that a trailer is a vehicle “when it has a frame with axles attached.”22 That interpretation is reasonable, it enables the agency to address a significant source of emissions from new motor vehicles consistent with section 202’s mandate and the underlying purposes of the Act, and should be accorded deference. [EPA-HQ-OAR-2014-0827-1886-A1 p.8]

EPA’s regulation of trailers is likewise consistent with and supported by the agency’s long-standing, holistic approach to addressing pollution from mobile sources. EPA identifies numerous examples, both of section 202 provisions that authorize regulation of specific components, as well as past agency regulations that address specific vehicle components, including by requiring testing of components and incomplete vehicles to certify compliance with emission standards.23 In addition to these provisions, EPA has, in other instances, reasonably established and assessed compliance with emissions standards based on the ability of the integrated vehicle system to secure reductions. [EPA-HQ-OAR-2014-0827-1886-A1 p.8]

Engine and Vehicle Standards. EPA and NHTSA’s joint Heavy Duty and Light Duty National Programs recognize the reality that reducing emissions from a class of vehicle requires a holistic approach. In the Phase 1 heavy-duty rule, for instance, EPA and NHTSA affirmed “the importance of addressing the entire vehicle in reducing fuel consumption and GHG emissions,”24 setting separate standards for the tractor cab and the engine installed in the tractor,25 including “improvements in the tractor (such as aerodynamics), tires, and other vehicle systems.”26 Similarly, in setting the Phase 1 standards for light-duty vehicles, EPA and NHTSA considered reductions that could be achieved by deploying advanced technologies and optimizing vehicle systems.27 [EPA-HQ-OAR-2014-0827-1886-A1 p.8]

Compliance Assessment. EPA’s Greenhouse Gas Emissions Model (GEM) for medium- and heavy-duty vehicles, supporting Phase 1 and 2, likewise reflects an integrated, holistic approach. GEM allows various vehicle characteristics to be evaluated for compliance with standards, including for Class 7 and 8 tractor manufacturers, inputs like aerodynamic drag, tire rolling resistance, vehicle speed limiter, vehicle weight reduction, and extended idle reduction.28 These inputs implicate numerous components of the vehicle including the tires, wheels, body, and transmission.29 [EPA-HQ-OAR-2014-0827-1886-A1 p.9]

Similarly, the OMEGA model for light-duty vehicles allows manufacturers to “choose from a myriad of CO2 reducing technologies,” so that “for a variety of levels of CO2 emission control, there are an
almost infinite number of technology combinations which produce the desired CO2 reduction.”

EPA’s past practice reflects a holistic approach to both establishing and assessing compliance with vehicle emission standards, which allows emission standards to be met through improvements to many portions of the integrated vehicle. In keeping with this longstanding approach, EPA has reasonably interpreted its authority to include establishing emission standards for trailers, a major source of emissions from the integrated heavy-duty vehicle.

b. EPA has Reasonably Required Trailer Manufacturers to Demonstrate Compliance with Trailer Standards.

TTMA likewise objects that each motor vehicle can have only one manufacturer, that the trailer manufacturer is not ‘the’ manufacturer for the combined tractor-trailer, and thus, that trailer manufacturers cannot be regulated.

As a threshold matter, section 202(a)(1)—the provision under which EPA has adopted these standards—requires that the agency adopt standards “applicable to . . . new motor vehicles” but does not describe whether one or more entities may be responsible for meeting these standards. In the absence of such a limitation, EPA reasonably determined that standards could apply to trailer manufacturers as well as tractor manufacturers, given that “[t]he trailer manufacturer sets the design specifications that affect the GHG emissions attributable to pulling the trailer.”

Even so, EPA reasonably determined that trailer manufacturers fall within statutory definition of manufacturer in section 216, which is defined as:

any person engaged in the manufacturing or assembling of new motor vehicles, new motor vehicle engines, new nonroad vehicles or new nonroad engines, or importing such vehicles or engines for resale, or who acts for and is under the control of any such person in connection with the distribution of new motor vehicles, new motor vehicle engines, new nonroad vehicles or new nonroad engines.

This definition is capacious and in no way suggests a new motor vehicle must have a single manufacturer. EPA has determined that “[i]t is reasonable to view the trailer manufacturer as ‘engaged in’ (section 216 (1)) the manufacturing or assembling of the tractor-trailer,” and its responsibility under section 202 of the CAA to “prescribe (and from time to time revise) . . . standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles . . . which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare” includes the authority to regulate the manufacturer of the trailer component of the combined tractor-trailer.

TTMA points to several provisions in Title II to support its alternative construction, but these provisions do not compel its single-manufacturer interpretation. Moreover, as EPA notes, the single-manufacturer interpretation would result in an unworkable system where entities without design or manufacturing authority would face compliance obligations.

Accordingly, the agency’s determination to set standards applicable to trailer manufacturers—given that the trailer is a major contributor to the emissions of the heavy duty vehicle—is a reasonable interpretation of the statutory scheme it is entrusted to administer. As such, the decision warrants deference.
c. NHTSA has Clear Authority to Regulate Trailers

TTMA likewise challenges NHTSA’s authority to adopt trailer standards, but those challenges are equally without merit. The Energy Independence and Security Act (EISA) requires NHTSA to create a medium- and heavy-duty fuel efficiency program “designed to achieve the maximum feasible improvement” in fuel efficiency. Inclusion of trailers in NHTSA’s program is reasonable, consistent with the statute, and crucial to satisfying NHTSA’s mandate to improve fuel efficiency. Moreover, inclusion of trailers in the program reasonably harmonizes EISA with NHTSA’s authority under the Motor Vehicle Safety Act (MVSA) and with EPA authority. [EPA-HQ-OAR-2014-0827-1886-A1 p.11]

EISA’s fuel economy standards for medium- and heavy-duty on-highway vehicles and work trucks amends 49 U.S.C. 32902, by adding a subsection (k). EISA also amends the defined terms contained in section 32901 by adding the terms, ‘automobile,’ ‘commercial medium- and heavy-duty on-highway vehicle,’ ‘non-passenger automobile,’ and ‘work truck,’ each of which is defined as a ‘vehicle’ of a particular type. For example, a commercial medium- and heavy-duty on-highway vehicle is “an on-highway vehicle with a gross vehicle weight rating of 10,000 pounds or more.” [EPA-HQ-OAR-2014-0827-1886-A1 p.11]

As NHTSA notes in the rule proposal, EISA does not define ‘vehicle,’ a term that appears repeatedly in the provisions creating the fuel efficiency program for commercial medium- and heavy-duty on-highway vehicles and work trucks, as well as in the definitions of the added terms. Nor is ‘vehicle’ an otherwise defined term under section 32901. In light of this silence, NHTSA reasonably looked to its organic statute, the MVSA, contained at the same subtitle, which defines motor vehicle as “a vehicle driven or drawn by mechanical power and manufactured primarily for use on public streets, roads, and highways, but does not include a vehicle operated only on a rail line.” Relying both on the terms of the MVSA and EISA, NHTSA reasonably determined that trailers be included within the fuel efficiency program. [EPA-HQ-OAR-2014-0827-1886-A1 p.11]

TTMA asserts that the statutory reference to “gross vehicle weight rating” (GVWR) combined with the distinction that EPA drew in a previous rulemaking between GVWR and ‘gross combined weight rating’ (GCWR) somehow expressly forecloses NHTSA’s regulation of trailers. However, at most this reference helps to elucidate the types of tractors contemplated by the regulation and does not expressly (or otherwise) foreclose regulation of trailers. Moreover, contrary to TTMA’s assertion, EPA’s definition of GVWR considers the “loaded weight” of the vehicle, “in operational status with all standard equipment.” Indeed, the term, ‘gross combined weight rating,’ does not appear in any provision under Title 42 or Title 49. [EPA-HQ-OAR-2014-0827-1886-A1 p.11-12]

Accordingly, NHTSA reasonably concluded that trailers fall within the definition of commercial medium- and heavy-duty on highway vehicle. Doing so is consistent with the statutory text; and reasonably furthers NHTSA’s mandate to secure “maximum feasible” improvements in fuel efficiency from medium- and heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1886-A1 p.12]

23 EPA, Legal Memorandum Discussing Issues Pertaining to Trailers, Glider Vehicles, and Glider Kits under the Clean Air Act, at 3 (citing examples including section 202 (a)(6) (standards for onboard vapor recovery systems on light-duty vehicles, requiring installation of such systems); section 202 (a)(5)(A) (standards to control emissions from refueling motor vehicles, requiring consideration of, and possible design standards for, fueling system components); 202 (k) (standards to control evaporative emissions from gasoline-fueled motor vehicles); and 40 C.F.R. 86.146-96 and 86.150-98 (refueling spitback and refueling test procedures)).

27 EPA and NHTSA reviewed a wide range of technologies available to manufacturers, including gasoline direct injection, downsized engines that use turbochargers, advanced transmissions, start-stop technology, improved tire rolling resistance, reductions in vehicle weight, and improvements in vehicle air conditioners, including low leak systems. 75 Fed. Reg. 25332.

29 In fact, a number of commenters on the proposal requested “that cab doors, cab sides and backs, cab underbodies, frame rails, cross members, clutch housings, transmission cases, axle differential carrier cases, brake drums, and other components be allowed to be replaced with light-weight versions” to meet the tractor fuel consumption and CO2 emissions standards.” 76 Fed. Reg. 57151.

30 75 Fed. Reg. 25452. Inputs to the OMEGA model include low rolling resistance tires, low friction lubricants, engine friction reduction, aggressive shift logic, early torque converter lock-up, improved electrical accessories, low drag brakes, and advanced gasoline engine and transmission technologies such as turbo/downsizing, gasoline direct injection, and dual-clutch transmission. 75 Fed. Reg. 25449-50.

36 EPA, Legal Memorandum, at 6.

37 See Chevron, U.S.A. v. Natural Resources Defense Council, Inc., 467 U.S. 837, 844 (1984) (Courts “have long recognized that considerable weight should be accorded to an executive department's construction of a statutory scheme it is entrusted to administer.” When an agency’s authority “on a particular question is implicit rather than explicit . . . a court may not substitute its own construction of a statutory provision for a reasonable interpretation made by the administrator of an agency.”).

38 49 U.S.C. 32902(k).

39 The EISA defines both the ‘commercial medium- and heavy-duty on-highway vehicle’ and the ‘work truck’ under section 32901 as a ‘vehicle’ of a particular gross vehicle weight rating. 49 U.S.C. § 32901(a)(7), (19).

43 Comment submitted by John Freiler, Engineering Manager, Truck Trailer Manufacturers Association (TTMA), at 6 (“EISA’s definition of “commercial medium- and heavy-duty on-highway vehicle” excludes trailers. GVWR is distinct from the gross combined weight rating (“GCWR’), which includes both the weight of a loaded trailer and the weight of the tractor.”).

44 40 CFR 86.1803-01. GVWR is defined as “the value specified by the manufacturer as the maximum design loaded weight of a single vehicle, consistent with good engineering judgment.” ‘Loaded weight’ is defined as “the vehicle’s curb weight plus 300 pounds.” ‘Curb weight’ is defined as “the actual or the manufacturer's estimated weight of the vehicle in operational status with all standard equipment, and weight of fuel at nominal tank capacity, and the weight of optional equipment computed in accordance with § 86.1832-01.”

**Organization:** National Association of Clean Air Agencies (NACAA)

2. February 2016 draft EPA Legal Memorandum Discussing Issues Pertaining to Trailers, Glider Vehicles, and Glider Kits under the Clean Air Act

NACAA is a strong proponent of regulating greenhouse gas emissions associated with trailers. In our September 29, 2015 comments, we commended the agency for proposing such regulations for the first time at the national level. In fact, we noted our belief that EPA’s proposed trailer provisions missed several opportunities to maximize fuel efficiency technologies in the heavy-duty trailer sector and urged the agency to consider our recommendations for additional provisions in the final rule. NACAA has also expressed support for the agency’s proposal to close the existing loophole for glider kits and glider vehicles, under which pre-2013 engines – with no limit on age – may be installed into new glider kits without meeting applicable standards. We believe EPA has the environmental obligation to regulate
trailers, glider vehicles and glider kits, as well as the legal authority to do so in the way it proposes and, in fact, could go further. NACAA, therefore, welcomes the agency’s draft legal memorandum on this issue that provides clarification of the firm legal basis for its proposed actions. [EPA-HQ-OAR-2014-0827-1890-A1 p.2]

**Organization:** Stoughton Trailers

Non-Vehicle

A trailer is not powered for self-transportation and does not directly produce CO2; therefore, is not under the authority of EPA with regard to the area of focus. [EPA-HQ-OAR-2014-0827-1212-A2 p.2]

**Organization:** Truck Trailer Manufacturers Association (TTMA)

**Regarding Section (g) of the Memo: Alternative Provisions for Trailer Manufacturers.**

We would first like to comment on Section (g) of the Memo, which states that EPA is considering an alternative rule that would simply require trailer manufacturers to label and/or provide some test data to show that the trailer is capable of being assembled into a compliant tractor-trailer, and then impose the responsibility of combining compliant trailers with compliant tractors on the motor carriers. While we would want to see the specifics of such a regulation and carefully consider the statutory authority and practical implications, in general we find this approach be superior to the approach taken in the original proposal, for again, as we understand this proposal, the agency would be placing the compliance obligation on the motor carrier in matching tractors to trailers in daily use so as to achieve the regulatory goals. [EPA-HQ-OAR-2014-0827-1873-A2 p.2]

Presuming that the Agencies can regulate the combination of tractors to trailers under the CAA, we could, in principal, agree with the idea that marketing a trailer constructed in such a way that it could not be used to meet those requirements or willfully mislabeled so as to nullify the regulations on the combination of tractors and trailers could be viewed as a defeat-device under the regulation. We would caution that there would undoubtedly be designs of trailers that could be legitimately used in accordance with these regulations the Agency is considering, or be misused by an end user, and the possibility of such misuse must not constitute “causing” the use of a defeat device. [EPA-HQ-OAR-2014-0827-1873-A2 p.2]

**Regarding the remainder of Memo as it pertains to Trailer Manufacturers:**

Section 3 of our previous comment on the proposed rulemaking, submitted on September 30, 2015, contained, set forth our objections to the Agencies’ assertion of legal authority to regulate manufacturers of non-motorized trailers, and we again incorporate that discussion here and add the following summary comments: [EPA-HQ-OAR-2014-0827-1873-A2 p.2]

**EPA Authority:** Congress, in enacting the Clean Air Act, did not authorize EPA to regulate trailers: [EPA-HQ-OAR-2014-0827-1873-A2 p.2]

A trailer is not a “motor vehicle” as that term is defined in the Clean Air Act (i.e. it is not “self-propelled”). [EPA-HQ-OAR-2014-0827-1873-A2 p.2]
Tractors and trailers are manufactured and sold separately by different sets of manufacturers to customer populations that are not the same. As such, the tractor and the trailer cannot be considered a single motor vehicle. [EPA-HQ-OAR-2014-0827-1873-A2 p.2]

The language and structure of the Clean Air Act requirements and prohibitions contemplate a single manufacturer of each new motor vehicle or each new motor vehicle engine. In the case of separate manufacturers of the tractor and various trailers that might be hauled by that tractor, the requirements to test, certify, and warrant “the motor vehicle” cannot on their face apply as written, since there is no single manufacturer of “the motor vehicle.” It also is unclear which of the manufacturers would be responsible for selling an uncertified motor vehicle. [EPA-HQ-OAR-2014-0827-1873-A2 p.2-3]

That the Clean Air Act authorizes EPA to establish standards for certain types of emission-related vehicle components (e.g., onboard vapor recovery systems) does not grant EPA an open-ended license to regulate any vehicle component. To the contrary, that Congress authorized EPA to regulate certain types of components establishes that EPA is not authorized to regulate those components not specifically enumerated in the Act. EPA’s position is limitless and suggests that EPA has authority to regulate the design characteristics of any component or portion of the vehicle, which thereby renders more specific provisions in the Act superfluous, contrary to well-established rules of statutory interpretation. [EPA-HQ-OAR-2014-0827-1873-A2 p.3]

In short, Congress authorized EPA to regulate both engines and complete motor vehicles (containing engines), but Congress did not authorize EPA to regulate a trailer, which is not self-propelled, even if that trailer might be regarded as essential to the purpose of a tractor to transport property. [EPA-HQ-OAR-2014-0827-1873-A2 p.3]

NHTSA Authority: Congress, in enacting the Energy Independence and Security Act (“EISA”), did not authorize NHTSA to regulate trailers. [EPA-HQ-OAR-2014-0827-1873-A2 p.3]

The EISA defines “commercial medium- and heavy-duty on-highway vehicle” to mean “an on-highway vehicle with a gross vehicle weight rating [GVWR] of 10,000 pounds or more.” This definition excludes trailers. In particular, GVWR is widely understood, including by EPA and NHTSA in prior rulemakings, to include only the loaded weight of the tractor, and specifically to exclude the weight of the trailer. [EPA-HQ-OAR-2014-0827-1873-A2 p.3]

GVWR is distinct from the gross combined weight rating (“GCWR”), which includes both the weight of a loaded trailer and the weight of the tractor itself. And indeed, EPA and NHTSA recognized this important distinction in promulgating GHG emission standards and fuel efficiency standards for medium and heavy-duty engines and vehicles in 2011, stating: “GVWR describes the maximum load that can be carried by a vehicle, including the weight of the vehicle itself. Heavy-duty vehicles also have a gross combined weight rating (GCWR), which describes the maximum load that the vehicle can haul, including the weight of a loaded trailer and the vehicle itself.” See 76 Fed. Reg. 57,106, 57,114 (Sept. 15, 2011). [EPA-HQ-OAR-2014-0827-1873-A2 p.3]

In other words, the EISA definition is tethered to GVWR. If Congress intended the definition of “commercial medium- and heavy-duty on-highway vehicle” to include trailers, it could have done so either explicitly or by defining the category of vehicles by reference to GCWR instead of GVWR. [EPA-HQ-OAR-2014-0827-1873-A2 p.3]

The statutory directive for the agency to regulate the fuel economy of commercial medium- and heavy duty on-highway vehicles and work trucks indicates that Congress did not intend to encompass trailers.
Specifically, Section 32902(k) directs the Secretary of Transportation to examine “the fuel efficiency of commercial and medium- and heavy-duty on-highway vehicles,” to determine procedures and methods “for measuring the fuel efficiency of such vehicles,” to take into consideration the “work performed by such on-highway vehicles” and to implement “fuel economy standards.” But trailers do not actually have any source of power, do not consume fuel, and do not do any work by themselves. As discussed above in relation to EPA authority, trailers may be hauled by multiple different tractors, resulting in different fuel economy for the various tractor-trailer combinations. Even if trailers might have aerodynamic characteristics that affect the fuel economy of the tractor that actually uses fuel, the trailer does not itself have “fuel efficiency,” and Congress did not authorize the Secretary to establish aerodynamic requirements. [EPA-HQ-OAR-2014-0827-1873-A2 p.3-4]

Conclusion

While direct regulation of trailer manufacturers remains outside the statutory authority granted under the Clean Air Act or the Energy Independence and Security Act, there is a method suggested in Section (g) of the Memo and laid out in our comments to the proposed rulemaking to accomplish the Agencies’ goals that may be fall within the bounds of statutory authority. While we stand by our contention that EPA’s SmartWay program provides the optimal solution to reducing greenhouse gas emissions and fuel consumption in the heavy duty freight sector, we hope that if the Agencies feel that additional regulation is needed, they will pursue the “Alternative Provisions” approach and work with the trucking industry to create a set of reasonable and effective regulations. [EPA-HQ-OAR-2014-0827-1873-A2 p.4]

Once again, we appreciate the Agencies’ outreach to the trailer manufacturers and pledge to continue our cooperation in efforts to develop the most effective regulations possible within the existing legal framework. [EPA-HQ-OAR-2014-0827-1873-A2 p.4]

22 E.g. 80FR40612 Table 1 of §1037.107 – Phase 2 CO2 Standards for Trailers.

23 For Long Dry Vans, the proposal goes from a baseline of 87.6 to 77 g/ton-mile of CO2 or a 12% reduction. Fuel required roughly scales with the cube of speed, so a reduction of 4% to speed limits, or reducing 65 to 62 would do that.

29 As pointed out in the text, member companies cannot share specifics through the Truck Trailer Manufacturers Association. We will be encouraging individual members to cite this footnote and supply supporting materials as confidential business information.

Organization: Utility Trailer Manufacturing Company

Along with its persistent commitment to building the industry’s strongest, lightest, and safest trailers, Utility is an excellent steward of the environment. Utility Trailer therefore appreciates the Agencies’ overall goal of reducing greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1183-A1 p.1]

Unfortunately, by extending its Proposed Rule to semi-trailers, the EPA has adopted an unprecedented interpretation of its authority that exceeds its Congressional authorization. Additionally, the Agencies have based its analysis on assumptions that are completely untethered from the real world, resulting in proposed regulations that will yield minimal, if any, net greenhouse-gas reduction while imposing crippling administrative burdens on the semi-trailer industry. Utility Trailer respectfully requests that the Agencies reconsider the wisdom of pursuing its foray into regulating the aerodynamic performance
of trailers, and – if they nonetheless are committed to this path – to reform their rules to minimize unnecessary burdens on the industry. [EPA-HQ-OAR-2014-0827-1183-A1 p.1]

Organization: Volvo Group

Also included in the NoDA were arguments related to the Agencies’ authority to regulate glider vehicles and trailers. The Volvo Group fully supports EPA’s and NHTSA’s efforts to achieve efficiency gains and criteria emissions reductions as related to gliders and trailers, and offer our comments that follow accordingly. [EPA-HQ-OAR-2014-0827-1928-A1 p.3]

Comments on Legal Memorandum Pertaining to Trailers, Glider Vehicles, and Glider Kits under the CAA - EPA-HQ-OAR-2014-0827-1627

Volvo further supports EPA’s proposal to regulate trailers, although we have no comment with respect to the Agency’s position on its legal authority to do so. The regulation of trailers is integral to the success of EPA’s Phase II GHG regulation. As EPA’s Proposed Rule notes, the Agency predicts that between 3 percent and 8 percent of anticipated fuel consumption and CO2 improvements from the Phase II regulations are expected to come from proposed trailer requirements. While it may be possible, with significant investment, research and development, to design tractors to meet these limits using advanced aerodynamic trailers, and while it may be possible to certify tractors using such trailers, these efforts will be significantly undermined in the absence of regulations requiring the development of aerodynamic trailers. The imposition of stringent new GHG standards on tractors is unreasonable in the absence of similar standards for trailers given the relatively low benefits derived from what will require a very substantial investment for vehicle manufacturers. [EPA-HQ-OAR-2014-0827-1928-A1 p.25]

Organization: Wabash National Corporation

B. Granting “Small” Manufacturers Exemptions Appears Legally Problematic

EPA’s legal basis for temporarily exempting small trailer manufacturers is questionable. While EPA relied on the Regulatory Flexibility Act to create special provisions for small trailer manufacturers, “[t]he Regulatory Flexibility Act’s requirements are purely procedural and only require the agency to describe the required topics.”54 The Regulatory Flexibility Act therefore “does not alter the substantive mission of the agencies under their own statutes; rather, the Act creates procedural obligations to assure that the special concerns of small entities are given attention in the comment and analysis process. . . .”55 [EPA-HQ-OAR-2014-0827-1242-A2 p.22]

Here, Section 202 of the CAA sets “the substantive mission” of EPA, authorizing the agency to set emissions standards for on-road vehicles and engines.56 But the text of Section 202 says nothing about authorizing EPA to grant special exemptions for small manufacturers. In contrast, several other sections of the CAA contain small business exemptions.57 Reading a similar small business exception into Section 202 is dubious because “[w]here Congress explicitly enumerates certain exceptions to a general prohibition, additional exceptions are not to be implied, in the absence of evidence of a contrary legislative intent.”58 [EPA-HQ-OAR-2014-0827-1242-A2 p.22]

The legislative history of Section 202 suggests that Congress did not intend to grant EPA authority for a small manufacturer exemption. In the 1977 CAA amendments, Congress amended Section 202 to create a small manufacturer exemption for certain model years of motor vehicles. That exemption, however,
expired in the 1982 model year and was then repealed as part of the 1990 amendments of the CAA.\footnote{EPA-HQ-OAR-2014-0827-1242-A2 p.22} Section 317 of the CAA bolsters the view that Congress never intended EPA to alter or adjust Section 202 emissions standards for small manufacturers. Consistent with the Regulatory Flexibility Act, Section 317 of the CAA requires EPA to prepare a procedural analysis of the “effects” of CAA rulemakings “with respect to small business.”\footnote{EPA-HQ-OAR-2014-0827-1242-A2 p.22} However, Section 317 further provides that “[n]othing in Section 317 ‘shall be construed’ to ‘alter the basis on which a standard or regulation is promulgated under this chapter,’” including Section 202.\footnote{EPA-HQ-OAR-2014-0827-1242-A2 p.23} Congress, moreover, stripped courts of jurisdiction to consider any claims arising from EPA’s procedural analysis of small business impacts under Section 317.\footnote{EPA-HQ-OAR-2014-0827-1242-A2 p.23} None of these elaborate references to small businesses in the CAA would make much sense if EPA could rely on implied authority to craft small business exemptions.\footnote{EPA-HQ-OAR-2014-0827-1242-A2 p.23} Wabash respectfully submits that all trailer manufacturers, including the remaining 80% of the industry that EPA deems small businesses, comply with the proposed Phase 2 standards. [EPA-HQ-OAR-2014-0827-1242-A2 p.23]

---

\footnote{50 See id. at 40,285, 40,544–46. In addition to proposing that small manufacturers receive a one-year delay in complying with the 2018 deadline, EPA requested comment on whether a similar one-year delay maybe warranted when the trailer standards become more stringent in 2021 and 2024. \textit{Id.} at 40,285. EPA also requested comment on whether compliance might be delayed in the future where LRR tires and ATIS might be unavailable for small manufacturers. \textit{Id.} Wabash opposes these vague proposals for future delays because they are speculative, unjustified, and unlawful. Generalized fears about the ability to comply years down the road are no basis to grant additional delays now. If concrete problems arise during the implementation of the rule, small manufacturers may petition EPA for relief, which could then be handled pursuant to the agency’s ordinary procedures.}

\footnote{51 See id. at 40,616 (proposed 40 C.F.R. § 1037.150) (“Standards apply on a delayed schedule for manufacturers meeting the small business criteria specified in 13 CFR 121.201.”).}

42 U.S.C. § 7617(e)(1); see also id. § 7617(c) (“Nothing in this section shall be construed to provide that the analysis of the factors specified in this subsection affects or alters the factors which the Administrator is required to consider in taking any action referred to in subsection (a) of this section.”).

42 U.S.C. § 7617(e)(3) (“Nothing in this section shall be construed. . . to authorize or require any judicial review of any such standard or regulation, or any stay or injunction of the proposal, promulgation, or effectiveness of such standard or regulation on the basis of failure to comply with this section.”); see also Motor & Equip. Mfrs. Ass’n v. Nichols, 142 F.3d 449, 467 (D.C. Cir. 1998) (holding that Section 317(e)(3) deprived the court of subject matter jurisdiction to review auto suppliers claims that EPA failed to analyze the small business impacts of a Section 202 rule).

See Michigan v. EPA, 268 F.3d 1075, 1084 (D.C. Cir. 2001) (“EPA cannot rely on its general authority [under the CAA] to make rules necessary to carry out its functions when a specific statutory directive defines the relevant functions of EPA in a particular area.”).

Organization: Rubber Manufacturers Association (RMA)

IV. EPA Should Not Add Regulatory Text Giving the Agency Authority to Recall Trailer Tires

In its October 1, 2015 comments, RMA provided several legal and policy reasons why EPA should not give itself recall authority over tires. RMA’s comments seem to be in line with an EPA legal memorandum recently added to the docket and mentioned in the NODA. Specifically, RMA supports EPA’s acknowledgement in the legal memorandum that tire manufacturers are not vehicle manufacturers under the Clean Air Act, meaning that the agency would not have recall authority over tire manufacturers. [EPA-HQ-OAR-2014-0827-1933-A1 p.5]
In the legal memorandum, EPA distinguished tire manufacturers from trailer manufacturers in such a way to make clear that tire manufacturers should not be considered vehicle manufacturers. First, EPA pointed out that GHG emissions attributable to the trailer are a substantial portion of the total GHG emissions from the tractor trailer. Next, the agency noted that the trailer is a significant, integral part of the finished motor vehicle. Then, because of those reasons, EPA asserted that a trailer manufacturer is not analogous to a part or component manufacturer such as a tire manufacturer or a manufacturer of a side skirt. By making these arguments, EPA acknowledged that a tire’s impact on a trailer’s overall GHG emissions is more attenuated, recognized that tires alone are not a significant portion of a finished motor vehicle, and correctly identified tire manufacturers as part manufacturers. [EPA-HQ-OAR-2014-0827-1933-A1 p.5]

Therefore, by EPA characterizing tire manufacturers as part manufacturers, not vehicle manufacturers, the agency is essentially acknowledging that it would not have recall authority over tire manufacturers. RMA supports this determination for several legal and policy reasons discussed below and in prior comments. [EPA-HQ-OAR-2014-0827-1933-A1 p.6]

In the Preamble to the proposed rule, EPA requested comment on whether it should add regulatory text that would essentially give the agency authority to recall trailer tires that do not conform to the regulations. As support for this idea, EPA pointed to section 207(c)(1) of the Clean Air Act, the Act’s recall provision. Section 207(c)(1) notes that: [EPA-HQ-OAR-2014-0827-1933-A1 p.6]

If the Administrator determines that a substantial number of any class or category of vehicles or engines, although properly maintained and used, do not conform to the regulations ... of this title, when in actual use throughout their useful life ... [the Administrator] shall require the manufacturer to submit a plan for remedying the nonconformity of the vehicles or engines... [EPA-HQ-OAR-2014-0827-1933-A1 p.6]

Section 216 of the Clean Air Act defines manufacturer as “any person engaged in the manufacturing or assembling of new motor vehicles ... or [any person] who acts for and is under control of any such person.” As noted in past comments, the plain language of these provisions seems to provide EPA with recall authority over manufacturers of vehicles and engines only, not over other part manufacturers. [EPA-HQ-OAR-2014-0827-1933-A1 p.6]

The legislative history provides additional evidence that Congress did not intend to give EPA recall authority over other part manufacturers. The portions of the U.S. House Committee Report and the Conference Report that covered section 207 only mention vehicles and engines as the products that could be recalled under that section of the Clean Air Act. The House Committee also envisioned testing of vehicles and engines to be quick, easy, and uniform, which seems incongruous to the testing process for tires. [EPA-HQ-OAR-2014-0827-1933-A1 p.6]

Additionally, tires are a consumable item, not a durable component of the trailer and EPA has historically focused on durable components of vehicles for recall purposes. In addition, unlike many other emissions-related vehicle components, a tire’s efficiency improves (tire rolling resistance decreases) as a tire wears, thus improving the tire’s contribution to fuel economy. In the most recent and publicly available guidance document on recalls, EPA tracked vehicle and engine recalls by problem category and none of the categories seem comparable to tires. For example, EPA recalls have primarily been related to the catalytic system, the fuel delivery system, or the computer system based on their direct impact on emissions. A tire’s impact on emissions is more attenuated. [EPA-HQ-OAR-2014-0827-1933-A1 p.7]
If EPA’s recall regulations were applied to tires, it is unclear how they would be enforced. The agency has acknowledged that insignificant defects do not warrant recalls. But in the proposal EPA does not discuss tolerances or other policies to account for manufacturing or testing variability. Similar issues have been addressed in Europe, where regulations setting rolling resistance performance thresholds set a regulatory allowance of 0.3 kg/t to accommodate sources of variability. [EPA-HQ-OAR-2014-0827-1933-A1 p.7]

Other global regions that have adopted the allowance of +0.3 kg/t allowance for conformity of production testing include: [EPA-HQ-OAR-2014-0827-1933-A1 p.7]

• The Brazilian Regulation # R544 “Conformity Assessment Requirements For New Tires”

• South Korea “Regulations for Measurement of Energy Efficiency of Tires for Motor Vehicles, and Its Rating and Identification”

Without an alignment procedure that addresses sources of testing variability (machine alignment, machine drift, production variation, etc.), demonstrating non-compliance would be very difficult. [EPA-HQ-OAR-2014-0827-1933-A1 p.7]

Response: General EPA Authority Issues

Levels of the Standards and Alternative 4

As described in the FRM preamble and in Chapter 2 of the RIA, the agencies have adopted technology-forcing standards that are fully consistent with the agencies’ respective statutory authorities. However, the agencies have determined that the so-called Alternative 4 pull ahead vehicle standards would not provide sufficient lead time (raising, among other things, issues of technical reliability, as noted by a number of commenters), and thus would not be appropriate under either agency’s authority.

Authority to Exempt Small Businesses

Wabash Corp. argues that section 202 (a)(1) and (2) do not provide authority for EPA to create exemptions for small businesses. (The comment does not address NHTSA’s parallel authority under EISA). The gist of the argument is that section 202 (a)(1) and (2) do not explicitly mention exemption authority or small business impacts, that section 202 previously contained such a provision which was removed in the 1990 amendments, and that other provisions of the Act (notably section 317) do address small business impacts showing that Congress was explicit when desiring EPA to consider such impacts, at least in an exemption context. The comment is perplexing. EPA is required to consider “cost of compliance” in establishing standards under section 202 (a)(2). An aspect of considering costs is (or, at the very least, can be) to consider impacts on small entities. Regulatory costs can impact small businesses disproportionately, and also result in standards which are less cost effective due to the smaller volumes of pollutant emitted. These are all factors EPA at the very least may consider in determining an appropriate regulatory regime. Any exemptions EPA chooses to create as part of this consideration must have a reasoned factual basis, but are certainly not outside EPA’s delegated authority. The commenter’s reference to the former section 202 (b) (1), which was removed by the 1990 amendments, is misplaced. That provision required EPA to consider a different NOx standard and lead time for vehicles manufactured in the 1981 and 1982 model years by smaller volume producers who did not produce their own catalytic converters and lacked the resources to do so. See American Motors Corp. v. Boyd, 603 F. 2d 978 (D.C. Cir.1979). The provision was undoubtedly removed in the 1990 amendments because it was moot. Certainly, there is nothing about that former provision
suggesting that EPA cannot consider whether regulation is warranted under section 202 (a)(2) as part of consideration of costs. Cf. U.S. Sugar Corp. v. EPA, No. 11-1108 (D.C. Cir. July 29, 2016) slip op. at 52 (“Under the CAA, the EPA may sometimes act with a soft touch, rather than a firm hand”).

Authority to Establish Delegated Assembly Provisions

Daimler Truck maintains that EPA lacks authority to establish delegated assembly provisions, largely based on a convoluted argument that Congress intended a more restrictive definition of “commerce” in the Clean Air Act (or perhaps in Title II), and that pre-sale vehicles aren’t introduced into commerce under that restricted definition. At the beginning of this argument, Daimler states that EPA bases its delegated assembly regulations on the authority to regulate the “introduction into commerce”. However, this is incomplete and misleading. The relevant statutory prohibition in section 203(a)(1) prohibits not only the “introduction into commerce” of uncertified vehicles, but also the “distribution in commerce” or “sale” of uncertified vehicles (among others). Daimler does not dispute that, without the exemption provided by the delegated assembly regulations, selling and/or distributing vehicles that are not in a certified configuration is prohibited because such vehicles are not actually covered by a valid certificate of conformity. However, because Daimler’s comment focuses on “introduction into commerce”, the remainder of this response addresses that aspect of their comment.

Delegated assembly provisions are, of course, not unique to this rule and have been in place for many years. See, e.g. 73 FR 59034, 59137-38 (Oct. 8, 2008). Daimler has operated under these provisions (as it acknowledges), and so may be raising its comment far out of time. In this regard, EPA has already addressed the issue of the relationship between the “introduced into commerce” provision of section 203 (a)(1) and the need for delegated assembly allowances in light of that provision, and so has already addressed the scope of the delegated assembly allowance. See 70 FR 40424-25 (July 13, 2005). EPA did not reopen, reconsider, or otherwise seek comment on this longstanding interpretation. However, in the event this seemingly untimely comment requires response, EPA believes that Daimler is mistaken for the reasons set out below.

Daimler’s comment presents the following questions:

1. Does EPA have authority to promulgate pre-sale regulations? More specifically, are pre-sale regulations authorized as regulation of vehicles’ “introduction to commerce” under Sec. 202(a)(1))?

2. Assuming EPA’s ability to regulate pre-sale matters, is EPA authorized to regulate contracts between the primary manufacturer and any secondary manufacturers for the installation of emissions-related components?

These questions can be answered simply:

1. Yes. Pre-sale regulations fall within the scope of EPA’s general Title II authority. In addition, “introduction into commerce” includes pre-sale activities, as “commerce” is not narrowly defined in the Clean Air Act.

2. Yes. EPA may condition the granting of certificates of conformity on a wide range of factors, especially when the primary manufacturer is relying on a secondary manufacturer for partial assembly of the vehicle.

We explain these answers below.
I. Pre-sale regulation clearly falls within the scope of EPA’s general Title II authority.

For most of Title II, no line is drawn for the point at which EPA may begin to regulate. In fact, much of Title II specifically contemplates pre-sale regulation. For example, Sec. 203(a)(3)(A) forbids removal or tampering with devices installed “in compliance with regulations under this subchapter prior to its sale…” and Sec. 203 (a)(3)(B) expressly prohibits “any person to manufacture or sell, or offer to sell, or install, any part or component…where a principle effect of the part is to” render such devices inoperative. Certification under section 206 necessarily addresses pre-sale vehicles.

II. The Clean Air Act does not create a narrow definition of “commerce.”

The commenter relies on context clues to argue that the definition of “commerce” under the Clean Air Act (or at least Title II) is narrower than Congress’s authority over commerce. There is no direct evidence of Congressional intent to shrink the definition of commerce in the Clean Air Act, however. In fact, Sec. 216(6) defines “commerce” as “(A) commerce between any place in any State and any place outside thereof; and (B) commerce wholly within the District of Columbia.” (The commenter, surprisingly, does not even cite this provision). If Congress had meant to define commerce differently from its well-accepted and heavily litigated legal definition, which, as the commenter point out, extends to manufacturing activities, it would have done so expressly in Sec. 216.

III. “Introduction into commerce” includes pre-sale activities.

Congress also meant “introduction into commerce” to include manufacturing and other pre-sale activities. The commenter argues that “if Congress considered ‘introduction into commerce’ to include manufacturing, then the ‘manufacture for sale’ is surplusage in the sections of the CAA where it sits alongside mention of sale or introduction into commerce.” However, it is clear that the lists of activities outlined in various parts of the Clean Air Act and quoted in part by the commenter are repetitive by design—otherwise, the same surplusage logic applies with equal force to the term “introduction to commerce” itself. The use of “introduction to commerce” in these lists across the Clean Air Act is instructive:

- Sec. 183(e)(3)(A) (42 U.S.C. Sec. 7511b(e)(3)(A)): “In order to carry out this section, the Administrator may, by regulation, control or prohibit any activity, including the manufacture or introduction into commerce, offering for sale, or sale of any consumer or commercial product…”
- Sec. 187(b)(3) (42 U.S.C. Sec. 7512a(b)(3)): “The State shall submit a revision to require that gasoline sold, supplied, offered for sale or supply, dispensed, transported or introduced into commerce…be blended…”
- Sec. 203(a)(1) (42 U.S.C. Sec. 7522(a)(1)) (the provision at issue here): “In the case of a manufacturer…the sale, or the offering for sale, or the introduction, or delivery for introduction, into commerce [is prohibited]…”
- Sec. 211(a) (42 U.S.C. Sec. 7545(a)): “No manufacturer or processor of any such fuel or additive may sell, offer for sale, or introduce into commerce such fuel or additive…”
- Sec. 211(c)(1) (42 U.S.C. Sec. 7545(c)(1)): “The Administrator may…by regulation, control or prohibit the manufacture, introduction into commerce, offering for sale, or sale of any fuel or fuel additive for use in a motor vehicle…”
- Sec. 211(f)(2) (42 U.S.C. Sec. 7545(f)(2)): “It shall be unlawful for any manufacturer of any fuel to introduce into commerce any gasoline which contains a concentration of manganese in excess of .0625…”
- Sec. 211(h)(1) (42 U.S.C. Sec. 7545(h)(1)): “The Administrator shall promulgate regulations making it unlawful for any person during the high ozone season…to sell, offer for sale, dispense, supply, offer for supply, transport, or introduce into commerce gasoline…”

It is unclear from many of these lists what independent work “introduce into commerce” is doing. What does it mean, if not “sale, offer for sale, dispense, supply, offer for supply, [or] transport”? It seems to have been designed by Congress as a catch-all term that allows EPA to regulate commerce-related activities, manufacturing included.

Furthermore, those sections of the Clean Air Act either specifically apply to manufacturers (Secs. 203(a)(1), 211(a), and 211(f)(2)), specifically include manufacturing (Secs. 183(e)(3)(A) and 211(c)(1)), or regulate a product in which manufacturing restrictions would be absurd (Sec. 187(b)(3)), which requires gasoline to be blended with oxygen-rich fuels in certain areas and during certain times of the year to provide for attainment of carbon monoxide NAAQS, and Sec. 211(h)(1), which has a similar time- and place-specific requirement to provide for attainment of the ozone NAAQS).

If a manufacturer is being regulated for what it can “introduce into commerce,” that regulation naturally extends to the manufacturing itself. Congress only needed to include “manufacture” in the list of activities that could be regulated for provisions that applied to a broader set of actors than manufacturers themselves.

The commenter also attempts to draw a parallel between “introduction into commerce” and the “useful life” provisions of Title II. That parallel does not seem to exist in any statutory language or legislative history of which EPA is aware. “Useful life” and “introduction into commerce” are used in very different ways in distinct sections of the Clean Air Act, and thus do not inform each other’s definitions.

IV. Legislative history supports the view that Sec. 203 allows for regulation of pre-sale activities.

The commenter draws attention to changes in the language of Sec. 203 during the passage of the 1970 Clean Air Act Amendments, but brings up no evidence that these changes actually restrict EPA authority to regulate pre-sale activities. Throughout the debates and eventual passage of the 1970 amendments, Congress made sure to characterize all of the changes made to Sec. 203 as either the status quo (“Sections 203, 204, and 205 would be, for practicable purposes, repetition of existing law.” S. Rep. No. 91-1196, at 28) or as expansions of EPA’s authority (“This revised section [203] extends the prohibitions now in the Act” in numerous areas. S. Rep. No. 91-1196, at 61).

Statements made during the House debate of the bill support this interpretation. In regards to Sections 203 and 206, “the bill provides for tighter automotive emission control standards and for new testing and certification procedures to insure that new motor vehicle engines comply with the regulations.” 116 Cong. Rec. 19,220 (1970) (statement of Rep. Monagan). The same is true for hearings in the Senate. “We wrote the law with the intention of giving the Secretary every authority he could conceivably need” in regards to certificates of conformity. Air Pollution – 1970: Hearing on S. 2466 Before the Subcomm. on Air and Water Pollution of the S. Comm. on Public Works, 91st Cong. (1970) (Statement of Sen. Muskie).
V. EPA’s testing and inspection authority extends to creation of the “delegated assembly” regulatory provisions.

Under Sec. 206(a)(1), EPA is authorized to issue certificates of conformity to manufacturers whose products pass testing requirements laid down by EPA (“tested in such a manner as [the Administrator] deems appropriate”). Part of that testing regime is being able to understand how individual components of the vehicle contribute to emissions or emissions reductions. Sec. 206(a)(3) explains that such a certificate may only be issued if “any emissions control device, system, or element of design” abides by applicable regulations in Sec. 202(a)(4), which allows for the Administrator to consider a number of factors.

As noted above, delegated assembly provisions were created by EPA years ago to handle the realities of the manufacturing process, especially for heavy duty vehicles, in accord with the structure of the Clean Air Act. If most of a vehicle is built by a primary manufacturer, and then emissions control devices or any other part are installed by a secondary manufacturer, EPA must inquire into the communications and contracts between those manufacturers to verify that the correct parts are going on the correct vehicles consistently, and the installation process is occurring according to the regulations. Certificates of conformity are how Congress empowered EPA to verify the consistency of the manufacturing and recordkeeping processes taken by manufacturers so that the agency didn’t have to require extensive testing of every vehicle that came off the line. Delegated assembly provisions, including certain requirements for contracts between primary and secondary manufacturers, allow EPA to continue to issue certificates of conformity for manufacturers who do not assemble the entire vehicle on their own. Without those provisions, EPA would be unable to verify that Sec. 206(a)(3)’s statutory mandate was fulfilled.

The commenter argues that even if EPA can regulate prior to first sale of a vehicle, it still can only adopt “test-based” provisions, and concludes that “prescribing procedures relating to contracts between manufacturers is not ‘testing’”. This argument fails for the reasons just given. The delegated assembly provisions are a necessary adjunct to the certification (i.e. testing) requirements which are the heart of Title II’s compliance regime. This is not regulating the means of manufacture, as the commenter would have it, but rather part of the process of assuring that the vehicle will be assembled in its certified condition.

Finally, Daimler omits mention of several additional relevant points. First, delegated assembly is an option provided as a flexibility in multi-manufacturer situations, but Daimler is free to be the sole manufacturer of the motor vehicle. Second, even if (against our view) one were to accept the commenter’s argument of a restrictive definition of commerce, “the offering for sale” and the “delivery for introduction, into commerce” of vehicles without a certificate would still be prohibited. See section 203 (a)(1) of the Act. (As noted above, these additional prohibitions also indicate on their face that pre-sale activities are within EPA’s authority under Title II.) Thus, a vehicle must evidently be in certified condition pre-sale by some means. The delegated assembly provisions provide flexibility in multi-manufacturer situations but they are voluntary. Daimler remains free to act as a sole manufacturer should it not wish to utilize the delegated assembly flexibility.

Recall Authority over Tires

The Rubber Manufacturers Association maintain that recall authority exists only with respect to vehicles and engines, and because tires are a part, and not a vehicle or an engine, tire manufacturers cannot be compelled to recall tires. The commenter also points to EPA’s discussion in the context of trailers and glider kits which it believes illustrates that, unlike trailers and glider kits, tires are parts, not vehicles.
CAA section 207(c)(1) requires “the manufacturer” to remedy certain in-use problems. The remedy process is generally called recall, and the regulations for this process are in 40 CFR part 1068, subpart F. EPA requested comment on whether to apply these requirements to tire manufacturers in the case of in-use problems with trailer tires. EPA is not adopting this suggestion in the Phase 2 rules, and so we are not requiring that component manufacturers conduct recalls independent of the certificate holder. The Rubber Manufacturers Association indicates correctly that tires are not incomplete vehicles and hence that the recall authority does not apply. However, EPA remains of the view that in the event that trailers do not conform to the standards in-use due to nonconforming tires, tire manufacturers would have a role to play in remedying the problem. In this (hypothetical) situation, a tire manufacturer would not only have produced the part in question, but would have significantly more resources and knowledge regarding how to address (and redress) the problem. Accordingly, EPA would likely require that a component manufacturer responsible for the nonconformity assist in the recall to an extent and in a manner consistent with the provisions of CAA 208 (a). This section specifies that component and part manufacturers “shall establish and maintain records, perform tests where such testing is not otherwise reasonably available under this part and part C of this subchapter (including fees for testing), make reports and provide information the Administrator may reasonably require to determine whether the manufacturer or other person has acted or is acting in compliance with this part and part C of this subchapter and regulations thereunder, or to otherwise carry out the provision of this part and part C of this subchapter...”. Any such action would be considered on a case-by-case basis, adapted to the particular circumstances at the time.

Response: EPA Authority for Gliders and Trailers

In this final rule, EPA is establishing first-time CO₂ emission standards for trailers hauled by tractors. 80 FR 40170. Certain commenters, notably the Truck Trailer Manufacturers Association (TTMA), maintained that EPA lacks authority to adopt requirements for trailer manufacturers, and that emission standards for trailers could be implemented, if at all, by requirements applicable to the entity assembling a tractor-trailer combination. The argument is that trailers by themselves are not “motor vehicles” as defined in section 216 (2) of the Act, that trailer manufacturers therefore do not manufacture motor vehicles, and that standards for trailers can be imposed, if at all, only on “the party that joined the trailer to the tractor.” Comments of TTMA, p. 4; Comments of TTMA (March 31, 2016) p. 2.

EPA also proposed a number of changes and clarifications for rules respecting glider kits and glider vehicles. 80 FR 40527-40530. As shown in Error! Reference source not found., a glider kit is a tractor chassis with frame, front axle, interior and exterior cab, and brakes. It is intended for self-propelled highway use, and becomes a glider vehicle when an engine, transmission, and rear axle are added. Engines are often salvaged from earlier model year vehicles, remanufactured, and installed in the glider kit. The final manufacturer of the glider vehicle, i.e. the entity that installs an engine, is typically a different manufacturer than the original manufacturer of the glider kit. The final rule contains emission standards for engines used in glider vehicles and for greenhouse gas emissions from glider vehicles, but does not contain separate standards for glider kits.²

² As discussed below, however, manufacturers of glider kits can, and typically are, responsible for obtaining a certificate of conformity before shipping a glider kit. This is because they are manufacturers of motor vehicles, in this case, an incomplete vehicle. Note that Daimler, in its comments, essentially indicates (in the context of comments related to delegated assembly provisions) that EPA may adopt “test-based” provisions for manufacturers of incomplete vehicles (“even if the EPA could regulate prior to the first use of an engine or
Many commenters to both the proposed rule and the NODA supported EPA’s interpretation. However, a number of commenters, including Daimler, argued that glider kits are not motor vehicles and so EPA lacks the authority to impose any rules respecting their sale or configuration. Comments of Daimler, pp.

vehicle, Congress authorized only test-based standards …testing of vehicles or engines is the means by which the EPA determines the compliance that is necessary for a vehicle or engine’s introduction into commerce”) The provisions applicable to glider kits are just this type of testing provision, examples being testing of tires and aerodynamic components to generate inputs used in the certification process. (The commenter’s arguments that other aspects of the delegated assembly provisions are impermissible are addressed earlier in this same Response).
Under the Act, “motor vehicle” is defined as “any self-propelled vehicle designed for transporting persons or property on a street or highway.” CAA section 216 (2). At proposal, EPA maintained that tractor-trailers are motor vehicles and that EPA therefore has the authority to promulgate emission standards for complete and incomplete vehicles – both the tractor and the trailer. 80 FR 40170. The same proposition holds for glider kits and glider vehicles. Id. at 80 FR 40528. The argument that a trailer, or a glider kit, standing alone, is not self-propelled, and therefore is not a motor vehicle, misses the key issues of authority under the Clean Air Act to promulgate emission standards for motor vehicles produced in discrete segments, and the further issue of the entities – namely “manufacturers” – to which standards and certification requirements apply. Simply put, EPA is authorized to set emission standards for complete and incomplete motor vehicles, manufacturers of complete and incomplete motor vehicles can be required to certify to those emission standards, and there can be multiple manufacturers of a motor vehicle, each of which can be required to certify.

Standards for Complete Vehicles – Tractor-Trailers and Glider Vehicles

Section 202 (a)(1) authorizes EPA to set standards “applicable to the emission of any air pollutant from any … new motor vehicles.” There is no question that EPA is authorized to establish emission standards under this provision for complete new motor vehicles, and thus can promulgate emission standards for air pollutants emitted by tractor-trailers and by glider vehicles.

Daimler maintained in its comments that although a glider vehicle is a motor vehicle, it is not a “new” motor vehicle because “glider vehicles, when constructed retain the identity of the donor vehicle, such that the title has already been exchanged, making the vehicles not ‘new’ under the CAA.” Daimler Comments p. 121; see also the similar argument in Daimler Truck Comments (April 1, 2016), p. 4. Daimler maintains that because title to the powertrain from the donor vehicle has already been transferred, the glider vehicle to which the powertrain is added cannot be “new.” Comments of April 1, 2016 p. 4. Daimler also notes that NHTSA considers a truck to be "newly manufactured" and subject to Federal Motor Vehicle Safety Standards when a new cab is used in its assembly, "unless the engine, transmission, and drive axle(s) (as a minimum) of the assembled vehicle are not new, and at least two of these components were taken from the same vehicle." 49 CFR 571.7(e). Daimler urges EPA to adopt a parallel provision here.

First, this argument appears to be untimely. In Phase 1, EPA already indicated that glider vehicles are new motor vehicles, at least implicitly, by adopting an interim exemption for them. See 76 FR 57407 (adopting 40 CFR 1037.150(j) indicating that the general prohibition against introducing a vehicle not subject to current model year standards does not apply to MY 2013 or earlier engines). Assuming the argument that glider vehicles are not new can be raised in this rulemaking, EPA notes that the Clean Air Act defines “new motor vehicle” as “a motor vehicle the equitable or legal title to which has never been transferred to an ultimate purchaser” (section 216(3)). Glider vehicles are typically marketed and sold as “brand new” trucks. Indeed, one prominent assembler of glider kits and glider vehicles advertises that “Fitzgerald Glider Kits offers customers the option to purchase a brand new 2016 tractor, in any configuration offered by the manufacturer… Fitzgerald Glider Kits has mastered the process of taking the ‘Glider Kit’ and installing the components to work seamlessly with the new truck.” 3

---

3 Advertisement for Fitzgerald Glider kits in Overdrive magazine (December 2015)(emphasis added).
of a “new truck” necessarily takes initial title to that truck. Daimler would have it that this ‘new truck’ terminology is a mere marketing ploy, but it obviously reflects reality. As shown in Error! Reference source not found. above, the glider kit constitutes the major parts of the vehicle, lacking only the engine, transmission, and rear axle. The EPA sees nothing in the Act that compels the result that adding a used component to an otherwise new motor vehicle necessarily vitiates classification of the motor vehicle as “new.” See 80 FR 40528. Certainly, there is no language in the definition of “new motor vehicle” which directly addresses this issue. Indeed, as noted in Preamble section I.E.1, the definition of “new motor vehicle engine” encompasses engines of any vintage. At the least, this shows that the model year of the engine is not determinative of whether the motor vehicle is “new”. Put another way, a “new motor vehicle” can contain an earlier model year engine. See CAA section 216 (3). Many commenters agreed. See, e.g. Comments of MECA (“Glider vehicles are classified as “new motor vehicles” because they use a new chassis, although they can continue to use engines that are 10-15 years old and emit 20-40 times more pollution than vehicles equipped with a new engine”). Thus, EPA is reasonably interpreting the Act to indicate that adding the engine and transmission to the otherwise-complete vehicle does not prevent the glider vehicle from being “new” – as marketed. As to the suggestion to adopt a provision parallel to the NHTSA definition, EPA notes that the NHTSA definition was developed for different purposes using statutory authority which differs from the Clean Air Act in language and intent. There consequently is no basis for requiring EPA to adopt such a definition, and doing so would impede meaningful control of both GHG emissions and criteria pollutant emissions from glider vehicles, the latter being an imperative, immediate public health concern (see RTC 14.2).

Standards for Incomplete Vehicles

Section 202 (a)(1) not only authorized EPA to set standards “applicable to the emission of any air pollutant from any … new motor vehicles,” but states further that these standards are applicable “whether such vehicles … are designed as complete systems or incorporate devices to prevent or control such pollution.” The Act in fact thus not only contemplates, but in some instances, directly commands that EPA establish standards for incomplete vehicles and vehicle components. See CAA section 202 (a)(6) (standards for onboard vapor recovery systems on “new light-duty vehicles,” and requiring installation of such systems); section 202 (a)(5)(A) (standards to control emissions from refueling motor vehicles, and requiring consideration of, and possible design standards for, fueling system components); 202 (k) (standards to control evaporative emissions from gasoline-fueled motor vehicles).

Both TTMA and Daimler argued, in effect, that these provisions are the exceptions that prove the rule and that without this type of enumerated exception, only entire, complete vehicles can be considered to be “motor vehicles.” This argument is not persuasive. Congress did not indicate that these incomplete vehicle provisions were exceptions to the definition of motor vehicle. Just the opposite. Without amending the new motor vehicle definition, or otherwise indicating that these provisions were not already encompassed within Title II authority over “new motor vehicles”, Congress required EPA to set standards for evaporative emissions from a portion of a motor vehicle. Congress thus indicated in these provisions: 1) that standards should apply to “vehicles” whether or not the “vehicles” were designed as complete systems; 2) that some standards should explicitly apply only to certain components of a

4 Fitzgerald states “All Fitzgerald glider kits will be titled in the state of Tennessee and you will receive a title to transfer to your state.” https://www.fitzgeraldgliderkits.com/frequently-asked-questions. Last accessed July 9, 2016.

5 EPA has also previously addressed the issue of used components in new engines and vehicles explicitly in regulations in the context of locomotives and locomotive engines in 40 CFR part 1033. There we defined remanufactured locomotives and locomotive engines to be “new” locomotives and locomotive engines. See 63 FR 18980; see also Summary and Analysis of Comments on Notice of Proposed Rulemaking for Emission Standards for Locomotives and Locomotive Engines (EPA-420-R-97-101 (December 1997)) at pp. 10-14.
vehicle that are plainly not self-propelled. Congress thus necessarily was of the view that incomplete vehicles can be motor vehicles.

Emission standards EPA sets pursuant to this authority thus can be, and often are focused on emissions from the new motor vehicle, and from portions, systems, parts, or components of the vehicle. Standards thus apply not just to exhaust emissions, but to emissions from non-exhaust portions of a vehicle, or from specific vehicle components or parts. See the various evaporative emission standards for light duty vehicles in 40 CFR part 86, subpart B (e.g., 40 CFR 86.146-96 and 86.150-98 (refueling spitback and refueling test procedures); 40 CFR 1060.101-103 and 73 FR 59114-59115 (various evaporative emission standards for small spark ignition equipment); 40 CFR 86.1813-17(a)(2)(iii) (canister bleed evaporative emission test procedure, where testing is solely of fuel tank and evaporative canister); see also 79 FR 23507 (April 28, 2014) (incomplete heavy duty gasoline vehicles could be subject to, and required to certify compliance with, evaporative emission standards)). These standards are implemented by testing the particular vehicle component, not by whole vehicle testing, notwithstanding that the component may not be self-propelled until it is installed in the vehicle or (in the case of non-road equipment), propelled by an engine.6

EPA thus can set standards for all or just a portion of the motor vehicle notwithstanding that an incomplete motor vehicle may not yet be self-propelled. This is not to say that the Act authorizes emission standards for any part of a motor vehicle, however insignificant. Under the Act it is reasonable to consider both the significance of the components in comparison to the entire vehicle and the significance of the components for achieving emissions reductions. A vehicle that is complete except for an ignition switch can be subject to standards even though it is not self-propelled. Likewise, as just noted, vehicle components that are significant for controlling evaporative emissions can be subject to standards even though in isolation the components are not self-propelled. However, not every individual component of a complete vehicle can be subjected to standards as an incomplete vehicle. To reflect these considerations, EPA is adopting provisions stating that a trailer is a vehicle “when it has a frame with one or more axles attached,” and a glider kit becomes a vehicle when “it includes a passenger compartment attached to a frame with one or more axles.” Section 1037.801 definition of “vehicle,” paragraphs (1)(ii) and (iii); see also Section XIII.B of the FRM Preamble.

TTMA and Daimler each maintained that this claim of authority is open-ended, and can be extended to the least significant vehicle part. As noted above, EPA acknowledges that lines need to be drawn, but whether looking at the relation between the incomplete vehicle and the complete vehicle, or looking at the relation between the incomplete vehicle and the emissions control requirements, it is evident that trailers and glider kits should properly be treated as vehicles, albeit incomplete ones.7 They properly fall on the vehicle side of the line. When one finishes assembling a whole aggregation of parts to make a finished section of the vehicle (e.g. the trailer), that is sufficient. You have an entire, complete section made up of assembled parts. Everything needed to be a trailer is complete. This is not an engine block, a wheel, or a headlight. Similarly, glider kits comprise the largely assembled tractor chassis with front axles, frame, interior and exterior cab, and brakes. This is not a few assembled components; rather, it is an assembled truck with a few components missing. See CAA section 216 (9) of the Act, which defines

---

6 “Non-road vehicles” are defined differently than “motor vehicles” under the Act, but the difference does not appear relevant here. Non-road vehicles, like motor vehicles, must be propelled by an engine. See CAA section 216 (11) (“nonroad vehicle’ means a vehicle that is powered by a nonroad engine”). Pursuant to this authority, EPA has promulgated many emission standards applicable to components of engineless non-road equipment, for which the equipment manufacturer must certify.

7 Cf. Marine Shale Processors v. EPA, 81 F. 3d 1371, 1383 (5th Cir. 1996) (“[w]e make no comment on this argument: this is simply not a thimbleful case”).

Page 57 of 2127
“motor vehicle or engine part manufacturer” as “any person engaged in the manufacturing, assembling or rebuilding of any device, system, part, component or element of design which is installed in or on motor vehicles or motor vehicle engines.” Trailers and glider kits are not “installed in or on” a motor vehicle. A trailer is half of the tractor-trailer, not some component installed on the tractor. And one would more naturally refer to the donor drivetrain being installed on the glider kit than vice versa. See Figure 1 above. Furthermore, as discussed below, the trailer and the glider kit are significant for purposes of controlling emissions from the completed vehicle.

Incomplete vehicle standards must, of course, be reasonably designed to control emissions caused by that particular vehicle segment. The standards for trailers would do so and account for the tractor-trailer combination by using a reference tractor in the trailer test procedure (and, conversely, by use of a reference trailer in the tractor test procedure). The Phase 2 rule contains no emission standards for glider kits in isolation, but the standards for engines installed in glider vehicles, and the greenhouse gas standards for the glider vehicles, necessarily reflect the contribution of the glider kit.

Application of Emission Standards to Manufacturers

In some ways, the critical issue is to whom do these emission standards apply.\(^8\) As explained in this section, the emission standards apply to manufacturers of motor vehicles, and manufacturers thus are required to certify compliance to test and to certify compliance to those standards. Moreover, the Act contemplates that a motor vehicle can have multiple manufacturers. With respect to the further question of which manufacturer certifies and tests in multiple manufacturer situations, EPA rules have long contained provisions establishing responsibilities where a vehicle has multiple manufacturers. We are again applying the principles already established in these rules in the Phase 2 provisions. The overarching and common sense principle is that the entity with most control over the particular vehicle segment due to producing it is usually the most appropriate entity to test and certify.\(^9\) EPA is implementing the trailer and glider vehicle emission standards in accord with this principle, so that the entities required to test and certify are the trailer manufacturer and, for glider kits and glider vehicles, either the manufacturer of the glider kit or glider vehicle, depending on which is more appropriate in individual circumstances.

Definition of Manufacturer

Emission standards are implemented through regulation of the manufacturer of the new motor vehicle. See, e.g. section 206 (a)(1) (certification testing of motor vehicle submitted by “a manufacturer”); 203 (a)(1) (manufacturer of new motor vehicle prohibited from introducing uncertified motor vehicles into commerce); 207 (a)(1) (manufacturer of motor vehicle to provide warranty to ultimate purchaser of

---

\(^8\) This issue is independent of the discussion above, and thus is not dependent on whether trailers are motor vehicles. Under any theory, EPA may issue emission standards for new motor vehicles and engines. Manufacturers of these vehicles and engines can be required to comply with these standards by testing and certification, and the Act contemplates multiple manufacturers to whom these obligations can attach.

\(^9\) See discussion of standards applicable to small SI equipment fuel systems, implemented by standards for the manufacturers of that equipment at 73 FR 59115 (“In most cases, nonroad standards apply to the manufacturer of the engine or the manufacturer of the nonroad equipment. Here, the products subject to the standards (fuel lines and fuel tanks) are typically manufactured by a different manufacturer. In most cases the engine manufacturers do not produce complete fuel systems and therefore are not in a position to do all the testing and certification work necessary to cover the whole range of products that will be used. We are therefore providing an arrangement in which manufacturers of fuel-system components are in most cases subject to the standards and are subject to certification and other compliance requirements associated with the applicable standards.”).
compliance with applicable emission standards); 207 (c) (recall authority); 208 (a) (recordkeeping and testing can be required of every manufacturer of new motor vehicle).

The Act further distinguishes between manufacturers of motor vehicles and manufacturers of motor vehicle parts. See, e.g. section 206 (a)(2) (voluntary emission control system verification testing); 203 (a)(3)(B) (prohibition on parts manufacturers and other persons relating to defeat devices); 207 (a)(2) (parts manufacturer may provide warranty certification regarding use of parts); 208 (a) (recordkeeping and testing requirements for manufacturers of vehicle and engine “parts or components”).

Thus, the question here is whether a trailer manufacturer or glider kit manufacturer can be a manufacturer of a new motor vehicle and thereby become subject to the certification and related requirements for manufacturers, or must necessarily be classified as a manufacturer of a motor vehicle part or component. EPA may reasonably classify trailer manufacturers and glider kit manufacturers as motor vehicle manufacturers.

Section 216 (1) defines a “manufacturer” as:

“any person engaged in the manufacturing or assembling of new motor vehicles, new motor vehicle engines, new nonroad vehicles or new nonroad engines, or importing such vehicles or engines for resale, or who acts for and is under the control of any such person in connection with the distribution of new motor vehicles, new motor vehicle engines, new nonroad vehicles or new nonroad engines, but shall not include any dealer with respect to new motor vehicles, new motor vehicle engines, new nonroad vehicles or new nonroad engines received by him in commerce”

It appears plain that this definition was not intended to restrict the definition of “manufacturer” to a single person per vehicle. The use of the conjunctive, specifying that a manufacturer is “any person engaged in the manufacturing or assembling of new motor vehicles . . . or who acts for and is under the control of any such person…” (emphasis added) indicates that Congress anticipated that motor vehicles could have more than one manufacturer, since in at least some cases those will plainly be different people. The capacious reference to “any person engaged in the manufacturing of motor vehicles” likewise allows the natural inference that it could apply to multiple entities engaged in manufacturing.  

The provision also applies both to entities that manufacture and entities that assemble, and does so in such a way as to encompass multiple parties: manufacturers “or” (rather than ‘and’) assemblers are included. Nor is there any obvious reason that only one person can be engaged in vehicle manufacture or vehicle assembling.

Reading the Act to provide for multiple motor vehicle manufacturers reasonably reflects industry realities, and achieves important goals of the CAA. Since title II requirements are generally imposed on “manufacturers” it is important that the appropriate parties be included within the definition of manufacturer ---“any person engaged in the manufacturing or assembling of new motor vehicles.” Indeed, as set out in Chapter 1 of the RIA, most heavy-duty vehicles are manufactured or assembled by multiple entities; see also Comments of Daimler (October 1, 2015) p. 103. One entity produces a

---

10 See United States v. Gonzales, 520 U.S. 1, 5, (1997) (“Read naturally the word `any' has an expansive meaning, that is, `one or some indiscriminately of whatever kind’); New York v. EPA, 443 F.3d 880, 884-87 (DC Cir. 2006).

11 “The EPA should understand that vehicle manufacturing is a multi-stage process (regardless of the technologies on the vehicles) and that each stage of manufacturer has the incentive to properly complete manufacturing …[T]he
chassis; a different entity manufactures the engine; specialized components (e.g. garbage compactors, cement mixers) are produced by still different entities. For tractor-trailers, one person manufactures the tractor, another the trailer, a third the engine, and another typically assembles the trailer to the tractor. Installation of various vehicle components occurs at different and varied points and by different entities, depending on ultimate desired configurations. See, e.g. Comments of Navistar (October 1, 2015), pp. 12-13. The heavy-duty sector thus differs markedly from the light-duty sector (and from manufacturing of light duty pickups and vans), where a single company designs the vehicle and engine (and many of the parts), and does all assembling of components into the finished motor vehicle.

Controls on Manufacturers of Trailers

It is reasonable to view the trailer manufacturer as “engaged in” (section 216 (1)) the manufacturing or assembling of the tractor-trailer. The trailer manufacturer designs, builds, and assembles a complete and finished portion of the tractor-trailer. All components of the trailer – the tires, axles, flat bed, outsider cover, aerodynamics – are within its control and are part of its assembling process. The trailer manufacturer sets the design specifications that affect the GHG emissions attributable to pulling the trailer. It commences all work on the trailer, and when that work is complete, nothing more is to be done. The trailer is a finished product. With respect to the trailer, the trailer manufacturer is analogous to the manufacturer of the light duty vehicle, specifying, controlling, and assembling all aspects of the product from inception to completion. GHG emissions attributable to the trailer are a substantial portion of the total GHG emissions from the tractor-trailer. Moreover, the trailer manufacturer is not analogous to the manufacturer of a vehicle part or component, like a tire manufacturer, or to the manufacturer of a side skirt. The trailer is a significant, integral part of the finished motor vehicle, and is essential for the tractor-trailer to carry out its commercial purpose. See 80 FR 40170; see also the comment of EDF at n. 104, explaining that trucking companies do not provide insurance protection for truckers when operating a truck-tractor without an attached trailer; it is considered to be a non-business activity. Although it is true that another person may ultimately hitch the trailer to a tractor (which might be viewed as completing assembly of the tractor-trailer), as noted above, EPA does not believe that the fact that one person might qualify as a manufacturer, due to “assembling” the motor vehicle, precludes another person from qualifying as a manufacturer, due to “manufacturing” the motor vehicle. Given that section 216(1) does not restrict motor vehicle manufacturers to a single entity, it appears to be consistent with the facts and the Act to consider trailer manufacturers as persons engaged in the manufacture of a motor vehicle.

This interpretation of section 216(1) is also reasonable in light of the various provisions noted above relating to implementation of the emissions standards – certification under section 206, prohibitions on entry into commerce under section 203, warranty and recall under section 207, and recall under section 208. All of these provisions are naturally applied to the entity responsible for manufacturing the trailer, which manufacturer is likewise responsible for its GHG emissions.

EPA should continue the longstanding industry practice of allowing primary manufacturers to pass incomplete vehicles with incomplete vehicle documents to secondary manufacturers who complete the installation.”

12 The relative contribution of trailer controls depends on the types of tractors and trailers, as well as the tier of standards applicable; however, it can be approximately one-third of the total reduction achievable for the tractor-trailer.

13 Truckers must separately purchase ‘bobtail insurance’ to be covered between dropping off one trailer load and picking up the next one. See, e.g. Insure My Rig, http://www.insuremyrig.com/what-is-bobtail-insurance.html (last visited Sept. 29, 2015); Understanding the Difference Between Bobtail and Non-Trucking Liability Insurance.
TTMA maintains that if a tractor-trailer is a motor vehicle, then only the entity connecting the trailer to the tractor could be subject to regulation.\(^{14}\) This is not a necessary interpretation of section 216 (1), as explained above. TTMA does not discuss that provision, but notes that other provisions refer to “a” manufacturer (or, in one instance, “the” manufacturer), and maintains that this shows that only a single entity can be a manufacturer. See TTMA Comment pp. 4-5, citing to sections 206 (a)(1), 206 (b), 207, and 203 (a). This reading is not compelled by the statutory text. First, the term “manufacturer” in all of these provisions necessarily reflects the underlying definition in section 216(1), and therefore is not limited to a single entity, as just discussed. Second, the interpretation makes no practical sense. An end assembler of a tractor-trailer is not in a position to certify and warrant performance of the trailer, given that the end-assembler has no control over how trailers are designed, constructed, or even which trailers are attached to the tractor. It makes little sense for the entity least able to control the outcome to be responsible for that outcome. The EPA doubts that Congress compelled such an ungainly implementation mechanism, especially given that it is well known that vehicle manufacture responsibility in the heavy-duty vehicle sector is divided. Moreover, the reference to “a” rather than “the” manufacturer in the provisions of section 206(a)(1) and 203(a)(1) – the provisions on vehicle certification and prohibited acts which are the most critical to Title II’s implementation -- is ambiguous as to whether there can be multiple manufacturers. See Webster’s New Collegiate Dictionary (1979) (definition of “a” includes “any”, the same capacious term used in the section 216 definition of “manufacturer”).

TTMA further maintains that the various requirements and prohibitions in Title “on their face do not work as applied to ‘two detachable parts’ of a single motor vehicle that are mixed and matched. In the case of separate manufacturers of the tractor and various trailers that might be hauled by that tractor, the requirements to test, certify, and warrant ‘the motor vehicle’ cannot on their face apply as written, since there is no single manufacturer of ‘the motor vehicle.’ And responsibility for violations, such as by selling an uncertified new motor vehicle, is unspecified.”

EPA disagrees. As just explained, the definition of “manufacturer” plainly contemplates that more than one entity can be the manufacturer of a motor vehicle (as do the references to “a manufacturer”). The fact that portions of the CAA refer to “a manufacturer” does not amend the explicit definition of “manufacturer” to limit it to a single entity per motor vehicle — it merely indicates the responsibilities that can attach to any entity that manufactures motor vehicles. EPA has long interpreted and applied these provisions in a manner that comports with Congressional intent and industry practice to place the responsibilities for certification with the most appropriate of those entities. This can be done by explicitly assigning certification responsibility, or by having multiple manufacturers determine among themselves which are the most appropriate to certify given their particular division of responsibilities. Thus, in the case of tractor-trailers, the entity that has control over design and emissions performance of the tractor is responsible for testing and certifying that the tractor will comply with applicable standards, while the entity that has control over design and emissions performance of the trailer is responsible for testing and certifying that the trailer will comply with applicable standards. The long-standing provisions on delegated assembly and secondary manufacturing are examples of the second situation where manufacturers determine among themselves testing, documentation, and certification responsibilities. See 40 CFR 1037.620, 1037.621, 1037.622, and Preamble Section I.F.2.e.

EPA is therefore reasonably interpreting the definition of “manufacturer” and the various implementation provisions using that term to reflect the realities of the heavy duty vehicle industry whereby multiple manufacturers are responsible for assembling the motor vehicle.

\(^{14}\) Consequently, the essential issue here is not whether EPA can issue and implement emission standards for trailers, but at what point in the implementation process those standards apply.
Controls on Manufacturers of Glider Kits

Application of these same principles indicate that a glider kit manufacturer is a manufacturer of a motor vehicle and, as an entity responsible for assuring that glider vehicles meet the Phase 2 vehicle emission standards, can be a party in the certification process as either the certificate holder or the entity which provides essential test information to the glider vehicle manufacturer. As noted above, glider kits include the entire tractor chassis, cab, tires, body, and brakes. Glider kit manufacturers thus control critical elements of the ultimate vehicle’s greenhouse gas emissions, in particular, all aerodynamic features and all emissions related to steer tire type. Glider kit manufacturers would therefore be the entity generating critical GEM inputs – at the least, those for aerodynamics and tires. Glider kit manufacturers also often know the final configuration of the glider vehicle, i.e. the type of engine and transmission which the final assembler will add to the glider kit. This is because the typical glider kit contains all necessary wiring, and it is necessary, in turn, for the glider kit manufacturer to know the end configuration in order to wire the kit properly. Thus, a manufacturer of a glider kit can reasonably be viewed as a manufacturer of a motor vehicle under the same logic as above: there can be multiple manufacturers of a motor vehicle; the glider kit manufacturer designs, builds, and assembles a substantial, complete and finished portion of the motor vehicle; and that portion contributes substantially to the GHG emissions from the ultimate glider vehicle. A glider kit is not a vehicle part; rather, it is an assembled truck with a few components missing. The ultimate point here is that both of these entities are manufacturers of the glider motor vehicle and therefore both are within the Act’s requirements for certification and testing.

EPA rules have long provided provisions establishing responsibilities where there are multiple manufacturers of motor vehicles. See 40 CFR 1037.620 (responsibilities for multiple manufacturers), 40 CFR 1037.621 (delegated assembly), and 40 CFR 1037.622 (shipment of incomplete vehicles to secondary vehicle manufacturers). These provisions, in essence, allow manufacturers to determine among themselves as to which should be the certificate holder, and then assign respective responsibilities depending on that decision. The end result is that incomplete vehicles cannot be introduced into commerce without one of the manufacturers being the certificate holder.

Under the Phase 1 rules, glider kits are considered to be incomplete vehicles which may be introduced into commerce to a secondary manufacturer for final assembly. See 40 CFR 1037.622(b)(1)(i) and 1037.801 (definition of “vehicle” and “incomplete vehicle”) of the Phase 1 regulations (76 FR 57421). Note that 40 CFR 1037.622(b)(1)(i) was originally codified as 40 CFR 1037.620(b)(1)(i). EPA is expanding somewhat on these provisions, but in essence, as under Phase 1, glider kit and glider vehicle manufacturers could operate under delegated assembly provisions whereby the glider kit manufacturer would be the certificate holder. See 40 CFR 1037.621 of the final regulations. Glider kit manufacturers would also continue to be able to ship uncertified kits to secondary manufacturers, and the secondary manufacturer must assemble the vehicle into certifiable condition. 40 CFR 1037.622.

Additional Authorities Supporting EPA’s Actions

15 PACCAR indicated in its comments that manufacturers of glider kits may not know all details of final assembly. Provisions on delegated assembly, shipment of incomplete vehicles to secondary manufacturers, and assembly instructions for secondary vehicle manufacturers allow manufacturers of glider kits and glider vehicles to apportion responsibilities, as appropriate, including responsibility as to which entity shall be the certificate holder. See 40 CFR 1037.130, 1037.621, and 1037.622.

16 Under this provision in the Phase 2 regulations, the glider kit manufacturer would still have some responsibility to ensure that products they introduce into U.S. commerce will conform with the regulations when delivered to the ultimate purchasers.
Even if, against our view, trailers and glider kits are not considered to be “motor vehicles,” and the entities engaged in assembling trailers and glider kits are not considered to be manufacturers of motor vehicles, the Clean Air Act still provides authority for the testing requirements adopted here. Section 208 (a) of the Act authorizes EPA to require “every manufacturer of new motor vehicle or engine parts or components” to “perform tests where such testing is not otherwise reasonably available.” This testing can be required to “provide information the Administrator may reasonably require to determine whether the manufacturer … has acted or is acting in compliance with this part,” which includes showing whether or not the parts manufacturer is engaged in conduct which can cause a prohibited act. Testing would be required to show that the trailer will conform to the vehicle emission standards. In addition, testing for trailer manufacturers would be necessary here to show that the trailer manufacturer is not causing a violation of the combined tractor-trailer GHG emission standard either by manufacturing a trailer which fails to comply with the trailer emission standards, or by furnishing a trailer to the entity assembling tractor-trailers inconsistent with tractor-trailer certified condition. Testing for glider kit manufacturers is necessary to prevent a glider kit manufacturer furnishing a glider kit inconsistent with the tractor’s certified condition. In this regard, we note that section 203 (a)(1) of the Act not only prohibits certain acts, but also prohibits “the causing” of those acts. Furnishing a trailer not meeting the trailer standard would cause a violation of that standard, and the trailer manufacturer would be liable under section 203 (a)(1) for causing the prohibited act to occur. Similarly, a glider kit supplied in a condition inconsistent with the tractor standard would cause the manufacturer of the glider vehicle to violate the GHG emission standard, so the glider kit manufacturer would be similarly liable under section 203 (a)(1) for causing that prohibited act to occur.

In addition, section 203 (a)(3)(B) prohibits use of ‘defeat devices’ – which include “any part or component intended for use with, or as part of, any motor vehicle … where a principal effect of the part or component is to … defeat … any … element of design installed … in a motor vehicle” otherwise in compliance with emission standards. Manufacturing or installing a trailer not meeting the trailer emission standard could thus be a defeat device causing a violation of the emission standard. Similarly, a glider kit manufacturer furnishing a glider kit in a configuration that would not meet the tractor standard when the specified engine, transmission, and axle are installed would likewise cause a violation of the tractor emission standard. For example, providing a tractor with a coefficient of drag or tire rolling resistance level inconsistent with tractor certified condition would be a violation of the Act because it would cause the glider vehicle assembler to introduce into commerce a new tractor that is not covered by a valid certificate of conformity. Daimler argued in its comments that a glider kit would not be a defeat device because glider vehicles use older engines which are more fuel efficient since they are not meeting the more rigorous standards for criteria pollutant emissions. (Daimler Truck Comment, April 1, 2016, p. 5). However, the glider kit would be a defeat device with respect to the tractor vehicle standard, not the separate engine standard. A non-conforming glider kit would adversely affect compliance with the vehicle standard, as just explained. Furthermore, as explained in RTC 14.2, Daimler is incorrect that glider vehicles are more fuel efficient than Phase 1 2017 and later vehicles, much less Phase 2 vehicles.

In the memorandum accompanying the Notice of Data Availability, EPA solicited comment on adopting additional regulations based on these principles. EPA has decided not to adopt those provisions, but again notes that the authorities in CAA sections 208 and 203 support the actions EPA is taking here with respect to trailer and glider kit testing.

Standards for Glider Vehicles and Lead Time for Those Standards

At proposal, EPA indicated that engines used in glider vehicles are to be certified to standards for the model year in which these vehicles are assembled. 80 FR 40528. This action is well within the
agency’s legal authority. As noted above, the Act’s definition of “new motor vehicle engine,” includes any “engine in a new motor vehicle” without regard to whether or not the engine was previously used. Given the Act’s purpose of controlling emissions of air pollutants from motor vehicle engines, with special concern for pollutant emissions from heavy-duty engines, it is reasonable to require engines placed in newly-assembled vehicles to meet the same standards as all other engines in new motor vehicles. Put another way, it is both consistent with the plain language of the Act and reasonable and equitable for the engines in “new trucks” (see Section I.E.(1)(a) of the FRM Preamble) to meet the emission standards for all other engines installed in new trucks.

Daimler challenged this aspect of EPA’s proposal, maintaining that it amounted to regulation of vehicle rebuilding, which (according to the commenter) is beyond EPA’s authority. Comments of Daimler, p. 123; Comments of Daimler Trucks (April 1, 2016) p. 3. This comment is misplaced. The EPA has authority to regulate emissions of pollutants from engines installed in new motor vehicles. As explained above, glider vehicles are new motor vehicles. As also explained above, the Act’s definition of “new motor vehicle engine” includes any “engine in a new motor vehicle” without regard to whether or not the engine was previously used. CAA section 216(3). Consequently, a previously used engine installed in a glider vehicle is within EPA’s multiple authorities. See CAA sections 202 (a) (1) (GHGs), and 202 (a)(3)(D) (pollutants from rebuilt heavy duty engines).

As explained in more detail in Section XIII.B of the FRM Preamble, the final rule requires that as of January 1, 2017, glider kit and glider vehicle production involving engines not meeting criteria pollutant standards corresponding to the year of glider vehicle assembly be allowed at the highest annual production for any year from 2010 to 2014. See section 1037.150 (t)(3). (Certain exceptions to this are explained in Section XIII.B. of the FRM Preamble). The rule further requires that as of January 1, 2018, engines in glider vehicles meet criteria pollutant standards and GHG standards corresponding to the year of the glider vehicle assembly, but allowing introduction into commerce of engines meeting criteria pollutant standards corresponding to the year of the engine for up to 300 vehicles per year, or up to the highest annual production volume for calendar years 2010 to 2014, whichever is less. Section 1037.150 (t)(1)(ii) (again subject to various exceptions explained in Section XIII.B. of the FRM Preamble). Glider vehicles using these exempted engines will not be subject to the Phase 1 GHG vehicle standards, but will be subject to the Phase 2 vehicle standards beginning with MY 2021.

---

17 Comments from, e.g. Mondial and MEMA made clear that all of the donor engines installed in glider vehicles are rebuilt. See also http://www.truckinginfo.com/article/story/2013/04/the-return-of-the-glider.aspx (“1999 to 2002-model diesels were known for reliability, longevity and good fuel mileage. Fitzgerald favors Detroit’s 12.7-liter Series 60 from that era, but also installs pre-EGR 14-liter Cummins and 15-liter Caterpillar diesels. All are rebuilt ......”).
There are compelling environmental reasons for taking these actions in this time frame. As shown in a separate Sensitivity Analysis of Glider Impacts (Appendix A to Section 14 of this RTC), the restriction on 2017 production is projected to prevent the use of high polluting pre 2002-engines in 5,000 to 10,000 glider vehicles, and would prevent the emission of 207,500-415,000 tons of NOx and 3,400-6,800 tons of PM over the lifetime of those vehicles and engines. This is estimated to prevent 350 to 1,600 premature mortalities. If these restrictions were delayed until MY 2021, as commenters argued, this could mean the production of 30,000 to 40,000 additional glider vehicles using the older high polluting engines. Using the same assumptions as above, these three additional model years of production are estimated to result in an additional 2,100 to 6,400 premature mortalities.

These estimates are conservative. They do not account for diesel exhaust PM being a likely human carcinogen (see Preamble section VIII.A.6), and so do not assess potential additional cancers caused by exposure to diesel PM exhaust from these glider vehicles. Nor do these estimates evaluate premature mortality attributable to increased generation of, and exposure to ozone resulting from the increased NOx emissions.

With regard to the issue of lead time, EPA indicated at proposal that the agency has long since justified the criteria pollutant standards for engines installed in glider kits. 80 FR 40528. EPA further proposed that engines installed in glider vehicles meet the emission standard for the year of glider vehicle assembly, as of January 1, 2018 and solicited comment on an earlier effective date. Id. at 40529. The agency noted that CAA section 202 (a)(3)(D) requires that standards for rebuilt heavy-duty engines take effect “after a period … necessary to permit the development and application of the requisite control measures.” Here, no time is needed to develop and apply requisite control measures for criteria pollutants because compliant engines are immediately available. In fact, manufacturers of compliant engines, and dealers of trucks containing those compliant engines, commented that they are disadvantaged by manufacturing more costly compliant engines while glider vehicles avoid using those engines. Not only are compliant engines immediately available, but, as commenters warned, there can be risk of massive pre-buys. Moreover, EPA does not envision that glider manufacturers will actually modify the older engines to meet the applicable standards. Rather, they will either choose from the many compliant engines available today, or they will seek to qualify under other flexibilities provided in the final rule. See Section XIII.B of the FRM Preamble. Given that compliant engines are immediately available, the flexibilities provided in the final rule for continued use of donor engines for traditional glider vehicle functions and by small businesses, and the need to expeditiously prevent further perpetuation of use of heavily polluting engines, EPA sees a need to begin constraining this practice on January 1, 2017. However, the final rule is merely capping glider production using higher-polluting engines in 2017 at 2010-2014 production levels, which would allow for the production of thousands of glider vehicles using these higher polluting engines in 2017, and unlimited production of glider vehicles using less polluting engines.

Various commenters, however, argued that the EPA must provide four years lead-time and three-year stability pursuant to section 202 (a) (3)(C) of the Act, which applies to regulations for criteria pollutant emissions from heavy duty vehicles or engines. For criteria pollutant standards, CAA section 18

---

18 The engine rebuilding authority of section 202 (a)(3)(D) includes removal of an engine from the donor vehicle. See 40 CFR section 86.004-40 and 62 FR 54702 (Oct. 21, 1997). EPA interprets this language as including installation of the removed engine into a glider kit, thereby assembling a glider vehicle. Daimler, in its comments, questioned whether engine rebuilding authorities were at issue here when EPA did not propose to amend the specific regulations relating to engine rebuilding. EPA has added a conforming cross-reference to the final rule. See section 1068.120 (f).

202(a)(3)(C) establishes lead time and stability requirements for “[a]ny standard promulgated or revised under this paragraph and applicable to classes or categories of heavy duty vehicles or engines.” In this rule, EPA is generally requiring large manufacturers of glider vehicles to use engines that meet the standards for the model year in which a vehicle is manufactured. EPA is not promulgating new criteria pollutant standards. The NO$_X$ and PM standards that apply to heavy duty engines were promulgated in 2001.

We are not amending these provisions or promulgating new criteria pollutant standards for heavy duty engines here. EPA interprets the phrase “classes or categories of heavy duty vehicles or engines” in CAA 202(a)(3)(C) to refer to categories of vehicles established according to features such as their weight, functional type, (e.g. tractor, vocational vehicle, or pickup truck) or engine cycle (spark-ignition or compression-ignition), or weight class of the vehicle into which an engine is installed (LHD, MHD, or HHD). EPA has established several different categories of heavy duty vehicles (distinguished by gross vehicle weight, engine-cycle, and other criteria related to the vehicles’ intended purpose) and is establishing in this rule GHG standards applicable to each category. By contrast, a “glider vehicle” is defined not by its weight or function but by its method of manufacture. A Class 8 tractor glider vehicle serves exactly the same function and market as a Class 8 tractor manufactured by another manufacturer. Similarly, rebuilt engines installed in glider vehicles (i.e. donor engines) are not distinguished by engine cycle, but rather serve the same function and market as any other HHD or MHD engine. Thus, EPA considers “glider vehicles” and engines installed in glider vehicles to be a description of a method of manufacturing new motor vehicles, not a description of a separate “class or category” of heavy duty vehicles or engines. Consequently, EPA is not adopting new standards for a class or category of heavy duty engines within the meaning of section 202 (a)(3)(C) of the Act.

EPA believes this approach is most consistent with the statutory language and the goals of the Clean Air Act. The date of promulgation of the criteria pollutant standards was 2001. There has been plenty of lead time for the criteria pollutant standards and as a result, manufacturers of glider vehicles have many options for compliant engines that are available on the market today—just as manufacturers of other new heavy-duty vehicles do. We are even providing additional compliance flexibilities to glider manufacturers in recognition of the historic practice of salvaging a small number of engines from vehicles involved in crashes. See Section XIII.B of the FRM Preamble. We do not believe that Congress intended to allow changes in how motor vehicles are manufactured to be a means of avoiding existing, applicable engine standards. Obviously, any industry attempts to avoid or circumvent standards will not become apparent until the standards begin to apply. The unreasonableness of the commenters’ interpretation becomes apparent when one realizes that it would effectively preclude EPA from curbing many types of avoidance, however dangerous, until at least four years from detection. As noted above, EPA estimates conservatively that thousands of premature mortalities are at issue here, emphasizing the need to take expeditious action.

As to Daimler’s further argument that the lead time provisions in section 202 (3)(C) not only apply but also must trump those specifically applicable to heavy duty engine rebuilding, the usual rule of construction is that the more specific provision controls. See, e.g. *HCSC-Laundry v. U.S.*, 450 U.S.1, 6 (1981). EPA also does not accept Daimler’s further argument that section 202 (a)(3)(C) lead time provisions also apply to engine rebuilding because those provisions fall within the same paragraph. First, as explained above, section 202 (a)(3)(C) applies to categories of vehicles and engines established according to features such as their weight, functional type, or engine cycle, or weight class of the vehicle into which an engine is installed. Rebuilt engines are not distinguished by engine cycle, but

---

20 Note, however, the Phase 2 GHG standards for tractors and vocational vehicles do not apply until MY 2021.
rather serve the same function and market as any other engine. Consequently, EPA does not believe that section 202 (a)(3)(C) is applicable here. Moreover, the interpretation advocated by the commenters would render the separate lead time provisions for engine rebuilding a virtual nullity. \footnote{The argument that the lead time provision for rebuilt engines means that standards for rebuilt engines can take effect only after three model years but can be even longer makes no practical sense. As discussed in the text above, the concept of model year has no basis for rebuilt engines. Even more basically, it does not make sense for Congress to have allowed more lead time for rebuilt engines when less time is needed due to engine rebuilding being an engine-by-engine decision which can be made at any time unconstrained by engine design cycles.} The sense of the provision is that Congress intended there to be independent lead time consideration for the distinct practice of engine rebuilding. For example, section 202 (a)(3)(C) specifies three “model years” of needed lead time. The concept of model years is a virtual non-sequitur as applied to engine rebuilding, when there is no specific model year (or year-by-year) production involved. Rather, individual engines from any year are being rebuilt. More generally, the purpose of long lead time, to accommodate manufacturers’ necessarily long design and redesign cycles and to allow time for research and development plus field testing, again do not apply to engine rebuilding. Engines can be rebuilt at any time, and rebuilding is not tied to design cycles or R&D decisions. It involves an engine-by-engine, ad hoc decision. Under these circumstances, it is at least ambiguous as to whether the reference to “paragraph” in section 202 (a)(3)(C) (assuming, against our view that the provision applies at all) encompasses the separate lead time provision for rebuilt engines in section 202 (a)(3)(D). \cite{Desert_Citizens_Against_Pollution_v._EPA, 699_F. 3d 524, 527-28 (D.C. Cir. 2013) (reference to “section” held to be ambiguous where applying provisions of that section leads to results at odds with the overall statutory scheme).}

### 1.3.2 NHTSA Authority\footnote{EPA-HQ-OAR-2014-0827-1284-A1 p.11-12}

**Organization:**  
Allison Transmission, Inc.

**EPA and NHTSA Face Statutory Constraints in Requiring New Technology; Alternative 4 is Not Supported in The Record**

The Proposed Rule states that several steps have been taken in the rulemaking to address concerns about disrupting the market, including providing considerable lead time, phasing-in of the standards, preserving technology choices, allowing emission averaging, banking and trading and economic savings over time through reduced fuel costs. But these steps only can go so far in a market which is driven by customer demands for vehicles that accomplish specific tasks. EPA and NHTSA cannot conflate necessary flexibility in implementation of new standards with a statutory ability to increase the stringency of emission and fuel efficiency standards beyond a reasonable projection of future technology specific to MD/HD vehicles and the lead time necessary for market adoption. Both Clean Air Act (“CAA”) section 202 and NHTSA’s statutory authority in 49 U.S.C. §32902(k) are not unbounded, but must be read in context of the MD/HD market, including such periods as are necessary to “permit the development and application of requisite technology.”\footnote{EPA-HQ-OAR-2014-0827-1284-A1 p.11-12} EPA indicates that it has “significant discretion in assessing, weighing, and balancing the relevant statutory criteria.” As discussed above, this discretion to the extent it exists must be based on solid record evidence regarding the ability of the MD/HD market to develop and deploy additional technologies that will, in fact, be purchased by end users. This record is lacking in this rulemaking and EPA is thereby constrained in its legal ability to adopt Alternative 4. Indeed, unlike the most recent
LDV rule, EPA and NHTSA have not proposed to include a regulatory “mid-term evaluation” period that would allow for future adjustment of standards if projections contained in this Proposed Rule prove to be erroneous during the early and mid-2020s. Given this lack of a correcting mechanism, EPA (and by implication NHTSA) must be correspondingly cautious to provide such necessary period of time for the development and application of new technology to this sector. [EPA-HQ-OAR-2014-0827-1284-A1 p.12]

NHTSA indicates that it has “broad discretion to weigh and balance” various statutory factors contained in the Energy Independence and Security Act (“EISA”). The Proposed Rule, however, does not discuss in detail possible constraints on this authority. First, NHTSA authority under EISA references a National Academy of Sciences study as a predicate for a rulemaking to establish a fuel efficiency program. That study has been completed and the statute does not reference any additional studies. Second, NHTSA’s authority is described with regard to “a rulemaking proceeding” to occur “[n]ot later than 24 months after completion of the [NAS] study.” This statutory structure indicates that a singular rulemaking was directed and, indeed, subsection (k)(2) references only “a rulemaking proceeding . . .” (Emphasis added). Third, provisions mandating that adequate lead time be allowed for new fuel efficiency regulations again reference only a “commercial medium- and heavy-duty on-highway vehicle and work truck fuel economy standard . . .” (Emphasis added). Thus, under the plain terms of the statute, only a singular NAS study was required and a singular rulemaking proceeding was to occur, both of which have now happened. This raises the issue of NHTSA’s authority to adopt standards that incorporate increasingly stringent requirements departing from those employed in Phase 1. [EPA-HQ-OAR-2014-0827-1284-A1 p.12]

12 Id. at 40,155

13 CAA section 202(a)(2). (Emphasis added). In addition, while in its discussion of legal authority for this rulemaking EPA cites the endangerment finding for the Phase 1 LDV rule, that finding is related to the ability to regulate GHGs as air pollutants under the CAA; it does not directly determine the stringency of standards in this rulemaking. Further, EPA also relies on Utility Air Regulatory Group v. EPA, 134 S. Ct. 2427 (2104) as authority, yet that case cautioned the Agency that it also may not adopt “unreasonable interpretations of statutory provisions and then edit other statutory provisions to mitigate the unreasonable.” Id. at 2446. While the decision related specifically to stationary source permitting, the court expressed an unwillingness to allow the Agency to engage in a “multiyear voyage of discovery” when interpreting CAA permitting provisions and their application to small sources. In the context of this rulemaking, EPA must interpret CAA section 202 rationally in relation to the current MD/HD market and the unique factors which dominate this market versus the LDV market. NHTSA is also constrained with respect to limits contained in 49 U.S.C. 32902(k) discussed in more detail in Section II.

Organization: American Iron and Steel Institute

B. NHTSA Has Comparable Authority to Use Life Cycle Analysis

NHTSA derives its authority to address GHG emissions from motor vehicles from the Energy Policy Conservation Act (‘EPCA’), as amended by the Energy Independence and Security Act (‘EISA’). NHTSA cites as statutory authority for this rulemaking EISA Section 103, 49 U.S.C. § 32902(k). As described in the Proposed Rule, this section authorizes a fuel efficiency improvement program, designed to achieve the maximum feasible improvement to be created for commercial medium- and
heavy-duty vehicles and work trucks, to include appropriate test methods, measurement metrics, standards, and compliance and enforcement protocols that are appropriate, cost-effective and technologically feasible. Thus, under the plain language of this section, NHTSA may promulgate 'appropriate' methods, metrics and standards for medium- and heavy-duty vehicles that may reasonably include life cycle analysis.\footnote{It should be noted that with reference to light duty standards, NHTSA has asserted that it maintains significant discretion pursuant to 40 U.S.C. §32902(f) to weigh EPCA statutory factors which, in the case of such vehicles are technological feasibility, economic practicability, the effect of other governmental standards and energy conservation. While the Proposed Rule utilizes authority in 40 U.S.C. §32902(k) versus (f), arguably NHTSA would possible similar ability to weigh the statutory factors specified for 'commercial medium- and heavy-duty on-highway vehicle and work truck[s].' Indeed, NHTSA asserts that it has 'broad discretion to balance the statutory factors in Section 103 [of EISA] in developing fuel consumption standards to achieve the maximum feasible improvement.' 80 Fed. Reg. at 40,170. Further, NHTSA references authority within the Motor Vehicle Safety Act with reference to the regulation of trailers as 'vehicles.' Id. at 40,171.} [EPA-HQ-OAR-2014-0827-1275-A1 p.5]

NHTSA has also indicated that it interprets its EPCA authority to include evaluation of energy use and energy conservation. Specifically, after citing authority in 49 U.S.C. § 32902(k) and CAA Section 202(a)(1)-(2), the Proposed Rule indicates that 'Congress enacted EPCA and EISA to, among other things, address the need to conserve energy . . . .' While, in the Proposed Rule, the general focus of energy use is with respect to the amount of fuel consumed, NHTSA may fairly interpret its EPCA authority in the context of the nation's overall energy policy. In other words, NHTSA's statutory mandate to consider energy conservation in setting fuel efficiency improvements for medium- and heavy-duty vehicles provides an ability for the agency to address broader concerns regarding the vehicle's life cycle impact on the use of energy. [EPA-HQ-OAR-2014-0827-1275-A1 p.5-6]

Indeed, EISA specifies that standards for medium- and heavy-duty vehicles are to center on 'a commercial medium- and heavy-duty on-highway vehicle and work truck fuel efficiency improvement program . . . .' In contrast to 'fuel economy' standards that have been imposed in the light-duty sector, 'a fuel efficiency improvement program' is a new statutory term that provides broader authority in the area of medium- and heavy-duty vehicles. This can also be seen given the statutory structure of Section 32902(f) where, as a precondition to rulemaking, the National Academy of Sciences is directed to examine several factors, including consideration of the 'work' performed by vehicles and 'such other factors and conditions that could have an impact on a program to improve commercial medium-and heavy-duty on-highway vehicle and work truck efficiency.\footnote{8 See 49 U.S.C. §32902(a)-(k).} This serves as further confirmation that NHTSA may take into account a wide variety of factors that impact Class 2 to Class 8 vehicles. Also, as will be shown below, within the Proposed Rule, EPA and NHTSA have already interpreted their statutory authority to consider life cycle emissions with respect to at least a portion of the medium- and heavy-duty vehicle fleet.\footnote{11 It should be noted that with reference to light duty standards, NHTSA has asserted that it maintains significant discretion pursuant to 40 U.S.C. §32902(f) to weigh EPCA statutory factors which, in the case of such vehicles are technological feasibility, economic practicability, the effect of other governmental standards and energy conservation. While the Proposed Rule utilizes authority in 40 U.S.C. §32902(k) versus (f), arguably NHTSA would possible similar ability to weigh the statutory factors specified for 'commercial medium- and heavy-duty on-highway vehicle and work truck[s].' Indeed, NHTSA asserts that it has 'broad discretion to balance the statutory factors in Section 103 [of EISA] in developing fuel consumption standards to achieve the maximum feasible improvement.' 80 Fed. Reg. at 40,170. Further, NHTSA references authority within the Motor Vehicle Safety Act with reference to the regulation of trailers as 'vehicles.' Id. at 40,171.} [EPA-HQ-OAR-2014-0827-1275-A1 p.6]
inconsistency. Several differences in statutory authority, including the ability to impose regulations on the same timeframe, were accommodated by EPA and NHTSA in the Phase I medium- and heavy-duty truck rulemaking. NHTSA and EPA have also cited Massachusetts v. EPA, 549 U.S. 497 (2007) as support for their ability to proceed cooperatively on engine and vehicle standards despite issuing separate and distinct standards. In the MY 2012-2016 LDV rule, EPA cited the Supreme Court’s conclusion in Massachusetts that “[t]he two obligations may overlap, but there is no reason to think that the two agencies cannot both administer their obligations and yet avoid inconsistency’ as support for their different, but aligned regulatory approaches. 75 Fed. Reg. at 25,327. It should be noted that this perspective should apply equally to both EPA and NHTSA should the former agency believe it is constrained from incorporating lifecycle analysis within a final rule.

Organization: California Air Resources Board (CARB)

Alternative 4 is Consistent with NHTSA’s Statutory Authority

NHTSA is promulgating the proposed fuel efficiency standards pursuant to the statutory authority of the EISA, which amends the Energy Policy and Conservation Act (EPCA) of 1975. Specifically, section 102 of EISA (49 USC section 32902(k)(2)) authorizes NHTSA to implement “a commercial medium- and heavy-duty on-highway vehicle and work truck fuel efficiency improvement program designed to achieve the maximum feasible improvement, and [to] adopt and implement appropriate test methods, measurement metrics, fuel economy standards, and compliance and enforcement protocols that are appropriate, cost-effective, and technologically feasible for commercial medium- and heavy-duty on-highway vehicles and work trucks.” [EPA-HQ-OAR-2014-0827-1265-A1 p.27]

The fuel efficiency standards that correspond to the GHG emission standards associated with Alternative 4 are consistent with section 32902(k)(2) of EISA. In the Phase 1 rulemaking, NHTSA stated that it has the discretion to balance the factors specified in section 32902(k)(2) of EISA “in a way that is technology-forcing ... but not in a way that requires the application of technology which will not be available in the lead time provided by the rule, or which is not cost-effective, or is cost-prohibitive ...”[EPA-HQ-OAR-2014-0827-1265-A1 p.27]

As demonstrated above, Alternative 4 is consistent with the statutory provisions of section 202(a)(2) of the CAA regarding adequate lead times and costs of compliance associated with the proposed greenhouse gas emission standards. To the extent that NHTSA’s considerations of lead times and compliance costs for the technologies needed to comply with fuel efficiency standards are consistent with the lead time and cost of compliance factors that U.S. EPA considered in developing the GHG emission standards associated with Alternative 4, the corresponding fuel efficiency standards are arguably consistent with the factors specified in section 32902(k)(2), and are consistent with NHTSA’s statutory directive to achieve the maximum feasible improvement in fuel efficiency standards from commercial medium- and heavy-duty on-highway vehicles and work trucks. [EPA-HQ-OAR-2014-0827-1265-A1 p.27]

Support Comment

Comment - Interpretation that 49 U.S.C. 32919(a) does not extend to commercial medium- and heavy-duty on-highway vehicles and work trucks

NHTSA states that in the Phase 1 rulemaking it concluded that EPCA’s express preemption provision of 49 U.S.C. 32919(a) (which expressly preempts any State or local government from adopting or enforcing a law or regulation related to fuel economy standards or average fuel economy standards for
automobiles covered by an average fuel economy standard under 49 U.S.C. Chapter 329) does not extend to the fuel efficiency standards established in the Phase 1 rulemaking because commercial medium- and heavy-duty on-highway vehicles and work trucks are not “automobiles,” as defined in 49 U.S.C. 32901(a)(3). NHTSA states that it is reiterating that conclusion for the proposed Phase 2 standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.28]

CARB staff concurs with NHTSA’s reasoning and conclusion that 49 U.S.C. 32919(a) does not extend to the fuel efficiency standards established under the Phase 1 rulemaking or to the proposed fuel efficiency standards established under the Phase 2 rulemaking. [EPA-HQ-OAR-2014-0827-1265-A1 p.28]

Organization: Center for Biological Diversity

The NHTSA is also expressly required to consider “the effect of other motor vehicle standards of the Government on fuel economy.” 20 This factor is implicated in two sets of regulations: (1) regulations developed by the State of California under its Clean Air Act § 202 waiver and (2) light-duty truck Corporate Average Fuel Economy (“CAFE”) standards promulgated by the Agencies. Both sets of regulations are “motor vehicle standards of the Government” that create important context for determining “maximum feasible improvement” for the purposes of the instant rulemaking. [EPA-HQ-OAR-2014-0827-1460-A1 p.5]

Organization: Daimler Trucks North America LLC

In-Use Standards - NHTSA and the EPA propose to add an in-use requirement to NHTSA’s regulations, applicable through the regulatory useful life, appropriateness of seeking civil penalties for failure to comply with its fuel efficiency standards in these instances. 80 FR 40342. NHTSA also proposes to add civil penalties for failure to conform to such standards. While it is appropriate for NHTSA’s standards to mirror the EPA’s, we think that it would be inappropriate for NHTSA to assess civil penalties in addition to those that the EPA assesses. The two agencies have essentially identical regulations and should not assess duplicative penalties. [EPA-HQ-OAR-2014-0827-1164-A1 p.131]

Organization: Navistar, Inc.

Specifically for NHTSA, some of these concerns have added force. In particular, this includes the effective requirement to have a compliant engine over a year prior to the nominal start year of 2021. As we discussed extensively in our Comments in docket EPA-HQ-OAR-2014-0827, the need for an engine fuel map to use with the GEM tool prior to 2021 effectively pulls the requirement for a compliant engine over a year ahead of the 2021 nominal start year, as early as 15 months, which would be in 2019. By the time the Proposed Rule is adopted, it appears that this will not comport with the requirement for four years of lead time in the Energy Independence and Security Act. [NHTSA-2014-0132-0094-A1 p.3]
Organization: Newell Coach Corporation

We would like to note that while EPA has clear authority to regulate vocational vehicles like motorhomes, we disagree with NHTSA's view that the Energy, Independence and Security Act of 2007 (EISA) gives them the authority to regulate motorhomes. Motorhome are not commercial vehicles and they should not be subject to NHTSA's proposed standards. Fundamentally, we believe that the EPA and NHTSA have an obligation to establish regulations that are consistent with each other. If NHTSA cannot legally regulate non-commercial vehicles, rather than establish conflicting requirements, EPA should exclude motorhomes from its rule. [EPA-HQ-OAR-2014-0827-1319-A1 p.2]

Organization: Recreational Vehicle Industry Association (RVIA)

RVIA sets forth the following points in its comments. As an initial matter, NHTSA lacks legal authority over non-commercial vehicles, such as motorhomes, and so cannot set fuel consumption standards for such vehicles. Thus, motorhomes should continue to be exempt from NHTSA fuel consumption standards as they were in the Phase 1 rule. Further, for the very purposes of consistency and uniformity the agencies espouse, EPA should recognize this limitation and exclude motorhomes from its standards as well. [EPA-HQ-OAR-2014-0827-1261-A1 p.4]

Motorhomes Should Be Exempt from the Proposed Rules

NHTSA lacks authority to regulate motorhomes since they are not commercial vehicles.

When NHTSA first proposed its Phase 1 fuel efficiency standards for commercial medium and heavy-duty vehicles, it properly recognized its authority under EISA was limited to commercial vehicles; thus, it excepted from its regulation 'recreational vehicles, such as motor homes, since recreational vehicles are not commercial.' However, NHTSA announced in the final rule that it might revisit this interpretation of its EISA authority in light of a comment filed by Oshkosh Corporation. NHTSA added that, upon reconsideration, its phase 1 interpretation might 'effectively read words into the statutory definition' and create 'illogical results, i.e., treating similar vehicles differently.' For purposes of Phase 1, NHTSA decided to continue to exclude motorhomes because they were not included in the proposed rule but would 'address this issue in the next rulemaking.' [EPA-HQ-OAR-2014-0827-1261-A1 p.10]

In the Proposed Phase 2 Rule, NHTSA did indeed reconsider its position; it completely retreated from its initial Phase 1 proposed interpretation, raising essentially the same arguments it set forth in the final Phase 1 rule. NHTSA asserted that the definition of 'commercial medium- and heavy-duty on-road highway vehicles' was based on weight alone: “on-highway vehicles with gross vehicle weight ratings of 10,000 pounds or more.” NHTSA also repeated the same argument that excluding motorhomes would be illogical. It further added that including the category would be consistent with the goal of creating one national program since EPA already covers such vehicles. NHTSA offered no other evidence supporting its position. [EPA-HQ-OAR-2014-0827-1261-A1 p.10]
While the goal of uniformity may be desirable, it cannot create legal authority where there is none. Rather than avoiding reading words into a definition, NHTSA is effectively eliminating key statutory language from the definition. Congress plainly limited NHTSA's authority under EISA to 'commercial' medium and heavy-duty vehicles. There is no similar limitation for work trucks, a category which is defined separately, nor on NHTSA authority for regulating automobiles. Hence, the term 'commercial' cannot be mere surplusage; Congress must have intended a meaning if it used the term only in connection with medium and heavy-duty vehicles. Moreover, the term 'commercial' doesn't simply appear once in the relevant portions of EISA. Rather, Congress used the term repeatedly in section 32902(k). Indeed, the very title of that statutory section uses the term, and it is used before 'medium-and heavy-duty on-highway vehicles' every time those vehicles are mentioned in that section. Had Congress intended to include all medium and heavy-duty vehicles in its grant of authority to NHTSA, it surely would have done so and eliminated the 'commercial' modifier. [EPA-HQ-OAR-2014-0827-1261-A1 p.10-11]

When Congress defined the term 'commercial medium- and heavy-duty on-highway vehicles' in section 103 of EISA it didn't include the term 'commercial' in the definition but neither did it repeat any of the other words in that same term: 'medium- and heavy-duty on-highway vehicles.' It simply defined the full term, focusing on the weight of the vehicles. The most rational and reasonable reading of this definition would be that only 'commercial' vehicles of that weight would constitute 'commercial medium- and heavy-duty on-highway vehicles.' Yet NHTSA's reading unjustifiably expands its purported authority over any vehicle, commercial or not, based solely on weight. Rather than reading in a term to a definition, NHTSA proposes to entirely eliminate the key modifier established by Congress. Notably, in its own regulations implementing EISA, NHTSA doesn't go this far. It defines 'heavy-duty vehicles' as 'any commercial medium- and heavy-duty on highway vehicle or work truck,' as defined in section 32901(a)(7). Even NHTSA doesn’t purport in its existing regulations to define 'heavy-duty vehicles' as any vehicles above a certain weight. [EPA-HQ-OAR-2014-0827-1261-A1 p.11]

Moreover, there is an important and rational reason for distinguishing between commercial heavy-duty vehicles and non-commercial vehicles like motorhomes. EISA authorizes NHTSA to set fuel consumption standards for heavy-duty vehicles used in commercial activities. As NHTSA recognized properly back in 2010, non-commercial recreational vehicles such as motorhomes are used by families and individuals for recreational purposes. Motorhomes are very different from commercial vehicles. For example, they are generally very low-mileage and their costs generally cannot be recovered through commercial use.19 Indeed, the California Air Resource Board (CARB) expressly recognized this distinction in its proposed regulations for In-Use On-Road Diesel Vehicles, where it excluded personal use motor homes from regulation. CARB explained: [EPA-HQ-OAR-2014-0827-1261-A1 p.11]

Staff has proposed to exempt non-commercial motor homes from the scope of the proposed regulation for a number of reasons. First, owners of these vehicles do not have the ability to offset the compliance costs since personal use motor homes do not generate income nor appreciate in value. In addition, these vehicles typically operate very few miles in California, and as such, do not contribute significantly towards emissions relative to other vehicles covered by the proposed regulation.20 [EPA-HQ-OAR-2014-0827-1261-A1 p.11-12]

Thus, motorhomes are not similar to commercial vehicles in the aspects that are most relevant in the Phase 2 proposal. They are not the same in terms of vehicles miles travelled so gas savings are less and payback time for fuel savings is longer. They are not the same in terms of cost offsets since typical motorhome owners cannot recoup cost outlays through income generation or appreciation in value. And they are not the same in terms of emissions because of the lower number of vehicle miles travelled. Thus, contrary to NHTSA’s conclusions, Congress' decision to treat commercial vehicles and
motorhomes separately, as CARB and even NHTSA at one point have done, is a correct and entirely practical approach. [EPA-HQ-OAR-2014-0827-1261-A1 p.12]

NHTSA should exempt motorhomes entirely from its Phase 2 fuel consumption standards because it lacks statutory authority over non-commercial medium and heavy-duty vehicles in this regard. [EPA-HQ-OAR-2014-0827-1261-A1 p.27]

19 Some motorhomes are rented for commercial purposes, but this number is a statistically insignificant percentage of all motorhomes currently in use. In Phase 1, NHTSA did not attempt to distinguish between personal use and rental motorhomes, nor does RVIA believe such a distinction is even possible.

20 CARB, Technical Support Document: Proposed Regulation for In-use On-road Diesel Vehicles, at 256 (Oct. 2008), available at http://www.arb.ca.gov/regact/2008/truckbus08/td.pdf. While the CARB regulation directly affected owners through a retrofit requirement, rather than chassis manufacturers as in the Proposed EPA Phase 2 Rules, the commercial/non-commercial distinction is still valid since the nature of motorhomes is the same. The cost is just imposed, in the first instance, on the chassis manufacturer and reaches the customer eventually through higher prices.

Organization: Truck Trailer Manufacturers Association (TTMA)

In our “Authority Objections” section (3), we will discuss the legal rationale the agencies are putting forward for regulating trailers, why that rationale is flawed, and that the agencies should focus their efforts on end users, which they actually do have authority to regulate. [EPA-HQ-OAR-2014-0827-1172-A1 p.2]

EPA and NHTSA do not have statutory authority to adopt GHG emission and fuel efficiency standards applicable to trailers. [EPA-HQ-OAR-2014-0827-1172-A1 p.3]

NHTSA lacks statutory authority.

NHTSA’s claim to authority relies on the Energy Independence and Security Act (EISA), which does not itself define the term “vehicle” to include trailers. To do this, NHTSA relies on the language under its organic statute, the Motor Vehicle Safety Act. It is important to note that the Safety Act’s definition is put forward “to reduce traffic accidents and deaths and injuries resulting from traffic accidents.” As we will describe below, many parts of the proposal are at odds with this mission and we urge NHTSA to carefully consider their mandate as they propose trading safety for assumed fuel savings. Here, the point is simply that NHTSA is grasping for statutory authority for the proposed rule by citing an enabling statute that has nothing to do with greenhouse gas emissions.

Additionally, NHTSA cites the EISA direction to create standards for commercial medium- and heavy-duty on-highway vehicles and work trucks in 49 USC 32902(k). That section includes a 24 month window for rulemaking to take place: “(2) RULEMAKING.—Not later than 24 months after completion of the study required under paragraph (1), the Secretary, in consultation with the Secretary of Energy and the Administrator of the Environmental Protection Agency, by regulation, shall determine in a rulemaking proceeding how to implement a commercial medium- and heavy-duty on-highway vehicle and work truck fuel efficiency improvement program designed to achieve the maximum feasible improvement, ...” The study referred to in paragraph (1) was to be completed within one year of the
publication of a National Academy of Sciences study that was published in 2010. That brings the maximum window for NHTSA to bring regulations under this law to 2013. The proposal being put forward, coming after the window set forth under law, lacks congressional authorization.

Further, NHTSA contends that the Energy Independence and Security Act (“EISA”) gives it statutory authority to regulate trailers. Specifically, NHTSA points to a provision in the EISA that directs NHTSA to “determine in a rulemaking proceeding how to implement a commercial medium- and heavy-duty on-highway vehicle and work truck fuel efficiency improvement program designed to achieve the maximum feasible improvement . . . .” The EISA defines “commercial medium- and heavy-duty on-highway vehicle” to mean “an on-highway vehicle with a gross vehicle weight rating [GVWR] of 10,000 pounds or more.” NHTSA contends that, “[b]ecause Congress did not act to exclude trailers when defining GVWRs . . . it is reasonable to interpret the provision to include them.”

However, this definition shows just the opposite – that EISA’s definition of “commercial medium- and heavy-duty on-highway vehicle” excludes trailers. GVWR is distinct from the gross combined weight rating (“GCWR”), which includes both the weight of a loaded trailer and the weight of the tractor. EPA and NHTSA recognized this important distinction in promulgating GHG Phase One emission standards and fuel efficiency standards for medium- and heavy-duty engines and vehicles in 2011, stating: “GVWR describes the maximum load that can be carried by a vehicle, including the weight of the vehicle itself. Heavy-duty vehicles also have a gross combined weight rating (GCWR), which describes the maximum load that the vehicle can haul, including the weight of a loaded trailer and the vehicle itself.” (emphasis added). In other words, the trailer is not included in the definition of “commercial medium-and-heavy-duty on highway vehicle” as previously interpreted by NHTSA, since that definition refers only to a tractor’s GVWR and does not refer to a combination tractor and trailer GCWR. It is therefore reasonable (and it is consistent with the agencies’ previous interpretation) to exclude trailers when interpreting 40 U.S.C. § 32902(k)(2).

We understand that the agencies may take issue with our claims as to the way the law interacts with the truck trailer industry and the agencies’ proposal, so we will address further comments at both EPA and NHTSA parts of the proposal. This is intended to instruct both agencies as to ways that the proposal could be improved with regard to the truck trailer industry without condoning the agencies’ proposed expansion without legal authority.

5 80FR4071: “Although EISA does not define the term “vehicle,” NHTSA’s authority to regulate motor vehicles under its organic statute, the Motor Vehicle Safety Act (“Safety Act”), does.”

Response:

Generally, with respect to issues regarding NHTSA’s legal authority, please see Section I. E. of the final rule notice. Topics in this section not discussed in this document or in Section I. E. of the Preamble are discussed in the relevant sections of the associated rulemaking documents.

With respect to Daimler’s comment regarding duplicative civil penalties, NHTSA addressed a similar comment from EMA, Volvo, and the Truck Renting and Leasing Association in the Phase 1 rule. NHTSA maintains what it stated in those notices—that neither agency intended to impose duplicative civil penalties, and that both agencies would give consideration to civil penalties imposed by the other
in the case of non-compliance with its own regulations. See 75 FR 74280. The possibility of more than one prosecution or enforcement action arising from the same overall body of facts does not present a novel issue. It commonly arises where there is overlapping jurisdiction, such as where the federal government and a state government have jurisdiction. The issue of multiple or sequential prosecutions may be addressed as a matter of administrative policy and discretion. Both NHTSA and EPA are charged with regulating medium-duty and heavy-duty vehicles; NHTSA regulates them under EISA and EPA regulates them under EISA and EPA regulates them under the CAA. Both agencies also have compliance review and enforcement responsibilities for their respective regulatory requirements. The same set of underlying facts may result in a violation of EISA and a violation of the CAA.

1.4 General Compliance Provisions

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Useful life and in-use standards for hybrids

The NPRM “requests comment on the possibility of mismatched engine and vehicle useful-life values and on any possible implications this may have for manufacturers’ ability to design, certify, produce and sell their engines and vehicles.” (page 40326 of the NPRM). The NPRM notes that “This could lead to a situation where the engine and the vehicle are subject to emission standards over different useful-life periods.” However, the NPRM suggests that “While such a mismatch in useful life values could be confusing, we don’t believe it poses any particular policy problem that we need to address.” CARB staff believes that the mismatching in engine and vehicle classes is a significant issue that needs to be fully addressed. All heavy-duty engines that are certified for sale have to comply with warranty requirements, which apply to the proper functioning and performance of emission-related components over the warranty period. The useful life requirements for heavy-duty vehicles of different classes are shown in the table below. [EPA-HQ-OAR-2014-0827-1265-A1 p.90]

As can be seen from the table above, the useful period for a lighter vehicle class is much less than the emission warranty period for a heavier vehicle (i.e., 435,000 vs. 110,000 miles). If a light heavy-duty engine is used in a heavy heavy-duty vehicle, as in using a downsized engine in a hybrid vehicle, there is a disconnect between the two different sets of useful life requirements, a difference of 325,000 miles. The purchaser of a heavy heavy-duty vehicle is protected by regulations that provide 435,000 miles of emissions warranty if the vehicle has a heavy heavy-duty engine installed. However, if a light heavy-duty engine was installed in the same vehicle, the manufacturer of that engine is only liable for 110,000 miles of emissions warranty. Since the light heavy-duty engine and its emission-related components were designed to achieve the required target of 110,000 miles, it is highly uncertain whether it could continue to meet the certified emission standards if it is operated well beyond its useful life. As such, the purchaser of the vehicle would not be protected to the extent provided by the regulations. In addition, since the emissions performance of the light heavy-duty engine are only warranted for up to 110,000 miles, its installation in a heavy heavy-duty vehicle when being operated beyond that mileage is subject to potential emissions increases without recourse for corrective action. [EPA-HQ-OAR-2014-0827-1265-A1 p.90-91]
Another significant issue is engine durability. Heavy-duty engines are designed and manufactured for an acceptable period of use, separate from the emissions warranty useful life. A heavy-duty engine in an over-the-road tractor application is expected by fleet operators to have an operating life of one million miles. A light or medium heavy-duty engine, if installed in that vocational application, is not expected to be able to last that long and may need to be replaced with a new engine some number of times over the life of the vehicle. This would result in an additional cost that may not be anticipated by the purchaser, and may not have been accounted for in the cost analysis of the NPRM, if the NPRM is assuming a certain level of engine downsizing penetration into the heavy heavy-duty vehicle application. [EPA-HQ-OAR-2014-0827-1265-A1 p.91]

CARB staff believes that these are significant issues that need to be addressed in the Phase 2 rulemaking. One possible approach that was used by CARB in the Interim Certification Procedures for Heavy-Duty Hybrid Vehicles was the requirement that the hybrid vehicles, with or without engine downsizing, have to comply with the same useful life requirements as for the conventional diesel engine that would have been normally used in the same intended vehicle class. [EPA-HQ-OAR-2014-0827-1265-A1 p.91]

**Organization:** Daimler Trucks North America LLC

**DF process:** Continue the Phase 1 approach on DFs - EPA requests comments regarding the appropriateness of continuing the practice of engine manufacturers adopting assigned DFs for CO2 emissions. 80 FR 40206. During Phase 1 discussions, DTNA shared data from laboratory and field tests with EPA to demonstrate the in-use fuel efficiency performance of its products, showing that the DF should be zero. In particular, these data illustrated that fuel efficiency remains stable over the course of high mileage testing and thereby support EPA’s rationale of allowing manufacturers to adopt a 0.0 g/bhp-h additive deterioration factor for CO2 emissions. DDC’s experience with engine emissions supports that these past trends continue to today’s products and can be expected to continue with its new products. DTNA similarly agrees with the agencies’ proposal that it is prudent for EPA to consider, subject to good engineering judgment, allowing the same assigned DF for advanced or off-cycle technologies. [EPA-HQ-OAR-2014-0827-1164-A1 p.119]

**Useful Life and Maintenance** – The agencies discuss the concern that the EPA regulations apply for the useful life of a vehicle and therefore involve vehicle owners to perform maintenance, which bears associated costs. 80 FR 40325. We think that there is little need for additional regulation to enforce maintenance requirements, especially when it comes to fuel efficiency. The way that the EPA regulations for criteria pollutants have worked until now is that manufacturers pass maintenance instructions to the vehicle owners and then do useful life testing based on those maintenance intervals. With criteria pollutant emission-control systems, an emission failure would not necessarily bother a vehicle owner. For example, if the EGR system stopped pumping EGR or the DPF broke, the engine could still operate and perhaps even have better fuel efficiency than with the emission-control systems intact. (In fact, however, we design our engines and aftertreatment to be very robust and do not expect such failures, plus we use OBD systems to catch them and warn drivers). By contrast, with systems designed to optimize fuel efficiency and minimize GHG emissions, system failure would degrade fuel efficiency, thus providing vehicle owners more monetary incentive to maintain their vehicles and engines. Therefore, we believe that the agencies should expect an even higher likelihood of vehicles and engines being properly maintained under the proposed regulations than under past criteria pollutant regulations, and those regulations have worked. In short, the agencies should be adequately assured that FE-related maintenance is being performed in the field. [EPA-HQ-OAR-2014-0827-1164-A1 p.118-119]
We agree with the use of a zero DF for vehicles' and engines' CO2, based on the same data that we showed the agencies in Phase 1. Second, the agencies premise that the Phase 2 standards will use very costly technologies, like hybridization for which battery replacement can be cost-prohibitive, but the agencies explicitly state that they have not quantified maintenance costs for any technology other than hybrids. 80 FR 40325. Although we do not expect maintenance within the period of a DF test, there should be some maintenance requiring battery replacement during the vehicles’ actual life. Accurately capturing both the up-front and in-use costs of technologies is extremely important in determining when the fuel saving technologies are cost-effective, and we believe that the agencies dramatically underestimated the costs of (for example) hybrids. In turn, we think it likely that customers will do as New York's hybrid bus operators did and not maintain the hybrid systems, converting back to conventional powertrains. So correcting underestimated costs for fuel saving technologies is an important part of the agencies' post NPRM work. [EPA-HQ-OAR-2014-0827-1164-A1 p.119]

Organization: Allison Transmission, Inc

Comments on Hybrid Battery Replacement/Useful Life

EPA is proposing to continue its Phase 1 approach to deterioration factors and anticipates that hybrid systems will experience “some deterioration of effectiveness with age of the storage device.” In EPA’s opinion, the regulations at 40 C.F.R. 1037.241 provide adequate information to manufacturers in order to develop deterioration factors, but requests comment on whether any changes to this process are required. [EPA-HQ-OAR-2014-0827-1284-A1 p.61]

The criteria referenced in 40 C.F.R. 1037.241 are contingent upon an EPA finding that emissions controls are likely to deteriorate during useful life. We would note that although EPA anticipates that some hybrid powertrain systems may experience deterioration of effectiveness that the Agency is not acting specifically within this rulemaking to make such a determination with regard to any specific system. In general, Allison believes that each hybrid manufacturer can develop a method of determining a battery performance design limit. (Indeed, in the context of certification of hybrid systems, Allison would expect that the amount of credits generated for a hybrid system will be dependent, in part, to battery performance at that design limit). With respect to determining hybrid deterioration factors, we would therefore expect that such design limits should be a sufficient basis for any deterioration factors that are required. [EPA-HQ-OAR-2014-0827-1284-A1 p.61]

Otherwise, Allison would note that 40 C.F.R. 1037.125 provides for the provision of maintenance instructions for properly maintaining a vehicle, including its emission control systems. Allison recommends that a prognostic feature be included in vehicles to warn an operator when measured Amp-Hour throughput surpasses the battery design limit and maintenance must be performed. Such systems would ensure that maintenance was reasonably likely to be done at recommended intervals in accordance with this provision. This is also a good way to take into account each specific vehicle’s duty cycle’s effect on lifespan. In addition, under this recommendation, the costly battery would not need to be replaced until it had deteriorated to the set design limit. [EPA-HQ-OAR-2014-0827-1284-A1 p.61]

Organization: Daimler Trucks North America LLC

The agencies point out that there is the possibility of a mismatched engine useful life and vehicle useful life for components in the same vehicle, and the agencies correctly note that this does not pose any particular policy problem that needs to be addressed. 80 FR 40326. The engine UL is based on the engine's service class, which is the primary intended application of an engine. (See, e.g., 40 CFR § 86.085-2). It is not the sole application of an engine. So there might be, for example, a relatively small
number of medium heavy-duty engines that go into heavy heavy-duty vehicles. And the agencies should not seek to end this practice, as a 'downsized' engine that can meet a vehicle's driving needs can be lighter and more fuel efficient than the larger engine. In other words, if the agencies required that manufacturers certify each engine to the heaviest service class in which the engine will ever be used, then manufacturers would have to limit certain engines' usage, thus depriving fleets of potential fuel savings in those limited cases when a downsized engine will suffice for a vehicle. The agencies took the correct approach. [EPA-HQ-OAR-2014-0827-1164-A1 p.119]

Organization: Caterpillar Inc., et al.

Regulation must appropriately reflect real-world reductions

Reduced petroleum consumption and GHG mitigation depend on real-world reductions, not regulatory measurements and calculations. Fuel cost, typically one of the top two operating expenses for owners of heavy-duty vehicles, must be managed to survive in a transportation market with slim margins and many competitors. Vehicle owners are able to pay for efficiency technology only to the extent that it provides adequate return on investment in their operation. As manufacturers, we must design and specify our vehicles to comply with the Phase 2 regulation, while at the same time optimizing to the specific operation of each customer. This situation is only manageable if the regulation results accurately mirror real world results for the majority of applications, while also providing the flexibility to meet unique requirements of applications that do not match regulatory duty cycles. Of course, it is impossible, in any regulatory construct, to match the specific freight efficiency performance in many diverse operations. But it is both possible and our expectation that the regulation accurately compares the relative performance between any two vehicle specifications in the majority of applications. Unless this is achieved, the regulation will not accomplish its goals - goals fully shared by regulators, manufacturers, and vehicle owners. Regulatory outcomes that do not match real-world results will result in failure to meet environmental objectives, combined with economic disruption to our entire industry, because owners will not purchase expensive vehicles, particularly if burdened with complex new technologies that do not deliver adequate results by their measurement - the cost of fuel and other operational costs for these vehicles. [EPA-HQ-OAR-2014-0827-1215-A1 p.3-4]

Organization: Enovation Controls (ENC)

Combustion Type Classification - ENC agrees with classification of vehicle technologies based on end user expectations for useful life and emissions system upkeep. [EPA-HQ-OAR-2014-0827-1203-A1 p.1]

2.2 Emissions Warranty and Durability - ENC submits that EPA Phase 2 rules should be purely CO2-regulating. Emissions warranty language should addressed in CARB and EPA standards (CCR Title 13, Section 1971.1 and 40CFR 86.010-18, respectively) to maintain consistency with the separation of emissions functionality guarantees enabled by extensive and sophisticated on-board diagnostics from regulation of OEM as-delivered products. Furthermore, all references to criteria pollutants should reflect the critical pollutants emitted from a specific combustion type. Specifically, critical emissions for Compression Ignition engines are NOx and PM, and critical emissions for Spark-Ignition engines are NOx and NMHC. [EPA-HQ-OAR-2014-0827-1203-A1 p.2]

Organization: FCA US, LLC

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 62.]
We support the flexibility mechanisms that are included in the rule, averaging, banking and trading, and the recognition of the benefits of technologies that are not fully captured on the laboratory drive cycles. We will work with the agencies to make these processes more efficient in the second phase of this program.

**Organization:** General Motors

Third, we have been gaining valuable experience concerning the importance of flexibility mechanisms, contained in the light duty vehicle greenhouse gas and fuel efficiency regulations, and these lessons can be applied to the medium and heavy duty fleet.

All of these flexibility mechanisms that have been successful for light duty trucks can be applied equally to the Class 2B and Class 3 pickups and vans covered by this proposed regulation.

**Organization:** McNicols

Modifications to measurements and certification methods may be required, and flexibility to adapt these processes to accommodate promising and impactful technologies will be crucial. Some of these challenges include organizational empowerment, policy overhaul, working level encouragement and grace for risk taking, and flexible compliance throughout your organizations.

**Organization:** National Association of Clean Air Agencies (NACAA)

Finally, NACAA urges that EPA do everything feasible to implement in-use compliance verification. We support EPA’s testing regime for engines and the requirement for manufacturers to submit data from chassis testing – these are good first steps. However, we believe the current whole-vehicle provisions should be complemented with some type of whole-vehicle validation to ensure long-term compliance by vehicles in-use. For example, tracking vehicle weight and speed with engine carbon dioxide and nitrous oxide emissions could be used as a tool to determine overall vehicle performance for corrections/correlations to EPA’s Greenhouse Gas Emissions Model moving forward. [EPA-HQ-OAR-2014-0827-1157-A1 p.5]

**Organization:** Navistar, Inc.

Navistar feels the following are key areas the agencies must address: [NHTSA-2014-0132-0094-A1 p.2]
• The burdens of testing must be rational and related to ensuring compliance. [NHTSA-2014-0132-0094-A1 p.2]

• Customers should be allowed to make acceptable modifications to engines and vehicles in accordance with past standard practice. [NHTSA-2014-0132-0094-A1 p.2]

• Model years must be aligned so that the emission standards for engine and vehicle start at the same time and so that certain vehicle segments, such as school bus, are not overly impacted because of their unique sales seasons. [NHTSA-2014-0132-0094-A1 p.3]

For example, engine re-rating is a routine practice when a different engine horsepower is required by a second or third owner of a vehicle or the first owner if working conditions change or the initial specifications were not adequate to the task. Because of legitimate differences in use, an engine sometimes will be altered to a different horsepower rating. Transmission calibration may also be changed based on particular applications. Finally, rear axle ratios may be modified based on a particular use. [EPA-HQ-OAR-2014-0827-1199-A1 p.15-16]

By potentially incorporating these elements into certification, there is a significant danger that the opposite will occur to what is intended, that is, these elements will be discouraged. This may negatively impact stock trucks ordered by dealers and second and subsequent owners. Each of these potential modifications reflects a legitimate use. However, in the Proposed Rule, because these elements may have been part of the initial certification, these elements may be “frozen” in a way that has not been the case previously. Navistar is concerned that this could cause serious market disruption. It may cause a manufacturer to certify in a way that shows that vehicle as a “worst case” scenario to guard against the worst possible GHG emissions configuration. The other possibility is that dealers would halt buying stock trucks and wait for a particular customer to order their particular vehicle, which would significantly change that part of the market effectively eliminating stock trucks. A third possibility is that the secondary market for vehicles that have unusual but fixed configurations will be seriously restricted, impacting their value. [EPA-HQ-OAR-2014-0827-1199-A1 p.16]

We agree with EMA’s recommendations in this regard. The agencies should seek to avoid negative impacts to the market. [EPA-HQ-OAR-2014-0827-1199-A1 p.16]

We also have concerns regarding the anticipated technology penetration rates. For the majority of the technologies the agencies project 50% penetration in the vocational sector, with parasitic/friction reduction being the highest at 60% in the first year of this Proposed Rule. This creates two issues: 1) insufficient time, particularly with the vehicle and engine model year mismatch, to develop and implement the new standard, and 2) it would require that each manufacturer establish two parallel, complete engine development programs, given the basic engine architectural changes assumed by the Proposed Rule in the 2021 timeframe. [EPA-HQ-OAR-2014-0827-1199-A1 p.21]

Navistar feels that the provisions with regard to warranty have stricken the correct balance. Navistar does not feel it necessary to change the language as proposed. [EPA-HQ-OAR-2014-0827-1199-A1 p.41]

**Organization:** Owner-Operator Independent Drivers Association (OOIDA)

Impacts on niche segments of the industry
Niche segments such as oversized and heavy haul are recognized as being unique. The agencies have acknowledged that niche industries present unique concerns not shared with the most prevalent truck operations. However, one area that the agencies have not adequately addressed is post-purchase modification, which is a specialty for small business owner-operators. In particular, owner-operators are able to change their schedule in order to meet a customer’s demands with relative ease. This can mean that a truck which was spec’d for one particular niche might need to be modified for use in another niche at a customer’s request, or as the markets change. This could require different types, or even sizes, of tires and a completely different type of trailer. These small-business owner-operators should not be penalized or prevented from making changes to their equipment in order to stay in business. [EPA-HQ-OAR-2014-0827-1244-A1 p.46]

The proposed rules would prohibit the future post-purchase modification of the new proposed technologies in a truck unless it can be shown that the modifications improve fuel economy. While OOIDA appreciates this flexibility, it is concerned that this important issue is not explained in adequate detail. For example, as stated above, a standard truck built for pulling a dry van trailer might be used to pull a flatbed, or the original purchaser of the truck might decide to change from a dry van operation to flatbed operation by removing the dry van-focused roof fairing. According to the current proposal, such modifications could be a violation of the Clean Air Act, unless it would improve the vehicle’s fuel efficiency. OOIDA members would appreciate more specific information on how they would be able to prove the merits of their modifications, well short of being a defendant accused of violating the Clean Air Act. [EPA-HQ-OAR-2014-0827-1244-A1 p.46-47]

**Organization:** Truck & Engine Manufacturers Association (EMA)

**Model Year Mismatch**

The agencies have proposed to require the use of engines and vehicles designated with the same model year. However, engine model years are generally aligned with the calendar year, while vehicle model years often extend up to one calendar year plus 364 days. The proposed Phase 2 requirement will disrupt the vehicle manufacturing process without achieving any true environmental benefit. [EPA-HQ-OAR-2014-0827-1269-A1 p.27]

Based on the current market dynamics for vehicle model implementation, model year 2021 vehicles will have either a model year (“MY”) 2019, 2020, or 2021 engine installed in them. This is problematic for engine manufacturers as they may not have a certified Phase 2 engine map for pre-2021 engines for use in the 2021 vehicle. It is also an issue for vehicle manufacturers since the MY2019 and MY2020 engine will likely not be designed to comply with the Phase 2 stringencies. [EPA-HQ-OAR-2014-0827-1269-A1 p.27]

EMA is proposing an alternative to address the mismatch between the start of the vehicle and engine model years. Under this alternative, the model year of the installed engine would define the “greenhouse gas” year (GY) for the vehicle. The GY would define the stringency level for each vehicle. This would allow the engine and vehicle to be matched in model year for the purposes of the Phase 2 GHG/FE regulation. [EPA-HQ-OAR-2014-0827-1269-A1 p.27]

The diagram below shows the relationship between the vehicle marketing model year, which is used in the VIN as the vehicle model year, the vehicle GHG/FE year, and the engine model year. With this recommended implementation alternative, as is shown below, the engine MY2020 aligns with vehicle GY2020 and VIN for 2021. Engine MY2021 creates vehicle GY2021 and 2022 VIN. Thus, under this alternative, the issues stemming from the misalignment between available engine and vehicle
technologies – including an unwarranted one-year pull-ahead of the Phase 2 engine standards – are eliminated for all three steps in the Phase 2 regulation. The additional compliance burden of MY2019 and MY2020 engine fuel maps is also eliminated. [EPA-HQ-OAR-2014-0827-1269-A1 p.27]

The proposal’s definition of Model Year (see p 40663) differs from NHTSA’s 24 and penalizes manufacturers who are making trailers with forward reaching model years for sales purposes. EPA staffers have verbally assured us that the model year as required under this rule does not need to be the same model year used for sales purposes. We will be in position of potentially selling trailers marketed and marked on the VIN plate as Model Year 2019, while marking on the EPA plate “THIS VEHICLE COMPLIES WITH U.S. EPA REGULATIONS FOR 2018 HEAVY-DUTY VEHICLES.” Any proposed definition of Model Year should explicitly state this. For example, §1037.801 could be expanded to include a new paragraph: [EPA-HQ-OAR-2014-0827-1172-A1 p.15]

* * *

(3) The model year as used in this part need not correspond with the model year used for VIN and marketing purposes. [EPA-HQ-OAR-2014-0827-1172-A1 p.15]

* * *

while the same paragraph should be added to §535.4’s definition of MODEL YEAR. [EPA-HQ-OAR-2014-0827-1172-A1 p.15]

Additionally, modify the labeling requirements in 1037.135(8) to read: [EPA-HQ-OAR-2014-0827-1172-A1 p.16]

(8) State: “THIS VEHICLE COMPLIES WITH U.S. EPA REGULATIONS FOR [MODEL YEAR] HEAVY-DUTY VEHICLES.” Optionally, the word “MANUFACTURED” may be added after the model year. [EPA-HQ-OAR-2014-0827-1172-A1 p.16]

This will make it clear that if a trailer manufacturer adopts a calendar year model year for this rule, it can continue its practice of using an advance model year for VIN and marketing purposes and to avoid confusion, the Emission Control Label on a vehicle with a 2019 Model Year on the VIN plate manufactured in 2018 could read “THIS VEHICLE COMPLIES WITH U.S. EPA REGULATIONS FOR 2018 MANUFACTURED HEAVY-DUTY VEHICLES”. If authority comes through NHTSA, a similar label requirement could be used in §535. [EPA-HQ-OAR-2014-0827-1172-A1 p.16]

24 49CFR565.12(m) – “Model year means the year used to designate a discrete vehicle model, irrespective of the calendar year in which the vehicle was actually produced, provided that the production period does not exceed 24 months.”

Organization:  PACCAR, Inc.

Implementation and Definitional Issues
Engine and Vehicle Model Year Designations

The Agencies have proposed to require the use of engines and vehicles designated with the same model year. However, engine model years are generally aligned with the calendar year, while vehicle model years often extend up to one calendar year plus 364 days. The proposed requirement will disrupt the manufacturing process without achieving any true environmental benefit. [EPA-HQ-OAR-2014-0827-1204-A1 p.28]

Based on the current market dynamics for implementation, the model year 2021 vehicles will have either a model year 2019, 2020, or 2021 engine installed in them. This is problematic for the engine manufacturer as they may not have a certified engine map for pre-2021 engines for use in the 2021 vehicle. It is also an issue for the vehicle manufacturers since the MY2019 and MY2020 engine will likely not be designed to comply with the Phase 2 stringency. [EPA-HQ-OAR-2014-0827-1204-A1 p.28]

EMA has proposed an alternative to address the mismatch between the start of the vehicle and engine model years. In this alternative the model year of the installed engine would define the “greenhouse gas” year (GY) for the vehicle. This would allow the engine and vehicle to match in model year for purposes of the Phase 2 GHG regulation. This proposal is also included in EMA’s comments. [EPA-HQ-OAR-2014-0827-1204-A1 p.28]

EPA has suggested in a meeting with EMA and the other Agencies that this alternative would, in their view, delay the implementation of Phase 2 and somehow reduce the GHG emissions reductions. In fact, since the calculations for GHG reductions are by model year of the regulation, all emissions will be counted and no net shortfall would be realized in GHG reductions. [EPA-HQ-OAR-2014-0827-1204-A1 p.28]

PACCAR supports the EMA proposal and is committed to engaging with the Agencies either through EMA or alone to identify and mitigate issues with the above proposal so that a mutually acceptable alternative can be finalized. [EPA-HQ-OAR-2014-0827-1204-A1 p.28]

Powertrain Modifications

The ability to modify powertrain components, such as engine ratings, transmission calibrations, and rear axle ratios in the field to optimize the performance of the vehicle for the vehicle’s actual job requirements and duty cycle is imperative for owners of commercial vehicles. A sub-optimized vehicle will burn more fuel and perform poorly. [EPA-HQ-OAR-2014-0827-1204-A1 p.28]

In Phase 2, with the powertrain components for the vehicle being added as input into GEM’s GHG vehicle assessment, these components become regulated by the GHG rule. As written, the draft regulation would make any modifications to these components illegal under the tampering provisions of the Clean Air Act. EMA’s comments provide extensive details supporting the need for the ability to modify powertrain components in the field without this modification being deemed “tampering.” [EPA-HQ-OAR-2014-0827-1204-A1 p.29]

It is typical of fleets to buy numerous vehicles with the same spec and then modify the powertrain calibrations based on where the vehicle will operate, such as on flatter terrains versus more mountainous regions. [EPA-HQ-OAR-2014-0827-1204-A1 p.29]
To mitigate the concern regarding extensive use of powertrain changes shortly after vehicle build to improve GHG scores of vehicles, PACCAR would be willing to update the GHG end of year reporting data for a chassis to reflect any field modifications that are made known to us. If changes are made to the powertrain configurations post manufacturing, then the modifying party is responsible for communicating these to the vehicle manufacturer for inclusion in their 270 day report. If communication of the change is not provided to the vehicle manufacturer, then the party responsible for modifying the configuration will be held responsible for reporting the change to the Agencies. [EPA-HQ-OAR-2014-0827-1204-A1 p.29]

PACCAR strongly supports the EMA recommendation to add language to the regulation that spells out that these modifications are not tampering actions. [EPA-HQ-OAR-2014-0827-1204-A1 p.29]

**Organization:** Volvo Group

**Tampering Prohibitions**

As with the Phase 1 regulation, the Phase 2 regulation restricts the ability of an OEM, dealer, or vehicle owner to modify an engine or vehicle’s operating parameters anytime within the vehicle’s life. The agencies do allow for post-useful life vehicle modifications to reduce emissions of GHGs under 40 CFR 1037.655 where there is a “reasonable technical basis for knowing that such modification will not increase emissions of any other pollutant” and where you “have information that would lead an engineer or other person familiar with engine and vehicle design and function to reasonably believe that the modifications will not increase emissions of any regulated pollutant”. The post-useful life flexibility does not apply to engine modifications or recalibrations. [EPA-HQ-OAR-2014-0827-1290-A1 p.57-58]

Under the Phase 1 GHG and current criteria emissions regulations, there is limited concern that prohibited modifications may occur due to the fewer regulated components and the engine family construct, under which all engines within the family are certified to the parent engine level. Under Phase 1 and criteria emissions regulations, the engine calibration, transmission gear ratios and calibration, and drive axle ratios can be modified at any time without impacting a vehicles certified emissions. Dealers use this flexibility in the case of stock trucks that are ordered in the absence of a specific customer order; and owners use it to meet the changing demands of a vehicle’s application or to improve resale value. In Phase 2, this is no longer the case. [EPA-HQ-OAR-2014-0827-1290-A1 p.58]

In the proposed Phase 2 regulation, engines may be optionally certified as part of a powertrain and, in any case, the torque rating will have some impact on the vehicle’s GHG emissions. As well, since the transmission efficiency, gear ratios and calibration, along with drive axle ratios would all become part of the vehicle’s certified configuration, they would also become subject to tampering restrictions, and could not be modified unless it could be demonstrated that the changes did not increase GHG emissions (a task that few dealers or owners could accomplish). The result of this would be a disruption of the new, used, and in-use vehicle markets. Dealers would no longer be able to stock new trucks to meet the needs of customers who require a truck immediately. Buyers on the secondary market would not be able to either purchase a used truck that met their requirements, or modify a truck to do so. The primary purchaser’s overall cost of ownership would necessarily increase due to this lack of flexibility to make a used truck more suitable for the secondary market, the result of which would be longer trade cycles and increased operation of older vehicles, along with the resultant decrease in new truck sales and loss of emissions benefits from those new trucks. Lastly, those customers who must modify a vehicle’s configuration to meet changing operational demands (e.g. moving a vehicle from a mostly flat to hilly region) will no longer be able to modify that vehicle, since the resultant emissions would likely be greater (and even if not, could not be easily demonstrated). [EPA-HQ-OAR-2014-0827-1290-A1 p.58]
Truck owners will not have the capability or knowledge to determine whether any modification may result in increased emissions to the extent required by the agencies in Section 1037.655. Most modifications of this type would require a new GEM analysis which would require OEM support. Given the number of trucks in the fleet it would not be possible for OEMs to support this activity without excessive burden, even if the OEM knew of the modification. In many cases, and particularly for vendor supplied components, the OEM has no means to know that a modification has occurred. From this perspective, it would unfairly burden OEMs to quantify and report the impact of changes to OEM supplied components while vendor components could be modified without consequence. [EPA-HQ-OAR-2014-0827-1290-A1 p.58]

Volvo Group requests that the agencies allow for vehicle modifications such that disruption to the market is limited. In this regard, Volvo Group supports the EMA comments in this area and the proposal wherein OEMs would only be required to track new vehicle modifications that occur prior to delivery to the ultimate purchaser and to include such modifications in year-end reports when those modifications occur at least 60 days ahead of submission of the final report to the agencies. [EPA-HQ-OAR-2014-0827-1290-A1 p.58-59]

Response:

Useful Life and DFs – Including for Engines in Hybrid Vehicles

We are adopting as proposed our approach regarding deterioration factors. Vehicle manufacturers may certify that installed technology will remain effective throughout the vehicle useful life by either demonstrating that critical emission-related maintenance will occur or by applying deterioration factors, or both. However, in light of comments expressing concerns with mismatched engine and vehicle useful life, we have reconsidered those provisions. As provided in 40 CFR 1037.140 of the final regulations, we have structured the vehicle regulations to generally apply the same useful life for the vehicle that applies for the engines. However, these regulations also allow vehicle manufacturers to certify their vehicles to longer useful lives. The agencies see no problem with allowing vehicles to have longer useful lives than the engines.

For hybrid vehicles, Allison is correct that we are not making a determination with regard to the need for a non-zero DF for any specific hybrid systems. Rather, we are highlighting that manufacturers must use good engineering judgment to account for any deterioration of emission controls.

Representativeness of Test Methods

While no test methods can perfectly replicate in-use performance for each operator and each application, the methods developed by the agencies should accurately reflect in-use improvements in a relative sense. Thus, we expect operators to be generally satisfied with the performance they observe.

Eaton commented in support of powertrain testing. In some respects, powertrain testing can be considered to be a reference method for this rulemaking. Because manufacturers have the option to perform powertrain testing instead of engine-only fuel mapping, the stringency of the final standards can be traced to powertrain testing. In other words, methods that can be shown to be equivalent to powertrain testing, can be considered to be consistent with the testing that was used as the basis of the final Phase 2 standards.

In a related context, it may be useful in the future to consider equivalency to powertrain testing as an appropriate criterion for evaluating changes to GEM to address new technologies. Consider, for example, a new technology that is not represented in GEM, but that is reflected in powertrain testing.
The agencies could determine that it would be appropriate to modify GEM to reflect the technology rather than to require manufacturers to perform powertrain testing. In such a case, the agencies would not consider the modification to GEM to impact the effective stringency of the Phase 2 standards because the new version of GEM would be equivalent to performing powertrain testing.

Finally, we agree with Navistar that testing should be rational and related to ensuring compliance.

**Flexibility Provisions**

Several commenters expressed support for the numerous flexibility provisions proposed. General Motors also commented in support of applying light-duty vehicle flexibility provisions to heavy-duty vehicles. As discussed in Chapter 7, we do not believe it is invariably appropriate to apply light-duty provisions directly to heavy-duty vehicles because of differences in test procedures and in-use duty cycles.

McNicols stated that “[m]odifications to measurements and certification methods may be required, and flexibility to adapt these processes to accommodate promising and impactful technologies will be crucial.” We believe the final regulations will provide the agencies significant ability to adapt methods to address unforeseen circumstances.

**In-use Compliance Assurance**

NACAA urged EPA to “do everything feasible to implement in-use compliance verification.” As described later, EPA has adopted substantial program to evaluate both certification and production engines and vehicles. In addition, EPA will collect in-use CO2 data as part of our existing in-use testing program. The agencies are also requiring all technologies to be durable.

**Post-Production Modifications**

Navistar commented that “[c]ustomers should be allowed to make acceptable modifications to engines and vehicles in accordance with past standard practice.” Under 40 CFR part 1037, it is generally prohibited for any person to remove or render inoperative any emission control device installed to comply with the requirements of part 1037. However, in 40 CFR 1037.655 EPA clarifies that owners may modify a vehicle for the purpose of reducing emissions, provided they have a reasonable technical basis for knowing that such modification will not increase emissions of any other pollutant. This essentially requires the owner to have information that will lead an engineer or other person familiar with engine and vehicle design and function to reasonably believe that the modifications will not increase emissions of any regulated pollutant.

Other manufacturers also commented that manufacturers (and their authorized agents) should be allowed to modify powertrain components, such as engine ratings, transmission calibrations, and rear axle ratios after production to optimize the performance of the vehicle for the vehicle’s actual job requirements. The agencies agree that manufacturers should be allowed to make such modifications, provided the final configurations are accurate in the end of year reports. For example, this could allow reconfiguration of stock vehicles at dealerships. However, any modifications made prior to the delivery to the ultimate purchaser that are not reflected in the end of year reports will be considered violations, whether more or less than 60 days before the end of year reports.

OOIDA expressed similar concerns for trucks owned by independent operators. However, the CAA generally prohibits removal of emission controls. While EPA has in the past interpreted this to not restrict modifications that maintain or improve emissions performance, the CAA clearly does not allow modifications that increase emissions. Thus, an independent operator wishing to maintain operational
flexibility should purchase a lower technology vehicle, which is permissible if the vehicle is certified to a higher FEL under the emissions averaging program for manufacturers. For example, an operator concerned about aerodynamic fairings on the tractor could purchase a Bin I tractor (which includes no upper limit on aerodynamic drag), which would allow the operator to make any aerodynamic modifications without risking the modification taking the vehicle out of its certified configuration.

Volvo suggested that operator will often lack the expertise necessary to provide the reasonable technical basis for the modifications. However, they overstated the level of knowledge EPA assumes when referring to a “reasonable technical basis”. Nevertheless, operators should be aware that some knowledge is required before modifying the vehicle. While this may disrupt prior practices, the Clean Air Act creates a fairly clear presumption that vehicles should remain in their certified configurations in-use.

Model Year Mismatch

Under the normal engine and vehicle manufacturing processes, many vehicles may be produced with engines having an earlier model year than the commercial model year of the vehicle. For example, we expect that most Class 6 and heavier vehicles commercially sold as model year 2021 vehicles will be produced in calendar year 2020 with MY 2020 engines. Some manufacturers commented that MY 2020 engines should not be subject to Phase 2 requirements, based on NHTSA’s statutory 4-year lead-time requirement and because the potential higher fuel consumption of MY 2020 (i.e., Phase 1) engine maps could force vehicle manufacturers to install additional technologies that were not projected by the agencies for compliance. The agencies considered these comments along with the potential cost savings for manufacturers to align the timing of both their engines’ and vehicle’s Phase 2 product plans and certification paths. The agencies also considered how this situation would repeat in MY 2024 and MY 2027 and possibly with future standards as well. Based on these considerations, we have decided that it would be more appropriate to harmonize the engine and vehicle standards, starting in MY 2021.

Other General Comments

Enovation supported narrowing the scope of the EPA Phase 2 standards with respect to issues such as warranty and “critical emissions”. However, such changes would be inconsistent with the general regulatory construct provided by the Clean Air Act. Navistar commented that it does not support the proposed changes to the warranty language, but these changes are primarily clarifications, rather than fundamental changes.

With respect the McNicols’ general comment in support of compliance flexibility, we note that the agencies are committed to maintaining the proper balance of compliance assurance, flexibility, and conformance with statutory requirements.

1.4.1 Advanced Technology Credits and Multipliers

Organization: Allison Transmission, Inc.

EPA and NHTSA Should Not Continue Phase 1 Programs to Incentivize Hybrids, Fuel Cell and EVs

Allison supports provisions of the Proposed Rule that would end specific Phase 1 incentives for hybrids, fuel cell and electric vehicles (“EVs”). We concur with the agencies that the potentially large credits that may be available for such vehicles through certification of very low emission rates should provide
sufficient incentive for improved introduction of such vehicles into the commercial MD/HD fleet. As
the agencies indicate at the beginning of the Proposed Rule, the Phase 2 standards are intended to be
technology-forcing. While the agencies’ ability to require technology-forcing standards is not
unbounded,
manufacturers should not receive what could amount to a “double credit” of meeting their
compliance obligations through hybrids, fuel cell and electric vehicles are receiving additional credits
on account of this action. [EPA-HQ-OAR-2014-0827-1284-A1 p.51]

As the agencies indicate at the beginning of the Proposed Rule, the Phase 2 standards are intended to be
technology-forcing. While the agencies’ ability to require technology-forcing standards is not
unbounded,
manufacturers should not receive what could amount to a “double credit” of meeting their
compliance obligations through hybrids, fuel cell and electric vehicles are receiving additional credits
on account of this action. In addition, we would note that expanded delegated assembly for vehicles is
an additional avenue whereby new technologies can be introduced into the market. [EPA-HQ-OAR-

Organization: American Gas Association (AGA) et al.

We Recommend that the Agencies Incorporate an Advanced Technology Credit that Incentivizes Engines that Emit No More than 0.02 g/bhp-hr of NOx Emissions

The HD Phase 1 Rule provided Advanced Technology Credits (“ATC”) for hybrid powertrain designs
that included energy storage systems, Rankine cycle waste heat recovery systems attached to an engine,
all-electric vehicles, and fuel cell vehicles. The agencies justified the use of this credit for these
specific technologies on the notion that the Phase 1 standards could be met without the use of advanced
technologies, and that, therefore, the standards were not premised on their use. Thus, the agencies felt
that there needed to be additional incentives to stimulate those particular technologies. [EPA-HQ-OAR-

In the Phase 2 Proposal, the agencies have opted not to include the ATC because the proposed rules “are
premised on the use of some advanced technologies, making them equivalent to other fuel-saving

However, given the low market penetration of the technologies afforded the ATC and the expectation of
further air quality and GHG imperatives over the course of the timeline of the proposed rule (i.e.,
2021-2027), we strongly urge the agencies to include an expanded ATC in the final Phase 2 rule. [EPA-

More specifically, we strongly urge the agencies to reinstitute the ATC and expand it to provide credit
for engines that are certified at NOx levels at or below 0.02 grams per brake horsepower-hour (g/bhp-

We see multiple benefits from an expanded ATC that includes ultra-low NOx engines:

- It will align with California’s efforts to incentivize the commercialization of these engines through
their Optional Low NOx Standard for on-road heavy-duty engines. [EPA-HQ-OAR-2014-0827-1223-
A1 p.11]
• If successful, it will help spur the commercial development of engines that will be necessary to help states meet their obligations under any future ozone National Ambient Air Quality Standard (NAAQS).[EPA-HQ-OAR-2014-0827-1223-A1 p.11]

• It will lay the groundwork for the next generation of heavy-duty engine technology. Given that EPA has not adopted criteria pollutant standards since 2001, it is timely to consider—and to signal to industry—the next level of potential emissions performance.[EPA-HQ-OAR-2014-0827-1223-A1 p.11]

• It will help incentivize engines that will reduce ground-level ozone, a short-lived climate pollutant that should be reduced for both climate and health reasons.[EPA-HQ-OAR-2014-0827-1223-A1 p.11]

• It is worth noting that an expanded ATC that includes ultra-low NOx engines would be available to all engines regardless of fuel type. This would maintain the fuel-neutrality of the overall program, and incentivize cleaner diesel engines, as well as cleaner natural gas engines.[EPA-HQ-OAR-2014-0827-1223-A1 p.11]

42 HD Phase 1 Rule, page 57245.

43 Phase 2 Proposal, page 40158.

Organization: American Lung Association

The American Lung Association offers the following recommendations to strengthen the stringency and timing of the proposal and address several key elements of California’s commitment to protecting public health and air quality. [NHTSA-2014-0132-0087-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.143-144.]]

Advanced technology credits, or a similar mechanism, should be maintained in Phase 2, rather than phased out. Given the severe air quality conditions in the South Coast and San Joaquin Valley, California needs truly zero emission technologies to be moving our freight. Without a strong commitment to advanced technologies and electrification in this sector, the overall proposal is missing a critical tool that California needs. In particular, battery electric, fuel cell, hybrid and other advanced technologies are vital to achieving the major reductions needed here. Retaining the focus on advanced technologies will also allow for a stronger overall standard and greater health and fuel saving benefits to be achieved. Zero emission technologies must be moved forward to protect public health from pollutants today and an unsustainable dependence on fossil fuels that threatens health for generations. [NHTSA-2014-0132-0087-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.145-146.]]

Organization: American Trucking Associations (ATA)

Use of Advanced Technology Credits Should Continue
Hybrid and electric technology applications continue to be of interest to the trucking industry, especially in the vocational segment. While these technologies provide fuel savings and reduced tailpipe emissions, the cost of these technologies can be substantial. EPA estimates the added cost of hybrid technologies are in the range of $20,000 to $40,000 for larger vocational vehicles and tractors while full electric technologies are in the $50,000 to $150,000 range. These costs are the highest of all the fuel efficient technologies identified and, as previously discussed, are likely to result in lower adoption rates than estimated. [EPA-HQ-OAR-2014-0827-1243-A1 p.23]

In order to continue to advance these technologies and their adoption, the incentive-based approach used in Phase 1 should be retained. Specifically, the agencies should preserve the advanced technology credits which provide a credit of 1.5 in order to promote the use of hybrid and electric vehicles in larger vocational vehicles and tractors. A continuation of these credits will provide an incentive for OEM’s to pursue the development and sale of hybrid and electric vehicles. These credits will likely help drive down costs while more effectively promoting the advantages of this green-technology path as a path towards achieving the goals of the rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.23]

**Organization:** BYD Motors

My concern is that I do not believe that the rules alone will drive the adoption of advanced technologies like fuel cell, hybrid, and electric vehicles. These technologies are available today and should see continued growth in market share as component prices fall and fuel price volatility remains a fleet concern. [EPA-HQ-OAR-2014-0827-1182-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.227.]]

To achieve this outcome BYD must make sizable research and development investments and must generate a significant number of orders to support the large scale manufacturing build out and associated scale economies. At BYD we believe that the best approach to accelerate the necessary growth of the electric truck market is consistent and aggressive regulations in combination with incentives for advanced technology adoption. [EPA-HQ-OAR-2014-0827-1182-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.227.]]

The agencies noted appropriately that advanced technology credits should be eliminated for hybrid electric vehicles because while they are an important strategy for reducing fuel use from heavy-duty trucks in the vocational vehicle sector, the stringency of the regulation is based on significant adoption of the technology. Technologies such as plug-in electric vehicles and fuel cell vehicles are at the nascent levels of adoption, however, and could play a significant role in reducing fuel from the heavy-duty truck sector beyond 2029. A revised advanced technology program combined with a stronger rule could help drive the innovation necessary to achieve future reductions from the work truck fleet. The agencies should retain an advanced technology credit program that incentivizes manufacturers to innovate beyond the technologies considered broadly applicable in the timeframe of this rule, including battery-electric vehicles and hydrogen fuel cell vehicles. Such a program would not significantly undermine the environmental and oil reduction benefits of the rule due to relatively low sales volumes, but they could provide manufacturers sufficient incentive to begin ramping up production of these advanced technologies. [EPA-HQ-OAR-2014-0827-1182-A1 p.3]

Also, BYD supports programs like the Diesel Emission Reduction Act (DERA) and the funding opportunities that it provides. [EPA-HQ-OAR-2014-0827-1182-A1 p.3]

**Organization:** California Air Resources Board (CARB)
3. Include a greater reliance on advanced technologies

The Phase 2 proposal lacks sufficient stringency to drive market development of battery electric or fuel cell electric technologies. The proposal assumes only a modest level of hybrid technology and no use of battery electric or fuel cell electric technology, is generally pessimistic on the future of battery electric and fuel cell electric vehicles, and, in fact, eliminates the advanced technology credits included in the Phase 1 program that were intended to encourage development of these technologies. This is contradictory to CARB's position that the early deployment of advanced technologies is the foundation of California's pathway to achieving both its climate and air quality targets. [EPA-HQ-OAR-2014-0827-1265-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.24-25.]]

Furthermore, without any significant reliance on advanced technologies built into the proposed standards, CARB estimates that projected increases in truck activity will completely overtake projected greenhouse gas reductions by 2043 (with respect to the 2010 baseline), resulting in greenhouse gas levels from medium- and heavy-duty trucks in 2050 that are about six percent higher than 2010 levels. To actually offset the expected activity growth, advanced, near-zero emission technologies must be a significant part of the long-term solution. [EPA-HQ-OAR-2014-0827-1265-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.26.]]

Support Comment

Comment – Termination of the advanced technology multiplier for Rankine engines and class 2b-6 hybrids

The NPRM requests comment on the proposed termination of the advanced technology multiplier. CARB staff agrees that it is appropriate to terminate the advanced technology multiplier for Rankine cycle WHR at this point, since the standards proposed for Phase 2 presume some use of this technology. In addition, hybrids for class 2b through 6 trucks are also reasonably developed at this point, and the vocational vehicle standards were set assuming some penetration of hybrids. Thus, it would be appropriate to terminate the multiplier for these classes of hybrids as well. However, CARB staff believes that the advanced technology multiplier should be continued for class 7/8 hybrids as well as BEVs and FCEVs, as discussed in the following comment. [EPA-HQ-OAR-2014-0827-1265-A1 p.81]

Comment on Topic Where NPRM Requests Comment

Comment – Advanced technology credits

Effective with the 2021 MY, U.S. EPA and NHTSA propose eliminating all Advanced Technology Credits (1.5 multiplier) that were included in the Phase 1 GHG regulations to promote early implementation of advanced technologies. The Phase 2 standards anticipate the use of hybrids and Rankine cycle technology, for which advanced technology credits were previously allowed, as part of the technology path used by manufacturers to meet the proposed Phase 2 standards. U.S. EPA and NHTSA believe that the Phase 2 standards alone should provide sufficient incentive to continue to develop these and other advanced technologies. U.S. EPA and NHTSA welcome comments on the need for advanced technology credits for BEVs and FCEVs in Phase 2, including information on why an incentive in this time frame may be warranted, recognizing that the incentive would result in reduced benefits in terms of CO2 emissions and fuel use due to the Phase 2 program. CARB staff agrees that there is no further need for advanced technology credits for class 2b through 6 hybrids and Rankine cycle technology, but believes that these credits provide a further impetus to manufacturers to
manufacture other technologies such as BEVs and FCEVs, and that the furtherance of this technology development will, over time, offset the temporary reduction in benefits attendant with the use of a multiplier credit. To minimize the potential emissions impact, the incentive could be phased out at a certain manufacturer volume or with a certain MY. Advanced technology credits, as they relate to class 7 and 8 vehicles, are discussed in the following comment. [EPA-HQ-OAR-2014-0827-1265-A1 p.81-82]

Oppose (Comment on Topic Where NPRM Requests Comment)

Comment – Reinstate advanced technology multiplier for class 7/8 hybrids, BEVs, and FCEVs

The Phase 1 GHG regulation included an advanced technology multiplier to create an incentive for the adoption and early introduction of advanced technologies, namely, Rankine cycle technology, hybrids, BEVs, and FCEVs. According to U.S. EPA and NHTSA, the advanced technology incentives were “intended to promote the commercialization of technologies that have the potential to provide substantially better GHG emissions and fuel consumption if they were able to overcome major near-term market barriers” (page 40389 of the NPRM). CARB staff believes such incentives are needed, especially given the magnitude of California’s GHG emission reduction goals. Accelerated deployment of hybrid and zero-emission trucks and buses is critical for California to meet its air quality, climate and petroleum reduction goals. We anticipate these technologies will be increasingly critical nationally in the years ahead as federal ozone standards become more stringent and the impacts of climate change continue to manifest themselves. [EPA-HQ-OAR-2014-0827-1265-A1 p.82-83]

Thus, CARB staff believes that the advanced technology multiplier should be continued for BEVs and FCEVs in all classes and for full hybrids in class 7 and 8 tractor and regional vocational applications, for the reasons discussed below. In addition to maintaining the advanced technology multiplier, CARB staff encourages U.S. EPA and NHTSA to look for other creative ways in the context of the Phase 2 standards to encourage the development of these critical advanced technologies. [EPA-HQ-OAR-2014-0827-1265-A1 p.83]

- Proposed standards are not based on these technologies. 40 CFR 1036.615 (k)(7) of the Phase 2 proposal limits the advanced technology multiplier to Phase 1 vehicles, based on the premise that the Phase 2 standards presume the use of Rankine engines, as well as some hybrids. However, hybrid technologies for class 7 and 8 long haul tractor applications, as well as heavy duty hybrid technologies for regional vocational applications, were not assumed to have any penetration when setting the proposed Phase 2 standards. Hybrid technologies for such applications are still not fully developed and the costs of available hybrid technologies for these applications are still high. In addition, because U.S. EPA and NHTSA anticipate very limited use of BEVs and FCEVs and did not include any anticipated use of these advanced technologies when setting the emission standards proposed in the NPRM, it is appropriate to continue to offer the advanced technology multiplier to accelerate their development and adoption. [EPA-HQ-OAR-2014-0827-1265-A1 p.83]

- These technologies are potential game-changers and are worth the potential small emission disbenefit. These multipliers would reduce some of the benefits from the rule because manufacturers could use the advanced technology credits in lieu of reducing emissions. For example, a 1 ton emission reduction from using advanced technologies would allow a manufacturer to avoid 1.5 tons in emission reductions they would otherwise need to achieve from traditional vehicles. However, CARB staff expects this reduction in benefits to be insignificant, even under an extremely optimistic penetration scenario for advanced technologies in the Phase 2 timeframe. Also, in the long term, the reduction in benefits would
be worthwhile due to the anticipated support for development of advanced technologies. A footnote in the NRPM (page 40389 of the NPRM) expresses U.S. EPA and NHTSA’s opinion when applying multipliers for advanced technology in the light-duty vehicle fleet for MYs 2017 to 2021: It is “worthwhile to forego modest additional emissions reductions and fuel consumption improvements in the near-term in order to lay the foundation for the potential for much larger ‘game changing’ GHG and oil consumption reductions in the longer term.” U.S. EPA and NHTSA believe it was appropriate to provide multipliers in the light-duty vehicle fleet; BEV development and penetration for the light-duty vehicle fleet is at a much more advanced commercial level than BEVs for the medium- and heavy-duty fleet, with many light-duty vehicle models available in a variety of configurations with ever-increasing consumer acceptance. It is therefore even more appropriate to allow these credits to continue for the medium- and heavy-duty fleet. [EPA-HQ-OAR-2014-0827-1265-A1 p.83-84]

- These technologies currently have substantial incremental costs, which advanced technology credits could help bring down. These advanced technologies currently have higher initial costs compared to diesel or gasoline approaches due to low production volumes and higher manufacturer costs. For instance, incremental costs for vehicles using battery electric approaches is estimated at up to about $90,000 for a medium-duty vehicle (8,501 to 14,000 lbs GVWR), and substantially more for a vehicle in the heavier classes. Maintaining the 1.5 multiplier would help these technologies transition from prototype and small scale production to assembly line production, thereby reducing vehicle costs. By further encouraging early sales of these technologies, the multiplier would help drive down production cost and help zero-emission technologies become more cost-competitive. [EPA-HQ-OAR-2014-0827-1265-A1 p.84]

- Advanced technology credits would promote research, development and production of advanced technologies and eventual transfer of these technologies to other applications: These multipliers promote the investment by manufacturers in advanced technologies. Further encouraging development and deployment of plug-in hybrid and zero-emission truck and bus technology would help accelerate the rate of these technologies transfer to other applications, such as off-road equipment and marine vessels. [EPA-HQ-OAR-2014-0827-1265-A1 p.84]

- Advanced technology credits would accelerate consumer acceptance: One of the barriers to commercialization of plug-in hybrid and zero-emission trucks and buses is consumer reluctance to purchase unfamiliar technologies. The “energy paradox” identified in the NPRM (page 40435 of the NPRM) – whereby many readily available technologies that appear to offer cost-effective fuel efficiency benefits have not been widely adopted – is particularly difficult to overcome for the most advanced technologies such as hybrids and zero-emission vehicles. As the NPRM notes, there are numerous potential causes for the energy paradox, including behavioral rigidity among vehicle operators, imperfect information in the new and resale vehicle markets, and inherent distrust of new technologies. California has experienced these consumer acceptance challenges as we begin our transition to zero- and near-zero-emission technologies. These challenges, where the market does not act rationally to enable cost-effective technologies, underscore the need not only for robust federal standards to help bring these technologies to market, but potentially also for additional strategies to overcome initial consumer resistance to the most advanced technologies. [EPA-HQ-OAR-2014-0827-1265-A1 p.84-85]

The advanced technology multiplier provides an incentive for manufacturers to continue to develop BEVs and FCEVs in all class 2b through 8 categories, as well as hybrid technologies for the class 7 and 8 long haul tractor and regional vocational applications. CARB staff believes that continuing the advanced technology multiplier is an important part of promoting these technologies that, in the long term, offer a key approach to significant reduction of GHG emissions. In addition to the supply-level incentive that these credits support, CARB staff has and will continue to incentivize these technologies as well at the consumer level (demand incentive) through the use of its voucher programs, incentive
funds, and other types of consumer based credits to promote demand. These programs provide funds to partially offset the incremental costs of advanced technology heavy-duty vehicles compared to equivalent conventional vehicles. CARB has planned rulemakings that will promote substantial requirements for zero-emission transit buses as well as promote advanced technologies for last mile delivery applications and airport shuttles. These planned rulemakings are part of CARB’s Sustainable Freight Transport Initiative. [EPA-HQ-OAR-2014-0827-1265-A1 p.85]

By continuing to allow advanced technology credits for these technologies in the Phase 2 rule, the synergy between the Phase 2 rule and California’s incentive and regulatory programs for heavy-duty technologies could push further acceleration of advanced technologies development. To minimize the potential emissions impact, the incentive could be phased out at a certain manufacturer volume such as two percent of vehicles produced in that class or application. We encourage U.S. EPA and NHTSA to maintain the 1.5 multiplier for these critical technologies. [NHTSA-2014-0132-0093 p.85]

The status of hybrid, battery electric, and fuel cell electric technologies is presented through technology assessment reports, which will be posted at [http://www.arb.ca.gov/msprog/tech/report.htm](http://www.arb.ca.gov/msprog/tech/report.htm) when available. These technology assessments support our belief that these technologies are on the cusp of major potential deployment, which the continued use of the advanced technology multiplier will support. [EPA-HQ-OAR-2014-0827-1265-A1 p.85-86]

**Oppose/Requested Change Comment**

**Comment –Excess weight associated with fuel cell**

CARB staff has significant concerns regarding the following assertion: [EPA-HQ-OAR-2014-0827-1265-A1 p.101]

Hybrid powertrains, fuel cells and auxiliary power would not only present complex packaging and weight issues, they would further increase the need for reductions in the weight of the body, chassis, and powertrain components in order to maintain vehicle functionality. [EPA-HQ-OAR-2014-0827-1265-A1 p.101]

CARB staff disagrees with the statement made in the RIA that fuel cells present complex packaging and weight issues. With regard to packaging, the stack power density for a heavy-duty proton exchange membrane fuel cell (PEMFC) system (commonly used in on-road vehicles) ranges between 1,500 and 1,800 watts per liter (W/L) and the system power density is 200 to 300 W/L. The system specific power for heavy-duty PEMFCs is similar to conventional engines. For instance, a Cummins ISB 6.7 diesel engine that is used in hybrid transit buses is rated at 209 kW and with a system weight of 616 kg has a system specific power of 339 watts per kilogram (W/kg), falling in the range of a heavy-duty fuel cell system. The stack and system specific power and density are equivalent to commercial conventional engine products. Therefore, the volume and weight of a fuel cell system does not pose a “complex packaging and weight issue” for heavy-duty vehicles, nor does it compromise the vehicle’s functionality. [EPA-HQ-OAR-2014-0827-1265-A1 p.101-102]

The additional weight of FCEVs is not actually associated with the fuel cell engine. It is the electrified components that are used in hybrid electric vehicles, BEVs, and FCEVs that have some additional weight. Also, similar to compressed natural gas (CNG) vehicles, on-board hydrogen storage tanks weigh more than diesel tanks. CARB staff anticipates that weight reductions in both electrical components and hydrogen storage tanks are feasible within the Phase 2 timeframe and that heavy-duty FCEVs should

37 CARB staff estimates if 3 percent of all vehicles covered by the Phase 2 standards received advanced technology credits for model year 2027 and later (for example if 3 percent were battery or fuel cell electric), emissions will be increased by about 0.5 MMT in California as a result of the multiplier. This would reduce projected Phase 2 benefits by about 3% in 2050.

Organization: California Air Resources Board (CARB) – Supplemental Comments

In general, ARB tended to propose multipliers somewhat higher than the calculated cost ratios because manufacturers will need a push to take risks and try new technologies. A multiplier that exactly balanced the additional cost would be less likely to incentivize technological development. However, ARB’s proposed multipliers are not simply the calculated cost ratios “plus some” for several reasons. First, since these technologies are at different stages of development for different applications, the development risk to manufacturers varies. Second, for simplicity in the regulation, staff is recommending minimizing the number of different multipliers being used. For example, for simplicity, the proposed BEV multipliers for vocational vehicle and Class 2B/3 pickups and vans were all set to 4.5, despite the cost ratios ranging from 2.4 to 5.6 for these categories (see Table 1 and Table 2). Third, as previously mentioned, each of the categories contains a wide variety of vehicles, some of which are more suited to these technologies than others. In supplemental comments, CARB proposed the following values:

Organization: CALSTART

– Restore Advanced Tech credits – provide more flexibility for suppliers to generate for OEs (delegated assembly expansion) [EPA-HQ-OAR-2014-0827-1190-A1 p.2]

Advanced Technology Credit Inclusion. If combined with higher stringency, we believe greater flexibility to achieve the greater stringency levels is appropriate. We therefore believe mechanisms such
as the advanced technology credit should be restored to provide an early incentive to OEMs to start to integrate advanced technologies into their portfolio. We have heard some OEM objection to this on the grounds that it gives preference to certain technologies when the rule should remain neutral and performance-based to meet the stringency required. Generally, we are very sensitive to this concept. However, we believe it misses a critical point, and that is the need to be meeting current goals while also laying the framework for the next set of technologies needed, at higher volume, beyond Phase 2. Given the need for steep and continuing reductions in GHG emissions for the next 30 to 40 years, to meet climate stability while coping with transportation growth, the Phase 2 rules would be wise to include a mechanism for supporting development and early implementation of technologies that must be counted on next. This becomes doubly important, and achieves a co-benefit, when these same technologies are vital components of several regions’ criteria reduction plans, notably California, which relies on more advanced technologies to be moving into the market during the Phase 2 timeline for NOx reduction. [EPA-HQ-OAR-2014-0827-1190-A1 p.5-6]

An additional consideration involves market barriers to change. Even technologies showing strong results and solid payback face resistance in a marketplace where risk avoidance remains high. As an example, there is now strong data showing that technologies such as post-transmission hybrids can achieve 15-35 percent fuel economy gains in the right vocational applications, and their costs are dropping below $20,000 and approaching in some cases $10,000. Yet overcoming market inertia likely requires early and innovative measures to encourage OEMs and fleets to take this step. [EPA-HQ-OAR-2014-0827-1190-A1 p.6]

The credit could be available for technologies that are not included in the baseline assumptions of the rule but support regional goals (such as California and the Northeast states) for additional NOx reductions, are not currently expected to be widely utilized by the end of the rule, but will result in significant fuel and emission reductions. By way of example, advanced technology credits for plug-in electric and electric drive vehicles could incentivize earlier integration and production of these technologies. The exact structure of such a credit requires more time to develop than provided in the short timeline for rule comments. It is critical that the credits not be allowed to undermine the benefits from the rule, so a cap or declining credit multiplier might be reasonable. [EPA-HQ-OAR-2014-0827-1190-A1 p.6]

We can envision that a sliding scale of credit value, tied both to the performance benefit of the technology, and also starting higher in the early years of Phase 2 and ramping down over its life, might be an appropriate framework for encouraging early integration of the technology that will likely start in vocational niche markets. Some technology providers, which are currently often not OEMs and therefore not the point of regulation, have wondered about structures that could enable them to offer credits to OEMs to help reduce OEM risk and support innovation. We are discussing these ideas with industry and would welcome the opportunity to further flesh out these framework ideas as the rule is finalized. [EPA-HQ-OAR-2014-0827-1190-A1 p.6]

Equally important is that the process to apply for the credits be streamlined and clarified. In Phase 1, while the primary reason that advanced technology credits weren’t used was that the stringency was not high enough to drive their need, another barrier was the long process involved. Companies reported what they called an “open loop” approach whereby the exact level of testing or specific test results needed to qualify was not always clear. We would strongly urge establishment of a streamlined, clear set of data requirements and rules for qualifying for such credits so that companies could assess the costs and time required to fulfill the requirements in advance of starting the process. [EPA-HQ-OAR-2014-0827-1190-A1 p.6]
**Organization:** Center for Biological Diversity

The Center also requests that the Agencies restore advanced technology credits to incentivize the most advanced technologies, particularly those related to plug-in hybrid and battery electric trucks. These technologies have the potential to provide significant fuel savings but are still at a stage in development that necessitates continued incentives to promote early adoption and increased market penetration. [EPA-HQ-OAR-2014-0827-1460-A1 p.10]

**Organization:** Cummins, Inc.

*Cummins supports the elimination of advanced technology credits in Phase 2* [EPA-HQ-OAR-2014-0827-1298-A1 p.31]

The Agencies are requesting comment on discontinuing extra credit for Phase 1 advanced technologies after MY 2020. Cummins agrees with the elimination of advanced technology credits and 1.5x multiplier since GHG/FE improvements achieved with eligible technologies (e.g., hybrids, waste heat recovery (WHR)) will provide sufficient CO2 benefits to encourage implementation of such technologies. Furthermore, advanced technology credits can be exchanged between engines and vehicles which undermines the proposed separation of engine and vehicle standards. Eliminating advanced technology credit generation in Phase 2 mitigates this concern. [EPA-HQ-OAR-2014-0827-1298-A1 p.31-32]

**Organization:** Daimler Trucks North America LLC

5. Advanced Technology Credits

- **Ending the Advanced Technology Credit** - The agencies propose to stop providing extra credit for advanced technologies and request comment, including comment on whether there is sufficient incentive to develop fuel-savings technologies such as electric vehicle, plug-in hybrid, and fuel cell technologies. 80 FR 40331. Consistent with DTNA’s core philosophy that FE technologies should compete in the market—and in the regulations—based on their real-world total cost of ownership, we think it is appropriate to end credits for certain technologies and not for others. [EPA-HQ-OAR-2014-0827-1164-A1 p.120]

The agencies request comment on the need for incentives for advanced technologies in Phase 2, including information on why an incentive for specific technologies in this time frame may be warranted, recognizing that the incentive would result in reduced benefits in terms of CO2 emissions and fuel use due to the Phase 2 program. We think that the agencies’ proposed approach of crediting technologies proportionally to their FCRs, rather than distorting the scale with extra credits for some, is the right way to make the market decide on the best approach for meeting FCR targets. [EPA-HQ-OAR-2014-0827-1164-A1 p.81-82]

**Organization:** Edison Electric Institute

EEI is the association that represents all U.S. investor-owned electric companies. Our members provide electricity for 220 million Americans, operate in all 50 states and the District of Columbia, and directly employ more than 500,000 workers. With more than $108 billion in annual capital expenditures, the electric power industry is responsible for millions of additional jobs. Reliable, affordable, and sustainable electricity powers the economy and enhances the lives of all Americans. EEI has previously
engaged in the joint EPA and NHTSA rulemakings to address GHG emissions from both light-duty and medium- and heavy-duty vehicles, focusing on EVs and their potential to reduce significantly both GHG and criteria pollutant emissions from the transportation sector. In these rulemakings, EEI has focused on appropriate recognition for the environmental benefits of transportation electrification and the creation of the incentives needed to drive the commercial success of EVs to capture these benefits. EEI’s comments on the needed to drive the commercial success of EVs to capture these benefits. EEI’s comments on the proposed Phase 2 Program continue these themes. [EPA-HQ-OAR-2014-0827-1327-A2 p.2-3]

Electricity as a transportation fuel is a critical pathway to reducing GHG emissions and petroleum consumption in the transportation sector and the Phase 2 Program can be better designed to further the electrification transition. Furthermore, deployment of plug-in vehicles into the transportation sector represents an opportunity for our industry to offer new value-added services to our customers while ensuring that the integration of these vehicles into the grid provides benefits for all customers. In addition, EEI member companies operate a fleet of approximately 160,000 vehicles, the majority of which fall into the medium- and heavy-duty vehicle categories. Member company fleets, particularly vocational vehicle fleets, can incorporate electrification to further reduce US reliance on petroleum and reduce emissions. [EPA-HQ-OAR-2014-0827-1327-A2 p.3]

Finally, transportation electrification is beneficial to electric customers. First, as utilities are the primary “fuel” provider for plug-in vehicles, transportation electrification opens up new opportunities to serve customers and provide solutions, particularly as it relates to charging infrastructure. Second, as determined by ICF and E3 in the recent Transportation Electrification Assessment Phase 2 study, “additional revenue from [plug-in electric vehicles (PEVs)]/charging exceeds the marginal costs to deliver electricity to the customer, providing positive net revenues that put downward pressure on rates.” Accordingly, transportation electrification can benefit all of our customers, not just those who drive PEVs. [EPA-HQ-OAR-2014-0827-1327-A2 p.3]

While adoption of PEVs in the medium- and heavy-duty vehicle market has not yet reached the mainstream success of the light-duty vehicle sector, significant growth opportunities do exist. In fact, signs of progress and momentum are already emerging and should be fostered wherever possible and across all of the various technologies. PEV technologies occur along a wide spectrum, from plug-in battery powered electric vehicles to e-PTO systems that eliminate work site idling. This spectrum of PEV technologies are sufficiently distinct and impactful enough, in terms of fuel efficiency and emissions reductions that each should be supported, such as through the continuation of the advanced technology credits for heavy-duty pickups and vans, as well as through off-cycle technology credits for e-PTO systems, transport refrigeration units, and truck stop electrification. [EPA-HQ-OAR-2014-0827-1327-A2 p.4]

EPA and NHTSA should also recognize that one of the historic limitations to the growth of PEVs in these sectors has been the energy storage system, and more specifically, the energy density and cost of batteries. The continued advancements in battery technology, which are projected to be significant in as little as five years, stand to bring an even broader and more affordable set of vehicle applications to PEVs in this class. Given the potential fuel efficiency and emissions reduction potential of such advances, this is an important trend to note when considering proposed rules for the 2019-2027 timeframe. [EPA-HQ-OAR-2014-0827-1327-A2 p.4-5]

II. Significant Growth Opportunities Exist and Should be Fostered in the Medium- and Heavy-Duty Electric Vehicle Market
Technology and policy drivers have succeeded in growing the electric transportation market substantially in the last few years. In the light-duty vehicle sector, plug-in electric vehicle sales have surpassed 350,000 units since the Chevrolet Volt and Nissan LEAF first went on sale in December 2010, more than twice the adoption rate of hybrid electric vehicles in their first entry into the market.\(^4\) Today, more than 22 plug-in vehicle models are available from 15 mainstream automotive brands.\(^5\) [EPA-HQ-OAR-2014-0827-1327-A2 p.5]

In the medium- and heavy-duty sectors that are the focus of this proposed rule, adoption of plug-in vehicles have not yet reached a similar mainstream success, but signs of progress and momentum are emerging. A primary example is EEI’s efforts to lead by example through its Fleet Electrification Initiative, in which member companies commit at least five percent of their annual fleet procurement budget to plug-in vehicles and technologies. Over 70 EEI member operating companies have committed to this initiative.\(^6\) As announced in June, this commitment represents a $90 million investment by EEI members for the 2015 fleet budget cycle.\(^7\) Most of the PEVs procured as part of this initiative fall into the medium- and heavy-duty vehicle categories. [EPA-HQ-OAR-2014-0827-1327-A2 p.5]

Outside of the utility industry, there are many other examples of plug-in vehicles proliferating in the specific medium- and heavy-duty sectors. A few recent examples are: [EPA-HQ-OAR-2014-0827-1327-A2 p.6]

- United Parcel Service (UPS) procuring 125 plug-in hybrid delivery trucks from Workhorse;\(^8\) [EPA-HQ-OAR-2014-0827-1327-A2 p.6]
- The port of Shanghai and PG&E demonstrating vehicles built by EDI; and, [EPA-HQ-OAR-2014-0827-1327-A2 p.6]
- Growing deployment of electric transit buses from BYD, Proterra and New Flyer. [EPA-HQ-OAR-2014-0827-1327-A2 p.6]

While these procurements are relatively small, they are demonstrating the capabilities and benefits of electric drive in the medium- and heavy-duty sectors. Clearly, plug-in vehicles are not right for every application. For example, the energy density limitations of battery storage alone are not feasible for long haul trucks traveling hundreds of miles per day. However, these examples and many others show that PEVs can deliver operational and environmental benefits for a growing number of uses. These include certain applications for long haul trucks, such as in-cab driver comfort while the truck is stationary, and reducing engine idling. [EPA-HQ-OAR-2014-0827-1327-A2 p.6]

One of the major limitations to the feasibility of PEVs in the medium- and heavy-duty sectors is the energy storage system, specifically the current energy density and cost of batteries. However, improvements in battery technology are occurring rapidly. With respect to energy density, the recently released Quadrennial Technology Review notes that “in the next roughly five years, advances in lithium-ion technology could more than double the battery pack energy density from 120 Wh per kilogram to 250 Wh per kilogram.”\(^9\) With respect to cost, the report notes that “R&D has made significant progress, reducing the cost of lithium-ion batteries by nearly 70% and improved their energy density by 60% during the last five years.”\(^10\) These advances are happening quickly, in a timescale of approximately five years. As energy density and cost improve, a broader set of vehicle applications will be economically and operationally feasible for PEVs—an important trend to note when considering proposed rules for the 2019-2027 timeframe. [EPA-HQ-OAR-2014-0827-1327-A2 p.6]

III. The Proposed Phase 2 Program Must Recognize the Environmental Benefits of Electricity as a Transportation Fuel
Electricity as a transportation fuel offers significant long-term environmental benefits. This point was reinforced most recently by a report jointly released by the Electric Power Research Institute (EPRI) and the Natural Resources Defense Council (NRDC) that found that broad electrification of the transportation sector would reduce GHG emissions by 52 percent compared to current levels. Specifically within the commercial vehicle sector, which the report describes as including many of the medium-duty vehicle categories subject to this proposed rule, electrification would decrease net emissions by 39 percent in 2050. Similarly, the Transportation Electrification Assessment Phase 1 study forecasts material adoption of electrification technologies in the medium- and heavy-duty vehicle segments within the timeframe of the proposed rules, even in its most conservative adoption scenario. Third, as also noted by this report, PEVs have the long-term potential to help integrate more intermittent renewable energy resources into the electric system.

IV. Incentives Should Recognize the Environmental Benefits of EVs and Support Their Deployment into All Appropriate Vehicle Classes

In general, NHTSA and EPA are proposing to offer fewer incentives and credit programs for advanced technologies, including EVs in the Phase 2 Program than are available under the Phase 1 Program. In particular, the agencies propose to end advanced technology credit incentive multipliers for HD pickups and vans beginning in MY 2021 and to merge the innovative technology and off-cycle credit programs for vocational vehicles. The agencies specifically seek comment on whether the advanced technology credits for HD pickups and vans should be extended for advanced technologies, like EVs, and generally seek comment on the role of electrified accessories in the off-cycle technology credit program for vocational vehicles. Terminating any incentive credits and the incentive multipliers for HD pickups is premature, at least with respect to EVs, and EPA and NHTSA should create a pathway to recognize and incentivize the emission reductions benefits of electrification of accessories used in vocational vehicles.

PEV technologies occur along a spectrum, from e-PTO systems that eliminate worksite idling, to plug-in electric hybrid vehicles (PHEV) that offer some all-electric range (AER) in addition to conventional petroleum-powered propulsion, to battery electric vehicles (BEVs) that operate on electricity only. PEVs are distinct from hybrid electric vehicle (HEV) technologies, which offer some ability to store energy, but do not source electricity from the grid. The spectrum of PEV technologies are sufficiently distinct and impactful that they should be given due credit within the proposed rulemaking.

As discussed below in greater detail, e-PTO systems are sufficiently “mainstream” (and will likely continue to be more so in the model years subject to the proposed rules), that EEI believes these systems are best treated by considering the technology in the standard setting. If they are not considered when determining the stringency of the standards, their benefits should be captured through the test procedures and off-cycle technology credit procedures. In contrast, PHEV and BEV technology in the medium- and heavy-duty classes is more appropriately characterized today as being in the “pilot and demonstration” phase of the technology cycle. To incentivize the mainstream deployment of these technologies within the model years of the proposed rules, it is appropriate to continue advanced technology credits to vehicles equipped with these technologies. The vehicle classes most likely to adopt PEV technologies in the model years in the proposed rule are vocational vehicles and HD pickup trucks and vans.

A. EPA and NHTSA Should Continue the Advanced Technology Credits for HD Pickups and Vans to Drive Increased EV Deployment in this Vehicle Class
With respect to HD pickups and vans, the agencies state that “[t]he advanced technology incentives are intended to promote the commercialization of technologies that have the potential to provide substantially better GHG emissions and fuel consumption if they were to overcome major near-term market barriers.” EPA and NHTSA also state that these incentives are not intended to become permanent parts of the programs to reduce GHG emissions from the transportation sector and that it would be inappropriate to include credits for technologies upon which the standards are based. The continued availability of advanced technology credits for EVs is appropriate as EVs are not yet commercialized in the HD pickup and van category and the stringency of proposed Phase 2 Program standards for these vehicles is not predicated on the use of EVs in this category. [EPA-HQ-OAR-2014-0827-1327-A2 p.14]

As the agencies note, EVs (and fuel cell vehicles) “are not projected to be part of the path used by manufacturer[s] to meet the proposed Phase 2 standards for HD pickups and vans...” but “have the potential to provide the highest level of benefit.” By definition, then, EVs are exactly the type of advanced technology that should qualify for credits. The agencies, however, appear to predicate the denial of credits for EVs on concerns about “reduced CO2 emissions” if such credits were provided. As discussed in detail in Section III, above, contrary to the agencies’ unsupported assertions, upstream emissions related to electricity production will not erode the benefits of vehicle standards, which both agencies appropriately propose to be measured at the tailpipe. As NHTSA has noted, lifecycle emissions from EVs are less than those from conventional fueled vehicles. Accordingly, the final Phase 2 Program should retain the advanced technology credits for EVs in the HD pickup and truck category. [EPA-HQ-OAR-2014-0827-1327-A2 p.14]

Organization: Eaton Vehicle Group

From a regulatory perspective, we agree with the EPA approach to Hybrids, namely that these should be powertrain tested for actual fuel consumption. We believe that while the EPA is looking at not
continuing the Advanced Technology Credits program for Hybrids after 2021, the Hybrid market is still very fragile and driven by the cost of fuel. As we look toward a long period of lower cost fuel as predicted by the EIA, we do not see market conditions improving for Hybrid commercial vehicles except for a few mild Hybrid applications in the Class 3-4 segment. We are not optimistic that Hybrid technology will evolve significantly before the rule comes into effect, a situation similar to 2012-13 when the slump in Hybrid sales occurred. We believe contributing factors included hybrid OBD requirements during the low-volume phase of commercialization and unclear battery warrantee associated with useful life requirements that shifted development resources away from Hybrid cost reduction. [EPA-HQ-OAR-2014-0827-1194-A1 p.18-19]

**Recommendation:** Maintain the Phase 1 ATC program, at least until a certain threshold of hybrid market penetration is reached. ATC credits can use either powertrain test results or GEM simulations for the baseline vehicle in an A-to-B approach. [EPA-HQ-OAR-2014-0827-1194-A1 p.19]

**Organization:** Electric Drive Transportation Association (EDTA)

### Recognizing the Benefits of Electrification

As an important suite of technologies for reducing emissions and increasing efficiency of medium and heavy duty vehicles, EDTA recommends that the proposed rule appropriately recognizes and incentivizes battery electric, hybrid, and plug-in hybrid and fuel cell technologies and ensure that testing protocols accurately measure their emissions and efficiency benefits. [EPA-HQ-OAR-2014-0827-1217-A1 p.1]

In the medium- and heavy-duty segments, electric drive technologies offer flexible and diverse configurations for electrification in hybrid, plug-in hybrid, electric and fuel cell systems. These diverse systems offer substantial current and future benefits in reducing fuel consumption and emissions. The most recent documentation of the emissions benefits of electric drive released in 2015 by the Electric Power Research Institute and the National Resources Defense Council, the Environmental Assessment of a Full Electric Transportation Portfolio, found that use of grid electricity in fleets would result in substantial net emissions reductions on a life cycle basis. Specifically, “…widespread electrification of light-duty vehicles, medium-duty vehicles and non-road equipment could reduce greenhouse gas emissions by 540 million metric tons annually in 2050; equivalent to removing 100 million passenger cars from the road” [EPA-HQ-OAR-2014-0827-1217-A1 p.1-2]

### Advanced Technology Credits

In the light-duty segment, electric drive is growing, with a 3 percent market share that includes hybrid and plug-in electric vehicles; fuel cell vehicles are moving into the consumer market this year. In the medium- and heavy-duty segment, fleets are utilizing electric drive systems on the road today. Notably, the utility industry has made a substantial commitment to procuring plug-in electric vehicles in utility fleets in its 2015 Fleet Electrification Initiative, with medium- and heavy-duty vehicles comprising a majority of the vehicles to be procured by the participating utilities. Nevertheless, electric drive systems are still an emerging suite of technologies in the medium- and heavy-duty segment. Adoption is being
aided by aggressive public and private sector efforts to reduce costs and further enhance performance throughout the value chain. [EPA-HQ-OAR-2014-0827-1217-A1 p.2]

The proposed rule requests comment on the issue of discontinuing advanced technology credits provided in Phase I of the medium- and heavy-duty program for technologies, such as hybrid powertrains, all-electric vehicles, and fuel cell vehicles.5 [EPA-HQ-OAR-2014-0827-1217-A1 p.2]

Electric drive technologies, the proposed rule acknowledges, have unique potential to reduce emissions; are in an early market stage, and are not the basis for the standards being proposed. Based on the agencies’ enumerated criteria, electric drive is appropriately incentivized in both Phase I and Phase II of the program. We recommend maintaining the advanced technology credits for electric drive in Phase II. Further, noting that Phase 1 credits at a value of 1.5 were not heavily utilized, we suggest that the value of the credits should be increased above 1.5 to effectively drive adoption of the most advanced technologies. Concerns regarding over-reliance on credits could be addressed by instituting a cap on their availability. By facilitating adoption of advanced technologies, credits will also help to drive the advances in technology performance and cost reduction that will enable faster commercialization on a wider scale. [EPA-HQ-OAR-2014-0827-1217-A1 p.2]

5 Op cit.

Organization: FedEx Corporation

Maintain Incentives and Flexibilities: Credits intended to incentivize early market adoption of advanced GHG/Fuel Efficiency technology should be retained. The ATC and ITC programs from Phase 2 should be improved to increase the attractiveness of early adoption of advanced and emerging technologies (Hybrids; EVs; Route Automation, etc.). [EPA-HQ-OAR-2014-0827-1302-A1 p.3]

Organization: International Council on Clean Transportation (ICCT)

Advanced technology

We recommend that the agencies acknowledge the importance of advanced electric-drive technologies in order to achieve societal goals for long-term climate change mitigation in the transportation sector that are consistent with climate stabilization. Especially noting, based on the agencies’ analysis, that the Phase 2 regulation does not even guarantee absolute reduction in carbon emissions over the long-term, it is evident that the Phase 2 standards are not nearly sufficient to meet societies long-term climate goals. We suggest the EPA acknowledge the body of evidence that suggests that the heavy-duty sector will have to, like the automobiles, shift to electric-drive technology (including battery electric and hydrogen fuel cells), over the long-term. Such a shift would mean electric-drive vehicles start entering the market around 2020-2030 to pave the way for 2040-2050 ultra low carbon freight trucks. Along with the California Air Resources Board’s 2012 “Vision” analysis (CARB, 2012), there is Sharpe (2013), Silver and Brotherton (2013), Boer et al (2013), and Fulton and Miller (2015) that highlight many aspects of this long-term question that EPA and NHTSA will likely have address in the near future. [EPA-HQ-OAR-2014-0827-1180-A4 p.17]

Organization: Manufacturers of Emission Controls Association (MECA)
Furthermore, without incentives or credits, manufacturers will be forced to halt further development and optimization of emerging technologies to achieve the type of return on investment the trucking industry demands. [EPA-HQ-OAR-2014-0827-1210-A3 p.2]

In the absence of sufficiently stringent standards innovative technologies depend on incentives to achieve initial market penetration. Some of these technologies are not yet optimized to deliver the return on investment that truck owners require in today’s low cost fuel environment. We urge EPA to include the advanced technology credits, which were part of the first phase of these regulations, in the final Phase 2 regulation. These credits would help to support continued development, optimization and testing of efficiency technologies to deliver cost-effective CO2 reductions in the out years of the Phase 2 regulation and to meet future heavy-duty GHG requirements. [EPA-HQ-OAR-2014-0827-1210-A3 p.3]

Similarly experimental or developmental engine efficiency technologies rely on a stringent set of CO2 standards and incentives or advanced technology credits to penetrate the market. Credit opportunities offered under the Phase 1 program should be extended in the final Phase 2 rule. [EPA-HQ-OAR-2014-0827-1210-A3 p.14]

**Organization:** McNicols

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 272-274.]

As far as the ABT Program, it appears that the credits for applying advanced technology for the manufacturers has disappeared. The way the current proposal seems to be written still stops with the chassis OEMs, and does not allow for rollup of credits for applying energy saving technologies by delegated final stage manufacturers, such as vocational vehicle manufacturers.

We encourage you to take a broader view of how final stage or delegated assembly manufacturers might add additional carbon reduction value that could flow back to the OEM. Without a return for the tedious work of bringing a new innovative product or technology to market, vehicle developers and manufacturers are not incentivized to take such risks. The cost of bringing a game changing technology or product to market faces many obstacles in breaking out of the status quo and the established market inertia. The lack of adequate incentives and credits for this taking this path makes it less desirable, potentially keeping new technologies from impacting our environment due to the lack of sufficient inducement or flexibility in accounting for these general credits.

We are concerned that stringency levels alone may not drive the advanced technology, but there are also no credits to encourage them. Perhaps you will reconsider adding back in the credits for implementing advanced technology and find an equitable means of delegated final assembly OEMs to receive or roll up these credits. Your challenge will be to objectively new and innovative technologies and method applying these advanced approaches that do not fit the status quo.

**Organization:** Moving Forward Network

_Add Provisions to Promote for Advanced Technologies_ – For many of our communities zero emission technologies are the solution to address toxic pollution from the freight industry. The current regulation does not advance many zero emission technologies beyond traditional fossil fuel hybrid technologies in a meaningful way. We are seeing first hand that technology developers from around the country have solutions to the pollution crisis from the freight industry, but we must align our regulations and
incentives to provide the impetus to make these technologies a reality. The pessimism in the final rule about advanced technologies is unwarranted. In fact, the nation’s two largest seaports, the Ports of Los Angeles and Long Beach, are advancing programs to increase the use of battery and/or fuel cell technologies. This regulation can go a long way in sending a market signal to large entities like ports and railroads, in addition to private industry that EPA and NHSTA are serious about advanced technologies. [EPA-HQ-OAR-2014-0827-1130-A2 p.1-2]

Organization: National Association of Clean Air Agencies (NACAA)

Additionally, EPA assumes in the proposal only a modest level of hybrid technology and no use of other advanced technologies, such as electric or fuel cell. Further, the proposal lacks sufficient stringency to drive market development of these technologies and eliminates the Advanced Technology Credits included in the Phase 1 program intended to encourage development of these technologies. Therefore, we also recommend that EPA reinstate Advanced Technology Credits to help advance zero- and near-zero emission technologies and to make Alternative 4 more attractive and attainable. [EPA-HQ-OAR-2014-0827-1157-A1 p.3-4]

Organization: Natural Resources Defense Council (NRDC)

Consider regulatory incentives that promote the deployment of electric-drive technologies. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

Incentivize Electric-Drive Technologies

The agencies recognize that the stringency of the proposed rule is insufficient to drive the deployment of electric-drive technologies, include plug-in battery electric vehicles, plug-in hybrids and fuel cell vehicles. Numerous analyses point to the need for and benefits of widespread transportation electrification, including in feasible medium- and heavy-duty applications as necessary to meet 2050 climate and air quality targets.20 Recognizing the slow turnover of the on-road vehicle fleet, extensive electrification of new vehicles needs to start now to ensure high-levels of all-electric drive by 2050. For the Phase 2 rule, NRDC recommends that the agencies consider a regulatory incentive for electric-drive technologies to encourage industry investment in them. [EPA-HQ-OAR-2014-0827-1220-A1 p.8-9]

---

Organization: Odyne Systems LLC
Critical to achieving the highest level of fuel efficiency increases in medium and heavy-duty trucks is the ability to develop regulations that encourage the deployment of both incremental efficiency improvement technology and more advanced technologies. While Odyne Systems and others in the stakeholder community understand the rationale for the EPA to assume that these advanced technologies will be deployed within standard compliance without additional credits, we believe that including advanced technology credits in the Phase Two final rules will be critical for the development and near term deployment of these sorts of technologies that may not be considered by technology developers and manufacturers without these credits – even if they are deployed in small volumes. [EPA-HQ-OAR-2014-0827-1239-A1 p.27]

The current efficiency improvement assumptions of 16% across the nine categories of vocational vehicles proposed in Scenario Three would not likely drive incremental deployment of advanced technologies, like advanced hybrid systems, based on efficiency increases from current weight reduction, LRR tires, engine improvements, start/stop and idle improvement technologies. More stringent standards -- like those proposed in Scenarios Four and Five -- would need to be instituted for advanced technology like Odyne’s to be deployed through standard compliance. But even at that point, we believe OEMs should be given an incentive to drive accelerated adoption of more advanced technologies to drive further private sector R&D in these technologies, provide realistic pathways for proving and commercializing these technologies, and lowering their costs -all resulting in accelerated fleet wide increases in fuel efficiency. [EPA-HQ-OAR-2014-0827-1239-A1 p.27-28]

While hybrid technology can be extremely effective in lowering GHG emissions in appropriate vocational applications, the cost of hybrid systems are still relatively high (mostly due to battery cost) and may require higher engineering and development costs initially. The higher upfront costs of new technology can deter the availability of investment. In addition, the relatively low initial adoption rates of new technology in the commercial trucks sector can drive hybrid system designs that may be largely composed of components that are not physically located within existing powertrain components and are not always integrated with the powertrain at the time of chassis manufacturing (incomplete vehicle manufacturing stage). While those innovative systems can minimize initial integration cost, they may not be as cost effective in comparison to much more integrated systems that reach very high manufacturing volumes. There are also many other costs associated to introducing innovative or advanced technologies, other than higher component costs, that need to be accounted for such as non-recoverable engineering costs, the ability and need to prove the technology in the field, and educating the market and consumer on the technologies benefits and functionality. As this market is low volume and very fragmented with higher incremental costs, the current advanced credit multiplier of 1.5 is not currently a sufficient incentive for industry adoption and use in Phase One. Odyne recommends, in addition to adopting Scenario 4 or above (or a more stringent rule with Scenario 3 timelines), inclusion of a limited volume of credits per class of advanced technology credits at a multiplier/additionally factor higher than Phase One to help offset the high cost of new, more effective, advanced technology. We believe that a limited volume credit of at least 3x, or preferably higher dependent on volume limitations, could decrease overall fuel consumption and emissions based on the ability to bring more aggressive emission saving technology to market faster in higher volumes outside of demonstration volumes. [EPA-HQ-OAR-2014-0827-1239-A1 p.28-29]

Should EPA choose to retain advanced technology credits and include a volume, we would urge care taken to ensure equal opportunity for a diversity of advanced technologies to be deployed with credits. If the credits were to be designed to encourage deployment of advanced fuel and emission saving technology, it would not be in the interest of the program to allow a single technology, or worse, a
Concerning 80 FR 40596 (Columns 2-3), more clarification is needed as to how the EPA determines which technologies meet the requirements for these credits. Optimus’ current understanding is that alternative fuel engine conversions that reduce GHG emissions are not eligible for this credit. The purpose of these credits, as stated by the EPA, is to recognize technologies that “achieve CO2 reductions in the real world but where those reductions are not adequately captured on the test procedure used to determine compliance with the CO2 standards.” This seems to be a way to incentivize technologies that reduce lifecycle emissions (and cannot therefore be measured at the tailpipe). As such, Optimus Technologies believes the EPA should consider adding alternative fuel conversion technologies to the credit program to incentivize their use by engine/vehicle OEMs; this could be similar to the Advanced Technology Credits allowed in the Light-Duty Program for alternative-fueled vehicles (until MY 2015).

An example of how Optimus’ system reduces lifecycle GHG emissions: Using the baseline MPG for flat terrain at 80 FR 40247 of 7.33 MPG in 2015 and the Alternative 3 fuel economy improvement goal of 16.2% by 2027 (see 80 FR 40356), we can assume that a truck (with a useful life of ten years) purchased in 2027 that meets the fuel economy improvement goals reduces lifecycle CO2 emissions over ten years by 585,095 pounds (using assumptions in footnote). In comparison, the same truck purchased in 2015 and outfitted with Optimus’ biofuel conversion system reduces lifecycle CO2 emissions over ten years by 2,725,398 pounds. Today in 2015, Optimus’ biofuel conversion system can achieve almost 5 times that of the lifecycle CO2 emissions reductions achieved by 2037, 22 years from now. 

Organization: PACCAR, Inc.

The Agencies Should Provide Credits for Advanced/Innovative Technologies

Credits for innovative technologies and off-cycle improvements have been an integral part of EPA and NHTSA’s fuel economy/GHG programs for both light-duty and heavy-duty on-road vehicles. PACCAR believes the concept of credits helps promote innovation by incentivizing manufacturers to go beyond traditional research, development, and marketing programs. With this in mind PACCAR offers the following concepts and suggestions. However, none of these technologies should be taken into consideration when establishing baselines or setting stringency improvements in the final rule.

B-20 Capability

The use of non-petroleum based bio-fuels or fuels derived from other non-petroleum sources not only reduces petroleum demand, but can lead to lower fuel cycle GHG emissions. In order to accommodate higher bio-fuel blends, manufacturers need to modify engine designs and fuel system materials on the
vehicles to accommodate the use of such fuels. PACCAR believes credits should be provided for engines/vehicles that are capable of operating on levels at 20% biofuels. PACCAR will work with the Agencies to develop the proper credit value taking into account projected usage of such fuel blends. [EPA-HQ-OAR-2014-0827-1204-A1 p.24]

Hybrid Technology Multipliers

As noted earlier, concepts that are theoretically promising such as hybridization have experienced market resistance. For those manufacturers who continue to pursue this technology, the Agencies should provide a multiplier over and above the values derived from test cycles. PACCAR suggests 50% credit increase to encourage the development and use of this technology. Additionally, in no case should the Agencies consider hybridization as a baseline or stringency technology for the achievement of proposed standards. [EPA-HQ-OAR-2014-0827-1204-A1 p.24-25]

Other Advanced Technology Multipliers

The Agencies should encourage the development of ultra-low emission technologies such as fuel cells or other advanced technologies. The Agencies should provide significant, not incremental, credits for these technologies, as they can provide both fuel savings and emission reductions in certain priority applications – e.g., at ports or other distribution centers. The 50% credit bonus suggested above for hybridization is a concept for other advanced technologies. [EPA-HQ-OAR-2014-0827-1204-A1 p.25]

Organization: Proterra

Proterra supports the intended purpose of advanced technology credits, namely, ‘to promote the commercialization of technologies that have the potential to provide substantially better GHG emissions and fuel consumption if they were able to overcome major near-term barriers.’ That purpose is as true today as it was in 2011, when the agencies adopted the Phase I standards. And while market acceptance for zero-emission technology in the heavy-duty space is growing, incentive programs and rebates continue to play a major role in driving early adoption of electric transit vehicles, including the growth of programs such as the FTA’s Lo or No Emission Vehicle Deployment Program, Chicago’s Drive Clean Truck Voucher Program and New York’s Truck Voucher Incentive Program. [EPA-HQ-OAR-2014-0827-1160-A1 p.2]

Notwithstanding the above, Proterra strongly disagrees with the proposal to eliminate advanced technology credits in Phase 2 for any technology. The Phase 2 standards are critical to the U.S.’ continued development of world-leading advanced fuel-efficient technologies and to ‘spur[ring] innovation, encouraging the development and deployment of existing and advanced cost-effective technologies for a new generation of cleaner, more fuel efficient’ vehicles. [EPA-HQ-OAR-2014-0827-1160-A1 p.3]

During Phase I, the agencies had adopted a 1.5 credit value for advanced technologies with the purpose of promoting the early implementation of such technologies that were not expected to be widely adopted in the market in the 2014-2018 timeframe. (40 CFR 1037.150(i)) A 1.5 credit multiplier properly rewards innovation and the commitment of resources needed to develop and deploy advanced technologies that further reduce GHG emissions. [EPA-HQ-OAR-2014-0827-1160-A1 p.3]

The proposal to eliminate advanced technology credits in Phase 2 will slow the deployment of innovative, clean, and fuel efficient transit solutions. And the failure to provide advanced technology
credits for such innovations would surely bias the industry toward deploying only those technologies that meet - but not exceed - current regulatory standards. [EPA-HQ-OAR-2014-0827-1160-A1 p.3]

The agencies justify the revised approach in the Phase 2 NPRM based principally on two assumptions, which, with clarification, do not support the elimination of advanced technology credits. [EPA-HQ-OAR-2014-0827-1160-A1 p.3]

The initial rationale to propose eliminating the Phase 2 credits is that ‘any vehicle certified with this technology would provide such a large credit to a manufacturer that an additional incentive credit would not be necessary.’ But the focus should not be on what is ‘necessary’ for a manufacturer, but rather on how to effectively accomplish the primary purpose of the Phase 2 standards—to reduce carbon pollution, improve fuel efficiency, save money on fuel and other costs (e.g., healthcare) and support innovation. Manufacturers such as Proterra are contributing to these critical societal goals. Credits encourage manufacturers and suppliers to invest in developing more advanced and costly technology earlier, thereby obtaining significant emissions benefits, rather than simply meeting compliance standards today and developing new technology at a later date to meet a new regulatory standard. The additional incentive credits are necessary to accelerate the adoption of zero-emission advanced vehicle technology to meet the stated goals of the Phase 2 standards. Specifically, maintaining the Phase 2 credits are essential to sustaining a strong spark to accelerate deployment of state-of-the-art, ultra-low carbon vocational vehicles, such as fully-electric public transit buses. [EPA-HQ-OAR-2014-0827-1160-A1 p.3]

Second, the assumption that the 'incentive would result in reduced benefits in terms of CO2 emissions and fuel use due to the Phase 2 program' needs to be revisited. Any such reduction in benefits is only potentially true in the short-term because the deployment of zero-emission battery-electric buses will accelerate lower GHG emissions and fuel use in the long run. The Phase 2 incentives are key to driving manufacturers to innovate and develop the most fuel-efficient and lowest emitting vehicles and to contribute to the EPA's stated goal of building on the United States' position as a world leader in fuel-efficient trucking technologies. The earlier that advanced technology vehicles are brought to market, the sooner they can move along the adoption curve and become deployed on a widespread basis. The direct result of industry innovation will be less carbon pollution and more fuel saved. To date Proterra vehicles have saved nearly 300,000 gallons of fuel and prevented > 5 million pounds of CO2 emissions. Incentives will ensure that Proterra and other manufacturers continue to improve upon their clean mobility solutions that will help accelerate the deployment of more efficient vehicles to help local communities improve air quality, reduce GHG emissions and save fuel. Therefore, we recommend that the EPA continue advanced technology credits for zero-emission vehicles throughout the entire time frame of Phase 2. [EPA-HQ-OAR-2014-0827-1160-A1 p.3-4]

Proterra agrees with the agencies' proposal to extend the Heavy-Duty National Program beyond model year 2018. The Phase 2 Program will significantly reduce carbon emissions and improve fuel efficiency for heavy-duty vehicles, while at the same time address the challenges of global climate change and energy security. But these objectives should not come at the expense of those manufacturers pioneering the effort to produce the very advanced technology necessary to create a sustainable transportation system for generations to come. Rather than spur more innovation and improve upon today's clean and fuel efficient transit solutions, the proposed elimination of advanced technology credits has the potential to achieve the opposite result. We respectfully request that the agencies retain advanced technology credits for all-electric vehicles and extend the credits to later model years. [EPA-HQ-OAR-2014-0827-1160-A1 p.4-5]

**Organization:** Securing America's Future Energy
While we believe additional reductions are possible, the enabling (advanced engine and road load) technologies are less certain and more costly than those expected under Phase 2. Nevertheless, we believe that the Phase 2 rule could facilitate the early introduction of such technologies, providing valuable production and operating experiences prior to the adoption of Phase 3 standards, by incorporating provisions for advanced technology credits. [EPA-HQ-OAR-2014-0827-1282-A1 p.1]

Advanced Technology Credits for CO2

The EPA and NHTSA have proposed to eliminate the advanced technology credits that were available under the heavy-duty vehicle Phase 1 rule. Under that rule, credits (expressed in terms of a 1.5 times production multiplier, with specified class transfer caps) were available to promote the introduction of hybrid, Rankine cycle waste heat recovery, all-electric, and fuel cell technology. Under the proposed Phase 2 rule, these credits would be discontinued under the premise that the applicable standards presume the use of advanced technology and will, therefore, sufficiently incentivize market introduction. [EPA-HQ-OAR-2014-0827-1282-A1 p.7]

Here again, there is a stark contrast with regard to the treatment of advanced heavy-duty vehicle technology as compared to similar technology under the 2017-2025 light-duty rule. Under the light-duty rule, manufacturers can generate CO2 credits (expressed in terms of a production multiplier) through model year 2021 by introducing all-electric, plugin hybrid electric, fuel cell, and dedicated and dual fuel natural gas vehicles. These credits are intended to incentivize the early introduction of advanced technology to overcome market barriers and facilitate compliance with subsequent, more stringent standards. Natural gas is recognized for both its ability to serve as a bridge technology toward the introduction of hydrogen fuel cell vehicles and the fact that it faces similar market barriers to those of other advanced technologies (77 FR 62816). [EPA-HQ-OAR-2014-0827-1282-A1 p.7]

While the most stringent proposed Phase 2 standards for heavy-duty trucks may indeed presume some degree of advanced technology, with regard to waste heat recovery in particular, little if any hybrid, all-electric, fuel cell, or natural gas vehicle technology will be required to achieve the proposed standards. Thus, there is little difference in the role of these technologies in achieving the standards as currently proposed or adopted (as applicable) in the light- and heavy-duty sectors. The rationale offered by EPA and NHTSA for adopting advanced technology credits in the light-duty sector applies at least equally and without exception to the heavy-duty sector. In fact, the rationale is more pronounced in the heavy-duty sector given that the magnitude of advanced technology market barriers is higher due to substantially greater cost and engineering issues associated with heavy-duty vehicle development, production, and use. [EPA-HQ-OAR-2014-0827-1282-A1 p.7-8]

This differential treatment across sectors is amplified when one considers that under the light-duty rule, EPA and NHTSA adopted credits even for non-plug-in hybrid (and effectively equivalent) technology when installed on a full sized pickup truck. Supporting justification included: [EPA-HQ-OAR-2014-0827-1282-A1 p.8]

The agencies believe that offering incentives in the earlier years of this program that encourage the deployment of technologies that can significantly improve the efficiency of these vehicles and that also will foster production of those technologies at levels that will help achieve economies of scale, will promote greater fuel savings overall and make these technologies more cost effective and available in the later model years of this rulemaking to assist in compliance with the standards.’ (77 FR 62738) [EPA-HQ-OAR-2014-0827-1282-A1 p.8]
'Although there may not be inherent reasons for a lack of hybrid technology migration to large trucks, it is clear that this migration has nevertheless been slow to materialize for practical/economic reasons, including in-use duty cycles and customer expectations. These issues still need to be addressed by the designers of large pickups to successfully introduce these technologies in these trucks, and we believe that assistance in the form of a focused, well-defined incentive program is warranted.' (77 FR 62739) [EPA-HQ-OAR-2014-0827-1282-A1 p.8]

For so-called strong hybrids, these credits can be earned through the duration of the currently adopted light-duty standards (i.e., through model year 2025).20 As was the case for the general advanced technology credits, these same justifications not only hold true, but are magnified when expressed in terms of the 'in-use duty cycles and customer expectations' of the heavy-duty sector. [EPA-HQ-OAR-2014-0827-1282-A1 p.8]

While the introduction of advanced technology in the heavy-duty sector is worthy of a credit program based solely on cost and engineering issues that are compounded with size, the disparate treatment of such technology under the adopted light-duty and proposed heavy-duty programs is itself sufficient evidence of such need. There is simply no rational reason that heavy-duty manufacturers should be held to less flexible requirements than their light-duty counterparts. EPA and NHTSA should reconsider their proposal in this regard and implement a 'focused, well-defined' advanced technology incentive program for heavy-duty vehicles. Ideally, this program would mimic that of the light-duty sector, covering the same technology that is common to both and including any additional advanced technology specific to the heavy-duty sector. Thus, credits should, at a minimum, be established for hybrid, all-electric, fuel cell and natural gas technology. The earning period for the heavy-duty program should be adjusted from that of the light-duty rule to reflect the differential time periods of standards implemented under the applicable rules, allowing credits to be earned at least through model year 2026 (the last model year prior to the implementation of the most stringent proposed heavy-duty standards). [EPA-HQ-OAR-2014-0827-1282-A1 p.8-9]

[Figure 1, 'Comparison of Non-Petroleum Vehicle Allowance', can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1282-A1]

23 Note: Specific production multipliers are: (1) for all-electric and fuel cell vehicles, 2.0 in model years 2017 through 2019, 1.75 in model year 2020, and 1.5 in model year 2021, (2) for plugin hybrid electric and natural gas vehicles, 1.6 in model years 2017 through 2019, 1.45 in model year 2020, and 1.3 in model year 2021.

24 Note: Full sized pickup means a pickup with bed length and width of at least 60 and 48 inches respectively and payload and towing capacities of at least 1700 and 5000 pounds respectively.

25 Note: The specific credits are 10 grams CO₂ per mile (equivalent to 0.00113 gallons per mile) for mild hybrids, 20 grams CO₂ per mile (equivalent to 0.00225 gallons per mile) for strong hybrids, 10 grams CO₂ per mile (equivalent to 0.00113 gallons per mile) for vehicles demonstrating CO₂ performance 15 percent better than their footprint-based target, and 20 grams CO₂ per mile (equivalent to 0.00225 gallons per mile) for vehicles demonstrating CO₂ performance 20 percent better than their footprint based target. The 10 gram credits can be earned in model years 2017 through 2021, while the 20 gram credits can be earned in model years 2017 through 2025. To earn mild hybrid credits, the technology must be installed on 20, 30, 55, 70, and 80 percent of full sized pickup trucks in model years 2017 through 2021 respectively. To earn the 10 gram performance credits, the enabling technology must
be installed on 15, 20, 28, 35, and 40 percent of full sized pickup trucks in model years 2017 through 2021 respectively. Strong hybrid and 20 percent performance credits require installation on 10 percent of full sized pickup trucks in each model year 2017 through 2025. A vehicle cannot earn both a hybrid and performance credit.

26 A strong hybrid is a hybrid electric vehicle that recovers at least 65 percent of the braking energy used over the fuel economy test cycle.

Organization: Sierra Club

_Incentivize advanced technology_

Our organizations applaud the agencies for considering hybrid technology when setting the overall stringency. However, it is critical that the agencies account for the full effectiveness of hybrid technology and further incentivize advanced technologies such as battery electric and plug-in hybrid electric trucks. [EPA-HQ-OAR-2014-0827-1277-A1 p.2]

To fully account for the benefits of hybrid technology, the agencies should use real-world duty cycle data in addition to the GEM. This will help account for the benefits of electric power takeoff, now used in some utility bucket trucks. By accounting for the full benefits of hybrid technology, the agencies should increase the stringency of vocational vehicle standards. [EPA-HQ-OAR-2014-0827-1277-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.189.]]

Additionally, the agencies should restore advanced technology credits to incentivize the most advanced technologies, particularly plug-in hybrid and battery electric trucks. Early adoption and increased penetration of these technologies can help provide the needed cuts in carbon pollution and fuel consumption. [EPA-HQ-OAR-2014-0827-1277-A1 p.2-3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.190.]]

Organization: South Coast Air Quality Management District (SCAQMD)

U.S. EPA is proposing to eliminate the Advanced Technology Credits included in the Phase 1 regulation. The SCAQMD staff is strongly opposed to the proposed elimination of the credits given the work that is currently underway in California and by the U.S. Department of Energy to develop advanced zero-emission technologies for heavy-duty vehicles. These efforts include development and demonstration of traditional hybrid systems, plug-in hybrid electric trucks with all electric range, and dedicated battery-electric and fuel cell trucks that are appropriately designed for niche applications including package delivery and over the road Class 8 trucks. Elimination of the Advanced Technology Credits will impede the early market development of these technologies. Attachment 1 provides a summary of the zero-emission heavy-duty truck projects that are currently underway in the South Coast Air Basin that the SCAQMD staff strongly believes will be commercialized within the next five years if strong signals are provided to the technology providers and engine and truck manufacturers that zero-emission technologies are needed as early as possible to further reduce greenhouse gas emissions not only in the near-term, but also well beyond the timeframe of the proposed regulation. As such, we recommend that U.S. EPA reinstate the Advanced Technology Credits to help advance zero- and near-zero-emission technologies and to make Alternative 4 more attractive and attainable. [EPA-HQ-OAR-2014-0827-1181-A1 p.2-3]

[Attachment 1 can be found on p.10 of this docket]
Organization: Union of Concerned Scientists (UCS)

ADVANCED TECHNOLOGY VEHICLE CREDITS

The agencies noted appropriately that advanced technology credits should be eliminated for hybrid electric vehicles—while hybrids are an important strategy for reducing fuel use from heavy-duty trucks in the vocational vehicle sector, the stringency of the regulation is based on significant adoption of the technology, so therefore they cannot be considered “advanced”. [EPA-HQ-OAR-2014-0827-1329-A2 p.24]

However, technologies such as plug-in electric vehicles and fuel cell vehicles are at the nascent levels of adoption and could play a significant role in reducing fuel from the heavy-duty truck sector beyond 2029. A revised advanced technology program could help drive the investment in innovative technologies necessary to achieve future reductions from the work truck fleet. The agencies should therefore retain an advanced technology credit program, applicable only for advanced technologies which are expected to have little penetration in the near-term: plug-in electric vehicles, hydrogen fuel cell vehicles, and line-haul hybrid vehicles. Such a program would not significantly undermine the environmental and oil reduction benefits of the rule due to relatively low sales volumes, but they could provide manufacturers sufficient incentive to “pull forward” these advanced technologies. [EPA-HQ-OAR-2014-0827-1329-A2 p.24]

The value of any such credit is dependent entirely upon the stringency of the regulation—the use of these credits for compliance must partially offset more expensive research and development programs for technologies that will sell only in low volumes in the near-term. Therefore, it is critical that the agencies strengthen the stringency of the proposed regulations, to drive investments in innovative technologies in the timeframe of this rule and beyond. [EPA-HQ-OAR-2014-0827-1329-A2 p.24-25]

Organization: United Parcel Service (UPS)

Rule Must Encourage the Further Advancement of Hybrid Vehicles

Hybrid and electric technology applications continue to progress into the trucking sector, especially in the vocational segment. While these technologies provide fuel savings and reduced tailpipe emissions, the cost of these technologies can be substantial. EPA estimates the added cost of hybrid technologies are in the range of $20,000 to $40,000 for larger vocational vehicles and tractors while full electric technologies are in the $50,000 to $150,000 range. These costs are the highest of all the fuel efficient technologies identified, and as previously discussed, likely to result in lower adoption rates than estimated. [EPA-HQ-OAR-2014-0827-1262-A1 p.13]

In order to continue to advance these technologies and their adoption, the incentive-based approach used in Phase 1 should be retained. Specifically, the agencies should preserve the advanced technology credits which provide a credit of 1.5 in order to promote the use of hybrid and electric vehicles in larger vocational vehicles and tractors. A continuation of these credits will provide an incentive for OEM's to pursue the development and sale of hybrid and electric vehicles. These credits will likely help drive down costs while more effectively promoting the advantages of this green-technology path as a path towards achieving the goals of the rule. [EPA-HQ-OAR-2014-0827-1262-A1 p.13]

Organization: US Hybrid Corporation
While regulation is the main driver for technology and clean transportation, incentives are also needed to ensure that transition to a sustainable commercial deployment. Thus, we urge you to establish more incentive or zero and near-zero emission technologies. And this way, you can provide a path for companies that work hard to develop a product that enables us to reach our goal of 90 percent NOx reduction.

Organization:  US Hybrid Corporation

We urge you to further support zero-emission technologies, especially fuel cell. The impact of fuel cell and hydrogen is often overlooked. Recently our fuel cell power plant running, driving an a/c transit fleet up in Oakland exceeded 20,000 hours with zero stack failure, which putting the fuel cell on par with diesel and CNG engine.

Combustion engine technologies have improved a lot and can make a major contribution to vehicle fuel economy and emission for long-haul applications. However, they do little for operation in congested traffic. And traffic is not getting any better. For decades, the industries has tried various controller strategies, such as EGO and other methods. And now it is all of the last couple of decades we have been working on after treatments. After all of this effort and time and time again shows that combustion engine has reached a level of technology limit that is financially prohibitive to improve.

In contrast, fuel cell not only provides better fuel economy and the zero tailpipe emission, but also they are not sensitive or as sensitive to drive cycles, traffic congestions, and emission test method, steady-state versus cycle average, et cetera.

Therefore, on behalf of U.S. Hybrid, I urge you to further support zero-emission fuel cell medium-duty/heavy-duty vehicle, especially in urban settings. We really need this technology to achieve the California target of 90 percent NOx reduction, and your recommendations cannot get us there.

Organization:  VNG

The Need for Incentives

While NGVs are a relatively established technology compared to EVs and FCVs, they are still a very small part of the market and face significant near-term barriers to adoption with many fleets due to less infrastructure availability and higher up-front costs than petroleum-fueled vehicles. The fall in petroleum-based fuel prices has also reduced the economic case for NGVs, which was expected to drive market development after the shale gas boom. And, from a regulatory perspective, the growing likelihood that NGVs will be fueled by RNG creates positive externalities that are not captured by a focus on tailpipe emissions alone. [EPA-HQ-OAR-2014-0827-1208-A1 p.3-4]

While a lifecycle emissions focus could be a possible solution in theory, VNG agrees with Natural Gas Vehicles for America’s (NGVA) position that the incorporation of full lifecycle emissions in the GHG rule would create enormous complications and uncertainty in the accounting for every fuel, including
gasoline and diesel as well as alternatives like electricity, hydrogen, and natural gas. Keeping the regulation’s primary focus on tailpipe emissions will greatly simplify compliance planning for OEMs and ensure that emissions are reduced across vehicles of all fuel types. [EPA-HQ-OAR-2014-0827-1208-A1 p.4]

At the same time, the continued use of advanced technology incentives could play a distinct but important role in encouraging the development of technologies and fuels that will be able to provide more game-changing emissions benefits in the future. Moreover, because the majority of NGV fueling going forward can be expected to be RNG, the overall emission benefits of the rule are likely to increase instead of being reduced. Thus, it would be most effective – as well as most consistent with the precedent established by the Phase 1 regulation as well as the 2017-2025 light-duty vehicle regulations – to use a simple multiplier of at least 1.5 for NGVs, EVs, and FCVs. [EPA-HQ-OAR-2014-0827-1208-A1 p.4]

Regulatory incentives to encourage manufacturers to continue pursuing this vital near-term, near-zero alternative could be critical to sustaining this market during this challenging economic time for non-petroleum fuels, allowing for the long-term investments needed to reduce vehicle costs through higher production volumes. And, beyond the benefits for EPA’s GHG agenda, the promotion of RNG development through greater NGV demand will help EPA achieve its goals for the increase of cellulosic biofuel use under the RFS and the reduction of methane emissions. [EPA-HQ-OAR-2014-0827-1208-A1 p.4]

Response:

At the time of the proposal, the agencies believed it was no longer appropriate to provide extra credit for any of the technologies identified as advanced technologies for Phase 1, although we requested comment on this issue. The Phase 1 advanced technology credits were adopted to promote the implementation of advanced technologies that were not included in our basis of the feasibility of the Phase 1 standards. Such technologies included hybrid powertrains, Rankine cycle waste heat recovery systems on engines, all-electric vehicles, and fuel cell vehicles (see 40 CFR 1037.150(i)). The Phase 2 heavy-duty engine and vehicles standards are premised on the use of some of these technologies, making them equivalent to other fuel-saving technologies in this context. We stated that we believed the Phase 2 standards themselves will provide sufficient incentive to develop those specific technologies.

The Need for Advanced Technology Credit Multipliers

Several commenters expressed the view that advanced technology multipliers are needed to drive the development of “zero-emission” and other very advance technologies. CARB agreed with the agencies’ previously stated principle that multipliers lay the foundation for game-changing GHG and oil consumption reductions in the long term. It also argued that increased incentives are needed to overcome “consumer reluctance to purchase unfamiliar technologies.” MECA commented that “without incentives or credits, manufacturers will be forced to halt further development and optimization of emerging technologies to achieve the type of return on investment the trucking industry demands.” DTNA commented that technologies should compete in the market without extra credit incentives. While we agree to some extent with the DTNA comment as a general principle, we also agree with the other commenters that sometimes additional incentives are appropriate for very advanced technologies.

As already noted, a key principle behind the agencies’ decisions for advance technologies is that these multipliers should not apply for technologies that we project would be adopted in significant volumes
without additional incentives. This is consistent with Allison’s comment that “manufacturers should not receive what could amount to a “double credit” of meeting their compliance obligations through hybrids, fuel cell and electric vehicles are receiving additional credits on account of this action.” However, Allison’s comment goes further than this principle to support not providing these incentives for any advanced technologies, even if the agencies project neither the standards nor market forces would lead to their adoption by a significant portion of the fleet. Thus, the agencies do not agree completely with Allison. We believe it is appropriate to provide such large multipliers for these very advanced technologies at least in the short term, because they have the potential to provide very large reductions in GHG emissions and fuel consumption and advance technology development substantially in the long term. The potential to advance technology development (‘game changing’) is not fully encompassed in a tailpipe measurement, so that an additional credit can be appropriate. Nevertheless, because the advanced technology credits are so large, we also believe that we should not necessarily allow them to continue indefinitely. Therefore, the agencies are adopting them as an interim program that will continue through MY 2027. If the agencies determine that these credit multipliers should be continued beyond MY 2027, we could do so in a future rulemaking.

Qualifying Technologies

We specifically requested comment on this issue with respect to electric vehicle, plug-in hybrid, and fuel cell technologies. Although the Phase 2 standards are premised on some use of Rankine cycle waste heat recovery systems on engines and hybrid powertrains (which are considered to be advanced technologies for Phase 1), none of the Phase 2 standards are based on projected utilization of certain other even more-advanced technologies (e.g., all-electric vehicles, fuel cell vehicles). 80 FR 40158. Commenters generally supported providing credit multipliers for these advanced technologies, while ending the multipliers for waste heat recovery and conventional hybrids. Many agreed with the agencies’ general principle of basing this on whether or not such technologies were included in the feasibility analysis. However, Allison also supported ending the incentives for hybrids, fuel cells, and electric vehicles in Phase 2. Nevertheless, given the overall support for such incentives among operators, suppliers, and states, the agencies are adopting advanced technology credits for these three types of advanced technologies.

Multiplier Values

CARB provided suggestions for values larger than 1.5 that could be used to incentivize plug-in hybrids, electric vehicles, and fuel cell vehicles. CARB proposed specific larger values in supplemental comments. CALSTART commented in support of a sliding scale of credit value, tied both to the performance benefit of the technology, and also starting higher in the early years of Phase 2 and ramping down over its life. Other commenters supported adopting multipliers of 1.5 or larger.

The agencies are adopting advanced technology multipliers for these three types of advanced technologies equal to the estimates provided by CARB. Specifically, we are adopting the following multipliers:

- 3.5 for plug-in hybrid electric vehicles
- 4.5 for all-electric vehicles
- 5.5 for fuel cell vehicles

Our intention in adopting these multipliers is to create a meaningful incentive to those considering adopting these qualifying advanced technologies into their vehicles. CARB’s values were based on a cost analysis that compared the costs of these technologies to costs of other conventional technologies. Their costs analysis showed that adopting multipliers in this range would make these technologies much
more competitive with the conventional technologies and could allow manufacturers to more easily generate a viable business case to develop these technologies for heavy-duty and bring them to market at a competitive price.

Another important consideration in the adoption of these larger multipliers is the tendency of the heavy-duty sector to significantly lag the light-duty sector in the adoption of advanced technologies. There are many possible reason for this, such as:

- Heavy-duty vehicles are more expensive than light-duty vehicles, which makes it a greater monetary risk for purchasers to invest in unproven technologies.
- These vehicles are work vehicles, which makes predictable reliability even more important than for light-duty vehicles.
- Sales volumes are much lower for heavy-duty vehicles, especially for specialized vehicles.

As a result of factors such as these, adoption rates for these advanced technologies in heavy-duty are essentially non-existent today and seem unlikely to grow significantly within the next decade without additional incentives. The agencies believe it is appropriate to provide such large multipliers for these very advanced technologies because they have the potential to provide very large reductions in GHG emissions and fuel consumption and advance technology development substantially.

Other Technologies

Some commenters suggested that the agencies provide advanced technology credits for alternative fuels or engines with very low NOx emissions. SAFE pointed to the light-duty rules in support of providing credit for natural gas vehicles. PACCAR believes credits should be provided for engines/vehicles that are capable of operating on levels at 20% biofuels. However, the advanced technology multipliers being finalized are intended to address technologies for which industry is unlikely to develop and adopt without these incentives. This does not apply for these other alternative fuel technologies. We also note that EPA regulates NOx emissions separately and may mandate lower NOx emissions in the future.

CARB initially commented that the agencies should provide multipliers for conventional hybrids in long-haul tractor application because we did not consider such technologies in the feasibility analysis. Eaton and PACCAR supported credits for conventional hybrids more generally. However, other commenters supported the elimination of credit multipliers for conventional hybrids. Given our position that these multipliers should not apply for technologies that we project would be adopted in significant volumes without additional incentives, we are not finalizing Phase 2 multipliers for conventional hybrids.

Other Advanced Technology Issues

CARB staff also disagreed with the statement made in the Draft RIA that fuel cells present complex packaging and weight issues. Although we continue to believe this, we note that this position did not affect our decisions in this rule.

CALSTART commented that approval process needs to be streamlined and clarified. We remain open to improving the process.

EDTA commented that the agencies must ensure that testing protocols accurately measure emissions and efficiency benefits for advanced technologies. Sierra Club commented that the agencies should use real-world duty cycle data in addition to the GEM to fully account for the benefits of hybrid technology. We believe the final test procedures will appropriately recognize the advanced technologies.
McNicols commented that the rule should allow for credits for delegated final stage manufacturers, such as vocational vehicle manufacturers. However, as discussed in Sections 1.4.2 and 1.4.4, there are important policy reasons why credits are limited to certifying manufacturers.

### 1.4.2 Innovative and Off-Cycle Technologies

**Organization:** Allison Transmission, Inc.

EPA and NHTSA should also expand off-cycle programs to credit other technologies. Proposed regulations do not appear to allow a manufacturer to submit an A to B test plan for technologies that do not fit within the prescribed powertrain test. [EPA-HQ-OAR-2014-0827-1284-A1 p.3]

**EPA and NHTSA Should Adopt Powertrain Testing With Several Revisions**

**EPA and NHTSA Should Expand Off-Cycle Program Or Create Other Methodology To Credit Technologies Not Included in GEM or Measured By Powertrain Testing**

The agencies are proposing to continue the innovative technology program from Phase 1 but to redesignate this program as an “off-cycle program.” Allison supports continuation of this program, but recommends that the program be expanded to consider technologies that are not recognized in powertrain testing generally. [EPA-HQ-OAR-2014-0827-1284-A1 p.34]

In this regard, Section 1037.610 as proposed is designed to address vehicles with off cycle technologies. Section 1037.610(d) recommends that a manufacturer submit a test plan for approval prior to running an A to B test through either chassis or on-road testing. Section 1037.550 separately contains the required procedures for powertrain testing. But within Section 1037.550, there appears to be no accommodation for a manufacturer to submit an A to B test plan for technologies that do not fit within the prescribed powertrain test. [EPA-HQ-OAR-2014-0827-1284-A1 p.34-35]

Allison has fuel-saving technologies that are available today, but would not be recognized via the powertrain test process. Allison recommends that the off-cycle program be expanded to include the ability for manufacturers to propose an A to B powertrain test to recognize off-cycle powertrain technologies. This could be accomplished either through clarification of Section 1037.610 or 1037.550. Specifically, there are technologies associated with ATs that are not accounted for via powertrain testing and are not proposed for crediting within GEM. EPA and NHTSA should therefore create a mechanism by which such real world technology and resulting benefits can be recognized and credited. [EPA-HQ-OAR-2014-0827-1284-A1 p.35]

The benefits of this approach are substantial. In this regard, Allison would highlight these specific technologies: [EPA-HQ-OAR-2014-0827-1284-A1 p.35]

1. Dynamic Shift Sensing (“DSS”); this technology is used to select the optimal shift strategy based on mass and grade. DSS is becoming more common in the marketplace. In 2015 (to date), 63% of North American sales incorporated DSS. But DSS is not included within GEM and will not be measured through powertrain testing. Where DSS has been applied, it has resulted between 3 and 6% improvement in fuel economy, with some customers reporting as much as 13% improvement. [EPA-HQ-OAR-2014-0827-1284-A1 p.35]
(2) Acceleration Rate Management ("ARM") is a feature which controls the acceleration of a vehicle from a stop. ARM is standard on the TC10 and in transmissions for transit buses; it also is growing in penetration in other vocational vehicles. ARM can result in 2 to 8% improvement in fuel economy. [EPA-HQ-OAR-2014-0827-1284-A1 p.35]

(3) Super Econ Shift Schedule is a feature which activates while the vehicle is cruising in traffic and will operate the engine at the lowest speed possible while still maintaining vehicle speed. [EPA-HQ-OAR-2014-0827-1284-A1 p.35]

(4) Short shifting strategies: reducing engine speeds within reason leads to better fuel economy. Testing and analysis has shown reducing transmission shift speeds can improve fuel economy while only negligibly impacting vehicle performance. For example, reducing the shift speed 200 rpm from governed speed can result in a 2% improvement in fuel economy yet results in nearly identical 0-30 mph times (10.2 seconds vs 10.35 seconds). [EPA-HQ-OAR-2014-0827-1284-A1 p.35]

(5) Automatic preselects for engine braking has logic to avoid decelerating the vehicle below desired speed. If a vehicle slows down too much, then fuel is required to regain speed. Automatic preselect logic will learn a desired speed and select the proper transmission range for a given engine brake torque to obtain this speed. [EPA-HQ-OAR-2014-0827-1284-A1 p.35]

56 The configurations were 3000 Series (CR), Cummins ISB, P&D single axle truck, 5.04 rear axle ratio, 28,000 lb. Shift speed changed from 2600 (gov speed) to 2400.

Organization: American Iron and Steel Institute

EPA and NHTSA must also abandon or substantially revise weight reduction values that have been proposed for various vehicle components. There is a complete absence of technical support for these values in the administrative record for this rulemaking. If EPA and NHTSA decide to incorporate such weight reduction values into the final rule, the agencies must consider additional information concerning the weight reduction and performance benefits of steel, including the life cycle GHG benefits of steel. In the alternative, EPA should remove all weight reduction values for components included within the Proposed Rule. [EPA-HQ-OAR-2014-0827-1275-A1 p.3]

If GEM cannot reasonably be altered for this purpose, EPA and NHTSA could consider providing 'off-cycle' credits for emission reductions associated with life cycle emissions similar to the existing process for such credits that the agencies established in the Phase 1 rulemaking. To reduce administrative burdens, the agencies could specify such credits in advance of this rulemaking. For example, in the MY 2017-2025 LDV Rule, a 'pre-approved' list of off-cycle technologies was utilized to provide emission credit for the efficiency gains associated with such items as high efficiency exterior lighting and solar roof panels that would not be measured during normal certification of the vehicle. [EPA-HQ-OAR-2014-0827-1275-A1 p.11-12]

As explained in Part IV of this document, poor data quality can seriously undermine realization of regulatory objectives. Whatever life cycle analysis tool may be adopted for future Class 2 through 8 truck regulations, it must use data for materials manufacturing that is current, credible and verifiable. [EPA-HQ-OAR-2014-0827-1275-A1 p.12]
Comment on Topic Where NPRM Requests Comment

Comment – Tractor- off-cycle technology credits, penetration rate

The NPRM requests comment on providing credit for off-cycle innovative technologies. [EPA-HQ-OAR-2014-0827-1265-A1 p.77]

We agree with the concept of providing such credits, as credits can be an incentive for innovation. For example, such credits could support continued innovation in connected vehicle technologies such as platooning. The proposed Phase 2 standards were developed including benefits for predictive cruise control, a type of connected vehicle technology, and CARB staff supports allowing off-cycle credits for other connected vehicle technologies such as platooning. As discussed further in CARB’s Draft Technology Assessment: Engine/Powerplant and Drivetrain Optimization and Vehicle Efficiency, platooning is being tested in Southern California and can yield fuel consumption reductions of 10 to 21 percent. [EPA-HQ-OAR-2014-0827-1265-A1 p.77]

We also agree with the proposed removal of some types of off-cycle credits allowed in Phase 1 in light of Phase 2 GEM accounting directly for some of the Phase 1 innovative off-cycle strategies. [EPA-HQ-OAR-2014-0827-1265-A1 p.77]

The NPRM proposes requiring A to B testing on a chassis dynamometer to demonstrate the effectiveness of off-cycle technologies. CARB staff suggests caution in using A to B testing on a chassis dynamometer or by using portable emissions measurement systems (PEMS) to quantify sub percentage point efficiency gains. Care must be taken when the expected change is on the same order of magnitude as the test-to-test repeatability of the test method used. [EPA-HQ-OAR-2014-0827-1265-A1 p.77]

Support Comment/Request Clarification

Comment – Off-cycle credits and adjustments

CARB staff supports the requirements in 40 CFR 1036.610 (c), (e), and (f) that sufficient technological descriptions and data be required to allow adjustment of emission results for off-cycle credits, as well as the demonstration of the durability of the off-cycle technology. This section allows the use of the approved adjustments to be retained through the 2020 MY but that new approval will be required for MY 2021. CARB staff recommends clarification of whether approval for MY 2021 and beyond must be renewed annually or whether that approval will continue for similar off-cycle approaches as had been previously allowed under Phase 1 of the GHG regulations. CARB staff believes the latter approach would be appropriate. [EPA-HQ-OAR-2014-0827-1265-A1 p.78]

Work site vehicles have huge opportunities to use “off cycle” idle reduction tech that is not easily included in current rule design because most of it gets integrated in later production stages [EPA-HQ-OAR-2014-0827-1190-A1 p.2]
We offer some possible approaches to consider: [EPA-HQ-OAR-2014-0827-1190-A1 p.2]

– Streamline Off Cycle and AT credit testing processes with clear up front data needs and limits – eliminate open loop process [EPA-HQ-OAR-2014-0827-1190-A1 p.2]

Organization: Daimler Trucks North America LLC

And there are several costs that we could not find in the agencies’ cost-benefit analysis but that should have been included. One is the costs avoided when drivers do not have accidents and do not have to sit in traffic resulting from accidents. Such traffic has associated costs in unnecessary fuel consumption from idling engines, in wear on engines and brakes, in lost time (which is of particular importance to heavy-duty vehicle operators, for whom lost time is lost money). And avoiding such traffic decreases fuel consumption and GHG emissions. So the agencies should have considered as cost-beneficial technologies that reduce accidents, like Electronic Stability Control and Forward Collision Avoidance and Mitigation technologies. Considering those as beneficial FE technologies, and crediting them accordingly, would result. [EPA-HQ-OAR-2014-0827-1164-A1 p.129]

Organization: Dana Holding Corporation

Innovative Technology and Off-Cycle Credits

Dana is currently working on various innovations that will further improve the efficiencies of tractors and vocational vehicles by utilizing waste heat in other areas of the vehicle to quickly bring transmission oil and axle oil up to operating temperatures and to hold these oils at their operating temperature throughout the vehicle’s drive cycle. To achieve this, Dana is working on three technologies that have provided the light vehicle segment a 3% - 5% efficiency boost. The three technologies include: Exhaust Gas Heat Recovery heat exchanger (EGHR); Active Warm-up(AWU) for transmission oil; Axle Warmer heat exchanger. [EPA-HQ-OAR-2014-0827-1138-A1 p.4]

As noted in the proposed rule, these technologies are not currently commercially available for diesel engines (Section II.D.2.(a)(vii), pg. 40196). However, variations of these technologies have recently been launched within the light vehicle sector and range from full production components to prototype systems depending on the vehicle manufacturer considered. In fact, in 2012 Dana received a PACE “Innovation Partnership Award” for collaboration with Ford on our active warm-up technology. However, these technologies are not currently available for the heavy-duty and medium-duty segments. Dana continues to work on expanding the reach of these technologies for the commercial vehicle market. [EPA-HQ-OAR-2014-0827-1138-A1 p.4-5]

As Dana continues to develop these technologies, it is imperative that the rule provide a way to receive direct credit for the efficiency they provide. For this reason, Dana supports the redesignation of the Innovative Technology Credits as Off-Cycle Credits as proposed in Section I.C.1.(c), pg. 40158 of the proposed rule. We understand that this will be the mechanism to obtain efficiency credit for technologies that are not currently available. [EPA-HQ-OAR-2014-0827-1138-A1 p.5]

Organization: Edison Electric Institute

C. The Agencies Should Consider Transport Refrigeration Units and Truck Stop Electrification to be Eligible for Off-Cycle Technology Credits
In addition to the off-cycle technology credits for e-PTO systems, EEI suggests the agencies consider two additional technologies to be eligible for off-cycle technology credits:

- Transport refrigeration units: petroleum is displaced by grid-sourced electricity when cooling units on vehicles and trailers are plugged in while parked, rather than idling. Electrified Transport Refrigeration Units (eTRU), also known as “electric standby,” are available from a number of manufacturers. Carrier Transicold includes electric standby as standard on all of its Vector products, for example. While allowing vehicles to plug-in requires capital outlay at facilities, incentivizing the technology on the vehicle side through this rule would encourage more facilities to offer the capability. The Transportation Electrification Assessment Phase 1 study found favorable cost-benefit ratios and greenhouse gas savings for this technology.

- Truck stop electrification: petroleum is displaced by grid-sourced electricity when long-haul trucks are plugged in at rest stops, rather than idling or relying on petroleum-powered auxiliary power units (APUs). ShorePower is an example of a company offering plug-in capability for truck stop locations across the country. Like transport refrigeration units, incentivizing the technology on the vehicle side through this rule would encourage more facilities to offer the capability. The Transportation Electrification Assessment Phase 1 study also found favorable cost-benefit ratios and greenhouse gas savings for this technology.

For more information, see [http://www.shorepower.com/locations/](http://www.shorepower.com/locations/).

California Transportation Electrification Assessment, Phase 1: Final Report at 33.

**Organization:** Enhanced Protective Glass Automotive Association (EPGAA)

EPGAA strongly recommends the NHSTA and the EPA to adopt a final rule providing off-cycle credits and incentives for the use and installation of advanced glazing window technology as a means to reduce vehicle emissions, increase fuel efficiency and lower fuel costs for owners and operators of vehicles with medium and heavy duty engines.

Advanced glazing is increasingly being applied to multiple window openings in vehicles in order to provide a variety of benefits. In terms of fuel economy and emissions, advanced glazing with optional solar control features offers significant reduction of air conditioning loads as recognized within the off cycle credits within the latest light duty vehicle GHG and fuel economy standards. In addition, advanced glazing can weigh less than the tempered glass windows used widely today, and by its nature, filters over 98% of ultra violet rays, thus reducing associated occupant health risks. It also provides enhanced occupant retention as recognized in FMVSS 226, improves vehicle security and reduces transmitted noise.

In response to the Agencies’ request for comments regarding high efficiency glass, the EPGAA submits that recognition of the benefits offered by this technology should be part of any comprehensive package.
to assist Original Equipment Manufacturers (OEMs) in meeting emissions requirements as effectively as possible. OEM’s, based on their own manufacturing circumstances, should be provided with, and incentivized to use, as many options or tools as possible to improve overall engine performance, enhance vehicle efficiency and lower emissions. [EPA-HQ-OAR-2014-0827-1024-A1 p.2]

There should be no doubt that solar control cooling load reduction offers real and measurable benefits. Moreover, it has been proven and recognized by the previous work of the National Renewable Energy Laboratory (NREL), California Air Resources Board (CARB) and the 2017 light duty vehicle Greenhouse Gas and Emission Standards and Corporate Average Fuel Economy (CAFÉ) Standards. By providing credit for as many viable technologies as possible, the Agencies would enable OEM’s to optimize cost-effective approaches and thereby better manage the total cost of achieving the fleet emission requirements. In addition, this approach further encourages development of non-traditional technologies. [EPA-HQ-OAR-2014-0827-1024-A1 p.2]

In the 2017 light duty rule, the Agencies appropriately recognized the contribution of solar control advanced glazing by providing a calculation of an off-cycle credit based upon the enhanced glazing solar performance level versus the typical glass. The calculation is based upon the metrics of ISO 13837 Tts (Total Solar Transmission and the area of glazing affected). This calculation afforded advanced glazing the highest possible credit amongst off-cycle thermal control technologies. It should be noted that the credit within the light-duty rule is based upon benefits derived from reduced temperature of the parked vehicle only and its effects on initial cool down. It does not account for any driving benefit. Some may argue that this benefit is partially diminished while a vehicle is operating at speed due to an increase in convective cooling. Nevertheless, overall, the solar control technology will achieve beneficial results when a vehicle is stopped in traffic or idling. [EPA-HQ-OAR-2014-0827-1024-A1 p.2]

Although the cooling load for a light duty passenger vehicle represents a larger portion of the vehicle’s total load than is experienced in most heavy duty vehicles, many heavy duty vehicles spend far more time idling as a percentage of their operating time than do passenger cars; travel many more miles per year; thereby operating for much longer periods. Based on NREL study data¹ the Agencies provided a light-duty passenger truck credit for solar control glazing of up to 3.9 g/mile (0.0004 gal/mile). The glazing area and configuration of heavy duty truck cabs in general is similar to that of light duty trucks. In further testing on Class 8 truck cabs, NREL studied reductions in idle cooling loads². In those tests a continuous cooling load reduction of 13% was achieved by covering the forward glazing with a white film. The white film solar transmission was measured and compared with advanced solar glazing options which could provide appropriate visibility levels and meet safety standards. The advanced solar glazing options were found, based on this testing result, to be capable of reducing the cooling load by 6.5% or provide about 50% of the white opaque film benefit³. [EPA-HQ-OAR-2014-0827-1024-A1 p.3]

Given the aforementioned emissions reduction benefits, the EPGAA urges that the Agencies provide an appropriate off-cycle credit for solar control advanced glazing. The credit should be based on performance criteria of the glazing (Tts) which takes into account both the idling and initial cool down benefits. As the data above indicates, the idling benefit is likely more significant in heavy duty vehicles. And, as is the case in the light duty rule, we also urge that the credit be based on functions of Tts as well as glazing area affected in order to provide the best estimates of real world benefits as well as drive incentives to continually improve technology. [EPA-HQ-OAR-2014-0827-1024-A1 p.3]
3 Measurement of the white film on glass in a spectrophotometer and integration per ISO 13837 resulted in a $T_{ts}$ of 19.5% for the test configuration. Base tinted glass commonly used in HD vehicle glazing has a typical $T_{ts}$ of 57-60%. Commercially available solar control advanced glazing can demonstrate $T_{ts}$ values as low as approximately 40% while meeting the 70% visible transmission regulations for highway operation. Hence, solar control advanced glazing would represent approximately 50% of the benefit experienced in testing or approximately 6.5% cooling load reduction during idling since $T_{ts}$ is linearly related to the actual solar energy passing through the glazing into the cab.

**Organization:** FedEx Corporation

Drive GHG/Fuel Efficiency Improvement Technologies in Commercial Vehicles. [EPA-HQ-OAR-2014-0827-1302-A1 p.3]

**Organization:** General Motors

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 102-103.]

For example, the pre-defined and pre-approved list of mobile air conditioner greenhouse gas credits has incentivized a rapid improvement in the efficiency and leak integrity of light duty vehicle air conditioners. These incentives are now paving the way for an early transition to lower global warming air conditioner refrigerants as millions of new vehicles are being produced with the new refrigerants, many years in advance of any mandate to make the switch.

The success of these air conditioner provisions led to the expansion of this approach in 2014 for the light duty fleet with the introduction of an expanded off cycle list of pre-assigned and pre-approved credits for other technologies that reduce fuel usage and conditions not comprehended in the standard fuel economy test, such as colder weather, higher speeds, or extended idle times.

**Organization:** Lubrizol Corporation

Higher-performing lubricants will play an important role in helping the OEMs comply with the Phase 2 Rule. Indeed, as shown in Figure 1 below, many of the technologies and strategies that will be used by the OEMs will require HPLs to operate cleanly, efficiently, and without compromising equipment performance and durability. [EPA-HQ-OAR-2014-0827-1325-A1 p.2]

[Figure 1 can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1325-A1]

**Organization:** Meritor, Inc

**Allow a Supplier Driven Off-Cycle Technology Path**
Meritor is a strong supporter of building flexibility into the regulation by providing a mechanism to validate Off-Cycle Technologies. This is especially important since the regulatory timeframe is lengthy and thus cannot foresee new, currently-unaccounted-for technologies. Meritor is concerned, however, that the proposed regulation, by restricting Off-Cycle Technology applications solely to OEMs, will underutilize this important option. OEMs have limited resources which artificially restricts the number of technologies that they can pursue at any one time through the current Off-Cycle Technology path while the technology supplier has the resources and financial incentive to pursue the Off-Cycle credit. [EPA-HQ-OAR-2014-0827-1254-A1 p.2-3]

Meritor advocates developing a detailed process by which Off-Cycle Technologies can be proposed, tested and certified in coordination with the government by the either the OEM or the technology supplier. We believe this approach will leverage the capabilities and investment of the supplier community, encourage smart technology development and, ultimately, offer the OEMs greater options to comply with this regulation. Greater choice is in the best interest of the consumer, the OEM and the government. [EPA-HQ-OAR-2014-0827-1254-A1 p.3]

Organization:  Motor & Equipment Manufacturers Association (MEMA)

Allow Suppliers to Apply for Pre-Approval of Innovative Off-Cycle Technologies [EPA-HQ-OAR-2014-0827-1274-A1 p.10]

In the proposed rule, the agencies offer to account for future emerging innovative off-cycle technologies, by retaining the existing Phase 1 paths. However, this process is only open to the vehicle manufacturers. Suppliers must also be allowed to participate in this process independently. [EPA-HQ-OAR-2014-0827-1274-A1 p.10] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.196.]]

Under Phase 1, the application/petition path was not well utilized by vehicle manufacturers likely due to the lengthy and arduous process. Even though the agency is proposing to retain the same path options as Phase 1 in Phase 2, we are concerned that it may continue to be significantly under-utilized. Suppliers would seek a component-level pre-approval, similar to the light vehicle program off-cycle structure such that it can be broadly applied to any vehicle that utilizes that pre-approved technology. [EPA-HQ-OAR-2014-0827-1274-A1 p.10]

Only allowing vehicle manufacturers to petition for pre-approval limits the scope of potential for other improved, innovative off-cycle technologies offered by suppliers. Moreover, not including suppliers may impact commercially-viable technologies; if there is not a way to account for these technologies, then there is little incentive for the vehicle manufacturer to utilize the technologies. The resulting disbenefit could inadvertently stifle development and innovation of more effective and efficient technologies. This would be an unfortunate consequence and would be contrary to the overarching goals of the rule. [EPA-HQ-OAR-2014-0827-1274-A1 p.10]

Permitting only vehicle manufacturers to apply and petition for approval perhaps comes from the notion that only the OEMs are able to provide the data and substantive information needed to demonstrate the potential fuel efficiencies/emission reductions of commercialized, in-production systems or components. However, suppliers have a wide range of models and design tools available to them (such as high-performance computer simulation and functional 3D prototyping) to provide detailed information and supporting data necessary for evaluation of applications. Suppliers simply want the equal opportunity to apply and present the potential benefits of innovative off-cycle technologies provided they meet the criteria laid out in 40 CFR 86.1869-12, 1036.610, and 1037.610. Suppliers are
highly incentivized to dedicate resources, data collection and documentation to support the performance and efficiency benefits of their materials, components and systems. They have always worked closely with their customers, but even more so over the years as the technologies transition from “bolted on” to more fully integrated. Further, suppliers can adequately quantify the contributions of the technology for agency review. [EPA-HQ-OAR-2014-0827-1274-A1 p.10-11]

The ability for suppliers to be part of the innovative off-cycle pre-approval process is particularly critical if the agencies do not find a way to make the GEM more adaptable, as MEMA suggested above. [EPA-HQ-OAR-2014-0827-1274-A1 p.11]

Suppliers are well positioned to provide the resources, test protocols, data and documentation required to present viable petitions that can demonstrate “known quantifiable benefits.” Allowing suppliers to participate in this approval path enhances the viability of the program because it could potentially include a larger cross-section of innovative off-cycle technologies. Therefore, MEMA urges the agencies to allow suppliers direct access to the pre-approval process. [EPA-HQ-OAR-2014-0827-1274-A1 p.11]

Organization: Navistar, Inc.

The NPRM requests comment on whether the requirement to demonstrate that a technology was not in use prior to 2010 as part of an off-cycle demonstration should carry forward in this rule. Navistar opposes carrying forward that requirement. First, as the NPRM acknowledges, by the time this rule is fully mature 2010 will be 17 years in the past. That requirement will turn both the agencies and manufacturers into historians for no purpose. Second is that the requirement itself serves no purpose. As it relates to fuel economy technologies, 2010 was a somewhat arbitrary date to begin with and its relevance will continue to diminish. The main point should be whether a technology shows a benefit that cannot be captured on the test, whether GEM or the engine tests. Navistar expects that many technologies may not be captured by the tests and thus might be considered off-cycle technologies, including many of those under development as part of the SuperTruck program. [EPA-HQ-OAR-2014-0827-1199-A1 p.14]

In addition, the agencies should continue to explore areas of improvement as to the review of off-cycle technologies. During the implementation of the Phase 1, discussions regarding appropriate test methods for these technologies have been challenging. Standardized test methods for similar technologies should be developed. We recommend that EPA issue guidance for manufacturers setting out lessons learned from off-cycle application reviews. These could be anonymous as to the particulars of the technology, but give general guidance on comparison methods that have been acceptable to the agency. The guidance should also include templates and guidelines for meeting with agencies to reduce the burden of gaining approval for these technologies. [EPA-HQ-OAR-2014-0827-1199-A1 p.15]

We note that the NPRM states a general intention to develop an approach like the one suggested, with pre-approved testing methods as one route and a public approval route as a second option. However, this approach is not set forth clearly in the rule language itself. In fact, the contrast between this provision and the provision for light duty off-cycle technologies is stark. Whereas the light duty rule sets out detailed criteria for various potential technologies in the rule itself, that level of detail, or even mention of particular technologies, is entirely absent from the heavy duty equivalent. [EPA-HQ-OAR-2014-0827-1199-A1 p.15]

There should also be a high degree of flexibility as to what may be considered as an off-cycle technology. For instance, if a technology is difficult to model because it is highly dependent on user
activity (for example, an in-use based technology such as platooning), the agencies should consider real
time data collection methods showing actual field usage as a way to establish some credits for those
technologies. Real time connected vehicles may afford opportunities that did not exist in the past to

Given the key role that off-cycle technologies are to play in the Phase 2 standards, we urge the agencies
to make it as easy as possible to achieve recognition of the benefits of these technologies. As such, we
request that the rule better set out methodologies to the extent possible or set out a method of developing
pre-approved methods, such as the guidance method we suggested. [EPA-HQ-OAR-2014-0827-1199-
A1 p.15]

The EMA comments discuss the potential for disruption carried in the Proposed Rule by limitations
imposed on changes that were heretofore routinely made on certain vehicle elements that may be

The dropdown tables in GEM will force manufacturers to create separate families for each off-cycle
technology. As these technologies grow, we anticipate that being required to track each of these families
individually will become unwieldy and create an unnecessary burden. There is no reason to establish
separate vehicle families for off-cycle technologies. Just like all other vehicle attributes the off-cycle
technologies can be accounted for individually for each vehicle. The unique configurations are already
accounted for in the GEM runs. [EPA-HQ-OAR-2014-0827-1199-A1 p.41]

**Organization:** Odyne Systems LLC

**Off-Cycle Credits**

EPA’s draft proposal moves innovative technology credits from Phase One to an Off-cycle program in
Phase Two. In 2021, technologies that are not fully accounted for in the GEM or other testing would be
considered Off-cycle, including technologies that may not be considered innovative. The concern that
Odyne has relative to Off-cycle credits is how our system fits into this category. Since the EPA
considers the hybrid system a part of the transmission and not a separate system, hybrids would then be
fully accounted for in the GEM. Odyne does not believe that efficiency benefits are fully accounted for
when considered as a part of the transmission. As there is not a well-defined path for hybrids in the
GEM, we believe that the Off-cycle credit process would need to be used, and it needs more
clarification on how that would be handled.

In Phase One, the process was unclear for technologies to become eligible for these credits, which we
believe was a major hindrance for industry to drive these types of innovations. Odyne and other aligned
stakeholders like the EDTA and CalStart would also welcome the opportunity to work with the EPA on
developing these conditions and clear timelines for earning Off-cycle credits for the deployment of
hybrid or hybrid PTO technologies. [EPA-HQ-OAR-2014-0827-1239-A1 p.26] [This comment can also
be found in EPA-HQ-OAR-2014-08267-1372, p.232-233.]

Should the EPA in its final rule decide not to base its standards for vocational trucks on the use of
hybrid or e-PTO, Odyne strongly encourages the EPA to develop and establish clear and bounding
conditions for technologies to become eligible for Off-cycle credits. [EPA-HQ-OAR-2014-0827-1239-
A1 p.26] [This comment can also be found in EPA-HQ-OAR-2014-08267-1372, p.232.]

**Regulatory Coherence**
The California Air Resources Board (CARB) has put a strong focus on hybrid technology in its efforts to achieve its zero emission goals, as improvements in electrification technologies are necessary to going beyond incremental fuel efficiency increases. Odyne would recommend any methods to streamline Phase Two regulations with CARB Innovative Technology Regulation (ITR) efforts to ease regulatory burden on Innovative Technology in this space, and set common goals for the heavy-duty industry to meet. More detailed comments on commonalities sought between EPA and other regulatory bodies like CARB are included in other sections of these comments. [EPA-HQ-OAR-2014-0827-1239-A1 p.32]

**Organization:** Plastics Industry Trade Association (SPI)

**Revising the Lightweight Credit Menu**

SPI recommends that the agencies include a supplier-driven process for adding to the lightweight credit menu. This will encourage the development of new technologies over the course of Phase 2. Further, there should be an opportunity to adjust existing credits if such changes are required. These potential adjustments are necessary because many of the parts currently being translated from the light duty market will be commercialized for the medium and heavy duty markets by the time Phase 2 takes effect. [EPA-HQ-OAR-2014-0827-1225-A1 p.2]

Few credit petitions were received during Phase 1\(^2\), which is likely the result of requiring vehicle manufacturers to sponsor the credit petitions. The resources and incentive to document credits is with suppliers and they should be permitted to sponsor credit petitions. The agencies can ensure only legitimate applications are filed by placing testing and evidentiary requirements on suppliers. [EPA-HQ-OAR-2014-0827-1225-A1 p.3]

**Organization:** SABIC Innovative Plastics US LLC

We also encourage the agencies to consider supplementing the existing petition process with a supplier-driven process for adding additional technologies to the off-cycle credit menu during Phase 2. Advances in tools to validate new parts, including computer-aided design and modeling, predictive engineering, and rapid prototyping, have equipped suppliers to substantiate the benefits of such components independent of OEM commercialization and validation. Allowing suppliers to lead credit petitions will accelerate the pace at which innovative products enter the marketplace. [EPA-HQ-OAR-2014-0827-1207-A1 p.2]

**IV. Allow Suppliers to Lead Off-Cycle Petitions**

Since the inception of the Phase 1 program for medium- and heavy-duty vehicles, the agencies have required that petitions for off-cycle credit be brought forward by OEMs. The process of OEM validation was relied upon as substantive support for the commercial viability and real world fuel and emission benefits of new technologies. However, that requirement has likely hampered innovation, as few credit petitions were received during Phase 1.[EPA-HQ-OAR-2014-0827-1207-A1 p.5]
Recent years have seen rapid advances in tools to validate new parts, including computer-aided design and modeling, predictive engineering, and processes like 3D printing that allow for rapid prototyping. These tools place suppliers in a position to submit very substantive credit petitions that can demonstrate the real world fuel and emission benefits of for new technologies. These advanced modeling and prototyping techniques can also would support petitions to modify existing credits in light of new information. The same tools will prove useful to the agency in evaluating such petitions. [EPA-HQ-OAR-2014-0827-1207-A1 p.5-6]

Allowing suppliers to lead credit petitions will accelerate the pace at which innovative products enter the marketplace. SABIC recommends that the agencies supplement the existing OEM-led petition process for off-cycle credits with a supplier-led petition process during Phase 2. The Motor Vehicle Manufacturers Association (MEMA), of which SABIC is an active member, will address in its comments how a program could be structured to incentivize supplier-led innovation, while ensuring the merit of credit petitions. SABIC supports that proposal. [EPA-HQ-OAR-2014-0827-1207-A1 p.6]

SABIC encourages the agencies to provide a supplier-driven process for adding to the credit menu, which will accelerate the pace at which innovative products enter the marketplace. Advances in tools to validate new parts, including computer-aided design and modeling, predictive engineering, and rapid prototyping, have equipped suppliers to substantiate the benefits of such components independent of OEM commercialization and validation. [EPA-HQ-OAR-2014-0827-1207-A1 p.6]

**Organization:** Safety-Kleen Systems

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 257-260.]

We recommend allowing the manufacturers of relevant vehicles to obtain credit for significant greenhouse gas reduction benefits associated with re-refining lubricating oil when this oil is supplied as an original factory fill. And further, we would like to explore with the agencies how ABT mechanisms can be used to allow credit for re-refined oil supplied during subsequent routine maintenance. [EPA-HQ-OAR-2014-0827-1372 p.257]

Re-refining used lubricating oil generates significant environmental and energy benefits, and has been deemed by Federal agencies and national labs as an appropriate use for -- I'm sorry -- for conserving crude oil that is a non-renewable resource. [EPA-HQ-OAR-2014-0827-1372 p.257]

Our independent life cycle analysis published in the American Chemistry Society Journal after peer review describes how the use of re-refined oil reduces greenhouse gas emissions compared to the use of engine oil made from virgin crude. This analysis, conducted by Envira, a leading environmental consulting firm, estimates that production of re-refined engine oil generates 70 percent fewer greenhouse gas emissions than production of oil from virgin crude. For example, the total greenhouse gas savings from use of 50 million of refined oil is approximately 159,000 metric tons of CO2Eq. That's equal to avoiding emissions from the combustion of 15 million gallons of number two fuel oil. Simply put, every three gallons of re-refined engine oil used avoid emissions equivalent to burning a gallon of diesel fuel. [EPA-HQ-OAR-2014-0827-1372 p.257-258]

Our published analysis shows that even if we conservatively include other factors, such as emissions from collection of used oil, the use of re-refined oil represents 56 percent reduction in greenhouse gas emissions when compared to emissions from the production of lubricants made from the virgin crude.
This is because refining engine oil from previously refined used oil is a more efficient process than refining comparable engine oil from virgin crude. [EPA-HQ-OAR-2014-0827-1372 p.258]

Significant carbon reductions are achievable through use of re-refined oil to lubricate engines as original equipment and as part of maintenance of the vehicles. Allowing OEMs to receive credit for these greenhouse gas savings will provide them with additional flexibility to achieve the targets being set by the EPA and DOT. Further, allowing credits for initial fill and future maintenance will encourage more companies to use re-refined oil when studies show -- which studies show is preferable in terms of reducing greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1372 p.258-259]

When the total life cycle benefits are factored in, the use of re-refined oil has benefits comparable to the use of low rolling resistance tires. With this type of tire, the standards are drafted to provide environmental benefits throughout the prescribed lifetime of the vehicle. The same standard could be adapted to avoid greenhouse gas emissions with re-refined oil in original factor fill and service fill. [EPA-HQ-OAR-2014-0827-1372 p.259]

Credit for future maintenance could be provided on a tradable basis allowing the manufacturer to buy GHG reduction benefits each time the oil is changed using re-refined oil in the future and maintenance cycles. By allowing future tradable credit, the manufacturer would be given an incentive to promote the use of re-refined oil in future oil changes through sales of re-refined oil to their own network of maintenance facilities and dealers. [EPA-HQ-OAR-2014-0827-1372 p.259-260]

Organization: Truck & Engine Manufacturers Association (EMA)

Vehicle Families for “Off-Cycle” Technologies

The Agencies are proposing that vehicle manufacturers certify as a separate family any vehicle configuration that utilizes a unique innovative or “off-cycle” technology. As an initial matter, it is unclear whether this requirement necessarily applies to “off-cycle” technologies. If not, then the requirement to treat any innovative technology as a distinct family for certification should be removed, since it will only add to the burden and costs of the Phase 2 program with no real corresponding benefits. [EPA-HQ-OAR-2014-0827-1269-A1 p.43]

Organization: XL Hybrids

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 242.]

we recommend expanding the trading compliance paths for additional flexibility to allow major OEMs to take advantage of the fuel and emissions savings technologies deployed by third party up-fitters, like ourselves.

Response:

The agencies are continuing the Phase 1 innovative technology program, but re-designating it as an off-cycle program for Phase 2. In other words, beginning in MY 2021 technologies that are not fully accounted for in the GEM simulation tool, or by compliance dynamometer testing (for engines or chassis certified vehicles) will be considered “off-cycle”, including those technologies that may no longer be considered innovative technologies. Commenters generally supported this flexibility.
**Eligible Technologies**

The final rules provide that in order for a manufacturer to receive these credits for Phase 2, the off-cycle technology will need to meet the following requirements:

- The technology is not represented by the applicable test procedures and simulations.
- The technology was not in common use prior to MY 2010.

Navistar commented that the 2010 restriction will become harder to implement in the future. However, we believe it is prudent to continue this requirement to avoid the potential for manufacturers to receive windfall credits for technologies that they were already using before MY 2010. We recognize that because the Phase 2 program will be implemented in MY 2021 and extend at least through MY 2027, the agencies and manufacturers may have difficulty in the future determining whether an off-cycle technology was in common use prior to MY 2010. In order to avoid this approach becoming an unnecessary hindrance to the off-cycle program, the agencies will presume that off-cycle technologies were not in common use in 2010 unless we have clear evidence to the contrary. Neither the agencies nor manufacturers will be required to demonstrate that the technology meets this 2010 criteria. Rather, the agencies will simply retain the authority to deny a request for off-cycle credits if it is clear that the technology was in common use in 2010 and thus part of the baseline.

Several commenters identified specific technologies as potential off-cycle credit technologies. It would not be appropriate for the agencies to make determinations about these technologies based on the limited information provided in the comments. Nevertheless, we recognize that many of these technologies could qualify under the program being adopted. However, Odyne is correct that hybrids would generally not qualify where they are represented by the powertrain test.

**Test Procedures**

We do not disagree with the concern expressed by CARB about test-to-test variability confounding measurements. However, we believe that this can be addressed by proper experimental design.

Allison commented on the use of powertrain testing to demonstrate off-cycle improvements. Since improvements over the prescribed powertrain test would not be eligible for off-cycle credits (these improvements are obviously adequately measured by the applicable test procedure; this is the whole purpose of the powertrain test), we believe Allison is requesting that they be allowed to use modified versions of the powertrain procedure. We have revised the regulations to clarify that this is permissible.

**Carryover**

Manufacturers will be able to carry over innovative technology credits from Phase 1 into Phase 2, subject to the same restrictions as other credits. Manufacturers will also be able to carry over the improvement factor (not the credit value) of a technology, if certain criteria are met. We will require preapproval prior to the first use under Phase 2, but will not require additional subsequent approval beyond the normal certification process.

**Streamlining the Off-Cycle Approval Process**

The agencies will require documentation for all off-cycle requests similar to those required by EPA for its light-duty GHG program. Some commenters requested that the agencies develop a streamlined path for off-cycle technology approval. While we are not making fundamental changes from the proposal at this time, we remain open to working with stakeholders to look for ways to simplify the process.
Just as some technologies that were considered off-cycle for Phase 1 are being adopted as primary technologies in Phase 2, the agencies may revise the regulation in a future rulemaking to create a more direct path to recognize technologies currently considered off-cycle. For example, although we are including specific provisions to recognize certain electrified accessories, recognizing others would require the manufacturer to go through the off-cycle process. However, it is quite possible that the agencies could gather sufficient data to allow us to adopt specific provisions in a future rulemaking to recognize other accessories in a simpler manner. Because such a change would merely represent a simpler way to receive the same credit as could be obtained under the regulations being adopted today (rather than a change in stringency), it would not require us to reconsider the standards.

Some suppliers commented that the agencies should allow them to apply for off-cycle credit independent of any certifying OEMs. However, we believe it is important to include the certificate holder that would be responsible for the in-use performance of the technology.

Separate Families

EMA commented that the agencies should not require vehicles with off-cycle technologies to be certified in separate vehicle families. That was the approach adopted in the Phase 1 program, but the agencies proposed to eliminate this restriction. For the FRM, the agencies have made it clearer that we are ending this restriction.

Credit for Life Cycle Reductions

AISI commented that the agencies should provide off-cycle credits for life cycle reductions. See Section 1.8 of this chapter for a discussion of life cycle issues

1.4.3 Selective enforcement audits and confirmatory testing 133

Organization: American Automotive Policy Council

In-Use Compliance and Useful Life - AAPC agrees with continuing the 3 percent adjustment factor applied to the full useful-life certification standards for the purpose of determining in-use emissions and fuel consumption standards. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

In-Use Compliance and Useful Life

The agencies requested comment (80 Federal Register 40206) on the appropriateness of continuing the 3 percent adjustment factor applied to the full useful-life certification standards for the purpose of determining in-use emissions and fuel consumption standards. This adjustment factor was applied in Phase 1 based on the agencies’ assessment of testing variability inherent in comparing results among different laboratories and different engines. AAPC supports the continuance of this allowance for in-use testing. No material advances have occurred that would result in the variability factors relevant in Phase 2 being significantly different than they were in Phase 1. Furthermore, the appropriateness of the 3% allowance has not yet been assessed against actual in-use data on 2014 MY or later vehicles and engines near their full useful lives. Absent such data, a thorough assessment of the appropriateness of this allowance cannot be made. AAPC further notes that in-use verification program limits in Light-Duty are 10% to account for in-use variations. [EPA-HQ-OAR-2014-0827-1238-A1 p.16]

Organization: Caterpillar Inc, et al.
There are a number of new or updated test procedures in the Phase 2 proposal including aerodynamic coast-down, fuel mapping procedure, powertrain test procedure, rear axle efficiency, Selective Enforcement Audits (SEA), and in-use chassis dyno testing. The current proposal does not include compliance margins for modified or new procedures, such as aerodynamic and engine fuel map audits. To reduce some of the variability that is inherent in the proposed test procedures, we recommend that the Agencies perform confirmatory and SEA tests using the same method and location that the manufacturer used to certify the vehicle or component. Furthermore, we have worked with the Agencies to improve the accuracy of the procedures, for example we have recommended the inclusion of the yaw angle in the coast-down procedure to reduce the impact of wind conditions. To account for the remaining variability, compliance margins must be included in the Phase 2 regulation. If not corrected, these issues will subject manufacturers to risks simply as a result of expected test variation that can only be mitigated by downgrading our declared certifications to levels significantly worse than the actual test results, so as to cover the range of production and test variability. We estimate these issues have the impact of raising the de facto targets by approximately 12.5%; that is, we need to achieve 36.5% efficiency improvement to meet the stated 24% target for high-rise sleeper tractors. [EPA-HQ-OAR-2014-0827-1215-A1 p.8] 134

Organization: Cummins, Inc.

In 1036.301(b)(1), the agencies broadly define that “any applicable vehicle configuration” could be used during an engine fuel map SEA. With any vehicle configuration available for an SEA, there is no clear audit cycle on which to evaluate and optimize CO2 performance. Cummins recommends the fuel map SEA uses a predefined vehicle configuration. [EPA-HQ-OAR-2014-0827-1298-A1 p.26]

Organization: Daimler Trucks North America LLC

The agencies must resolve problems with audit procedures and compliance margins for those audits. Although we strongly support the agencies’ use of audits to find noncompliance, the problematic procedures and margins make the rest of the agencies’ proposed standards impracticable. [EPA-HQ-OAR-2014-0827-1164-A1 p.6]

Audits/In-Use Testing

Daimler Trucks North America (DTNA) starts our comments with some serious concerns about audits, before even getting to engine testing or GEM-based certification, as the manner of auditing and the compliance margins assumed for each audit have such profound impact on all other aspects of certification and compliance. There are problems with the agencies’ audit proposals, but these can easily be rectified in order to make the program workable. [EPA-HQ-OAR-2014-0827-1164-A1 p.6]

1. SEAs, generally

SEAs in § 1037.301 - The EPA should clarify that a vehicle fails an SEA only if it fails by a margin larger than the uncertainty involved in testing the component(s) that the agency audited. If an SEA shows a 1% higher emission than the manufacturer submitted to the EPA, but the uncertainty in testing components is 3%, then the 1% exceedance may be due to test variability. If, on the other hand, the agency expects that manufacturers will build into each vehicle’s FEL the (say) 3% necessary to pass
SEAs, then the EPA must also include this 3% buffer in its standards (i.e., the g CO2/ton-mile numbers) given that the standards the EPA assigned lacked this buffer and therefore will not be achievable with the EPA’s assumed technology mixes. [EPA-HQ-OAR-2014-0827-1164-A1 p.7]

**Suspending or revoking certificates based on SEAs, § 1037.301(f):** The agencies propose to give themselves the authority to suspend or revoke certificates based on the results of an SEA. § 1037.301(f), 80 FR 40622. If a vehicle family fails an SEA, for example for aerodynamics, then the family’s aerodynamic drag values for use in GEM should be revised. But as long as the family can still meet limit values, perhaps with AB&T credits, there is no reason that the EPA should be able to suspend or revoke the family's certificate. [EPA-HQ-OAR-2014-0827-1164-A1 p.7]

2. GEM and Fuel Map Audits

**GEM SEA:** With the introductory text of § 1037.551 (particularly that “engine-based measurements may be used for confirmatory testing ... or for selective enforcement audits”), the agencies appear—and the text is not clear on this topic—to give themselves great flexibility in auditing, up to allowing them to audit vehicles in a manner unlike the lawful manner that the manufacturer used to certify. If that is the agencies’ intention, then we disagree with this approach. The reason is that it fails to find when a manufacturer submitted bad data and instead confounds test-to-test variability into the audit process. Rather, the manner in which the EPA should audit manufacturers, whether for compliance using GEM or for anything else, is to first start with a process audit. The EPA should evaluate whether the manufacturer is following allowable procedures at each step within the certification or compliance procedure--given that there are a number of different options at many steps within the procedure and each one could cause slightly different GEM results. So for example, rather than auditing a fuel-map based GEM result using a powertrain test, the EPA should audit the fuel map, as auditing an engine fuel map result through powertrain testing confounds the differences between the tests with the test results themselves. Similarly, regarding aero SEAs, the agency should not audit a manufacturer’s CFD-based aero value through coast-down and ARC; the EPA should audit the CFD result. In short, if the manufacturer chose a lawful procedure for generating GEM inputs, then the agencies would focus their analysis on the results of that lawful process and would omit any audit of what the results would be if the manufacturer had used some other (equally lawful) process. [EPA-HQ-OAR-2014-0827-1164-A1 p.8-9]

**Fuel Map SEA and Confirmatory Testing** - The EPA proposes to audit fuel maps as part of confirmatory testing (1036.235). EPA proposes to audit fuel maps on a point by point basis, including points rarely encountered in drive cycles but captured in the 143 point fuel map. Some of these points have relatively high variability of CO2 emissions on a percentage basis, because of the low fuel consumption rates. Because these points are rarely encountered in drive cycles, they should not receive the same scrutiny as points that factor highly into driving operation. In turn, point by point fuel map auditing will force manufacturers to build sometimes large compliance margins (or buffers) into points within the fuel map. While this does solve the variability problem and protect against audits, it leads to the EPA receiving potentially misrepresentative fuel map information. Better would be for the EPA to remove point by point auditing so that the agency gets accurate—rather than misrepresentative—information from manufacturers. An alternative method is provided. [EPA-HQ-OAR-2014-0827-1164-A1 p.9]

Second, the EPA’s proposal would confound normal engine to engine variability with GEM noncompliance, which is a vehicle-side issue. If in an SEA the EPA selects an engine with fuel consumption toward the high end of the engine family’s distribution, then any GEM run using that engine’s measured fuel map will indicate high fuel consumption, incorrectly indicating that the vehicle
manufacturer may have misstated GEM-based emissions. Because neither the EPA nor the vehicle manufacturer will know a priori whether the engine is at the high end of the fuel consumption distribution, any failure of a GEM audit is immediately suspect. [EPA-HQ-OAR-2014-0827-1164-A1 p.9]

Third, the EPA’s proposal confounds errors of the output of GEM, which is the agency’s responsibility, with errors of the input of GEM, which is the vehicle manufacturer’s responsibility. In an SEA, the EPA should be concerned that a vehicle manufacturer 1) uses correct inputs to GEM and 2) uses the agency’s supplied GEM. Where an input comes from a supplier other than the vehicle manufacturer, the EPA should require only that the vehicle manufacturer used that supplier’s input in good faith, as the EPA currently does with tire inputs. [EPA-HQ-OAR-2014-0827-1164-A1 p.9]

The result is that the proper way to audit GEM and its inputs is: 1) require that engine manufacturers submit fuel maps and that they be held accountable for the maps’ accuracy, as they currently are through SEAs that are RMC-based (an integrated, rather than point by point compliance measure) and FTP based (integrated over a test cycle); 2) do not conduct confirmatory testing of fuel maps on a point by point basis, as doing so highlights areas of variability that are unimportant yet downplays areas that are important; 3) audit vehicle manufacturers’ inputs to GEM; and 4) audit that the vehicle manufacturer properly used the agency’s GEM. In other words, the proper way to audit is a step by step auditing process, checking inputs individually, rather than confounding potential sources of error or, worse, highlighting errors that are unimportant. [EPA-HQ-OAR-2014-0827-1164-A1 p.9-10]

As an alternative for SEA testing, the agencies should establish regulations that recognize engine to engine variability and the need for an AQL in audits. The agencies would start by clarifying what vehicle configurations will be used for GEM inputs in fuel map audits, then test an engine or engines to generate fuel maps, use those fuel maps in GEM, and compare the results to those that the manufacturer would have gotten with its original fuel map. If the difference is above the test-to-test variability—and here we would suggest 3%, like the variability that created the FCL to FEL ratio—in a large enough number that the manufacturer did not meet an established AQL level (e.g., 40%), then and only then does the manufacturer fail the audit. This procedure is justifiable, given statistical variation, whereas the agencies’ current proposal is not. [EPA-HQ-OAR-2014-0827-1164-A1 p.10]

Similarly for confirmatory testing EPA should consider evaluating a manufacturer’s fuel map via GEM simulation wherein GEM results using the EPA generated fuel map are compared to results using the manufacturers certified fuel map. Pass criteria should be established based on the certified fuel map GEM result plus the aforementioned 3% compliance margin. Should the GEM result using the EPA generated fuel map be above the pass criteria, the manufacturer should be required to accept the EPA fuel map for certification purposes. [EPA-HQ-OAR-2014-0827-1164-A1 p.10]

**Fuel map compliance (SEA and Confirmatory Testing)** - The agencies originally proposed to conduct SEA of fuel map compliance through GEM to rectify the problem that points of low fuel consumption (and hence poor signal to noise) or of infrequent applicability during driving (and hence little importance) be audited as fully as the main driving points. The agencies recognized that point-by-point compliance is even more stringent than current compliance requirements on the SET-RMC test, which is audited based on the weighted result of the thirteen points. Consequently, the agencies proposed to incorporate GEM into audits and not to overwrite individual points but to have a more statistically-based audit procedure. We applaud use of GEM for SEA audit of engine fuel map results. Further, for confirmatory testing we agree with the agencies’ revised view that audit engine map differences (high only points) should be not used to modify cert fuel map. We suggest that, for both confirmatory testing and SEA, the agencies use 3% compliance margin applied to GEM output using the
certified fuel map as both a pass criteria for SEA and as the criteria for determining in confirmatory testing whether the manufacturer fuel map should be replaced by the EPA measured map (but that if the map is replaced, it be replaced in its entirety). [EPA-HQ-OAR-2014-0827-1164-A1 p.48-49]

**Organization:** International Council on Clean Transportation (ICCT)

**Confirmatory testing.** The U.S. EPA memo on Selective Enforcement Audit and Confirmatory Testing provides a welcome addition to the regulatory development of protocols to monitory compliance with the regulation. Previously, there were limited such details on questions about aerodynamic testing protocols, allowable measurements, thresholds, and margins, so the memo provides helpful guidance and also helps narrow the testing and compliance margins. This opens up a broader set of questions regarding how the agencies will confirm the regulatory compliance data, such as the GEM inputs for various technology-specific drop-down menus, tire low rolling resistance, etc. We would ask that the agencies consider sharing similar details in the Final Rule and/or in guidance memos on how all regulatory input data will be confirmed as valid for vehicles in real-world settings. Confirmatory testing of aerodynamics and GEM inputs, and production vehicle chassis testing, is key to ensuring CO2 and fuel use reductions over the certification tests correlate with reductions in the real world (Sharpe et al, 2014; ICCT, 2015). In order for the real-world testing program to be successful, it will be critical that the emission results from the testing program are shared publicly and that the testing program starts as soon as possible (i.e., in2016 ideally) to discern ongoing and future trends from the earliest possible time. [EPA-HQ-OAR-2014-0827-1876-A1 p.2]

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

Therefore OEMs would have to report worse aero performance to ensure passing an audit, with as much as 5% impact. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]

No compliance margin is provided for engine fuel map audits, compared to the 3% margin allowed in Phase 1 for engine efficiency. Consequently OEMs will likely declare lower engine efficiency than their certification measurement to ensure meeting stringency. In sum, faulty assumptions driven by technology penetration rates, the absence of audit compliance margins could add as much as 17% greater reduction in fuel consumption than the proposed rule estimates. If not addressed, this could prove to be an untenable threshold and market disruptions could very possibly follow. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]

**Organization:** National Association of Clean Air Agencies (NACAA)
1. February 19, 2016 EPA memorandum, *Additional Discussion of Selective Enforcement Audit and Confirmatory Testing for Aerodynamic Parameters for Combination Tractors and for Trailers*

On February 19, 2016, EPA issued a memorandum, *Additional Discussion of Selective Enforcement Audit and Confirmatory Testing for Aerodynamic Parameters for Combination Tractors and for Trailers*, discussing potential approaches to applying the longstanding principles behind selective enforcement audits and confirmatory testing for aerodynamic measurements. In our September 29, 2015 comments on the Phase 2 proposal, NACAA urged EPA “to do everything feasible to implement in-use compliance.” We believe firmly that the integrity of the Phase 2 program and achieving the associated emissions reductions rely upon strong enforcement and compliance tools and that it is imperative for EPA to finalize a program that is enforceable and auditable and includes confirmatory testing. We are, therefore, pleased that the agency has issued this memorandum to provide further insight into enforcement of and compliance with the Phase 2 program (and, potentially, the Phase 1 tractor program). [EPA-HQ-OAR-2014-0827-1890-A1 p.2]

**Organization:** Navistar, Inc.

The NPRM proposes changes in Selective Enforcement Audit (SEA) provisions in both engine and vehicle. The engine compliance margins were carried over in the engine regulation, but not included in the vehicle regulation. For instance, for the fuel map SEA the pass criteria are set at the GEM input value. The engine SEA includes a 3% margin due to variability of engines and test facilities. The SEA of the engine fuel map used in the GEM for the vehicle regulation should also include that same 3% margin. The number of runs does not effectively make up for the lack of a vehicle compliance margin because test variability arising from variations like location conditions may not change run to run. Of particular concern are the provisions that allow SEAs for each component included as a GEM input. This vastly expands the number of subsystems potentially exposed to SEA. [EPA-HQ-OAR-2014-0827-1199-A1 p.10]

The function of an SEA should be to confirm that the vehicle, as certified, achieves in-use emissions levels consistent with its certification. Necessarily, however, this must recognize the inherent variability of vehicle to vehicle performance, particularly when one is looking at one subsystem within the vehicle. Not only may there be variability vehicle to vehicle, but specific test methods with respect to particular systems may be variable as well. [EPA-HQ-OAR-2014-0827-1199-A1 p.10]

It is improper to attempt to create subcategories of features or systems subject to an audit. These functions are not subject to emissions limits in and of themselves. The vehicle or engine as a whole is subject to the emission standard, and that is what should be subject to an SEA. It is arbitrary and capricious to subject a manufacturer to liability for a system that might not meet the defined input when the vehicle as a whole may meet the emissions. This appears to be an inherent flaw in the use of the GEM model. [EPA-HQ-OAR-2014-0827-1199-A1 p.10]

Even if one were to accept that SEAs could apply to individual systems within the vehicle, we have concerns as to the proposal. The primary concern stems around whether the SEA appropriately replicates the conditions under which the certification tests were conducted. Variations between appropriately conducted certification tests and SEA methodology can create significant risks. [EPA-HQ-OAR-2014-0827-1199-A1 p.11]

In the ongoing EPA-sponsored laboratory “Round Robin” test exercise it has been demonstrated that it is unrealistic to expect repeatable CO2 emissions within 3% of the average from one test facility to another. This is the case despite the application of the same cycle validation criteria noted in Table 4 of
1037.550 for each of the participating engine test facilities. This variability is also minimized through
the use of the same engine and charge air coolers at each facility. The variability validates the premise
that individual engine dynamometers configured with equivalent coolant and charge air cooler
components can still yield statistically significant differences. The engine/dynamometer normalized test
schedule accommodates the inherent variability in rotating inertia, load response and speed control to
satisfy the cycle validation criteria. However, these inter-cell or intra-facility differences in
dynamometer configuration and control are sufficient to yield differing results as witnessed in the

This is of considerable concern, since EPA has taken the position that if the agency test arrives at a
different number during a confirmatory test than the number resulting from the manufacturer’s test, the
EPA number is substituted in the certificate of conformity. That number then becomes the official test
value for that vehicle, even if all of the procedures were properly followed by the manufacturer during
the initial certification test. That introduces an unacceptable amount of uncertainty into the certification
process. Confirmatory tests should not be used to change a manufacturer’s tested number based solely
on testing variability. [EPA-HQ-OAR-2014-0827-1199-A1 p.12]

We therefore request that the Proposed Rule be modified to specifically allow a test margin for all
confirmatory tests, or, at the very least, a provision that states that EPA will substitute its confirmatory
number for a manufacturer’s only if it identifies an error in the manufacturer’s certification test
procedures and identifies a different test number as a result. [EPA-HQ-OAR-2014-0827-1199-A1 p.12]

Organization: SmartTruck

In addition to commenting on aerodynamic testing methodology, we direct the following comments to
the Additional Discussion of Selective Enforcement Audit and Confirmatory Testing for Aerodynamic

SmartTruck supports the EPA in its effort to provide dependable validation for aerodynamic devices and
believes that a reliable testing protocol is necessary for the success of GHG Phase 2. The NPRM
outlines a basic guideline for SEA and confirmatory testing structure that closely aligns with the scale
and scope of tractor and trailer vehicle OEMs and provides a verification structure to ensure production
vehicles conform to their certifications. [EPA-HQ-OAR-2014-0827-1923-A1 p.3-4]

In the case of trailer aerodynamics, the agencies have proposed the Aerodynamic Device Testing
Alternative to allow device manufacturers to seek preliminary approval of aero-devices and supply
GEM inputs to trailer OEMs. Recognizing that trailer manufacturing OEMs may have little experience
with aerodynamic testing, it is likely that the majority of trailer aerodynamic testing will be performed
by aerodynamic device manufacturers and provided to trailer OEMs in the form of GEM model inputs
and will be subsequently used in the certification of their trailer families. We therefore seek an SEA and
confirmatory testing structure that will align with the scope and size of device manufacturers in order to
strengthen the GHG Phase 2 program and to utilize our experience with aerodynamic testing to expedite
the certification process for both trailer OEMs and EPA. [EPA-HQ-OAR-2014-0827-1923-A1 p.4]

Although the EPA has provided SEA guidelines for trailer OEMs, the business of manufacturing a
complete vehicle and manufacturing a vehicle component are fundamentally different and should be
reflected in testing protocol. In aerodynamic testing, tractor and trailer OEMs use a vehicle completely
manufactured or assembled by themselves whereas device manufacturers are testing a component
designed to be used on a variety of vehicles, such as dry vans, refrigerated units, and partial-aero
trailers, manufactured by a variety of different OEM manufacturers and a variety of different
configurations. While it makes sense to require a vehicle manufacturer to use the current model year for validation testing, it is unreasonable to require a device manufacturer to do so. For example, a device manufacturer should be able to test its model-year components on a tractor from a prior year. Especially considering that a trailer equipped with an aerodynamic device could be pulled by a tractor from any previous year. Allowing component manufacturers to test with glider kits will further ease the burden. A testing protocol specifically structured for device manufacturers would still give the EPA the right to choose the aero component to be tested but would also allow the device manufacturer greater flexibility in choosing the vehicle to be used for component testing. [EPA-HQ-OAR-2014-0827-1923-A1 p.4]

These fundamental differences are also present in relation to the size of device manufacturers compared to tractor and trailer OEMs, which greatly increase the burden on device manufacturers to comply with the proposed validation testing protocols. While vehicle OEMs have been around for several decades, the majority of aero-device manufacturers have emerged within the last ten years and are represented on just a portion of the market offered by trailer OEMs. Device manufacturers are less likely to have in-house testing facilities such as wind tunnels or test tracks and are less likely to have multiple vehicles of the current model year that can be utilized for testing. The majority of component manufacturers complete testing at third party locations which must be secured several months in advance. These factors further increase the difficulties and burden faced by device manufacturers in complying to a testing structure that is based on large vehicle manufacturers. A unique structure designated for device manufacturers should account for this by allowing device manufacturers greater flexibility in choosing testing facilities pre-approved by the EPA to ensure a greater confidence in SEA and confirmatory testing results. [EPA-HQ-OAR-2014-0827-1923-A1 p.4]

Lastly, in supporting the effort of creating a national greenhouse gas emissions program, aero-device manufacturers are in a position to work closely with the EPA to mitigate the cost and burden of compliance testing for the EPA and to provide trailer manufacturers with a confident process of compliance. By providing full disclosure of all confirmatory documentation to the component manufacturer, the EPA eases the burden by allowing component manufacturers the ability to identify possible concerns in testing results. The full disclosure of SEA and confirmatory testing criteria would also give device manufacturers the ability to mitigate validation proceedings by ensuring a greater confidence in initial certification validation. [EPA-HQ-OAR-2014-0827-1923-A1 p.5]

Organization: Truck & Engine Manufacturers Association (EMA)

A fourth core issue relates to the proposed requirement that engine manufacturers certify fuel maps as a part of their overall certification to the Phase 2 engine standards for reduced CO2 emissions, and that they be required to provide those “certified” fuel maps to vehicle manufacturers (for their input into the updated GEM model) beginning with the 2020 model year (or even as early as 2019). Engine manufacturers would be required to use a new steady-state engine dynamometer test procedure to generate detailed fuel maps for each of their various engine families, which unique fuel maps could be input into GEM during vehicle manufacturers’ certification of their various vehicle configurations. (See Proposed § 1036.535). As a corollary enforcement mechanism, the agencies also are proposing unique selective enforcement audit (“SEA”) provisions for the manufacturer-developed fuel maps. (See Proposed § 1036.301(b)). Such SEA testing would test production engines to determine the fuel-consumption rates at each of the specified points under the engine fuel map, and then would use those SEA-measured values as inputs in GEM to generate comparisons against the manufacturer’s declared GEM results at certification. EPA would be allowed to audit and test through GEM simulations up to ten (10) unique vehicle certifications using the SEA-derived fuel map. [EPA-HQ-OAR-2014-0827-1269-A1 p.5]
There are a number of very serious issues relating to the agencies’ proposed fuel-mapping and related SEA requirements. As an initial matter, the proposed engine fuel map would include 143 operating test points (13 speed points with 11 torque values at each speed point) and 4 idle test points, a very large number, which represents a dramatic increase over the Phase 1 engine testing requirements. Moreover, that testing burden would have very significant consequences, since the test results from the 143-point fuel mapping process would become the declared values that vehicle manufacturers would use for certification purposes. [EPA-HQ-OAR-2014-0827-1269-A1 p.5]

That leads to another fundamental concern. The agencies’ proposed SEA testing procedure includes no margin whatsoever for the modeled GEM emission results. Under the agencies’ proposal, if there is any shortfall between the GEM results using the SEA-derived fuel map (in up to 10 vehicle configurations) as compared against the GEM results reported using the engine manufacturer’s original fuel map (which, in effect, creates 10 chances to “fail”), the engine manufacturer’s certification could be suspended or revoked. (See Proposed § 1036.301(d)). Such a high-risk testing regime, with attendant liability, including the possible revocation of a manufacturer’s engine certification, is unreasonable and would impose inherently infeasible requirements on engine manufacturers. Lab-to-lab variability, test-to-test variability, and engine-to-engine variability all need to be accounted for through the allowance of sufficient data-driven testing margins. As it stands, the agencies’ proposed SEA process for the 143-point engine fuel maps is not reasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.5]

Unless EPA and NHTSA address the testing burdens and inherently infeasible SEA requirements associated with the proposed requirement for certified engine fuel maps, the Proposed Phase 2 vehicle standards could prove to be unworkable. As stated above, EMA stands ready to work with the agencies to implement the necessary revisions to the various engine-mapping issues. EMA’s recommendations in that regard are set forth below. [EPA-HQ-OAR-2014-0827-1269-A1 p.5-6]

As noted above, a compliance margin is needed for the proposed “certified” fuel maps. However, proposed section 1036.301 does not include any compliance margin whatsoever for an SEA of the fuel map input into GEM, despite the inherent inaccuracies in the fuel map development procedure (see Proposed § 1036.535). Without an audit compliance margin in the rule, manufacturers would have to build a margin into their fuel maps (resulting in higher GEM inputs) to ensure passing an SEA, which would make achieving the GEM output targets significantly more challenging. The Phase 1 rule provides a 3% compliance margin for the engine certification program. For the same reasons that the margin is used in engine certification, the 3% compliance margin (at a minimum) should be implemented for the fuel-map based GEM results as well. Stated differently, a 3% compliance margin should be applied to the GEM result obtained using a certified fuel map when assessing whether an engine/vehicle passes a confirmatory or SEA test. [EPA-HQ-OAR-2014-0827-1269-A1 p.23]

Recent collaborative emissions-measurement research has demonstrated the continuing need for and suitability of a 3% compliance testing margin for GHG emissions. More specifically, EPA and EMA are currently involved in a collaborative “round-robin” engine testing program (managed by Southwest Research Institute (“SwRI”)) to assess the extent of emissions-testing variability when the same test article (a heavy-duty motor vehicle engine) is tested at eight different Part-1065-compliant emissions-testing laboratories, including EPA’s facilities in Ann Arbor, Michigan. The round-robin testing program has assessed the lab-to-lab variability for a number of regulated emissions, including CO2. The round-robin results for CO2, which are presented below, show that there is a 2.0% variability (as a percentage of the relevant standard) for CO2 emissions assessed over the FTP test cycle. (Additional production variability, which ranges from +/- 2%, also needs to be accounted for). In light of those results, there is no basis for EPA to eliminate the 3% compliance margin that was included in the Phase 1 program. [EPA-HQ-OAR-2014-0827-1269-A1 p.23]
In addition, EMA is in the process of commissioning follow-up research at SwRI to derive data to better quantify and account for the specific test-to-test and production variability relating to any subsequent audits of fuel maps. A copy of the SwRI proposal for that follow-up research is attached as Appendix “1.” EPA and NHTSA should commit to co-funding and incorporating the results of that research into any final audit regulations and procedures. [EPA-HQ-OAR-2014-0827-1269-A1 p.26]

Finally, the fuel-map audit process should be more clearly defined and more predictable through the incorporation of pre-defined standard vehicle configurations for use in audit testing. [EPA-HQ-OAR-2014-0827-1269-A1 p.26]

**Organization:** Truck Trailer Manufacturers Association (TTMA)

The Truck Trailer Manufacturers Association (TTMA) is an international trade association representing approximately 90% of the truck-pulled trailers manufactured in the United States. TTMA has a history of working closely with regulators to help them understand the unique nature of the heavy-duty trailer industry and to act as a conduit between the member companies and regulators. TTMA is offering this comment in response to the Notice of Data Availability published in the Federal Register March 2, 2016. [EPA-HQ-OAR-2014-0827-1873-A1 p.1]

Specifically, we will be commenting on the Environmental Protection Agency’s Memorandum titled Additional Discussion of Selective Enforcement Audit and Confirmatory Testing for Aerodynamic Parameters for Combination Tractors and for Trailers (the Memo hereafter). [EPA-HQ-OAR-2014-0827-1873-A1 p.1]

As noted in the proposed rule’s Preamble, there are “a large number of small businesses in this industry”. The agencies recognized that performance testing requirements “would be the more challenging obstacles for this newly regulated industry.” As such the agencies designed the proposed rules in such a way as to allow most trailer manufacturers to build without full testing of trailers, by passing-through tested components and using a change in CDA value, along with a discounting formula when multiple devices are used. We anticipate that if the rule advances as written, most trailer manufacturers will make use of this pass through system, with the larger manufacturers performing some of their own testing, often relying on CFD and Wind Tunnel data to contain costs in an industry the agencies admit “is very competitive”. [EPA-HQ-OAR-2014-0827-1873-A1 p.2]

As such, the sort of repetitive coast-down tests (twenty to a hundred coast-down runs per device tested) will be rarely employed by trailer manufacturers. [EPA-HQ-OAR-2014-0827-1873-A1 p.2]

If EPA singles out a certain manufacturer for Selective Enforcement Action (SEA) and requires the manufacturer to pay for these expensive tests, we would view the SEA itself as punitive. [EPA-HQ-OAR-2014-0827-1873-A1 p.2]

For manufacturers who are only using pass-through data, they should be immune to SEA’s requiring coast-down tests in favor of investigations focusing on the supplier of the component. For those suppliers, the use of coast-down data related to the bin the eventual trailer it goes on are not properly applicable. An entirely different approach to audit a component manufacturers is called for: one that should focus on the integrity of the tests used to obtain a delta CDA or CRR (or even to verify the performance of an Automatic Tire Inflation System). [EPA-HQ-OAR-2014-0827-1873-A1 p.2]
In the proposed rule, §1037.301(d) requires that with respect to drag area, manufactures are directed to “use the same method you used for certification” which better reflects the realities of the trailer world. The Memo’s methodology of generally allowing extra tests to be performed if early tests show unexpected results can and should be applied to all approved certification methods. [EPA-HQ-OAR-2014-0827-1873-A1 p.2]

We thank you for this opportunity to comment on new data and remain available to answer any questions you may have. [EPA-HQ-OAR-2014-0827-1873-A1 p.2]

The assumption that there is no need to provide any compliance testing margin, SEA testing margin, engine fuel map margin, or coastdown testing margin is manifestly unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.72

Organization:  Volvo Group

The lack of margins for aerodynamic and engine map audits would force us to understate our certified efficiency inputs to ensure passing a subsequent audit. [EPA-HQ-OAR-2014-0827-1290-A1 p.10]

Excessive stringency results in uncertainty that the proposal can be implemented, excessive cost, unreliable products, delays in new vehicle purchases, production disruption, lay-offs, and delays in achieving benefits. Volvo supports comments by EMA relative to stringencies and we elaborate on our concerns below. [EPA-HQ-OAR-2014-0827-1290-A1 p.18]

Engine Fuel Mapping and Audit

As noted in EMA’s comments, at least 3% margin needs to be provided for a Selective Enforcement Audit (SEA) of the fuel map to account for production and measurement variability. Otherwise, even with 60% accepted quality level (AQL), we will be forced to downgrade our mapped efficiency due to production and test variability that is equal to, or greater than, the feasible engine improvement steps. Alternatively, the Agencies need to reduce the assumed baseline engine efficiencies and the vehicle standards that rely on engine map inputs. [EPA-HQ-OAR-2014-0827-1290-A1 p.37]

Furthermore, we cannot agree that the Agencies should be able to test the engine map over as many as 10 vehicle configurations, determined only at the time of an SEA, failure on any of which constitutes an audit failure. A single, predetermined vehicle configuration that exercises the typical range of engine operation is more than adequate. This vehicle configuration could be standardized for Class 8 tractor and vocational vehicles or could be agreed upon as part of each engine certification. [EPA-HQ-OAR-2014-0827-1290-A1 p.37]

Organization:  Cummins, Inc.

Cummins opposes engine-only testing for powertrain SEA [EPA-HQ-OAR-2014-0827-1298-A1 p.39]

As part of powertrain testing, 40 CFR 1037.550(q) requires manufacturers to record engine speed and torque over the powertrain cycles. The recorded engine speed and torque would then be used to test only the engine as part of an SEA instead of testing a complete powertrain. Cummins has concerns with this approach as a powertrain SEA surrogate. [EPA-HQ-OAR-2014-0827-1298-A1 p.39-40]
An SEA is the method EPA uses to assess a manufacturer’s certified configuration against submitted test results; however, if a powertrain SEA is completed using an engine-only test, the SEA would only verify the compliance of production engines over powertrain cycles. Absent are GHG/FE impacts associated with variation in powertrain characteristics such as transmission efficiency and, most importantly, the interaction of the engine and transmission controllers. The highly complex controls of the engine and transmission actively manage, together, how the vehicle required torque is met, which is a critical part of the integration of an optimized powertrain. Not capturing these control interactions may result in elevated emissions for an engine-only test and a failed SEA. Furthermore, it is not clear how efficiency losses from the transmission would be accounted for when running an engine-only powertrain SEA. [EPA-HQ-OAR-2014-0827-1298-A1 p.40]

For the above reasons, Cummins does not support the engine-only test as a means of a powertrain SEA. [EPA-HQ-OAR-2014-0827-1298-A1 p.40]

**Organization:** Eaton Vehicle Group

**Conformity testing issues**

A simple conformity testing procedure has been suggested as follows: at the time of powertrain certification, a time trace of the transmission gear and load should be recorded and then used in subsequent conformity testing actions on an engine dynamometer. Thus, conformity testing can be done in engine-only mode. However, this approach is close to the “simulated transmission” substitute for the powertrain test and we believe it cannot be applied to the highly integrated engine and transmissions. The two controllers exchange information in real time and make decisions based on each other’s inputs. Thus, when the engine is exposed to a time-trace of a previous run, A) it has no transmission ECU to communicate with, and B) the any results that differ from the initial run would be inconclusive. [EPA-HQ-OAR-2014-0827-1194-A1 p.10-11]

**Recommendation:** The conformity tests for powertrains should be clarified with discussions with engine, transmission and vehicle manufactures. [EPA-HQ-OAR-2014-0827-1194-A1 p.11]

**Response:**

EPA requested comment on our provisions related to confirming a manufacturer’s test data during certification (i.e., confirmatory testing) and verifying a manufacturer’s vehicles are being produced to perform as described in the application for certification (i.e., selective enforcement audits or SEAs). The EPA confirmatory testing provisions for engines and vehicles are in 40 CFR 1036.235 and 1037.235. The SEA provisions are in 40 CFR 1036.301 and 1037.301-1037.30. The NHTSA provisions are in 49 CFR 535.9(a).

Commenters generally supported the inclusion of confirmatory and SEA testing provisions. However, as discussed below, several industry stakeholders requested changes to the proposed provisions.

ICCT requested that we include additional details in the FRM, which we have done.
Compliance Margins

Some commenters suggested that the agencies should apply a compliance margin to confirmatory and SEA test results to account for test variability. However, other commenters supported following EPA’s past practice, which has been to base the standards on technology projections that assume manufacturers will apply compliance margins to their test results for certification. In other words, we effectively require manufacturers to design their products to have emissions below the standards by some small margin so that test-to-test or lab-to-lab variability would not cause them to exceed any applicable standards. Consistent with this policy, EPA has typically not set standards precisely at the lowest levels achievable, but rather at slightly higher levels – expecting manufacturers to target the lower levels to provide compliance margins for themselves. As is discussed in Sections II through VI of the FRM, the agencies have applied this approach to the Phase 2 standards.

It is also important to consider the specific consequences that occur if emissions (or other measured GEM inputs) measured during confirmatory or SEA testing are worse than the declared values. If this occurs during confirmatory testing, the manufacturer simply continues on with the certification process using the new EPA values. It is not considered a violation. For SEAs, the test engine would be considered a failure, but no action would be required unless a large number of engines failed. In neither case would small variations in measured results lead to financial penalties for the manufacturer.

As discussed in Section I.C.(1)(a) of the FRM Preamble, we assume manufacturers will incorporate appropriate compliance margins for all measured GEM inputs. In other words, they will declare values slightly higher than their measured values. As discussed in Section II.D.(5) of the Preamble, compliance margins associated with fuel maps are likely to be approximately one percent. For aerodynamic inputs, we believe the bin structure will eliminate the need for CdA compliance margins for most vehicles. However, for vehicles with measured CdA values very near the upper bin boundary, manufacturers will likely choose to certify some of them to the next higher bin values (as a number of commenters noted). For tire rolling resistance, our feasibility rests on the Phase 1 standards, consistent with our expectation that manufacturers will continue to incorporate the compliance margins they considered necessary for Phase 1. With respect to optional axle and/or transmission power loss maps, we believe manufacturers will need very small compliance margins. These power loss procedures require high precision so measurement uncertainty will likely be on the order of 0.1 percent of the transmitted power. All of these margins are reflected in our projections of the emission levels that will be technologically feasible.

Fuel Map Confirmatory Testing

We are making several changes to the proposed EPA confirmatory testing provisions in response to comments. First, the regulations being adopted specify that EPA will conduct triplicate tests for engine fuel maps to minimize the impact of test-to-test variability. The final regulations also state that we will consider entire fuel maps rather than individual points. Engine manufacturers objected to EPA’s proposal that individual points could be replaced based on a single test, arguing that it effectively made the vehicle standards more stringent due to point-to-point and test-to-test variability. We believe that the changes being adopted largely address the concerns raised in the comments. We are also applying this approach for axle and transmission maps for similar reasons.

Manufacturers pointed to a round-robin test program showing significant variability between test sites. However, those results were not corrected for fuel properties, as is required for both Phase 1 and Phase 2 testing. Thus, they do not represent variability that would be expected to occur with EPA compliance testing. Nevertheless, the agencies do see value in working with manufacturers on the type of research project suggested by EMA.
It is worth noting that round-robin data did show that test-to-test variability within a given laboratory (where fuel properties would be constant) is on the order of one-half percent with existing equipment. It is likely that, as long as differences in fuel properties are corrected, lab-to-lab variability should be similar. Thus, we believe that overall test variability for engine testing will be about one percent in the Phase 2 time frame.

Daimler commented that EPA should evaluate the manufacturer's fuel maps using GEM for confirmatory testing. However, it is not necessary to constrain EPA testing in this manner. EPA has long treated its confirmatory results as official emission results that are fully valid.

**SEAs for Fuel Maps**

We have revised the SEA procedures for fuel maps in response to comments. The final provisions will evaluate fuel maps using four pre-defined GEM vehicle configurations. Volvo recommended that EPA use a single GEM configuration, but we believe this would not cover a broad enough range of the fuel map.

**Aerodynamic Testing**

As described in Section 4, EPA has modified the SEA regulations for verifying aerodynamic performance. These revised regulations differ somewhat from the standard SEA regulations to address the unique challenges of measuring aerodynamic drag. In particular, EPA recognizes that for coastdown testing, test-to-test variability is expected to be large relative to production variability. This differs fundamentally from traditional compliance testing, in which test-to-test variability is expected to be small relative to production variability. To address this difference, the modified regulations call for more repeat testing of the same vehicle, but fewer test samples.

Comments from the trailer industry supported less burdensome confirmatory and SEA procedures, even to the point of excusing manufacturers relying on supplier data from any test requirements or liability. Although, the statutes do not allow us to completely excuse certifying manufacturers in this way, we understand these concerns. Therefore, the agencies plan to work with industry to minimize compliance burdens. In particular, we plan to limit SEAs to those cases in which we have a reason to believe the products are not fully compliant with the regulations.

**Test Procedures**

Daimler objected to text in the proposed §1037.551 that states:

> These engine-based measurements may be used for confirmatory testing as described in §1037.235, or for selective enforcement audits as described in §1037.301, as long as the test engine’s operation represents the engine operation observed in the powertrain test.

However, Daimler does not appear to understand how this provision would be used. First, they ignore the end of the text which clearly makes it apply only where “the test engine’s operation represents the engine operation observed in the powertrain test.” Under this provision, manufacturers certifying using powertrain testing are required to measure speed and load values to allow for engine testing. Thus, testing would only occur over the manufacturer’s specified cycle. Moreover, since the manufacturers perform all SEA testing, this would be an option for the manufacturer rather than something imposed by EPA. So perhaps Daimler objects to the narrow circumstance in which EPA performs confirmatory engine testing of an engine that was certified using powertrain testing, follows the manufacturer’s
specified engine test cycle, and ensures that the test accurately represents the engine’s performance during the powertrain test. However, it is not clear why this would be problematic. It is reasonable to assume that testing the engine in this way would result in equivalent emission results. Moreover, a strict requirement to require powertrain testing by EPA in such cases could lead to other problems for manufacturers. In particular, we note that in the case of an EPA confirmatory engine test indicating the manufacturer’s powertrain fuel map is not accurate, the alternative would be to delay certification until EPA can perform a confirmatory test of the powertrain.

Cummins and Eaton also raised concerns about this approach. In particular, Cummins stated that not capturing control interactions could result in elevated emissions for an engine-only test. But again, a condition of this provision is that the test engine’s operation must represent the engine operation observed in the powertrain test. Cummins’ question about how efficiency losses from the transmission would be accounted for when running an engine-only test ignores the specification that the cycle be specified based on engine torque rather than transmission torque. To the extent Cummins concerns remain, they would be free to certify their engines based on engine-only fuel maps rather than powertrain testing.

SmartTruck commented that a device manufacturer should be able to test its model-year components on a tractor from a prior year. This is allowed. SmartTruck also commented that the agencies should allow device manufacturers greater flexibility in choosing testing facilities pre-approved by the EPA to ensure a greater confidence in SEA and confirmatory testing results. However, the program is already structured to allow manufacturers to choose any facilities for their SEAs. With respect to confirmatory testing, we note that the agencies (not the manufacturers) perform that testing.

Supplier Data

Daimler commented that for inputs from a component supplier (such as an axle manufacturer) the agencies “should require only that the vehicle manufacturer used that supplier’s input in good faith” and suggested that this is the current policy for tire inputs. However, Daimler is not correct in claiming that this is the Phase 1 policy for tires. They appear to be misinterpreting text that attaches some liability for tire manufacturers to mean that there is no liability for vehicle manufacturers. In general, the certificate holder is responsible for compliance for all aspects of the vehicle covered by their certificate, even if the agencies find another manufacturer to also be responsible.

1.4.4 Delegated assembly (dividing responsibility among manufacturers) 147

Organization: American Automotive Policy Council

Vocational A/C Delegated Assembly Concerns

EPA is proposing to add vocational vehicles to the heavy-duty air conditioning leakage requirement beginning with MY2021 using the same SAE J2727 design approach used in Phase 1. While AAPC agrees that the design approach for calculating leakage is correct, we are concerned regarding responsibilities for compliance and certification. [EPA-HQ-OAR-2014-0827-1238-A1 p.20]

Currently, for non-air conditioning related system compliance, a secondary manufacturer can use the first manufacturer’s Certificate of Conformity (COC) if the system is not modified and the vehicle does not exceed certain criteria such as GVWR and Frontal Area. However, for heavy-duty applications, there will be numerous cases where the second manufacturer will modify or add to the air conditioning system. In these cases it should be clear that it is the second manufacturer’s responsibility for
compliance and certification of the completed air conditioning system for leakage. In such cases, the secondary manufacturer should also be responsible to attest to the durability of the complete A/C system. Once an A/C system has been modified, the integrity of the resulting system depends as much on the workmanship of the modifier as it does on the workmanship of the original manufacturer. Only the entity making the modifications can attest to durability of the final, as-modified system. Original manufacturers should not be held responsible for any alterations to the A/C system outside of their control. [EPA-HQ-OAR-2014-0827-1238-A1 p.20-21]

**Organization:** Truck & Engine Manufacturers Association (EMA)

[T]he proposed changes to the Phase 1 requirements for delegated assembly should not be finalized, as those changes also would amount to retroactive amendments to the overall stringency and cost of the Phase 1 program in violation of administrative due process and the CAA’s leadtime and stability provisions. In sum, there is no reason to pull those proposed provisions forward, especially when to do so would disrupt the implementation and feasibility of Phase 1. [EPA-HQ-OAR-2014-0827-1269-A1 p.22]

**Organization:** Daimler Trucks North America LLC

**Changes to Phase 1:** There should be no changes to Phase 1. 80 FR 40519. It is too late for us to revise aero numbers or our delegated assembly procedures, given the agencies’ lead time requirements, which require four years’ lead time for NHTSA and require a joint program for the EPA (see Massachusetts v. EPA 549 U.S. 497, 532, 2007, where the Supreme Court stated that “there is no reason to think the two agencies [EPA and NHTSA] cannot both administer their obligations and yet avoid inconsistency”). We are busy working on Phase 2, to go back and adjust computer systems or delegated assembly at this point in time is too much for our limited groups. [EPA-HQ-OAR-2014-0827-1164-A1 p.111]

**Organization:** Aperia Technologies

As a prospective certifying manufacturer of automatic tire inflation systems and for the reasons below, Aperia Technologies (Burlingame, CA) supports the delegated assembly provision proposed for inclusion in 40 CFR 1037.621 providing for an ‘allowance for vehicle manufacturers to sell or ship vehicles that are missing certain emission-related components if those components will be installed by a secondary vehicle manufacturer’: [NHTSA-2014-0132-0104 p.1]

- Impacts on real-world operational efficiency and greenhouse gas emissions of vehicle configurations are path-independent; it doesn’t matter who installs the device, just that it works. [NHTSA-2014-0132-0104 p.1]

- Such flexibility will enable faster adoption of good technology, no matter who builds it or when it gets installed. OEMs will be incented to find good technology partners, just as the market for development and commercialization of differentiated technologies by after-market manufacturers will be catalyzed toward higher competition and faster innovation. [NHTSA-2014-0132-0104 p.1]

- Certain technologies, like Aperia's Halo Tire Inflator, enable fast installation on both new and existing fleet vehicles. For such technologies, the delegated assembly provision applicable to new vehicles is likely to induce accelerated adoption among existing fleet vehicles. [NHTSA-2014-0132-0104 p.1]

We advocate the following specifically: [NHTSA-2014-0132-0104 p.1]
We recommend that automatic tire inflation systems be added to aerodynamic devices and air conditioning systems as key aftermarket technologies. Currently, draft Phase 2 regulation does not propose to limit the use of delegated assembly to aerodynamic devices and air conditioning systems, but nonetheless focuses only on those two. [NHTSA-2014-0132-0104 p.1]

Organization: Association for the Work Truck Industry (NTEA)

Deligated Assembly

Vehicles produced by NTEA member companies for commercial or vocational use include, but are not limited to, dump trucks, utility company vehicles, aerial bucket trucks, tow trucks, beverage delivery trucks, digger derricks, snow removal vehicles, agricultural platform and stake body trucks, fire trucks, ambulances and a host of other specialized configurations.

The typical NTEA distributor member (a FSM by NHTSA definition) is capable of producing an almost endless variety of vehicle configurations. They can mount any one of numerous body types and work equipment on a chassis of any size from any of the manufacturers. For instance, the same company may mount a utility body on a Dodge chassis one day, an aerial bucket on a Ford chassis the next day, a dump body on a Freightliner, a stake body on a GM or a telescoping crane on a Peterbilt, etc… Items such as toolboxes, winches, lift gates and ladders might also be added before the vehicle is completed.

The NTEA’s Membership Roster and Product Directory lists over 129 separate body types. Each of these body types could be mounted to multiple truck chassis from multiple chassis manufacturers. In addition, multiple combinations of equipment (ladder racks, winches, snow plows, salt spreaders, light bars, towing hardware, lift gates and hundreds of other mountable components) can be added to any of the aforementioned chassis/body combinations.

In EPA’s existing regulations (40 CFR 1068.261), engine manufacturers may sell or ship engines that are missing certain emission-related components if those components will be installed by the vehicle manufacturer. According to this proposal EPA would provide a similar allowance for vehicle manufacturers to sell or ship vehicles that are missing certain emission-related components if those components will be installed by a secondary vehicle manufacturer. [EPA-HQ-OAR-2014-0827-1187-A1 p.5]

The NTEA supports the EPA concept of delegated assembly. This concept could allow for greater adoption of advanced fuel savings and emission reducing technologies. Due to the nature of the manufacturing process for vocational trucks, there is little or no recognition currently for work done on a vehicle after it leaves the chassis manufacturer and before it is sold to the customer. Intermediate and final stage manufacturers can, and do, perform manufacturing operations that positively affect fuel efficiency and emissions. [EPA-HQ-OAR-2014-0827-1187-A1 p.5]

We would like to suggest that the requirement for written instructions for completion/alteration of the vehicle and/or its emissions-related components be made more flexible such that those instructions come from the most appropriate entity. For instance, if a chassis manufacturer has contracted with a hybrid drive manufacturer for installation of a hybrid drive system on the chassis manufacturer’s otherwise completed chassis, the instructions for installation may best be provided by the hybrid drive manufacturer rather than the chassis manufacturer. [EPA-HQ-OAR-2014-0827-1187-A1 p.5]

The NTEA supports the concept of delegated assembly in which manufacturers involved in the production of trucks after the emissions certification process by the engine and chassis manufacturers
can contribute and be recognized for the emissions reduction their work and products creates. These intermediate and final stage manufacturers or alterers would be bound contractually, rather than by regulation to install specified products that result in specified regulatory benefits that can be used by the certifying manufacturer. [EPA-HQ-OAR-2014-0827-1187-A1 p.6]

**Organization:** California Air Resources Board (CARB)

The CARB staff supports the approach delineated in 40 CFR 1037.620-622 which defines the responsibility for each entity involved in an engine/vehicle with multiple manufacturers. This clearly defined approach will make it evident which party is responsible for every facet of the engine/vehicle. [EPA-HQ-OAR-2014-0827-1265-A1 p.190]

CARB staff further believes that 40 CFR1037.622 (page 40654 of the NPRM, paragraph (5)) should use “site” instead of “cite” (“[T]he secondary manufacturer must identify the regulatory cite site identifying the applicable exemption instead of a valid family name when ordering engines from the original vehicle manufacturer.”). [EPA-HQ-OAR-2014-0827-1265-A1 p.190]

**Organization:** CALSTART

Delegated Assembly Modification. This is salient to flexibility for the following reasons. For example, while the draft fuel economy rule does call out work site idle as part of potential “off cycle” credits, because this equipment is often added in the final stage of assembly, or even the aftermarket, it is not normally added with the involvement of or at the designation of the chassis OEM. Therefore, we are concerned that without a mechanism that matches this market structure dynamic the rule will not adequately recognize such systems that can reduce or eliminate a significant component of idling, and there will be less regulatory compliance value in supporting the development and addition of these systems. The result will be leaving significant fuel savings and emission reductions off the table. As one industry supplier noted in private comments to us, “By nature, there is usually a lot of reluctance from [an] OEM to adopt and incorporate advanced technologies, especially when it comes from second or third tier suppliers. Credits, with potential multipliers, would give OEMs incentives to adopt these technologies.” [EPA-HQ-OAR-2014-0827-1190-A1 p.6-7]

One approach we think useful to explore could be an expansion or modification of the delegated assembly provision to allow final stage or aftermarket suppliers to generate credits beyond those “delegated” by an OEM, and to be able to offer those credits back to an OEM. Ideally, the long term goal is to drive greater integration of such functions, but realistically, the innovation and installation of such systems currently takes place outside the OEM and often without the direct control or knowledge of the OEM, and the rules as drafted do not recognize this. An approach such as this could be a highly valuable design that would capture these savings and make them available to the OEM for compliance flexibility. However, as noted, such as expansion is not useful if stringency levels remain at proposed levels, as the OEM would have no need to use them. [EPA-HQ-OAR-2014-0827-1190-A1 p.7]

The introduction of the “delegated assembly” provision for vehicle manufacturers increases the flexibility for both primary and secondary manufacturers but needs further refinement, as noted earlier in our comments. While the delegated assembly provisions better reflect the work truck market, they still require that the certifying manufacturers be aware of the final state of the vehicle. This does not reflect current business practices, where chassis are up fitted before final delivery to the customer but well after point of sale from a chassis manufacturer’s perspective. [EPA-HQ-OAR-2014-0827-1190-A1 p.8-9]
In the proposal, this provision was identified as a strategy for secondary manufacturers responsible for modest alterations to the vehicle (e.g., attaching aerodynamic devices); however, it is applicable to secondary manufacturers more broadly, including manufacturers whose systems alter the powertrain on the vehicle, and we request that the agencies explicitly identify this as a pathway for advanced technologies. These mechanisms could also be used for technologies that reduce fuel use in idling. [EPA-HQ-OAR-2014-0827-1190-A1 p.9]

We also request that the agencies expand the use of the “delegated assembly” provision to Class 2b/3 complete vehicles. These changes will help increase flexibility for manufacturers and provide additional certainty around how fuel reduction solutions from secondary manufacturers can be captured by the regulatory process. [EPA-HQ-OAR-2014-0827-1190-A1 p.9]

Organization: Daimler Trucks North America LLC

10. Delegated Assembly and Body Builder Instructions

· **Delegated assembly, general comment:** We believe that the EPA should not expand its current delegated assembly procedures either in Phase 1 or in Phase 2. The current procedures require that a manufacturer ensure a vehicle is in its certified configuration by the time it reaches the ultimate purchaser. But the current regulations allow manufacturers significant leeway in doing so. For example, the current § 1037.620 allows manufacturers to ship vehicles to secondary manufacturers as long as the vehicles “will be in their certified tractor [or vocational] configuration before they reach ultimate purchasers.” This allows manufacturers to, for example, send vehicles with natural gas engines to natural gas tank installers without any unnecessary paperwork burden. The EPA does provide that “delegated assembly provisions may apply” (emphasis added), but the agency does not provide that they do. Moreover, the existing delegated assembly provisions in Part 1068 do not apply in such circumstances. We recommend that the EPA continue this approach as 1) there is no evidence that manufacturers are somehow sending to ultimate purchasers uncertified vehicles and 2) the paperwork burden presented by delegated assembly is impossibly large. Regarding the paperwork burden, unlike with delegated assembly of engines for which there are a small number of vehicle manufacturers all of which are known to the engine manufacturers, there are a large number of secondary vehicle manufacturers and primary vehicle manufacturers might not even know them or what they do—thus making it extremely difficult to require the primary manufacturers contract with them. For example, there are secondary manufacturers that add aerodynamic components, modify sleepers, add auxiliary AC components, etc. But a primary manufacturer often has no awareness that this will happen. These secondary manufacturers are required to comply with the Part 1037 regulations and ensure that the resulting vehicle complies with the regulations prior to releasing the vehicle to the ultimate purchaser; that should be enough. Requiring the primary manufacturer to police all the people who might modify the vehicles is unnecessary. So as a general comment, we recommend that the EPA stick with the minimal delegated assembly rules. [EPA-HQ-OAR-2014-0827-1164-A1 p.103]

The agencies specifically ask for comments on how the procedures should be applied more broadly or more narrowly for specific technologies. 80 FR 40328. The above statements apply to all types of technologies: as happens with incomplete vehicles under NTHSA regulations, the EPA should understand that vehicle manufacturing is a multi-stage process (regardless of the technologies on the vehicles) and that each stage of manufacturer has the incentive to properly complete manufacturing—without burdensome contracts and audits. Rather, the EPA should continue the longstanding industry practice of allowing primary manufacturers to pass incomplete vehicles with incomplete vehicle documents to secondary manufacturers who complete the installation according to 1) their normal practices (with which the primary manufacturer is often not familiar) and 2) the IVDs. No more is
necessary, nor is more necessary for certain types of technologies. [EPA-HQ-OAR-2014-0827-1164-A1 p.103]

- **Complete vehicles:** We wish to clarify the agencies’ general approach, as discussed in meetings on August 25 and 26. The agencies stated that their intent with the proposed delegated assembly regulations is unclear. The agencies stated that they intend for tractors and chassis cabs to be considered complete vehicles under these regulations, so that the vehicles can be labeled as compliant and so that manufacturers need not follow any delegated assembly procedures with such vehicles. For example, the agencies stated that they do not intend to require primary vehicle manufacturers to provide components’ installation instructions to body builders unless the components are emission related components described in a certificate of conformity. We agree with this approach. [EPA-HQ-OAR-2014-0827-1164-A1 p.103-104]

- **Secondary manufacturers and delegated assembly:** it seems that the EPA has the right approach with 1037.620 and .801, where the EPA says that manufacturers only become secondary manufacturers if they put a vehicle into its final certified configuration or modify it from a certified configuration. Those are the only instances when the EPA should regulate the secondary manufacturer or the interaction between the primary and secondary manufacturers. Moreover, only when the primary manufacturer arranges for the secondary manufacturer to complete the process of getting a vehicle into its certified configuration should there be any reason to involve the primary manufacturer in delegated assembly requirements. Rather, if a primary manufacturer introduces into commerce a chassis-cab that meets the GHG regulations, that should be the end of the primary manufacturer's responsibilities; it should be between the EPA and the secondary manufacturer to ensure that the secondary manufacturer does not remove or render inoperative elements of emission control. On more minor notes: First, the EPA has a typo in 1037.621, in that the regulation references 'paragraph (f) of this section' yet the section only has paragraphs (a) and (b). Second, the EPA's addition of the provision in 1068.261(c)(7)(ii), that manufacturers add 'Del Assy' to the cert labels of incomplete vehicles, is unnecessary in many cases. Moreover it is burdensome. Labeling of vehicles is a lot more complex than labeling of engines, involving more calculations and varieties of information. In turn, it is more difficult to add text, especially if it is unnecessary. For many vehicles, like those sold without natural gas fuel systems (which the secondary manufacturers install), the vehicles cannot be driven until the secondary manufacturer completes its processes. So there is no concern about the vehicle being driven on road in a noncompliant state (except perhaps for driving as a part of manufacturing or testing). The EPA should not require additional burdensome labeling for such vehicles. 1037.650 / .621 / .801 [EPA-HQ-OAR-2014-0827-1164-A1 p.104]

- **Changes to secondary manufacturing and delegated assembly should be delayed until Phase 2, not implemented in the middle of Phase 1:** the EPA proposes to make changes to multi-stage manufacturing processes by adding the requirements of 1068.261, through 1037.621. This is a major change to the process necessary to manufacture vehicles and should not be implemented in a short time frame: manufacturers need a long time to work with their various secondary manufacturers and implement the procedures that the EPA demands (such as annual affidavits of part numbers, contractual obligations, and record keeping). While these are not huge burdens, they are new and they may involve many secondary manufacturers, including small businesses, such that implementation will take significant time and effort. Better yet, the EPA should simply regulate at the vehicles' sale to an ultimate manufacturer, not partway through the manufacturing process. Also the provisions of 1037.622(b)(5), the new (5), are unclear. Why would there be ‘no valid family name’ for a vehicle? When does this provision apply? 1037.621 [EPA-HQ-OAR-2014-0827-1164-A1 p.104]
Cert labels for delegated assembly vehicles: We agree that the EPA takes the right approach by omitting HDVs from provision § 1068.261(c)(7)(ii), which requires that manufacturers add 'Del Assy' to the cert labels of incomplete vehicles. This is burdensome and, in the case of HDVs, is unnecessary. Labeling of vehicles is a lot more complex than labeling of engines, involving more calculations and varieties of information. This complexity more difficult to add text, especially if it is unnecessary. For many vehicles, like those sold without natural gas fuel systems (which the secondary manufacturers install), the vehicles cannot be driven until the secondary manufacturer completes its processes. So there is no concern about the vehicle being driven on road in a noncompliant state (except perhaps for driving as a part of manufacturing or testing, which the agency explicitly allows). The EPA should not require additional burdensome labeling for such vehicles when there will be no benefit. [EPA-HQ-OAR-2014-0827-1164-A1 p.105]

Delegated Assembly – Concerns with the text as written: As the text that follows will show, we need some clarification that we have correctly understood the EPA’s intent. Assembly instructions for secondary vehicle manufacturers: it seems that the EPA wants truck manufacturers to include assembly instructions with each truck sold without the body (like the box van), which is nearly all trucks. In 1037.130, the EPA proposes to require that the truck manufacturers tell those body installers how to install bodies in a manner compliant with the GHG standards. But it is not clear how things like a box van are subject to the GHG regulations or how a truck manufacturer would have any expertise in installing box vans or the variety of bodies that might get put onto a truck. We request that the EPA clarify what the agency expects truck manufacturers to tell these body installers, and we suggest that the EPA limit any such instructions to areas of truck manufacturers’ expertise. In other words, manufacturers should not have to tell body installers how to mount equipment or van boxes—especially when such matters do not relate to the GHG regulations. Given all of this confusion, we wish for the EPA to clarify what the agency proposes. On a more minor note: the EPA has a typo in 1037.621, in that the regulation references ‘paragraph (f) of this section’ yet the section only has paragraphs (a) and (b). [EPA-HQ-OAR-2014-0827-1164-A1 p.105]

1037.622 is improperly named: it refers to shipping incomplete vehicles, when it should refer to partially complete vehicles, as the text is primarily focused on partially complete vehicles. The misnomer makes it unclear what we believe the EPA means: that the agency intends 1) to allow a primary vehicle manufacturer to certify an incomplete vehicle, such that the secondary manufacturer would have no need to certify the vehicle, but 2) to regulate the sale of partially complete vehicles (those not yet in their certified configuration at the time of sale to a secondary manufacturer). As written, the proposed text refers to secondary manufacturers getting certification in the case of partially complete vehicles in a section whose title refers to another type of vehicle. The EPA should clarify. [EPA-HQ-OAR-2014-0827-1164-A1 p.105]

Organization: Edison Electric Institute

D. Delegated assembly procedures may not provide sufficient incentive for PEVs, including e-PTO systems, as well as PHEVs and BEVs

In section V.E.2.c of the Preamble of the proposed Phase 2 Program, EPA and NHTSA also seek comment “on how the procedures should be applied more broadly or more narrowly for specific technologies.” In response, EEI offers the following comments. [EPA-HQ-OAR-2014-0827-1327-A2 p.17]

Delegated assembly procedures may not provide sufficient incentive for PEVs, including e-PTO systems, as well as PHEVs and BEVs. The proposed rule indicates that the delegated assembly
provisions “are focused on add-on features to reduce aerodynamic drag, and on air conditioning systems.” As proposed, the rule falls short in limiting the scope of the delegated assembly provisions to these technologies alone. [EPA-HQ-OAR-2014-0827-1327-A2 p.17]

End use customers, including EEI members, who wish to procure PEV technologies often turn to “upfitters” or secondary vehicle manufacturers when the product is not offered from the typical chassis manufacturers. In many cases, the chassis manufacturers or “upstream” manufacturers may not be aware of the technology being applied to their vehicles by secondary vehicle manufacturers before entering into service. Under the current structure of the proposed rule, the compliance depends entirely on the chassis manufacturers to certify the greenhouse gas performance of their vehicles. Such a focused application potentially risks ignoring major greenhouse gas reduction initiatives occurring in the regulated sector. [EPA-HQ-OAR-2014-0827-1327-A2 p.17-18]

“Upfitters,” or secondary vehicle manufacturers, should also be incentivized to deploy greenhouse gas reduction technologies as part of any final rule. One solution may be to allow secondary vehicle manufacturers to “opt-in” to the regulation. Such an option would require the secondary vehicle manufacturers to create an agreement with the otherwise regulated entity (i.e. the chassis manufacturer) to ensure the appropriate credit is apportioned between the two entities in a manner reflective of the total overall reductions. Another solution may be to create a “users’ council” that could propose to the agencies the full suite of downstream technologies being applied to upstream chassis. This users’ council could also serve to facilitate the establishment of agreements between chassis manufacturers and downstream manufacturers. [EPA-HQ-OAR-2014-0827-1327-A2 p.18]

Organization: Electric Drive Transportation Association (EDTA)

Delegated Assembly

The proposed rule’s delegated assembly procedures should provide increased clarity and certainty regarding electric and plugin hybrid systems, including electric PTO systems, as all of these systems are currently developed and deployed by third-party providers to Original Equipment Manufacturers (OEMs). The emphasis of the rule should be expanded beyond aero-dynamic and air conditioning to include the spectrum of electric drive systems. [EPA-HQ-OAR-2014-0827-1217-A1 p.3]

Delegated assembly procedures should also recognize the role of up-fitters and after-market manufacturers in compliance strategies. Several options for so doing are being offered by the industry, including allowing tradeable credits between manufacturers in the chain and allowing secondary manufacturers to “opt- in” to the regulation. We support providing the pathways to incentivize the increased recognition of this segment of the manufacturing chain and would like to work with the agencies’ to identify effective and feasible mechanisms to do so. [EPA-HQ-OAR-2014-0827-1217-A1 p.3]

Organization: Green Truck Association (GTA)

Delegated Assembly
Many of the member companies in the GTA produce products that are specifically designed to reduce fuel usage by vocational trucks. This reduction in fuel use and GHG emissions may be accomplished by advanced technologies (such as hybrid drive systems), alternative fuel conversions, reduced aerodynamic drag or use of lightweight materials. [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

In the past, many of the above mentioned products or technologies were not necessarily recognized by the regulations as they were installed after the engine and chassis had been certified. Applying the delegated assembly concept, perhaps with minor adjustments, could bring regulatory recognition of a sort to these significant fuel saving and emission reducing actions. This recognition could increase the adoption of these technologies and equipment, furthering the goals of these proposed rules. [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

In EPA’s existing regulations (40 CFR 1068.261), engine manufacturers may sell or ship engines that are missing certain emission-related components if those components will be installed by the vehicle manufacturer. According to this proposal EPA would provide a similar allowance for vehicle manufacturers to sell or ship vehicles that are missing certain emission-related components if those components will be installed by a secondary vehicle manufacturer. [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

The GTA supports the EPA concept of delegated assembly.

While we enthusiastically support the concept of delegated assembly, we also appreciate the Agencies’ willingness to consider minor modifications to the process. [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

The proposal notes, “We also request comment on any further modifications that should be made to the delegated assembly provisions to reflect the nature of manufacturing relationships or technologies that are specific to greenhouse gas standards for heavy-duty highway vehicles.” [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

We would like to suggest that the requirement for written instructions for completion/alteration of the vehicle and/or its emissions-related components be made more flexible such that those instructions come from the most appropriate entity. It certainly would be appropriate for the chassis manufacturer to contractually require proper installation. However, for instance, if a chassis manufacturer has contracted with a hybrid drive manufacturer for installation of a hybrid drive system on the chassis manufacturer’s otherwise completed chassis, the instructions for installation may best be provided by the hybrid drive manufacturer rather than the chassis manufacturer. [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

As such, the arrangement should allow the OEM to require proper installation of the equipment by the secondary manufacturer. The actual installation instructions should be written by the entity most qualified to do so. That may be the final stage manufacturer whose responsibility it is to mount pieces of equipment or the manufacturer of the equipment (for instance a fuel conversion kit manufacturer). [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

**Delegated Assembly Questions**

The proposed rules state that in order to utilize the proposed delegated assembly provisions, the certifying manufacturer would have “… a contractual obligation with the secondary manufacturer to complete the assembly properly and provide instructions about how to do so. Keep records to demonstrate compliance. Apply a temporary label to the incomplete vehicles. Take other reasonable
steps to ensure the assembly is completed properly. Describe in its application for certification how it will use this allowance.” [EPA-HQ-OAR-2014-0827-1188-A1 p.2]

The GTA would be interested in clarifying the scope of the delegated assembly provisions being proposed. Assuming that the procedural steps above have been taken, could the Agency provide clarification with regard to the following situations and whether or not the delegated assembly provisions could be applicable: [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

**Scenario 1. Aerodynamic Devices**

The coefficient of drag is one factor that determines the necessary horsepower, and subsequently fuel, to propel a vehicle forward. [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

A chassis manufacturer contracts with a final stage manufacturer who will be installing bodies and adding ladder racks to a significant number of identically prepared chassis to also install an aerodynamic shroud over the ladder rack. The vehicle would fall in the vocational category to be operated in the “regional” mode. The chassis manufacturer can quantify the aerodynamic improvement of the shroud. With the proper contractual arrangement, could the chassis manufacturer include the resultant reduction in emissions to their certification? [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

Similarly, on a regional mode vocational truck could the installation of aerodynamic mud flaps with a specified aerodynamic profile improvement over conventional mud flaps be the subject of such a contractual arrangement between chassis manufacturer and later stage manufacturer? [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

Could the chassis manufacturer and the later stage manufacturer negotiate between themselves the value attached to the later stage manufacturer’s efforts? [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

**Scenario 2. Hybrid**

A chassis manufacturer delivers a completed chassis (with drivetrain) to an intermediate stage manufacturer who installs a plug-in hybrid system on the chassis and then ships the chassis to a final stage manufacturer. The chassis will be operated in the urban mode and will likely be doing a lot of start/stop and operating a power take off unit to drive equipment at a jobsite. [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

First, can the chassis manufacturer enter into a contract with the installer of the hybrid drive system for “delegated assembly” purposes? [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

What information would the chassis manufacturer need in order to take advantage of the emissions improvements provided by the hybrid system over the standard (non-hybrid) chassis configuration for the certification process? [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

**Scenario 3. Alternative Fuel Conversion**

Similar to Scenario 2, a chassis manufacturer sends a completed diesel powered chassis to an intermediate stage manufacturer who installs an alternative fuel conversion (liquid propane autogas, CNG). First, can the chassis manufacturer enter into a contract with the converter for “delegated assembly” purposes? [EPA-HQ-OAR-2014-0827-1188-A1 p.3]
What information would the chassis manufacturer need in order to take advantage of any emissions improvements provided by the conversion of the chassis from diesel to the alternative fuel? [EPA-HQ-OAR-2014-0827-1188-A1 p.3]

**Scenario 4. Lightweighting**

A completed chassis is delivered to a final stage manufacturer for installation of the body in order to complete the vehicle. A lightweight body (fiberglass/composite material) is specified instead of a standard body resulting in a specified reduction in vehicle weight. [EPA-HQ-OAR-2014-0827-1188-A1 p.4]

First, can the chassis manufacturer enter into a contract with the final stage manufacturer for “delegated assembly” purposes? [EPA-HQ-OAR-2014-0827-1188-A1 p.4]

What information would the chassis manufacturer need in order to take advantage of any emissions improvements provided by the lightweighting of the completed vehicle? [EPA-HQ-OAR-2014-0827-1188-A1 p.4]

Could the contract be between the chassis manufacturer and the body manufacturer (whose multiple distributors could install the body in locations nationwide)? [EPA-HQ-OAR-2014-0827-1188-A1 p.4]

**Other**

If a delegated assembly provision were to be promulgated through this rulemaking, could it be used during the Phase 1 time period? [EPA-HQ-OAR-2014-0827-1188-A1 p.4]

**Conclusion**

The GTA supports the overall structure of the proposal as it relates to delegated assembly. This concept would allow the efforts of body and equipment, intermediate and final stage manufacturers to be recognized with regard to the fuel and emission reducing technologies they add to otherwise certified truck chassis. [EPA-HQ-OAR-2014-0827-1188-A1 p.4]

**Organization:** National Automobile Dealers Association (NADA)

Under Phase 2, vocational vehicles will continue to include what the other two motorized vehicle groupings do not. The range of Class 2b through Class 8 trucks, tractors, and buses is very wide, as is the scope of work functions and duty-cycles they engage in. Vocational vehicles often involve multi-stage manufacturing where one manufacturer builds the chassis or cab chassis and (at least) one other adds a body or other equipment to it. Often, vocational truck and tractor customers do not spec and purchase complete vehicles directly from a single manufacturer, but rather from a tractor and truck chassis dealership and a body and equipment manufacturer. The contractual arrangements involved are many. Vocational vehicle purchasers typically specify engines and other major components from a variety of suppliers with no single manufacturer having complete dominion over the finished product. Moreover, dealerships often alter or up-fit vocational vehicles prior to delivery. [EPA-HQ-OAR-2014-0827-1309-A1 p.9]

Vocational vehicle production can be both commercial (read “for stock”), or “custom” in nature. Regarding the latter, it is not at all unusual for “production” runs to involve just one vehicle. So, unlike...
for most on-highway combination tractors, there are literally thousands of unique and distinct potential vehicle combinations being produced by thousands of different manufacturers and alterers, which are sold by thousands of dealerships. [EPA-HQ-OAR-2014-0827-1309-A1 p.9]

NADA/ATD does not object to making OEMs primarily responsible for any and all components, including tires, which they install in their vehicles. Dealerships selling and purchasers buying commercial vehicles should not be burdened by having to look to several different potential OEMs when an issue arises. Instead, if and when an issue arises, the truck or tractor manufacturer should be required to work things out with the suppliers whose parts or components they install. On the other hand, OEMs should not be primarily responsible for the performance of parts and components installed by a downstream manufacturer or installer where they have no control over the manufacture or installation of such those parts or components. [EPA-HQ-OAR-2014-0827-1309-A1 p.11-12]

**Organization:** Navistar, Inc.

In general, Navistar agrees with EMA’s position on delegated assembly and secondary manufacturers but would like to emphasize certain points. The delegated assembly and secondary manufacturer are another area where it is useful to keep in mind the vast difference between the heavy duty commercial and light duty industries. Heavy duty vehicles, particularly vocational, are routinely customized to an extent not seen in the light duty world. Very often this customization takes place after control of the vehicle has passed to a dealer or customer. [EPA-HQ-OAR-2014-0827-1199-A1 p.12]

The number of delegated assembly agreements required by the NPRM would be nearly unmanageable and far beyond any benefit. In the past, delegated assembly agreements typically were between an engine manufacturer and a vehicle OEM. Now, in addition to those, a vehicle manufacturer may be required to maintain agreements with air conditioner installers, idle reduction technology installers, hybrid PTO installers and aerodynamic device installers. [EPA-HQ-OAR-2014-0827-1199-A1 p.12]

The RIA states that this requirement is justified because this has worked well with engine manufacturers. We would note, however, that the number of engine manufacturers and installing vehicle manufacturers is relatively small, and that most of these entities themselves tend to be larger, more accustomed to regulatory requirements and have adequate personnel to manage complicated regulatory requirements. By contrast, installers are far more numerous, often regional and generally smaller companies. These companies may not have the resources or infrastructure to enter into and manage numerous delegated assembly agreements. As a result, they may not be willing to enter into the agreements or may not have the resources to maintain compliance if they do enter into the agreements. This may lead to a reduced usage of the technologies or to their invisibility to the manufacturer or EPA. [EPA-HQ-OAR-2014-0827-1199-A1 p.13]

As to the latter point, we would like to highlight the possibility that this requirement could lead to the rule not capturing the benefit of many effective technologies. If the requirement of a delegated assembly agreement comes to be seen as a burden, we predict many secondary manufacturers will simply install these elements without an agreement. This means that, although the technology may be present, it would not be captured in the emission level for that vehicle. This will be an issue for both the manufacturer and the agencies. For the manufacturer, it means that a particular vehicle may be rated as having higher emission levels than is actually the case. For the agencies, they may not see all of the emission reductions that exist in the field. There should be some streamlined method of capturing the downstream installation of beneficial technologies. [EPA-HQ-OAR-2014-0827-1199-A1 p.13]
In addition, this proposal misunderstands the nature of the existing arrangements for the completion of primarily vocational, vehicles. Often items such as those described are ordered and installed either by dealers or directly by customers. Unlike with engines, vehicle manufacturers sometimes play little or no role in the installation of many of these technologies and are in no position to control their installation. There is almost always an existing contract between an engine manufacturer and a vehicle manufacturer. That contractual agreement typically does not extend between a vehicle manufacturer and an installer of, for example, a hybrid PTO. In that case, the contract is generally either between the installer and a dealer or a customer and the installer. [EPA-HQ-OAR-2014-0827-1199-A1 p.13]

Requiring a delegated assembly agreement is no way to encourage greater awareness of these technologies. The agencies should consider less intrusive and burdensome, methods of confirming the presence of these technologies. We also agree with EMA’s proposed resolutions to this issue. [EPA-HQ-OAR-2014-0827-1199-A1 p.13]

Organization:  Odyne Systems LLC

Delegated Assembly and Regulatory Compliance

Additionally, Odyne believes there could be a potential “chicken and egg” problem with how credits are held, if OEMs are the likely credit holder and the third party’s system – potentially Odyne – needing to be certified in advance. Separately, should EPA consider expanding the delegated assembly process to include hybrid up-fitting, this could offer a potential solution to reduce regulatory burden and drive easier adoption of hybrid technology. [EPA-HQ-OAR-2014-0827-1239-A1 p.25-26]

Odyne has been working with CARB as they developed their proposed Innovative Technology Regulation (ITR) process. Since we are not an OEM and are installed on already certified vehicles we have focused on the Aftermarket process versus the New Certification process. We believe this process has appropriately accounted for nuances in the truck manufacturing process that can cloud the point at which a truck reaches certification as a new vehicle versus an aftermarket vehicle. [EPA-HQ-OAR-2014-0827-1239-A1 p.29-30]

Our understanding of current regulatory compliance and accounting proposed in Phase Two for fuel efficiency and emission benefits added through technology like Odyne’s is as follows. OEMs would be required to work with third-party manufacturers, or at times called ‘up-fitters’, like Odyne to obtain credit for efficiencies made after a truck chassis is delivered, and typically already in a “certified” state. While it is theoretically possible for OEMs to delay certification, the combination of lower stringency requirements proposed in Scenario Three and extremely complex and diverse post-OEM applications for vocational trucks in particular make it difficult – and we believe too high a bar – for OEMs to seek credit for up-fitter improvements after the OEMs work is complete. In this case, should an OEM decide not to obtain credit for improvements made by up-fitters/intermediate stage manufacturers like Odyne, Oydne would not be able to become a credit holder, as the vehicle would technically be considered an aftermarket vehicle by the EPA. Even should up-fitters like Odyne be able to become a certification holder, we believe this would cause undue and unnecessary burden on small manufacturers. This would not be a preferred approach. [EPA-HQ-OAR-2014-0827-1239-A1 p.30]
We believe this lack of clarity could be a major roadblock for achieving the highest market penetrations of advanced emission and fuel saving technologies like Odyne’s and others in the hybrid space. [EPA-HQ-OAR-2014-0827-1239-A1 p.30]

One potential remedy for this issue could be including a similar process to the Delegated Assembly provisions that the EPA is considering for Phase Two for hybrid systems. We understand that a number of stakeholders may be suggesting a similar approach, but remain open to EPA thinking to address this issue. [EPA-HQ-OAR-2014-0827-1239-A1 p.31]

We highly recommend EPA convene stakeholders, including Odyne, to address what could be a major regulatory barrier for Phase Two rules in the development of final rules. [EPA-HQ-OAR-2014-0827-1239-A1 p.31]

The CARB ITR was developed to achieve a similar purpose, with the assumption that given the highly regulated nature of the heavy duty industry, new technologies need incentive – even in small volumes – to be tested and proven, and advanced credits can serve as the catalysts to drive the development of these technologies, while also enabling the potential for earlier widespread adoption of technologies that could move the industry even beyond the emission requirements set out in this rulemaking. As noted above, any methods to streamline EPA and NHTSA rulemaking with CARB regulatory efforts would be extremely helpful to the industry. [EPA-HQ-OAR-2014-0827-1239-A1 p.31]

Odyne also believes that other aspects of certification such as warranty could be handled separately. Since the OEM is typically responsible for the main emissions related systems (engine, exhaust, etc.) and they are certifying that base configuration, they should carry the warranty for those systems. The OEM would hold the warranty, with a sub-warranty being held by Odyne for its own systems, as it is also important to point out that hybrid systems have a different life cycle than traditional powertrains. For example the battery system can vary depending on the application (load, duty cycle). Odyne currently offers a 1 year / 12,000 mile warranty and the option to purchase extended warranty up to 3 years / 36,000 miles. In our applications it is more important to focus on time/duration than mileage since the stationary/jobsite operation out weights the driving operation. [EPA-HQ-OAR-2014-0827-1239-A1 p.31-32]

Odyne understands that this is a complex issue and we applaud the EPA in its understanding that regulatory burden on small and innovative manufacturers can be detrimental to the deployment of advanced technologies, like hybrid systems. [EPA-HQ-OAR-2014-0827-1239-A1 p.32]

Organization: Odyne Systems LLC

As described previously, it will also be important to properly account for the benefits of various technologies in GEM model and testing. Odyne specifically supports and encourages the inclusion of PHEV systems interfaced with automatic transmissions, idle reduction systems and ePTO systems in GEM model and testing. In addition, once the technology is properly accounted for and given the credits it has earned it will be very important to provide a method like Delegated Assembly to “sell” those credits to OEM’s to lower the burden on Small Companies and to recognize intermediate and final stage manufacturers that can integrate efficiency technology during the new vehicle build process to significantly reduce GHG emissions from medium and heavy duty vocational vehicles. [EPA-HQ-OAR-2014-0827-1920-A2 p.12-13]

Organization: PACCAR, Inc.
Secondary Manufacturers and Delegated Assembly Provisions

The Agencies’ proposal would impose complicated, burdensome delegated assembly requirements for secondary manufacturers. The proposed requirements are disproportional to the number of vehicles that undergo secondary manufacture and the types of alterations that are made, which have minimal effects on fuel consumption and GHG emissions. PACCAR also believes that the Agencies have significantly underestimated the number of secondary manufacturers currently operating in the heavy-duty and vocational vehicle areas, most that would be classified as small business. [EPA-HQ-OAR-2014-0827-1204-A1 p.27]

PACCAR requests that the small business exemption be carried over from Phase 1 and finalize it as a permanent flexibility, to again alleviate the potentially onerous certification and compliance requirements for these companies. This exemption would also eliminate the need for the burdensome delegated assembly requirements for OEMs and any company that cannot certify the modified vehicles with the Agencies. [EPA-HQ-OAR-2014-0827-1204-A1 p.27]

PACCAR also recommends that the Agencies clarify that any delegated assembly provisions, if finalized, do not apply to manufacturers of glider kits, nor to the dealers or others to whom the glider kits are sold. Applying delegated assembly requirements to glider assemblers could require OEMs to administer more than 200 individual contracts per year and would shift a significant portion of the compliance burden onto the OEM where the OEM has little true ability to oversee or control the process [EPA-HQ-OAR-2014-0827-1204-A1 p.27]

PACCAR requests that the Agencies consider modifying the statement regarding frontal area in §1037.622(a)(2). The intent of the provision is beneficial but sleepers added in the aftermarket and cab modifications such as those to create a crew cab generally increase the frontal area of the vehicle in either height and/or width as compared to the frontal area of the vehicle as it leaves the vehicle factory. PACCAR will work with the Agencies to modify the proposed regulatory text to accomplish the intent of this subsection. [EPA-HQ-OAR-2014-0827-1204-A1 p.27-28]

LNG Tank Issues

PACCAR recognizes the importance of being able to offer our customers a natural gas powered option. In order to encourage further growth in this segment, the proposed regulation needs to be modified with regard to tank installations. PACCAR does not believe it should be responsible for LNG 5-day boil-off limits. PACCAR does not install these tanks. This is performed by secondary manufacturers who add these tanks to customer specifications. PACCAR supports the EMA comments that the proposed LNG tank requirements should apply to the tank itself and not the vehicle. [EPA-HQ-OAR-2014-0827-1204-A1 p.29]

PACCAR should not be responsible via delegated assembly for the installation of LNG tanks. [EPA-HQ-OAR-2014-0827-1204-A1 p.30]

Organization: Truck & Engine Manufacturers Association (EMA)

Delegated Assembly and Secondary Manufacturers

Under the Phase 1 program, manufacturers of “incomplete vehicles” can enter into delegated assembly agreements with secondary manufacturers (such as cab-builders, sleeper-installers, A/C installers, LNG tank installers, etc.), pursuant to which the vehicle manufacturers provide instructions regarding the installation of GHG-related components to ensure that the vehicle is “completed” in an appropriate
GHG-certified condition. This arrangement is then confirmed through an incomplete vehicle document (“IVD”) that the vehicle manufacturer submits to EPA, which satisfies the vehicle manufacturer’s responsibility for that vehicle. Consequently, in any subsequent Phase 1 audit testing, the secondary manufacturer, not the original manufacturer of the incomplete vehicle, is responsible for any emissions exceedances caused by its improper completion of a vehicle. [EPA-HQ-OAR-2014-0827-1269-A1 p.32-33]

The Agencies should not adopt any new regulations that would undercut the viability of delegated assembly, especially since the Agencies have not assessed the economic impact of a potential shutdown of that segment of the vehicle manufacturing industry. Instead, the Phase 1 provisions relating to delegated assembly should be retained. [EPA-HQ-OAR-2014-0827-1269-A1 p.33]

In that regard, EMA agrees with the provisions of proposed section 1037.801, which provides generally that manufacturers can only be deemed as secondary manufacturers if they modify a vehicle from its original certified configuration. EMA further agrees that those are the only instances when the Agencies should regulate the secondary manufacturer or the interaction between the primary and secondary manufacturers, particularly given the very large number of entities that complete but do not “modify” heavy-duty vehicles. Moreover, only when the primary manufacturer arranges for the secondary manufacturer to complete the process of putting a vehicle into its certified configuration, and only when that modification is from a previously certified configuration, should there be any reason to involve the primary manufacturer in any delegated assembly requirements. Otherwise, if a primary manufacturer introduces into commerce a chassis-cab or tractor that meets the GHG regulations, that should be the end of the primary manufacturer’s responsibilities. After that point, it should be the secondary manufacturer’s duty under the federal Clean Air Act (“CAA”) to ensure that the secondary manufacturer does not remove or render inoperative any elements of emission control, including those relating to GHG emissions. Notwithstanding the foregoing, EMA requests clarification from the Agencies regarding these issues, as the current language of the proposed regulations is not sufficiently clear on these important points. [EPA-HQ-OAR-2014-0827-1269-A1 p.33]

EMA also supports the Agencies’ proposal to exclude heavy-duty vehicles from the provisions of section 1068.261(c)(7)(ii), which require that manufacturers add ‘Del Assy’ to the certification labels of incomplete vehicles. Including that language would be burdensome and, in the case of heavy-duty vehicles, is unnecessary. The labeling of vehicles is much more complex than the labeling of engines, involving many more calculations and varieties of information. That complexity makes it far more difficult to add text, especially if it is unnecessary. For many heavy-duty vehicles, like those sold without natural gas fuel systems (which the secondary manufacturers install), the vehicles cannot be driven until the secondary manufacturer completes its processes. Accordingly, there is no concern about the vehicle being driven on-road in a noncompliant condition (except perhaps for some very limited driving as a part of manufacturing or testing, which the Agencies explicitly allow). Consequently, EPA should not require additional burdensome labeling for heavy-duty vehicles when there will be no benefit. [EPA-HQ-OAR-2014-0827-1269-A1 p.33]

Turning to other specifics, it appears that proposed section 1037.622 is improperly captioned: it refers to shipping incomplete vehicles, when it should refer to partially complete vehicles, as the text is primarily focused on partially complete vehicles. Moreover, the Agencies never actually define the “partially complete” vehicles that are the subject of that section. The lack of definition of this key term makes EPA’s intent unclear. In particular, it is unclear whether the Agencies intend: (i) to allow a primary vehicle manufacturer to certify an incomplete vehicle and certain partially complete vehicles as described in 1037.622(a)(1-3), such that the secondary manufacturer would have no need to certify the vehicle; or (ii) to regulate the sale of partially complete vehicles that (a) will be certified by the
secondary manufacturer, or (b) will involve the secondary manufacturer having a significant role in the vehicle design. As written, the proposed text refers to secondary manufacturers obtaining certification in the case of partially complete vehicles, an undefined type of vehicle, in a section whose title refers to another type of vehicle. The Agencies need to clarify this regulatory provision. [EPA-HQ-OAR-2014-0827-1269-A1 p.33-34]

Further, any changes to the Agencies’ secondary manufacturing and delegated assembly requirements should be delayed until Phase 2, not implemented in the middle of Phase 1. This includes the proposed changes to the multi-stage manufacturing processes that would be implemented through proposed sections 1037.620 through 1037.622. Those proposed requirements amount to a major change to the process for manufacturing vehicles, and should not be implemented in a shortened time frame. Manufacturers need sufficient time to work with their various secondary manufacturers to implement the procedures that EPA seeks to impose (such as annual affidavits of part numbers, contractual obligations, and record-keeping). While those are not unmanageable burdens, they are new and may involve many secondary manufacturers, including small businesses, such that implementation will take significant time and effort. [EPA-HQ-OAR-2014-0827-1269-A1 p.34]

With respect to assembly instructions for secondary vehicle manufacturers, it seems that the Agencies are seeking to compel truck manufacturers to include assembly instructions with each truck sold without a body (like a box van), which is nearly all trucks. In proposed section 1037.130, the Agencies propose to require that the truck manufacturers instruct body-installers how to install bodies in a manner compliant with the GHG/FE standards. But it is not clear how trucks such as box vans are subject to the GHG/FE regulations, nor how a truck manufacturer would have any expertise with respect to the installation of box vans or the variety of other bodies that might get put onto a truck. Accordingly, EMA requests that the Agencies clarify what instructions they expect truck manufacturers to provide to body-installers. In that regard, EMA suggests that the Agencies limit any such instructions to topics within truck manufacturers’ expertise. In other words, manufacturers should not have to instruct body-installers how to mount equipment or van boxes – especially when such matters do not relate to the GHG/FE regulations. [EPA-HQ-OAR-2014-0827-1269-A1 p.34]

In today’s market, it is not uncommon for an end-user to bring a vehicle to a secondary manufacturer for post-factory modifications that can impact GHG/FE parameters, without the knowledge of the original vehicle manufacturer. Under Phase 1 of the GHG/FE regulations, any modifications made by the secondary manufacturer that could affect the GHG/FE configuration of the vehicle must be covered by a certificate of conformity (“CoC”), whether that be held by the secondary manufacturer or the original OEM. However, there are provisions that would allow for the secondary manufacturer to qualify for a small business exemption, thereby exempting the modified vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.34]

Under the Phase 2 proposal, that small business exemption would be eliminated starting in MY2022, which would add burden, or potentially restrict the ability for secondary manufacturers to maintain their business viability because they are not equipped to handle the certification, labeling, on-going compliance, and reporting for heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.34-35]

Phase 1 was only concerned with those modifications that could affect the vehicle’s GHG/FE parameters. For vocational vehicles, where bodies and/or crew cabs are commonly added, this meant that the only variable of concern was a modification in tires. The Phase 2 regulations would expand this to include modification of the air conditioning system and other vehicle systems, regardless of vehicle configuration. This would add significant burden to the certification and management of vehicles in the Vocational regulatory subcategories. The original manufacturer could now become responsible for the
A/C leakage rate resulting from the secondary manufacturer’s modification(s) if the secondary manufacturer did not hold a CoC for that make/model/regulatory subcategory. That is not a reasonable result. [EPA-HQ-OAR-2014-0827-1269-A1 p.35]

Additionally, for vehicles in the Tractor subcategory, modifications that affect vehicle aerodynamics are expected to continue as a major GHG/FE impact, especially in calculating roof heights for determining the appropriate regulatory subcategory and aerodynamic Bin as an input to GEM. Consequently, the original manufacturer would also have to know explicit details surrounding any down-stream modification if it affects roof height and/or aerodynamics to mitigate the risk of mislabeling or mischaracterizing the aerodynamic assessment of the vehicle. That is also problematic. [EPA-HQ-OAR-2014-0827-1269-A1 p.35]

Because it is unlikely for a secondary manufacturer to have the data or sophistication to support the many certification and compliance requirements for Phase 2, EMA recommends that the following options be added to the proposed language in the NPRM. One option for Phase 2 would be to allow specified exemptions for small businesses. In the NPRM, proposed section 1037.635(c) allows a limited exemption for small businesses that produce glider kits. EMA recommends that the Agencies provide a similar exemption for secondary manufacturers that are small businesses, subject to an annual production cap of 300 units, as specified under proposed section 1037.635(c), for both Tractor and Vocational vehicles. The exemption would apply to the vehicle-related GHG/FE requirements, other than the instruction and labeling requirements outlined in the Phase 1 regulations; the exemption would not apply to the engine-related GHG/FE requirements, or to the current criteria emission requirements. [EPA-HQ-OAR-2014-0827-1269-A1 p.35]

Another option would be to allow the vehicle to be built and labeled under the original manufacturer’s CoC. The original manufacturer ("OEM") would be required to provide the maximum allowable air conditioning leakage requirements, the regulatory references, and an explanation of the potential ramifications if those requirements were not met. The same would be true for all other GHG/FE certification parts and systems. No OEM monitoring, reporting, or compliance audits would be required. For aerodynamics, due to the vast array of modifications that could affect the frontal area of the vehicle, the vehicles would have to be conservatively scored in lower aerodynamic Bins. In some cases, however, the modifications could improve the aerodynamics, so this approach may not be prudent. [EPA-HQ-OAR-2014-0827-1269-A1 p.35]

To remedy that issue, the OEM could either obtain sufficient details from the secondary manufacturer regarding the modifications impacting aerodynamics to be able to use an EPA-approved alternative aerodynamic assessment methodology, or the OEM could use an equivalent cab or sleeper profile from its product line that is certified with the Agency and then use one aerodynamic Bin lower as the GEM input (i.e., the Bin with the next higher CdA GEM input value) for determining the GHG score through GEM for the modified vehicle. No additional assessment of aerodynamics and no compliance testing would be required of the OEM. Determination of the regulatory subcategory and associated labeling would be the responsibility of the OEM. The vehicle request process from Phase 1 would still continue. [EPA-HQ-OAR-2014-0827-1269-A1 p.35-36]

In addition to implementing the other necessary revisions discussed above relating to delegated assembly and secondary manufacturers, the Agencies should implement the foregoing options to address the aerodynamic performance of vehicles completed by secondary manufacturers. [EPA-HQ-OAR-2014-0827-1269-A1 p.36]

LNG Tank Requirements
Currently, and out to the foreseeable future, LNG fuel tanks are installed outside the OEM’s vehicle-manufacturing process and control. Dealers and/or customers work directly with the LNG tank manufacturer’s certified installers to complete the fuel system. Under the Phase 2 proposal, the fuel system would have to meet the requirements in Section 4.2 of SAE J2343, which specify that vehicles should meet a five-day hold time after a refueling event before the fuel reaches the point of venting to relieve pressure. However, since the tanks are designed, selected, and installed outside of the OEM’s manufacturing process, EMA believes that additional provisions under delegated assembly should be included that limit the OEM’s role simply to informing the tank supplier of the relevant requirements, while the tank supplier is held responsible for the design and installation of the LNG tank. An alternative is to require OEM communication of the tank leakage requirement to the dealer and tank suppliers/installers. Using precedence in other regulatory areas, such as the regulations relating to fuel hoses for small SI engines, the tank manufacturer could be required to certify their tanks with EPA to a modified leakage requirement, thereby fulfilling the intent of the current language. [EPA-HQ-OAR-2014-0827-1269-A1 p.44]

**Organization:** Union of Concerned Scientists (UCS)

**DELEGATED ASSEMBLY**

The delegated assembly provision for vehicles is a significant improvement because it better reflects the way in which the work truck market functions. The agencies should also expand the use of this provision to Class 2b/3 complete vehicles—cargo vans in particular may benefit from the application of technologies from secondary manufacturers, particularly for strong hybridization, which is already being applied to aftermarket vehicles. But despite the promise of the delegated assembly provision to drive innovation, it needs further refinement. [EPA-HQ-OAR-2014-0827-1329-A2 p.24]

The delegated assembly provisions still require that the certifying manufacturers be aware of the final state of the vehicle. This does not reflect current business practices, where chassis are upfit before final delivery to the customer but well after point of sale from a chassis manufacturer’s perspective. The agencies should work with secondary manufacturers to determine a way for the secondary or final stage manufacturer to “close the loop” on a vehicle’s certification, provided that the vehicle is still in its certified configuration and has not been delivered to the end user. While this may add complexity to the certification process for these vehicles, this will help capture all of the technologies most applicable to the sector. This is a preferable alternative to the inclusion of aftermarket technology credits, which could undermine the efficacy of the regulations. [EPA-HQ-OAR-2014-0827-1329-A2 p.24]

**Organization:** Volvo Group

Volvo Group supports the EMA comments concerning delegated assembly provisions in their entirety except as noted in the discussion regarding Glider Kits and Small Volume Manufacturers put forth later in this document. [EPA-HQ-OAR-2014-0827-1290-A1 p.49]

Volvo Group supports the EMA comments on vehicle and engine warranty provisions of the proposed Phase 2 Rule, but requests the Agencies add manufacturers of newly regulated components to 40 CFR 1037.650 and any additionally referenced or supporting sections. [EPA-HQ-OAR-2014-0827-1290-A1 p.57]

40 CFR 1037.650 provides that tire manufacturers choosing to provide test data and warranties to vehicle manufacturers in support of the certification and warranty requirements of the regulation are
responsible to the Agencies for meeting the requirements of the rule as they pertain to those components. Specifically, the tire manufacturer is responsible to the Agencies for the emission test data they provide and can be contractually obligated to the vehicle manufacturer to provide tire warranty and related defect tracking and reporting under the obligations of the regulation and associated parts. [EPA-HQ-OAR-2014-0827-1290-A1 p.57]

As with tires, vehicle manufacturers typically do not see warranty claims related to many vendor supplied components such as engines, transmissions and axles since many suppliers deem this as sensitive and confidential information, especially when dealing with vertically integrated OEMs who manufacture many of the same components. Many of these components, or systems made up of these components, will now be part of the OEMs’ certified vehicle configuration and some failures of these components may still allow for the vehicle’s continued operation at increased emissions levels, making them warrantable emissions systems under this part. [EPA-HQ-OAR-2014-0827-1290-A1 p.57]

Given this, Volvo Group requests that the Agencies amend 1037.650 to cover these newly regulated components and their manufacturers. Below is a list of components that Volvo Group believes should be covered under this provision; however, this list is not all inclusive, partly due to unforeseen technologies not considered in the rulemaking and unknown, future, off-cycle technology certification by Volvo Group or the suppliers. [EPA-HQ-OAR-2014-0827-1290-A1 p.57]

Components and manufacturers proposed to be covered under 1037.650 where they are part of the certified vehicle configuration: [EPA-HQ-OAR-2014-0827-1290-A1 p.57]

- Vendor engines
- Vendor hybrid systems
- Vendor certified powertrain systems (e.g. Cummins/Eaton alliance)
- Transmission systems (e.g. neutral at idle, shift calibration software, etc.)
- Axle systems intended to reduce emissions (e.g. part-time 6x2, low friction))
- LNG evaporative emission systems
- Auxiliary Power Units (pending inclusion as a creditable technology) [EPA-HQ-OAR-2014-0827-1290-A1 p.57]

Organization: XL Hybrids

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 243-244.]

While the EPA and NHTSA are regulating these primary manufacturers, we don't believe the agencies are prevented from measuring and assigning credits to third party products that produce measurable, robust, documentable savings that could then participate in a compliance credit marketplace. In XL Hybrids' current business model, our savings right now would primarily benefit just the end fleets when they could also be contributing in the phase 2 regulation goals. The benefits to the public would be a more market-driven process resulting in a faster introduction of these advanced savings technologies and the potential for achieving greater reductions and stringency. We recognize structuring such a program would be challenging, but we ask that the rules be modified to specifically allow for such a possibility so that such a program could be developed.
Response:

In EPA’s existing regulations (40 CFR 1068.261), we allow engine manufacturers to sell or ship engines that are missing certain emission-related components if those components will be installed by the vehicle manufacturer. The Phase 1 regulations likewise state that this provision may apply to heavy duty vehicles as appropriate, and so likewise provide a similar allowance for vehicle manufacturers to sell or ship vehicles that are missing certain emission-related components if those components will be installed by a secondary vehicle manufacturer. 40 CFR 1037.621.

EPA has found this provision to work well for engine manufacturers and is finalizing a new section 40 CFR 1037.621 that formalizes this process. As conditions of this allowance, manufacturers will be required to:

- Have a contractual obligation with the secondary manufacturer to complete the assembly properly and provide instructions about how to do so
- Keep records to demonstrate compliance
- Apply a temporary label to the partially complete vehicles
- Take other reasonable steps to ensure the assembly is completed properly
- Describe in its application for certification how it will use this allowance

Under delegated assembly, it is the upstream manufacturer that holds the certificate and assumes primary responsibility for all compliance requirements. Our experience applying this approach with engines has shown that holding the upstream manufacturer responsible ensures that they will exercise due diligence throughout the process. Commenters generally supported these provisions, but as described below, several requested changes to the proposed program.

See also the initial response in Section 1.4 for a discussion of permissible modifications to certified configurations, such as potential modifications to stock vehicles at dealerships.

Applicability

EPA proposed to apply this new section broadly. However, commenters raised valid questions about whether it is necessary to apply this formal process as broadly as proposed. In response, we have reconsidered this proposed approach and have determined that it would be appropriate to allow a less formal process with components for which market forces will make it unlikely that a secondary manufacturer would not complete assembly properly. In those cases, the certifying manufacturers will be required to provide sufficiently detailed installation instructions to the secondary manufacturers, who would then be obligated to complete assembly properly before the vehicles are delivered to the ultimate purchasers.

One example of a case for which market forces could ensure that assembly is completed properly would be air conditioning leakage requirements. Purchasers will have the expectation that the systems will not leak, and a secondary manufacturer should have no incentive to not follow the certifying manufacturer’s instructions.
As revised, §1037.621 will require the formal delegated assembly process for the following technologies if they are part of the OEM’s certified configuration but are not shipped with the vehicle:

- Auxiliary power units
- Aerodynamic devices
- Hybrid components
- Natural gas fuel tanks

Certificate holders will remain responsible for other certified components, but will not automatically be required to comply with the formal delegated assembly requirements. As is currently specified in §1037.621 and §1068.261, EPA will retain the authority to apply additional necessary conditions (at the time of certification) to the allowance to delegated assembly of certified emission components to secondary manufacturers. In particular, we would likely apply such additional conditions for secondary manufacturers that we determine to have previously not completed assembly properly.

Commenters supporting the formal delegated assembly provisions urged the agencies to further specify by regulation those technologies to be included within the process. The agencies are not limiting by regulation technologies for which the certificate holders may delegate final assembly in addition to the four technologies noted above (when the components are not shipped with the vehicle to the secondary manufacturer). Manufacturers may delegate final assembly for any components for which they can demonstrate during the certification process that the vehicles will be properly assembled before reaching the ultimate purchaser. For example, we generally agree with the Aperia Technologies comment that we should allow installation of automatic tire inflation systems to be delegated to secondary manufacturers.

In response to comments, we are also extending these delegated assembly allowances for complete HD pickups and vans regulated under 40 CFR part 86.

In response to the comments requesting clarity on applicability, we note that delegated assembly would only apply where components identified as part of the certified configuration are to be installed or modified by a secondary manufacturer. Manufacturers are also correct that delegated assembly does not include unauthorized modifications to a vehicle already in its certified configuration.

PACCAR commented that the proposed requirements would impose a disproportional burden relative to the actual impacts. EMA expressed similar concerns. While we believe the changes already discussed will ameliorate some of the manufacturers’ concerns, the changes do not go as far as they requested. We are not providing a blanket exclusion for small businesses, dealers, or glider vehicle assemblers that install engines into glider kits. As finalized, the regulations will allow manufacturers to work with the agencies to develop appropriate procedures to ensure that vehicles completed by such entities are in the certified configuration before reaching the ultimate purchasers.

**Process Issues**

NTEA commented that the requirement to provide instructions for completion of the vehicle be made more flexible such that those instructions come from someone other than the certificate holder. Such arrangements will generally be allowed under §1037.620, which provides that EPA’s focus will generally be on ensuring that a requirement is met rather than on who meets it. However, that process will work slightly differently than NTEA envisioned in their comments. NTEA stated that “intermediate and final stage manufacturers or alterers would be bound contractually, rather than by regulation, to install specified products that result in specified regulatory benefits that can be used by the
certifying manufacturer.” While it is true that secondary manufacturers will likely be contractually bound to complete assembly properly, they will also be required to do so by the regulations or be subject to penalties for tampering. See §1037.621(e).

It is also important to note that the regulations do not require a specific format for assembly instructions, provided the information is properly conveyed. The agencies would judge the sufficiency of the instructions by how well they ensure proper assembly. For example, detailed instructions on a website could be sufficient, as long as its location was well known to each secondary manufacturer.

EMA incorrectly stated that when final assembly is delegated, “the secondary manufacturer, not the original manufacturer of the incomplete vehicle, is responsible for any emissions exceedances caused by its improper completion of a vehicle.” Under both the existing and revised regulations, both manufacturers would be liable. Regarding downstream modifications more generally, EMA commented that the regulations would require the OEM “to know explicit details surrounding any down-stream modification if it affects roof height and/or aerodynamics to mitigate the risk of mislabeling or mischaracterizing the aerodynamic assessment of the vehicle.” However, we view the requirements as requiring the OEM to explain in the assembly instructions what modifications are not permissible.

Regarding Odyne’s comment on up-fitting a complete vehicle, the recommended paths under the regulations would be for Odyne to do one of the following:

1. Obtain its own certificate so that it would be allowed to purchase uncertified vehicles from the OEM. As the certificate holder, ODYNE would be eligible for emission credits
2. Work with the OEM to add the Odyne system to the OEM certificate.
3. Modify certified vehicles in a permissible manner that does not increase emissions. However no credits could be generated for the vehicle.

For each path, the certificate holder would be fully responsible for the warranty requirements, but could make contractual arrangements with the other manufacturer.

Daimler’s comment regarding labeling was unclear. They acknowledged that the labeling requirements in 40 CFR 1068.261(c)(7) do not apply for vehicles using delegated assembly under part 1037, and yet objected to them in a previous paragraph.

Section 1037.621(a) has been revised to eliminate the incorrect reference to paragraph (f). Section 1037.622(b)(5) has been revised to require the manufacturer to “identify the regulatory citation” for the applicable exemption. The title of 1037.622 has also been revised.

Volvo commented that the agencies should specify the obligations for manufacturers of the following components, similar to the existing requirements for tire manufacturers:

- Vendor engines
- Vendor hybrid systems
- Vendor certified powertrain systems (e.g. Cummins/Eaton alliance)
- Transmission systems (e.g. neutral at idle, shift calibration software, etc.)
- Axle systems intended to reduce emissions (e.g. part-time 6x2, low friction))
- LNG evaporative emission systems
- Auxiliary Power Units (pending inclusion as a creditable technology)
We have modified the regulations to reflect additional components.

**Custom Sleepers and Natural Gas Vehicles**

In 40 CFR 1037.622 we are allowing small businesses to modify certified tractors as long as they do not modify the front of the vehicle and so long as the sleeper compartment or natural gas tank does not exceed more than 102 inches wide or 162 inches in height. EPA is also finalizing an optional compliance path in 40 CFR 1037.150(x). This option allows small manufacturers to convert a low or mid roof tractor to a high roof configuration without recertification, provided it is for the purpose of building a custom sleeper tractor or conversion to a natural gas tractor. The allowance to convert low and mid roof tractors to high roof tractors is being adopted as an interim provision, although we have not established an end date at this time. We expect to reevaluate as manufacturers begin to make use of the provision and may decide to revise it in the future, potentially deciding to make it a permanent allowance. To be eligible for this option, the secondary manufacturer must be a small business manufacturer, and the original low or mid roof tractor must be covered by a valid certificate of conformity. The modifications may not increase the frontal area of the tractor beyond the frontal area of the equivalent high roof tractor paired with a standard box van.

Regarding evaporative emission standards for natural gas fuel tanks, we note that the regulations allow different manufacturers to hold the GHG and evaporative certificates (once again illustrating how the statute and regulations contemplate multiple manufacturers of a motor vehicle; see response in 1.3.1 above). In the circumstances identified by PACCAR, they would be allowed under §1037.622 to ship vehicles without the natural gas fuel tanks to secondary manufacturers, as long as the secondary manufacturer had a valid evaporative emission certificate for the vehicle.

The agencies received supplemental comments from American Reliance Industries recommending expansion of the allowances to also allow conversion of low-roof tractors to mid-roof configurations. We have modified the interim allowance in §1037.150 to allow this.

**Other Small Secondary Manufacturers**

EMA recommends the agencies provide an exemption for secondary manufacturers that are small businesses, subject to an annual production cap of 300 units. We generally do not permanently exempt small business from our regulations. We included a small business exemption in Phase 1 so that small businesses would have time to adjust to the new GHG requirements. However, Phase 2 does not start for these manufacturers until 2021. This provides more than enough time for them to become familiar with the applicable requirements.

**Credits for Non-Certifying Manufacturers**

Some commenters recommended that the agencies allow non-certifying secondary manufacturers to generate emission credits. However, EPA limits emission credits to certificate holders to ensure full compliance. The formal certification path includes many safeguards and procedures to ensure the vehicles are fully compliant. Without these provisions, it would be much more difficult for us to provide proper oversight. We believe the delegated assembly provisions will provide a sufficient pathway to incentivize these advanced technologies.
Changes to Phase 1

Manufacturers argued that applying the proposed changes to Phase 1 vehicles would amount to a retroactive change in stringency. However, this ignores the existing text in §1037.620(a) (a Phase I provision) noting that delegated assembly may apply with regard to vehicles shipped prior to completion of assembly into their final certified configuration. Daimler acknowledged this provision but incorrectly interpreted it, reading “may” to make the provision purely advisory. This is not a correct interpretation. The provision’s plain meaning is that delegated assembly provisions may sometimes apply when partially complete vehicles are introduced into commerce but are placed in their final certified configuration by a secondary manufacturer. Thus, we do not see the proposed changes as adding fundamentally new requirements to the Phase 1 provisions. Also, as described below, the changes being made to the delegated assembly process lessen the likelihood that there would be any significant changes for manufacturers who were already complying with the Phase 1 requirements.

While we do not agree with the comments arguing the proposed requirements are fundamentally new, we have made two changes that avoid the problems feared by the manufacturers. First, as already noted, we are reducing the number of components that will require the formal delegated assembly process. This will limit the formal process to a small number of vehicles. Furthermore, two of these components (i.e. hybrids and natural gas fuel tanks) are not part of the primary technology basis for Phase 1 standards and so delegated assembly for these components would not arise with any frequency with respect to Phase 1 vehicles. APUs and aerodynamic technologies are part of the basis for the Phase 1 tractor standard (although not the vocational vehicle standard), and so could potentially trigger this provision in the limited instance when the APU or aerodynamic components are not attached to or otherwise shipped with the vehicle to the secondary manufacturer by the primary manufacturer. This would be an unusual circumstance, especially for aerodynamic components. In addition, for these Phase 1 components, it is unclear how the certifying manufacturer would currently be ensuring that the vehicles they certify are in the proper certified configuration without having some process substantially similar to formal delegated assembly process being finalized.

Notwithstanding, we are delaying implementation of the changes until January 1, 2018 to provide manufacturers over a year of additional lead time. EMA raised concerns about the time needed “to work with their various secondary manufacturers to implement the procedures that EPA seeks to impose (such as annual affidavits of part numbers, contractual obligations, and record-keeping).” We believe in nearly all cases, the formal delegated assembly provisions will not apply and the additional lead time will be more than enough to put appropriate processes in place. To the extent that any manufacturer is currently relying on a secondary manufacturer to complete final assembly of any of the covered components, they should already have a substantial process in place under the Phase 1 regulations. So compliance with the formal process should also be achievable by January 1, 2018.
Specific Scenarios

In response to specific scenarios identified by GTA:

Scenario 1. Aerodynamic Devices

A certifying chassis manufacturer may contract with a final stage manufacturer who will be making aerodynamic improvements, and may input the improvement into GEM for certification if the certifying manufacturer (and the secondary manufacturer) comply with the delegated assembly provisions.

Scenario 2. Hybrids

A chassis manufacturer may contract with a hybrid installer for “delegated assembly” purposes, but the chassis manufacturer would need to test the hybrid system in order to take advantage of the emissions improvements in the certification process.

Scenario 3. Alternative Fuel Conversion

A chassis manufacturer may also contract with an alternative fuel converter for “delegated assembly” purposes, but the chassis manufacturer would need to have a certified fuel map for the converted engine.

Scenario 4. Light-weighting

We do not envision it to be possible for a certifying manufacturer to generate credit for lightweight body components because we cannot define the baseline configuration.

1.4.5 Labeling

Organization: Allison Transmission, Inc.

EPA and NHTSA Should Explore Emission Control Labels In Separate Rulemaking

Within the agencies discussion of emission control labels, EPA and NHTSA have requested comment on methods to provide for an electronic means to identify vehicles and access to databases that would include vehicle-specific information on the emission control system utilized in the vehicle. Currently, OEMs are required to report vehicle GHG certification level by VIN. If a vehicle had the VIN as a machine-readable code, this seems like reasonably simple technology that could be implemented without great cost to those responsible. As a component supplier, Allison believes that OEMs have the capability to configure a machine-readable code similar to the Vehicle Identification Number (VIN). It should be noted, however, that suppliers of electronic components do not always have the ability to label components prior to delivery to the vehicle OEM because vehicle OEMs program specific configurations on their assembly line. [EPA-HQ-OAR-2014-0827-1284-A1 p.48]

EPA has indicated that such electronic systems if they are considered would be subject to a separate rulemaking proceeding. Allison agrees that this would be the proper process in order to review options and receive informed comment on the benefits and costs of such systems. More broadly, in the context
of this rulemaking, if further reporting or management of GHG certification levels were to involve or otherwise obligate component suppliers, then Allison believes that a separate rulemaking is required. [EPA-HQ-OAR-2014-0827-1284-A1 p.49]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Labeling

The absence of a consumer fuel efficiency label for heavy-duty pickups and vans is a serious shortcoming of the program that should be remedied as soon as possible. In response to Phase 1 comments to this effect, EPA and DOT committed to “consider this issue as we begin work on the next phase of regulations, as we recognize that a consumer label can play an important role in reducing fuel consumption and GHG emissions” (76 Fed. Reg. (Sept. 15, 2011) at 57119). A subsequent letter from NHTSA Administrator David Strickland to Senator Dianne Feinstein stated: “We are currently working to include the consideration of fuel economy labels for large pickup trucks and commercial vans as part of the second phase of fuel efficiency and greenhouse gas standards for heavy-duty vehicles.” Despite this, the agencies have not addressed this issue at all in the Phase 2 proposal. [EPA-HQ-OAR-2014-0827-1280-A1 p.25]

Any consumer product regulated for fuel efficiency should be labeled for fuel efficiency. In the case of HD pickups and vans, the success of the standards depends on manufacturers’ addition of incremental technologies to save fuel. These technologies will typically increase the cost of the vehicle, and manufacturers will need to figure out how to recover that cost. The absence of a label or any other publicly available information stating the fuel efficiency of the vehicle at the time of sale means the consumer is in effect cut out of the market for efficiency. While this might not create a problem where the standard is applied as an efficiency threshold, standards that manufacturers meet on an average basis will only work properly when coupled with a market that values efficiency and allocates efficiency based on its comparative importance relative to other vehicle requirements. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]

While establishing a vehicle label is not a simple process, we believe it would be well worth the resources required. The general approach should be similar to light-duty vehicle labeling and could perhaps be carried out as a revision to that rule. While there are issues of duty cycle, test protocols, and comparability to be addressed, these are largely issues that would need to have been addressed in any case to establish a sound fuel efficiency program for these vehicles. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]

Absent a consumer label, the agencies should make certification data readily available to the public. This data should be available at a single location on the internet and should be available for all vehicles prior to their availability for sale. While we understand the limitations of the certified fuel efficiency vis-à-vis performance in the real world, the certification data would at least permit comparisons of these vehicles within their regulatory class. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]

- The final Phase 2 rule should commit the agencies to conducting a subsequent rulemaking for the labeling of heavy-duty pickups and vans and set out a timetable for the label rulemaking. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]
- Prior to the implementation of a labeling requirement for HD pickups and vans, certification values should be made publicly available for any vehicle model before it can be sold. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]

**Organization:** California Air Resources Board (CARB)

**Oppose/Requested Change Comment**

**Comment – Requirements for emission control labels for tractors and vocational vehicles**

CARB staff has significant concerns regarding the proposed removal of the requirements directing manufacturers to list the emission control system identifiers on the emission control labels for tractors and vocational vehicles certified to the Phase 2 standards. Specifically, CARB staff recommends leaving 40 CFR 1037.135(c)(6) as it currently reads, and not including the additional statement that “Phase 2 tractors and Phase 2 vocational vehicles (other than those certified to standards for emergency vehicles) may omit this information.” Having the emission control system identifiers on the emission control label is a simple and effective way of verifying that a vehicle is in a certified configuration, and is the most commonly used method of making a compliance determination during a vehicle inspection. Relying solely on an electronic method of identifying vehicles would limit vehicle inspections to areas where a sufficient internet connection could be obtained in order to access an online database, and is therefore not the most practical and efficient way of determining a vehicle’s compliance in all situations. For these reasons, CARB staff recommends that emission control identifiers continue to be listed on the emission control labels along with an electronic method of identifying vehicles similar to the label shown in Figure 5 below. If it is not practical to require that all emission control identifiers be listed, then CARB staff recommends at a minimum requiring that all visible components be listed. CARB staff also recommends that an additional requirement be included to make labels readily visible to the average person (for example, amend 40 CFR 1037.135(b) to include: “Attached in a location where the label will be readily visible to the average person after the vehicle manufacture is complete.”) [EPA-HQ-OAR-2014-0827-1265-A1 p.110-111]

[Figure 5 can be found on p.111 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

**Comment – Consumer label requirements for pickups and vans**

In 2011, U.S. EPA and NHTSA signed a final rule on requirements for window labels for new MY 2013 and later light-duty vehicles sold in the U.S. Such window labels provide fuel efficiency and environmental impact information to vehicle buyers, enabling them to make more informed choices and potentially buy more fuel efficient, lower GHG emitting vehicles. On page 57119 of the Phase 1 rule, U.S. EPA and NHTSA committed to consider requiring similar window labels for heavy-duty pickups and vans (Class 2b and 3 vehicles) as part of the Phase 2 proposal. However, the NPRM does not include such window label requirements. [EPA-HQ-OAR-2014-0827-1265-A1 p.112]

CARB staff encourages U.S. EPA and NHTSA to develop consumer label requirements for pickup and vans in Phase 2. Having window labels for heavy pickup and vans would give buyers of such vehicles better, more complete information to consider when purchasing new vehicles. It would also increase the likelihood that the more efficient, lower GHG emitting vehicles required by the proposed Phase 2 standards are embraced by consumers. [EPA-HQ-OAR-2014-0827-1265-A1 p.112]
Page 57119 of the Phase 1 Rule “As we did not propose a consumer label for heavy-duty pickups and vans in this action and have not appropriately engaged the public in developing such a label, we are not prepared to finalize a consumer-based label in this action. However, we do intend to consider this issue as we begin work on the next phase of regulations, as we recognize that a consumer label can play an important role in reducing fuel consumption and GHG emissions.” (Federal Register / Vol. 76, No. 179, Sept. 15, 2011).

Organization: Daimler Trucks North America LLC

12. Labels

i. Emission Control Identifiers

- **Label changes:** We agree with the EPA's approach of removing from labels the emission control identifiers, given that 1) those identifiers do not help demonstrate compliance and 2) there are far too many elements involved in compliance to track on a label, especially starting in Phase 2 when so many factors become relevant for GEM. A better approach, as the agency seems to recognize, for ensuring a vehicle is compliant is for manufacturers to store the vehicle's GEM inputs by VIN and to have the VIN on the certification label, such that a vehicle inspector could ask the manufacturer what items are on the vehicle. The EPA's Phase 2 approach does just this. So we agree with the changes. [EPA-HQ-OAR-2014-0827-1164-A1 p.108]

- **Vehicle build information versus electronic labels and database access** – The agencies comment on their need to get “detailed build information for a specific vehicle upon [an agency’s] request.” The agencies cite a need for same day response or within 24 hours at most, 80 FR 40251. We agree with the agencies’ concern and can generally provide that a response within one working day (obviously not one day response on weekends or holidays, because our Compliance staff is not a 24/7/365 operation, as the agencies understand). We think that such a turn-around is sufficient and that such rapid turn-around means it is not necessary to go through the cost and effort of developing and maintaining an electronic database with readable barcodes that could provide immediate access to such information, as the agencies suggest on the same page. That is, we agree with the agencies’ concern that there would be a tremendous level of effort required. Moreover, we have a concern about privacy and data security, for example if would-be thieves could learn that a vehicle had a particular vehicle speed limiter or idle shutdown feature. (Cargo theft is a very significant concern, so we do not want to create any avenues to increase such theft). In short, we think that our one-by-one responses to agencies’ requests should be the best balance of speed and safety. [EPA-HQ-OAR-2014-0827-1164-A1 p.108-109]

- **Emission Control Labels** - The agencies, recognizing the large number of inputs that go into certification and compliance compared to the small number of items that can reasonably be represented on an emission control label, propose to eliminate emission control identifiers from labels. We agree that this is the correct approach. It has never been appropriate, for example, to list certain components like ‘ATS’ (aerodynamic fuel tank side skirt) as a proxy for the coefficient of aerodynamic drag; the former is not regulated and the latter is. Plus so many vehicle components and their shapes and placements affect Cd that no small listing of parts will satisfactorily describe the regulated coefficient of drag. So we agree with the agency's approach of not requiring that we list items on the label that are not directly regulated. Moreover, as we discuss elsewhere, the agencies should follow this approach for all vehicles, not making specific exceptions for emergency vehicles. The emission control identifiers are irrelevant for all vehicles. Although the agencies state a desire to have available information with which to do inspections, in order to check that vehicle owners have not tampered with or rendered inoperative
emission controls, we think that if the emission controls offer the fuel savings that the agencies say they do, then there will be no reason for customers to tamper with them, thus making the tampering issue moot. [EPA-HQ-OAR-2014-0827-1164-A1 p.109]

ii. Emergency Vehicles

**Emergency Vehicle Labels** - The agencies propose to require unique vehicle labels for emergency vehicles. Such labels would contain emission control identifiers when no other vehicles’ labels do. We think this is 1) unnecessary for the reasons described above and 2) extremely problematic as we cannot create separate labeling computer systems within the one computer system that we have for all labels. Rather, we recommend that the agencies use the same approach for labeling of emergency vehicles as for all other vehicles. [EPA-HQ-OAR-2014-0827-1164-A1 p.109]

**Organization:** Environmental Defense Fund (EDF)

**Transparency of emissions and fuel economy for consumers through labeling and online resources is critical**

When faced with the decision of which new light-duty vehicle to buy, consumers are provided with valuable information including city and highway fuel economy, GHG rating, average annual cost and estimated cost savings over an average vehicle. This information is posted on the window of all new light-duty vehicles sold, and additional information is readily available from EPA’s Fuel Economy Guide and other online tools. In contrast, consumers of medium-duty pickup trucks and utility vans are not offered any information on fuel economy, emissions or relative costs. [EPA-HQ-OAR-2014-0827-1312-A1 p.46]

As discussed above, one of the many market barriers to the purchase of more efficient trucks is the lack of access to complete and reliable information. The agencies state in the Preamble that, “One common theme that emerges from these [barrier] studies is the inability of HDV buyers to obtain reliable information about the fuel savings, reliability, and maintenance costs of technologies that improve fuel efficiency.” Yet the Agencies have yet to provide this information to consumers, despite repeated commitments to do so. [EPA-HQ-OAR-2014-0827-1312-A1 p.46]

Indeed, in the Phase 1 rulemaking, the Agencies committed to consider window labels for pickups and vans in Phase 2 – “we do intend to consider this issue as we begin work on the next phase of regulations, as we recognize that a consumer label can play an important role in reducing fuel consumption and GHG emissions.” And this commitment was reiterated and reinforced by NHTSA in a letter to Senator Diane Feinstein last year, stating, [EPA-HQ-OAR-2014-0827-1312-A1 p.46]

“NHTSA supports the concept that providing information to consumers on energy use and emissions can play an important role in raising awareness, improving transparency, and ultimately, reducing fuel consumption and greenhouse gas emissions through informed decision-making...NHTSA recognizes the importance of this issue and we currently believe that we could best and most thoroughly address all of these issues by conducting rulemaking for fuel economy labels, in collaboration with EPA, as part of the second phase of fuel efficiency and greenhouse gas standards for heavy-duty vehicles.” (Attachment 3) [EPA-HQ-OAR-2014-0827-1312-A1 p.46-47]

Despite these commitments, there is no mention of window labels in the proposed rulemaking. [EPA-HQ-OAR-2014-0827-1312-A1 p.47]
Improving the fuel consumption information on 2b and 3 vehicles would significantly foster the deployment of cost-effective efficiency technologies, leveraging the standards being finalized in this rulemaking. EDF urges the Agencies to conduct label design and education outreach for Class 2b and 3 vehicles, similar to that conducted as part of the light-duty labeling rule. We also request that EPA and DOT finalize comparable window label requirements for all new 2b and 3 vehicles and provide online information for buyers of all classes of heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.47]

A. Large population, annual sales and miles travelled of Class 2b and 3 vehicles call for informing consumer choice

While their CO2 emissions are lower per vehicle than vocational trucks and tractor trailers, Class 2b and 3 pickup trucks and vans have the highest sales volumes in the heavy duty market and account for about 15-20 percent of all fuel use and GHG emissions in the truck market. In the Phase 1 RIA, EPA estimated 2b and 3 sales were 580,000 per year in 2010 and projected they would increase to between 700,000 and 800,000 per year for 2014-2021. However, a recent report by ICCT found the number of new registered 2b and 3 vehicles was about 450,000 in 2010, and increased to 1 million in 2012 and 1.2 million vehicles per year in 2013, concluding that, “the sales are increasing at a significantly greater rate than the agencies had projected.” DOT estimates that 2b and 3 vehicles travel about 35 percent of total medium- and heavy-duty vehicle annual miles. [EPA-HQ-OAR-2014-0827-1312-A1 p.47]

Because of their large population and large annual sales volume, providing window labels on 2b and 3 vehicles provides an important opportunity to reach a large portion of heavy-duty consumers. Providing these consumers with transparent information about efficiency, fuel savings and air pollution will help them make informed decisions. And because of the high number of miles traveled annually by 2b and 3 vehicles, when informed consumers buy more efficient vehicles, additional emissions reductions can be achieved, leveraging the standards being finalized under the fuel economy and GHG rulemaking. [EPA-HQ-OAR-2014-0827-1312-A1 p.47-48]

B. Similar use and configuration to their light-duty counterparts make labels feasible

Despite the definition and regulatory split between light-duty trucks and 2b and 3 trucks, they are very similar in use patterns as well as engine and transmission configurations and emissions control technology. EPA regulates criteria emissions from 2b and 3 vehicles under the light-duty Tier 3 rulemakings because, “Most are built by companies with even larger light-duty truck markets, and as such they frequently share major design characteristics and potential emissions control technologies with their LDT counterparts.” In fact, many 2b trucks are simply larger versions of a manufacturer’s 2a model with engines and transmissions that can be nearly identical in configuration. Like light-duty trucks, more than 90 percent of 2b and 3 vehicles are sold as ‘complete’ vehicles, as defined by EPA. EPA also confirms that the “Often, the technologies available to reduce fuel consumption and GHG emissions from this segment are similar to the technologies used for the same purpose on light-duty pickup trucks and vans, including both engine efficiency improvements (for gasoline and diesel engines) and vehicle efficiency improvements.” These technologies include, but are not limited to, engine improvements such as friction reduction, cylinder deactivation, cam phasing, and gasoline direct injection; aerodynamic improvements; low rolling resistance tires; and transmission improvements. In addition to the same efficiency technologies, Class 2a and 2b trucks are both certified with chassis dynamometer testing. [EPA-HQ-OAR-2014-0827-1312-A1 p.48]

The use of class 2b and 3 vehicles can vary widely but many of the uses are the same as light-duty trucks: they can be strictly personal-use vehicles, vehicles that double for both work and personal use, or vehicles that are used solely for commercial purposes (cargo vans). Many are purchased to perform a
certain work function, necessitating a specific workload and towing capacity. However, despite varying workloads and towing capacities of 2b trucks, their similarities outweigh their differences. [EPA-HQ-OAR-2014-0827-1312-A1 p.48]

Based on these similarities, EPA and NHTSA should develop window labels for 2b and 3 vehicles that provide comparable information afforded to consumers of light-duty cars and trucks. Given that these vehicles are often purchased to perform a certain work function, it may also be appropriate to provide payload and towing capacity on the label to allow for easy cross-vehicle comparisons in combination with fuel efficiency information. [EPA-HQ-OAR-2014-0827-1312-A1 p.48-49]

C. Agencies should immediately begin rulemaking process for labels

The updated light-duty labeling rule was finalized with updated fuel economy and GHG standards for light-duty vehicles. That provided EPA and DOT the opportunity to develop labels that would reflect the increased fuel economy and cost savings from advanced technologies like plug-in hybrids and electric vehicles. It also allowed manufacturers to harmonize the development and roll out of new vehicles and new labels at the same time. EPA should similarly develop window labels for 2b and 3 vehicles with the finalization of the Phase 2 fuel economy and GHG rule. This would provide manufacturers of 2b and 3 vehicles with integrated planning, similar to the issuance of light-duty labels and emissions standards, and provide important transparency for consumers. [EPA-HQ-OAR-2014-0827-1312-A1 p.49]

D. Consider carrying out an expert assessment to inform 2b/3 label design and rely on pertinent findings from the development of light-duty labels

EISA 2007 required DOT and EPA to update light-duty label designs and include GHG information. It also required the Agencies conduct consumer education outreach. The label redesign process included the following: [EPA-HQ-OAR-2014-0827-1312-A1 p.49]

- Literature review –examining vehicle buying process, information sources used by consumers as they shop for vehicles, the factors that influence consumer vehicle purchasing decisions, and the impact of the increasing availability of more efficient and lower emitting vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.49]

- Focus groups (in 3 phases) – 4 cities over 4 months, 32 focus groups including 257 people. [EPA-HQ-OAR-2014-0827-1312-A1 p.49]

- Expert panel – included executives from Zappos, Unilever, Pandora, Craigslist, and Gates Foundation. It was an intensive one-day workshop to elicit ideas. [EPA-HQ-OAR-2014-0827-1312-A1 p.49]

- National level online survey of new vehicle buyers – an Internet survey designed to elicit responses about new label ideas. [EPA-HQ-OAR-2014-0827-1312-A1 p.49]

- The innovative ideas and information collected from the redesign process resulted in consumer-friendly window labels that reduce the market barrier to purchasing cleaner, more efficient light-duty vehicles. We recommend the agencies consider the pertinent findings from the light-duty process and engage in consumer and expert outreach to inform label design for 2b and 3 vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.49]

E. Develop an online tool for all medium and heavy-duty vehicles
In addition to the label redesign, the Agencies launched an online education campaign for light-duty vehicles. Window labels direct buyers to the EPA website www.fueleconomy.gov to see the full Fuel Economy Guide. The website also allows a user to personalize their fuel economy information by inputting their specific driving habits and fuel prices and tells the buyer the cost to fill the tank, or the volume of the fuel tank, or how many miles could be driven on a tank. The information such as the miles per tank can be personalized to reflect a person’s relative amount of city and highway driving. This information is helpful to a potential consumer, as more consumers are starting their buying research online. [EPA-HQ-OAR-2014-0827-1312-A1 p.49-50]

Similar information could be provided to consumers of all types of medium- and heavy-duty vehicles. In addition to the labels, the Agencies could provide the same personalized online information for 2b and 3 consumers as the light-duty online tool. [EPA-HQ-OAR-2014-0827-1312-A1 p.50]

For vehicle classes 4-8, EDF encourages EPA to use the data and information collected during the development of the Phase 2 rule to develop a user-friendly online calculator or tool that would allow consumers to conduct personalized research of various vehicle configurations. The tool would produce average fuel economy over select duty cycles. This tool would provide rigorous, reliable information on vehicle efficiency and emissions performance to inform consumer choices. [EPA-HQ-OAR-2014-0827-1312-A1 p.50]

204 Preamble at 40436.

206 Letter from NHTSA Administrator David Strickland to Senator Diane Feinstein (date unknown). See Attachment 3.

210 A ‘complete vehicle’ can be a chassis-cab (engine, chassis, wheels, and cab) or a rolling-chassis (engine, chassis and wheels), while an ‘incomplete-chassis’ could be sold as an engine and chassis only, without wheels. Final RIA, Page 1-9. Control of Air Pollution From Motor Vehicles: Tier 3 Motor Vehicle Emission and Fuel Standards; Proposed Rule, 78 Fed. Reg. 29,816 (May 21, 2013) at 29874.

Organization: Institute for Policy Integrity at NYU School of Law

Consumer Labels: In our comments on the Phase 1 standards for heavy-duty vehicles, Policy Integrity explained why informational failures justify some additional labeling requirements for heavy-duty vehicles. EPA and NHTSA have developed sophisticated labels for light-duty vehicles to help consumers directly and easily compare vehicle options by their fuel efficiency, estimated fuel costs, and estimated emissions. No such labels exist for heavy-duty vehicles. While many consumers of heavy-
duty vehicles are commercial actors that, compared to average individuals, might have better access to information and more time and resources to make informed choices on their own, at least some heavy-duty vehicles are purchased by individuals (certain pickups, vans, mobile homes, and recreational vehicles). Moreover, there is no reason to assume that many government entities, non-profit entities, small businesses, and other commercial actors that purchase heavy-duty vehicles would not also benefit from easier access to clearer information. [EPA-HQ-OAR-2014-0827-1195-A1 p.1]

Policy Integrity was not alone in suggesting improved consumer labels during the Phase 1 rulemaking. A group of 18 U.S. Senators, New York State, and NACAA, as well as ACEEE, the American Lung Association, the Clean Air Task Force, EDF, the International Council on Clean Transportation, Sierra Club, and the Union of Concerned Scientists, all supported consumer labels. In response, they agencies noted that they “agreed” with the recommendation, but insisted that a label would be “too complicated” to finish during the Phase 1 rulemaking. They promised to “consider a consumer label in the context of our efforts with stakeholders to begin work on a second phase of this regulation.” [EPA-HQ-OAR-2014-0827-1195-A1 p.1-2]

Contrary to this promise, there is no discussion of a consumer label in the Phase 2 proposed rulemaking. Instead, EPA proposes scaling back the emission-control labels (which contain some limited information helpful for monitoring and enforcement, but are not designed to inform consumer comparisons of vehicle efficiency or emissions). Instead, the agencies should follow through on their promise to consider more informative consumer labels. If labels cannot be designed without delaying the final Phase 2 rule, the agencies should initiate a separate rulemaking specifically on labels. For more on the agencies’ statutory authority to create such labels and suggestions on the design of such labels, see our 2011 comments. [EPA-HQ-OAR-2014-0827-1195-A1 p.2]

Organization: Navistar, Inc.

The NPRM proposes to maintain the requirement for emergency vehicles. Navistar opposes maintaining the emission control label requirement for emergency vehicles. The vehicle labels are all printed from the same system so maintaining the requirement for emergency vehicles eliminates much of the benefit from the proposed change. As the NPRM states, the list of control technologies for Phase 2 is much larger that in Phase 1 so determining compliance by merely looking at the label is not practical, limiting the utility of the label as a source of information for purchasers. Therefore, removing the emission control information requirement on the label for all vehicles is the best solution. EPA also asks for comment on maintaining some label content for selected technologies. Navistar opposes any requirement for even limited emission control information content on the vehicle label. Again, even limited content requires more complex labeling systems with no actual benefit. [EPA-HQ-OAR-2014-0827-1199-A1 p.19]

As an additional improvement and as part of the proposed model year mismatch solution, Navistar agrees with EMA that the Agencies should eliminate the requirement for model year information on the vehicle label. In addition, Navistar does not support the proposal for electronic, scanable labels to the
extent such a program would require manufacturers to develop and build new websites dedicated solely to the Phase 2 GHG/FE program. [EPA-HQ-OAR-2014-0827-1199-A1 p.19]

**Organization:** Truck & Engine Manufacturers Association (EMA)

The proposed Phase 2 regulations also include an unnecessary labeling requirement in section 1037.103(f). Since the venting controls are completely contained on LNG tanks, it makes no sense for the vehicle manufacturer to specify the maximum fuel tank capacity for the vehicle. If the tank is certified to the evaporative emission requirements itself, its venting controls will be adequate and nothing on the vehicle will affect that performance. Accordingly, the vehicle labeling requirement set out in proposed section 1037.103(f) should be deleted since it serves no reasonable purpose. [EPA-HQ-OAR-2014-0827-1269-A1 p.45]

Electronic Vehicle Labeling

EMA supports the Agencies’ intent to minimize and simplify the information required on engine and vehicle labels. The amount of required information is already at the limit of what can fit and be accounted for on a label. Accordingly, and among other things, EMA believes that only one engine label and one vehicle label should be required and that, to facilitate such a uniform label, the Agencies should eliminate the requirement for model year information. That said, EMA does not support a requirement for electronic, scanable labels at this time to the extent such a program would require manufacturers to develop and build new websites dedicated solely to the Phase 2 GHG/FE program. [EPA-HQ-OAR-2014-0827-1269-A1 p.45]

General Comments Regarding Emission Labels

As mentioned above, the specific information that should be on the emission control information label is a long-standing concern. EMA, along with other engine manufacturers associations from around the world, have been working on a project to develop a new approach to providing emission control information. This industry effort appears to be quite similar to that discussed by the Agency in Paragraph III.E.(2)(f) of the Preamble entitled “Emission Control Labels,” which reads: [EPA-HQ-OAR-2014-0827-1269-A1 p.81]

We also request comment on approaches that would minimize burden for manufacturers to respond to requests for vehicle build information and would expedite an authorized compliance inspector’s visual inspection. For example, the agencies have started to explore ideas that would provide inspectors with an electronic method to identify vehicles and access on-line databases that would list all of the engine-specific and vehicle-specific emissions control system information. We believe that electronic and Internet technology exists today for using scan tools to read a bar code or radio frequency identification tag affixed to a vehicle that would then lead to secure on-line access to a database of manufacturers’ detailed vehicle and engine build information. Our exploratory work on these ideas has raised questions about the level of effort that would be required to develop, implement and maintain an information technology system to provide inspectors real-time access to this information. We have also considered questions about privacy and data security. We request comment on the concept of electronic labels and database access, including any available information on similar systems that exist today and on burden estimates and approaches that could address concerns about privacy and data security. Based on new information that we receive, we may consider initiating a separate rulemaking effort to propose and request comment on implementing such an approach. [EPA-HQ-OAR-2014-0827-1269-A1 p.82]
Over the ensuing years, EMA would like to see such a system developed. In that regard, EMA would support using such a system on a global basis for all regulatory categories. That would alleviate the types of issues being addressed through the proposed change to Part 1039.135(d). [EPA-HQ-OAR-2014-0827-1269-A1 p.82]

**Organization:** Volvo Group

**Electronic Database**

The Agencies have requested comment on the implementation of instantly accessible electronic databases for in-use audits, possibly in conjunction with scan-able bar code or RFID vehicle and engine labels. Currently, the Agencies must request certified configuration information for a specific vehicle or engine from the vehicle manufacturer, who then has 24 hours to respond. Volvo Group is not aware of any issues that have arisen from this method. Volvo Group’s concerns regarding this type of instantly accessible database lie in the development and maintenance burden, as well as information security. [EPA-HQ-OAR-2014-0827-1290-A1 p.42]

Given no notice from the Agencies regarding problematic issues with the current system, it is unclear what challenges they are attempting to resolve, but it is clear that the costs associated with development and maintenance of such a system would be substantial. First, a system to print a unique bar code would need to be developed and validated, or a commercially available system would need to be integrated into Volvo Group’s IT systems. Second, the bar code would then need to be linked to a secure web-based database, which itself would require substantial development and integration. This database would need to contain eight years of production information due to the Agencies’ requirements on the retention period of engine and vehicle GHG records. [EPA-HQ-OAR-2014-0827-1290-A1 p.42]

For other Volvo Group business units with regulated sales in the U.S. and Canada (specifically Volvo Powertrain, Volvo Bus, Nova Bus, and Prevost Motorcoach) these systems would need to be developed from the ground up to be incorporated into the overall database, as these systems are not on the same platform as Volvo Group Trucks and were excluded from the automated systems developed for Phase 1. This decision was taken in Phase 1 due to the bus and coach divisions’ limited volumes and/or limited certification data and configurations and resultant low benefit of an automated system versus the cost of development of such a system that could then be integrated across platforms to the Truck Group’s system. [EPA-HQ-OAR-2014-0827-1290-A1 p.42]

The Volvo Group spent nearly $2 million (2012$) dollars on the automated integration of the Phase 1 GEM and storage of the calculated vehicle data. Given that all of the previously mentioned additional systems will still be on multiple platforms when the Phase 2 regulation is implemented, it is likely that the development of an integrated and fully automated instantly accessible database and labeling system would require on the magnitude of $10 million dollars for Phase 2. This estimate does not account for any maintenance or additional security required, nor does it include any costs associated with an RFID chip in each engine and vehicle emissions label, nor the costs associated with end of line programming and validation of the data on the chip. Given that there is no vehicle customer benefit from this system, it would not be possible to increase pricing to cover the investment and cost of capital, especially given the cost increases already associated with the engine and vehicle technologies necessary to meet the GHG stringencies as set by the regulation. [EPA-HQ-OAR-2014-0827-1290-A1 p.42-43]

Given the latitude that the Agencies have in the data they can request and the fact that this data is considered commercially sensitive and proprietary in nature Volvo Group has serious concerns about security of a web based database for any purpose. This concern would be greatly increased by the
significant increase in certification data for both engines and vehicles, such as engine fuel maps, powertrain maps, axle efficiency maps, etc. [EPA-HQ-OAR-2014-0827-1290-A1 p.43]

Concerning RFID chips embedded in engine and vehicle labels, Volvo Group is concerned that this would enable tampering in that a chip could be potentially reprogrammed, erased, or intentionally damaged. Volvo Group is also concerned with the long-term survivability of an RFID chip in a HHD engine compartment. [EPA-HQ-OAR-2014-0827-1290-A1 p.43]

As a result of these concerns, Volvo Group does not support the implementation of such a strategy and further believes that the development of any such system that may be requested by the Agencies should be voluntary and open to further discussion on structural design. In addition, given the probable low number of in-use audits the Agency has the capacity to perform compared to the annual HHD production volumes for the N.A. market, it is not expected that these additional costs and security concerns are justified. [EPA-HQ-OAR-2014-0827-1290-A1 p.43]

**Organization:** Wabash National Corporation

**Labeling**

EPA has historically required that certified vehicles have a permanent emission control label affixed to the vehicle. For the Phase 2 trailer program, EPA is proposing that the label include the manufacturer, a trailer identifier such as the Vehicle Identification Number, the trailer family and regulatory subcategory, the date of manufacture, and compliance statements. EPA is also proposing that the label include emission control system identifiers, and that manufacturers would be required to maintain records that would allow EPA to verify that an individual trailer is in its certified configuration. [EPA-HQ-OAR-2014-0827-1242-A2 p.17]

As described above, trailers are highly customized and built to customers’ specifications, resulting in an endless array of potential configurations. Requiring the creation of custom labels to identify the exact devices on each trailer would be extremely burdensome. Instead, EPA should incorporate labeling requirements similar to those promulgated by the DOT on tank trailers, which require the manufacturer simply to certify that the trailer complies with applicable regulations at the time of manufacture. This approach would be much less burdensome and yet would accomplish the same goal of alerting an inspector whether a trailer should or should not include an aerodynamic device at the time of inspection. [EPA-HQ-OAR-2014-0827-1242-A2 p.17]

**Response:**

EPA proposed to largely continue the Phase 1 engine and vehicle labeling requirements, but to eliminate the requirement for tractor and vocational vehicle manufacturers to list emission control on the label. The agencies consider it crucial that authorized compliance inspectors are able to identify whether a vehicle is certified, and if so whether it is in its certified condition. To facilitate this identification in Phase 1, EPA adopted labeling provisions for tractors that included several items. The Phase 1 tractor label must include the manufacturer, vehicle identifier such as the Vehicle Identification Number (VIN), vehicle family, regulatory subcategory, date of manufacture, compliance statements, and emission control system identifiers (see 40 CFR 1037.135). EPA proposed to apply parallel requirements for trailers.

In Phase 1, the emission control system identifiers are limited to vehicle speed limiters, idle reduction technology, tire rolling resistance, some aerodynamic components, and other innovative and advanced
technologies. However, the number of emission control systems for greenhouse gas emissions in Phase 2 has increased significantly for tractors and vocational vehicles. For example, all aspects of the engine transmission and drive axle; accessories; tire radius and rolling resistance; wind averaged drag; predictive cruise control; idle reduction technologies; and automatic tire inflation systems are controls which can be evaluated on-cycle in Phase 2 (i.e. these technologies’ performance can now be input to GEM), but could not be in Phase 1. Due to the complexity in determining greenhouse gas emissions in Phase 2, the agencies do not believe that we can unambiguously determine whether or not a vehicle is in a certified condition through simply comparing information that could be made available on an emission control label with the components installed on a vehicle. Therefore, EPA proposed to remove the requirement to include the emission control system identifiers required in 40 CFR 1037.135(c)(6) and in Appendix III to 40 CFR part 1037 from the emission control labels for vehicles certified to the Phase 2 standards. Manufacturers generally supported the elimination of the emission control information from the vehicle GHG label, while CARB opposed it. We continue to believe these details are unnecessary.

Some commenters opposed the separate labeling requirements for custom chassis vehicles, but we believe it important for the labels to identify the standards to which each vehicle is certified.

**Electronic Labeling**

Although we are largely finalizing the proposed labeling requirements, we remain interested in finding a better approach for labeling. Under the agencies’ existing authorities, manufacturers must provide detailed build information for a specific vehicle upon our request. Our expectation is that this information should be available to us via e-mail or other similar electronic communication on a same-day basis, or within 24 hours of a request at the latest. The agencies have started to explore ideas that would provide inspectors with an electronic method to identify vehicles and access on-line databases that would list all of the engine-specific and vehicle-specific emissions control system information. We believe that electronic and Internet technology exists today for using scan tools to read a bar code or radio frequency identification tag affixed to a vehicle that could then lead to secure on-line access to a database of manufacturers’ detailed vehicle and engine build information. Our exploratory work on these ideas has raised questions about the level of effort that would be required to develop, implement and maintain an information technology system to provide inspectors real-time access to this information. We have also considered questions about privacy and data security. We requested comment on the concept of electronic labels and database access, including any available information on similar systems that exist today and on burden estimates and approaches that could address concerns about privacy and data security.

Manufacturers expressed some support for the goal of electronic labeling, they also agreed that any such changes should be considered in a separate rulemaking. Although we are not finalizing such a program in this rulemaking, we remain very interested in the use of electronic labels that could be used by the agencies to access vehicle information and may pursue these in a future rulemaking. Such a rulemaking would likely consider the feasibility of accessing dynamic link libraries in real-time to view each manufacturer’s build records (and perhaps pending orders). The agencies envision that this could be very useful for our inspectors by providing them access to the build information by VIN to confirm that each vehicle has the proper emission control features.

**Consumer Labels**

Several commenters expressed support for consumer fuel economy labels for heavy-duty vehicles. However, we did not propose such provisions, and consider the issue to be outside the scope of this rulemaking.
1.4.6 CBI and Compliance Data

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Absent a consumer label, the agencies should make certification data readily available to the public. This data should be available at a single location on the internet and should be available for all vehicles prior to their availability for sale. While we understand the limitations of the certified fuel efficiency vis-à-vis performance in the real world, the certification data would at least permit comparisons of these vehicles within their regulatory class. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]

Sound practices for the collection and dissemination of data are essential to the effective evaluation of the heavy-duty vehicle fuel efficiency and greenhouse gas emissions program. Data from the program should also greatly enhance understanding of heavy-duty vehicles and vehicle markets in the U.S. The lack of specifications of engine and transmission associated with a given vehicle, which is major gap in data collection in Phase 1, will be filled in Phase 2, now that vehicle certification uses actual power train specifications rather than default values as inputs to GEM. It is important that this information, along with all other GEM inputs and outputs, be made available to the public.

The agencies should make available in a timely fashion other data and information arising from the program as well, relating to individual vehicle and engine model certification, manufacturer compliance, and performance of the industry as a whole. Key information would include the contents of certification applications for engines and vehicles, and annual compliance reports showing each manufacturer’s status and usage of special credit provisions and credit balances. In the final rule, the agencies should commit to regular publications summarizing trends in the heavy-duty vehicle market, as EPA stated it would “make every effort to do” in its response to comments on the Phase 1 rule. A 2013 ACEEE working paper on heavy-duty vehicle fuel efficiency data set out in detail our concerns and recommendations in this area. Many remain relevant to the current proposal and are reiterated in the recommendations that follow.

CAFE data collection

NHTSA proposes (p.40540) changes to the way that manufacturers report CAFE data to the agency. NHTSA should take this opportunity to add the footprint of each vehicle to the model-by-model information required of the manufacturers. Moreover, footprint data together with fuel economy data for each model should be publically available. Given that footprint is the attribute on which the light-duty CAFE standards are based, analysts and others seeking to understand how the standards are working need this detailed information. Moreover, it is hard understand how the agencies could directly verify the accuracy of manufacturers’ calculations of their fleets’ compliance without having footprint data for individual models.

Recommendations: Data collection and dissemination

- Post all data collected in rule implementation that is not Confidential Business Information on the web in a timely fashion and in a form conducive to analysis. Posted data should include the information in certification applications for engines and vehicles and include all GEM inputs and outputs. The data should be made available in a database that is updated frequently so that key properties of engines and vehicles can be referenced as these products enter the market. Sales volumes at the most disaggregate level available should be added to the database as early as possible.
In annual compliance reports for the heavy-duty rule, report on each manufacturer’s use of special provisions (e.g., early credits, alternative engine certification, advanced and innovative technology credits), application of credit carry-forward/carry-back, and credit balance. Understanding the details of how manufacturers are complying with the standards, including their use of rule flexibilities, will provide insight into how the rule may be influencing the vehicle market and how rule design might be improved.

Produce an annual report on trends in heavy-duty vehicle technology, carbon dioxide emissions, and fuel economy. An annual heavy-duty vehicle trends report is necessary to track the directions of a rapidly evolving market for fuel efficiency technology. The report should present the agencies’ findings regarding the key fuel efficiency trends in the heavy-duty vehicle market with respect to vehicle and engine types, technologies, and manufacturers. Where relevant data on individual models or manufacturers is unavailable in the public online database, present that information in the least aggregated form compatible with CBI policy.

Consolidate analysis and reporting of data on heavy-duty pickups and vans with light-duty reporting. Include these vehicles in the agencies’ light-duty databases and in EPA’s annual Light-Duty Automotive Technology, Carbon Dioxide Emissions, and Fuel Economy Trends report.

(CAFE) Require manufacturers to include model-by-model footprint data when submitting fuel economy information for CAFE compliance. This model-level data should be made available to the public along with fuel economy and vehicle specifications, as well as sales volumes.

Organization: California Air Resources Board (CARB)

Additionally, the NPRM requests comment on whether the Phase 2 full vehicle simulation proposal, which potentially requires engine manufacturers to disclose proprietary engine performance information to vehicle manufacturers long before production, would enable the “reverse engineering” of engine manufacturers’ intellectual property, and if so, what steps U.S. EPA and NHTSA could take to address this issue. While CARB staff recognizes that this proposed approach will likely require engine manufacturers to disclose more detailed engine design and performance information early in production cycles, certainly earlier than currently occurs, CARB staff believes this will be a positive development that will facilitate better engine, component, and vehicle integration necessary for achieving maximum, cost-effective fuel efficiency improvements and GHG benefits. [EPA-HQ-OAR-2014-0827-1265-A1 p.103]186

Organization: Daimler Trucks North America LLC

Refuting the idea that a fuel map can be used to ‘reverse engineer’ engine manufacturers’ IP - The agencies question whether fuel maps that engine manufacturers pass to vehicle manufacturers could be
used to 'reverse engineer' intellectual property related to the proprietary design of engines, and the
agencies request comment on what steps the agencies could take to address this. 80 FR 40181. We
request comment on whether or not such information could be used to “reverse engineer” intellectual
property related to the proprietary design of engines, and what steps the agencies could take to address
this. Based on experience in benchmarking and investigation of competitive products over many
generations of technologies, DTNA believes such concerns to be unfounded. The fuel map of an engine
is an end result of the performance and integration of multiple design features that can be combined in
different ways to arrive at the same result. To illustrate, the fuel efficiency at a given operating point is a
function of turbocharger performance, injection control, timing of valve events, EGR flow, air system
pumping losses, application of intake throttling, thermal losses from the combustion chamber, energy
losses to bearings and ancillaries, and characteristics of lubricants. To reverse engineer an engine’s
system by only evaluating the end result is essentially impossible. To effectively reverse engineer an
engine’s systems requires actual operation of an engine in an appropriate test environment where
multiple temperatures, pressures, flows, electronic control inputs and outputs, and emissions outputs
from both the engine and the aftertreatment can be measured and recorded. Such detail measurements
are required, for example, to determine if the fuel efficiency at a given condition is the result of
combustion system optimization at high NOx levels in combination with highly efficient NOx
aftertreatment, or by less optimized combustion and aftertreatment combined with efficiencies gained
by other means such as lower pumping and friction. [EPA-HQ-OAR-2014-0827-1164-A1 p.13-14]

After the engine testing, one would need to test and examine multiple engine components to understand
component contributions. For example, to determine actual power losses to an engine pump that may
contribute or degrade performance would require measurements on a bench test. Detail examination,
performance testing, and metallurgical analysis of multiple components is often necessary for complete

Once a product is understood to the extent possible from these examinations, the processes to duplicate
and produce the actual critical designs, if not patent protected, requires additional resources and time.
One can easily conclude that a view of an engine fuel map reveals is essentially an insignificant first
step that in itself reveals little or nothing of the design content necessary to get to the end result. [EPA-

Moreover, vehicle manufacturers could theoretically derive a competitor’s engine fuel map soon after an
engine begins production. That said, it would require each vehicle manufacturer to put each engine on a
test stand and run a battery of tests, just to replicate information that the engine manufacturer already
has—a great waste of time and resources. In short, vehicle manufacturers could generate fuel maps if
there were IP in those maps, but we agree with the agencies’ proposal to require engine manufacturers
to create the maps. [EPA-HQ-OAR-2014-0827-1164-A1 p.14]

That said, if the engine manufacturer has concerns about IP before their engine is launched into
production, there are steps the engine manufacturer could take. The fuel map provided to the
manufacturer does not need to be the exact fuel map measured in the test cell. The fuel map provided to
the manufacturer needs only to not be lower than the actual measured fuel map. As is the case with other
emissions levels submitted to the agencies and which could be tested in a compliance audit, the levels
established by the engine manufacture in the fuel map would presumably be raised slightly for
compliance margin. Additionally the compliance margin may vary across the fuel map, for example, be
set higher in regions of the map that are seldom or not at all encountered in the vehicle simulation. To a
certain extent, the contours and levels of the actual fuel map can be masked by these and other even
Even if it were the case that a certification fuel map contained IP (which it does not), DTNA has proposed solutions to avoid passing IP. For example, data encryption techniques can be used, as these are readily available in the Matlab Simulink environment. Or the engine manufacturer could keep its fuel map and run GEM for vehicle manufacturers. Or the EPA could store the fuel map on a server, from which GEM would grab it during execution. Finally, in early stages of development with a vehicle manufacturer, an engine manufacturer can provide a fuel map that is an approximation of the actual fuel map which provides a similar GEM cycle result as the map that is ultimately provided which may be long after vehicle production begins, since actual credit calculations using final maps are not required until months after start of production. Any of these techniques would provide protection of the fuel map and any associated IP (if there were any) to the same level, if not better than, the idea of the cycle averaged mapping approach that the agencies propose in the NPRM. In conclusion, the agencies’ proposal for manufacturers to provide fuel map information to vehicle manufacturers need not be a concern and is in fact a necessary ingredient for a successful Phase 2 program. [EPA-HQ-OAR-2014-0827-1164-A1 p.14-15]

**CBI of the GEM inputs:** The EPA proposes to open GEM inputs up to FOIA inquiries rather than protect the inputs as CBI. While we appreciate the responsibility the agency has for disclosure of relevant emissions data to the public, we disagree with the agency on the idea of making public GEM inputs which are not emission results and should not be treated as such. Fuel economy is and has been one of the key concerns for our customers and one on which we compete with other manufacturers in the market. The advances made in technology over the past decades and those future advances on which the agencies are basing this rule on are a result of this competitive market. By declaring that information on the inputs that go into the GEM model are no longer confidential, the agencies will damage the market by sharing trade secrets and eliminating competitive advantages companies develop as soon as this technology is produced in a vehicle. Companies cannot invest millions of dollars to develop an advantage that the agencies will hand over to their competitors as soon as it is produced and sold. Much as the agencies have estimated “payback” time for customers purchasing technologies, companies must also be able to recuperate the costs of research and development of new technologies in order to justify the expenditures. By limiting this payback time to one year or less, the agencies are essentially limiting the ability of companies to invest and innovate. In Section IX-I of the Preamble, the agencies point out that: “Executive Order 13563 (January 18, 2011) directs federal agencies to consider regulatory impacts on, among other criteria, job creation. According to the Executive Order ‘Our regulatory system must protect public health, welfare, safety, and our environment while promoting economic growth, innovation, competitiveness, and job creation.’” The agencies should be mindful of the risk to job creation they may cause. [EPA-HQ-OAR-2014-0827-1164-A1 p.43-44]

Unlike with criteria pollutant certification data, which will generally not affect the market, the EPA’s proposal to open manufacturers’ highly competitive greenhouse gas and fuel economy data to FOIA disclosures could also distort the market in unexpected, unintended ways. For example, when fleets see that one manufacturer has better aerodynamics than a second one, the fleets could demand that the first make aero improvements; this could be problematic if the second manufacturer optimizes its vehicles not using aerodynamics but using hybrids or waste heat recovery—both of which compromise aerodynamics (as demonstrated by our Super Truck vehicle). In other words, individual GEM inputs can be meaningless or indeed misleading. The agency’s proposal is also problematic for those cases where the GEM model is misaligned with real-world FE reductions, for example where the generic regulatory drive cycles differ from actual ones; we would not want HDV purchasers misled by GEM information. In addition, the multiple methods the agencies have proposed to calculate inputs (e.g. powertrain testing and alternative testing) work against this data being of actual use to the public, as the confusion these inputs would generate far outweighs the data’s ability to be useful and meaningful to the public as opposed to just making the GEM output available. Even if the test procedures were all the same, the GEM inputs can be misleading, given that manufacturers often put in different safety margins against
selective enforcement audits, such that inputs such as aerodynamics may not be comparable, or may be misleading, from manufacturer to manufacturer. In summary, we think that if the agencies reverse course by removing CBI protection for GEM inputs, they risk skewing our market for the worse, improperly sharing the IP that companies develop and rely on, confusing rather clarifying fuel efficiency. [EPA-HQ-OAR-2014-0827-1164-A1 p.44]

Difficulty of reverse engineering - EPA requests comment an engine manufacturer concern that providing an engines fuel map to other manufacturers introduces a risk of lost intellectual property. 80 FR 40181. Based on experience in benchmarking and investigation of competitive products over many generations of technologies, DTNA believes such concerns to be unfounded. The fuel map of an engine is an end result of the performance and integration of multiple design features that can be combined in different ways to arrive at the same result. To illustrate, the fuel efficiency at a given operating point is a function of turbocharger performance, injection control, timing of valve events, EGR flow, air system pumping losses, application of intake throttling, thermal losses from the combustion chamber, energy losses to bearings and ancillaries, and characteristics of lubricants. To reverse engineer an engine system by only evaluating the end result is essentially impossible. Rather, reverse engineering an engine’s systems requires actual operation of an engine in an appropriate test environment where multiple temperatures, pressures, flows, electronic control inputs and outputs, and emissions outputs from both the engine and the aftertreatment can be measured and recorded. Such detailed measurements are required, for example, to determine if the fuel efficiency at a given condition is the result of combustion system optimization at high NOx levels in combination with highly efficient NOx aftertreatment, or by less optimized combustion and aftertreatment combined with efficiencies gained by other means such as lower pumping and friction. [EPA-HQ-OAR-2014-0827-1164-A1 p.46-47]

Beyond engine testing, one must examine and test multiple engine components to understand component contributions. For example, to determine actual power losses to an engine pump that may contribute or degrade performance would require measurements on a bench test. Detailed examination, performance testing, and metallurgical analysis of multiple components is often necessary for complete understanding. Once a product is understood to the extent possible from these examinations, the processes to duplicate and produce the actual critical designs (if they are not patent protected), requires additional resources and time. One can easily conclude that a view of an engine fuel map reveals is essentially an minor first step that in itself reveals little or nothing of the design content necessary to get to the end result. [EPA-HQ-OAR-2014-0827-1164-A1 p.47]

Moreover, the fuel map provided to the manufacturer may not even be the fuel map measured in the test cell. The fuel map provided to the manufacturer needs only to not be lower than the actual measured fuel map. As is the case with other emissions levels submitted to the agencies and which could be tested in a compliance audit, the levels established by the engine manufacture in the fuel map would presumably be raised slightly for compliance margin. Additionally the compliance margin may vary across the fuel map, for example, be set higher in regions of the map that are seldom or not at all encountered in the vehicle simulation. The contours and levels of the actual fuel map can be masked by these and other even more sophisticated approaches. [EPA-HQ-OAR-2014-0827-1164-A1 p.47]

Further, if IP were actually a concern, passing the fuel map could involve data encryption techniques like those internal to Matlab Simulink. Moreover, if IP were a concern, then in early stages of development with a vehicle manufacturer, an engine manufacturer can provide a fuel map that is an approximation of the actual fuel map which provides a similar GEM cycle result as the map that is ultimately provided which may be long after vehicle production begins, since actual credit calculations using final maps are not required until months after start of production. In short, manufacturers learn little about a competitor’s engine from the fuel map. The fuel map does not contain IP. And it can be
measured, once an engine is available, although doing such measurement would be a large expense for little value. For these reasons, DTNA agrees with agencies’ proposal that the Phase 2 program require engine manufacturers communicate fuel maps to vehicle manufacturers for use in GEM, either unprotected or encrypted. We agree with the agencies that the regulations should not require vehicle manufacturers to measure their own fuel maps (to be used for GEM input) for engines they do not manufacturer. Definition of the engine fuel map should be the sole responsibility of the engine manufacturer. DTNA concludes that EPA’s proposal for engine manufacturers to provide fuel map information to vehicle manufacturers need not be a concern and is in fact a necessary ingredient for a successful Phase 2 program.[EPA-HQ-OAR-2014-0827-1164-A1 p.47]

CBI of tire data: we request that the agencies develop a SmartWay-like page with or information about tires' relative performances, perhaps on a green yellow red basis (unlike today, which is essentially a green or nothing basis). This would help HDV owners and buyers determine what the appropriate tires are. We as vehicle manufacturers cannot develop such a page because of limitations on our use of tire manufacturers’ data. 80 FR 40216. [EPA-HQ-OAR-2014-0827-1164-A1 p.79]

Organization: International Council on Clean Transportation (ICCT)

Compliance data sharing. We would also like to take this opportunity to express how the data sharing about compliance of regulated vehicles does not appear to be nearly as detailed or as regular as that of the regulatory development data availability as indicated in this NODA. As stated in our previous comments, we recommend that the agencies make all GEM inputs and outputs fully available to the public. Just as actual emission certification results are made public, these GEM data are the certification compliance data and therefore should be made publicly available. Making the full certification database publicly available is critical to let truck fleets who purchase the technologies, fleet consultants who advise on the technology purchases, researchers, and citizen groups transparently see what otherwise is available to a select few government officials. In addition, we ask that the agencies include data on the sales (or production volume) by model year of each certified engine and vehicle, as regulatory compliance is based on a sales-weighted average of the results, and sales is a critical compliance determinant and a missing link to see industry and within-segment average CO2 and efficiency performance. [EPA-HQ-OAR-2014-0827-1876-A1 p.2-3

We especially point out this compliance data question because the EPA began a process to be more forthcoming about the compliance data (US EPA, 2014). The ICCT and other stakeholders provided detailed comments (e.g., see ICCT, 2014). This process has apparently been halted. To date, compliance data for model year 2014 (i.e., “Phase 1”) heavy-duty vehicles’ GEM inputs, CO2 outputs, and critically the production volume of all the vehicles and engines, has not been made available, when it would be key in allowing stakeholders to understand the ongoing Phase 2 analysis. Similarly, in other compliance areas, full data availability has been lacking. For example, light-duty vehicle CO2 emissions are based on vehicle model-specific CO2 emissions, footprint, off-cycle credits, and production volume of vehicles; however, EPA only shares parts of this data without allowing stakeholders to see or understand all the compliance calculations. In addition, to our knowledge EPA has not shared the data to demonstrate heavy-duty diesel in-use compliance (e.g., Portable Emissions Measurement System data) for model year 2010- through 2014-compliant vehicles. [EPA-HQ-OAR-2014-0827-1876-A1 p.3

We understand that this NODA is about Phase 2 regulatory development data. Nonetheless, we think data availability on compliance is at least as important as regulatory development data to ensure there is follow-through on the commitments and expectations put forth within each rulemaking. As a result, a full reporting of all model year 2014 vehicle and engine simulation input, testing, and output data needed to determine companies’ compliance standing, within the 2016 heavy-duty vehicle Phase 2 final rulemaking release, would clearly seem warranted. Clear statements in the 2016 Final Rule about the timeline and details for future year (i.e., model year 2015-2027) public compliance data availability would also seem appropriate. [EPA-HQ-OAR-2014-0827-1876-A1 p.3
**Organization:** Natural Resources Defense Council (NRDC)

Implement requirements to collect and disseminate data to the public on real-world technology adoption and performance to ensure that standards are leading to needed reductions in fuel use and carbon pollution. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

**C. Collect and Disseminate Performance Data**

NRDC believes that the agencies should design and implement programs to verify that improvements required under the standards are resulting in the expected fuel consumption and emissions reductions in real-world driving. Improvements included in Phase 2 GEM and the addition of new drive cycles with vocational vehicles signal a significant transition toward compliance that accounts for more fuel efficient technology across the vehicle. To ensure that new technologies are being applied in the market and delivering real-world savings, the agencies should develop a program to collect and publicly disseminate existing vehicle performance data and data generated in future model years. The agencies should also establish procedures to demonstrate progress and to enhance the program transparency. [EPA-HQ-OAR-2014-0827-1220-A1 p.7]

The agencies should collect and publicly disseminate vehicle configuration and performance data from new vehicle sales and, to the degree possible, for the existing on-road fleet. Requirements for public data are intended to accomplish three goals: [EPA-HQ-OAR-2014-0827-1220-A1 p.7]

(a) Establish a broad technical database to support transition from Phase 1 to Phase 2 GEM simulation that is validated by on-road measurements,

(b) Enhance public understanding of actual technology adoption, and

(c) Track actual on-road emissions and fuel consumption performance of new vehicles and the full on-road fleet.

The following recommendations are intended to address these goals. [EPA-HQ-OAR-2014-0827-1220-A1 p.7]

**i. Collect In-use Testing and Full Vehicle Testing Data and Make Data Publically Available**

EPA and NHTSA should build a public database of chassis and full-vehicle testing performed by manufacturers and the federal agencies. The agencies should expand its on-road testing to validate current compliance models and encourage manufacturers to provide more data. The agencies should make data available to the public to improve understanding of technology performance; where necessary, data can be aggregated to protect confidential business information. [EPA-HQ-OAR-2014-0827-1220-A1 p.8]

**ii. Build a Truck Market Database for Public Use and Evaluation**

Tracking fleetwide emissions is critical to understanding if improvements in per-truck emissions required under the standards are actually resulting in reductions of emissions from the entire on-road fleet. A future fleet of cleaner trucks could emit more carbon pollution than today’s fleet if the future fleet has a larger population or travels more miles. [EPA-HQ-OAR-2014-0827-1220-A1 p.8]
EPA and NHTSA should aggressively support federal efforts to reinstate surveys to collect truck market data. Such surveys should provide a description of the truck fleet population and its operating characteristics. A description of the existing fleet has been provided publicly in the past through the discontinued U.S. Census Vehicle Inventory and Use Survey (VIUS). The VIUS classified truck data by various characteristics including physical configuration (age, size, weight, body type, engine size, and mechanical equipment), operational uses (business purpose, range, efficiency, and geography) and fuel type. EPA and NHTSA should create a public database that includes current data from at least the same fields of the VIUS but also allows organization of data consistent with the subcategories used in the truck emissions and fuel economy compliance regime. 

iii. Publish an Annual Report Describing New and On-Road Fleet Performance

EPA and NHTSA should annually release a report that describes the emissions and fuel consumption performance of the current and past model year fleets and the overall on-road fleet. For new vehicles, the report should contain data similar to EPA’s annual publication of “Light-Duty Automotive Technology, Carbon Dioxide Emissions, and Fuel Economy Trends”. The report should be expanded to cover performance and summary characteristics of the existing fleet (from the market database described above) so an overall picture of medium- and heavy-duty truck emissions and fuel consumption progress is clear.

iv. Publish an Annual Report Describing Manufacturer Credit Balances and the Use of Any Credit Flexibility Mechanisms

EPA and NHTSA should annually release a report that describes the manufacturer credit balances within each compliance category. The report should also include the generation of credits under all allowed flexibility provisions.

Organization: Rubber Manufacturers Association (RMA)

EPA Should Not Make Rolling Resistance Data Public, but Should Develop a Rating System for Medium and Heavy Truck Tires, to Include Replacement Tires. Without an accurate and up to date rating system, publishing rolling resistance measurements could be counterproductive for operators.

The Agencies Should Not Publish Tire Rolling Resistance Measurements

The NPRM correctly states that tire manufacturers consider rolling resistance test data to be proprietary. The NPRM continues to state that per EPA policy, “tire rolling resistance measurements are not considered to be CBI and can be released to the public after the introduction into commerce date identified by the manufacturer.” The NPRM continues by requesting comment on whether “EPA should release such data on a regular basis to make it easier for operators to find proper replacement tires for their vehicles.” While RMA appreciates the interest EPA expresses in educating vehicle operators about tire rolling resistance in order to provide information about appropriate replacement tires, releasing rolling resistance measurements would not contribute to this goal. RMA therefore recommends that the Agencies not publish tire rolling resistance measurements and instead consider a more thoughtful approach to providing tire rolling resistance ratings to replacement tire purchasers.

More importantly, publishing test data would only serve to confuse the constituency the Agencies intend to assist. Rolling resistance test data submitted to an original equipment manufacturer (OEM) per this regulation would reflect test data from three tires, tested pursuant to the conditions specified in this
regulation. The test data would not provide any guidance about how to understand whether differences among these test data represent meaningful distinctions, from a fuel economy or greenhouse gas emissions standpoint, nor would it provide any information about test variability. Further, the test data would not provide any information about how the difference in rolling resistance between two tire models would translate to fuel savings on their specific type of vehicle. [EPA-HQ-OAR-2014-0827-1304-A1 p.13]

The challenges associated with publishing rolling resistance test data submitted pursuant to compliance with this regulation are heightened by the lack of a reference machine or alignment procedure. The alignment procedure developed in ISO 28580 was designed specifically for the purpose of facilitating meaningful comparisons among test data generated on different rolling resistance test machines. Without an alignment procedure, as RMA cited in its comments on the Phase 1 NPRM, differences in rolling resistance measurements of up to 20 percent can be seen in data generated on different well-controlled machines. Without limiting this source of variation and without explaining this statistical uncertainty, tire purchasers may make inaccurate assumptions about the granularity of the data published that could lead to inappropriate tire purchases. [EPA-HQ-OAR-2014-0827-1304-A1 p.13]

Even more compelling, if rolling resistance data were made available, it would not be actionable on the part of a truck or fleet operator, since similar information is not widely available for replacement tires. Providing rolling resistance data to the public only for tires sold as original equipment would disadvantage tires sold only as replacement tires, because information for those tires would not be similarly available on a government website. RMA does not oppose the concept of providing meaningful tire rolling resistance performance information to tire purchasers, if provided in an actionable, easy to understand format. In fact, today many RMA members provide fuel economy calculators for their truck tire customers freely on their websites. In addition, RMA has long supported providing tire rolling resistance consumer information (“tire efficiency” information) to consumers at point of sale for consumer vehicles. [EPA-HQ-OAR-2014-0827-1304-A1 p.13-14]

If the Agencies are serious about educating the replacement tire marketplace about rolling resistance performance of medium- and heavy-duty truck tires, RMA recommends that the Agencies develop a mandatory rating system for these products, applicable to tires used in original equipment fitments and those available in the replacement market. NHTSA is in the final stages of developing such a rating system for passenger car tires. In addition, the European Union has developed and implemented a similar rating system for tires sold in the EU. Information about the EU rating program is available at http://ec.europa.eu/energy/en/topics/energy-efficient-products-and-labels/tyres. If the Agencies were to develop such a rating system in the United States, it should include other important tire performance information, such as traction performance, to assure that tire purchasers make selections truly appropriate for their vehicle and driving needs. In addition, a tire should always match the vehicle and tire information placards’ specifications for tire and vehicle load ranges and speed ratings. [EPA-HQ-OAR-2014-0827-1304-A1 p.14]

In addition to providing tire replacement rolling resistance ratings for new tires, the Agencies should consider providing information to replacement tire purchasers about the benefits of retreaded tires, in terms of resource conservation as well as tire rolling resistance. Today, about 40 to 50 percent of the truck tires in service on America’s roads and highways are retreaded tires. EPA has recognized the significant role retreaded tires play in the truck tire market by including retreaded tires in the SmartWayTM Partnership technologies program. As EPA states on its SmartWayTM verified technologies website, “the EPA demonstrated that certain low rolling resistance retread products can reduce NOx emissions and fuel use of long haul class 8 tractor-trailers by 3 percent or more, relative to other popular high rolling resistance retread products.” The SmartWayTM verified technologies list
includes low rolling resistance treads (procure and mold cure) for retreaded tires that are at or below the target thresholds established for the treads of retreaded tires for drive and trailer use. [EPA-HQ-OAR-2014-0827-1304-A1 p.14]

**Rolling Resistance Machine Alignment.** RMA renews its call for the Agencies to establish a reference laboratory for use in correlating rolling resistance data generated in support of this rule and to provide a clear and unambiguous guide to the compliance tests that the Agencies may conduct to enforce this regulation. [EPA-HQ-OAR-2014-0827-1304-A1 p.35]

**EPA Should Not Make Rolling Resistance Data Public, but Should Develop a Rating System for Medium and Heavy Truck Tires, Including Replacement Tires.** Without an accurate and up to date rating system, publishing rolling resistance measurements could be counterproductive for operators. [EPA-HQ-OAR-2014-0827-1304-A1 p.35]

**Organization:** Truck & Engine Manufacturers Association (EMA)

**GEM Inputs and Fuel Map CBI Issues**

The proposed fuel-map requirements raise significant issues for some manufacturers relating to the disclosure of confidential business information (“CBI”). Compelling engine manufacturers to provide 143-point fuel maps to third-party vehicle manufacturers (including in-advance of the production availability of the engines at issue) and to the public could result in the disclosure of engine manufacturers’ highly proprietary engine designs and fuel efficiency strategies, resulting in potentially significant adverse competitive effects. While encryption programs may be available to alleviate those concerns, those programs, as well as their potential integration into GEM, have not been assessed or finalized. [EPA-HQ-OAR-2014-0827-1269-A1 p.26]

Moreover, the Agencies are proposing to make GEM inputs subject to FOIA inquiries rather than to protect those inputs as CBI. That is not appropriate, and EMA objects to this aspect of the Proposed Phase 2 Standards. GEM inputs are not emission results and should be treated as CBI. It is not sufficient for the Agencies to safeguard this information only until the vehicle/engine is introduced into commerce. The GEM-input information goes to the core of market competition, and the Agencies must recognize that. Unlike the case with respect to criteria pollutant certification data, which will generally not affect the market, the Agencies’ proposal to open manufacturers’ highly competitive GHG/FE data to FOIA disclosures could distort the market in unexpected ways. For example, if fleets perceive that one manufacturer has better aerodynamics than another, the fleets could demand that the second manufacturer make aerodynamic improvements. This could be problematic if the first manufacturer optimizes its vehicles using technologies that actually compromise aerodynamics. The bottom line from this example is that the only thing that matters is on-road fuel efficiency or, as a surrogate, GEM results - the outputs, not the inputs. Moreover, the GEM inputs can be misleading, given that manufacturers often put in different compliance margins to better insure against SEAs, with the result that inputs such as aerodynamics may not be comparable, or may be misleading, from manufacturer-to-manufacturer. The concerns relating to engine fuel map data are just as significant, as noted above. In summary, the Agencies risk skewing the market for the worse if they reverse course by removing CBI protection for GEM inputs. [EPA-HQ-OAR-2014-0827-1269-A1 p.26-27]

EPA is also seeking comment on whether the Agency should consider notch-specific engine/alternator efficiencies to be confidential business information. Under the current “Class Determination 1-13, Confidentiality of Business Information Submitted in Certification Applications for 2013 and subsequent model year Vehicles, Engines and Equipment,” there are three possible ways such information could be
treated: 1) as information not entitled to confidential treatment; 2) as information entitled to confidential treatment until introduction into commerce; or 3) information entitled to confidential treatment. The “Class Determination” document, authored by EPA’s Office of General, provides guidance as to how to determine which of these three treatment options is appropriate for various types of information. [EPA-HQ-OAR-2014-0827-1269-A1 p.75][This section can also be found in section 14.4.12 of this comment summary]

The following table, taken from the Class Determination document, lists the information that can be entitled to confidential treatment. [EPA-HQ-OAR-2014-0827-1269-A1 p.75][This section can also be found in section 14.4.12 of this comment summary]

[Table 3, ‘Manufacturer Information Entitled to Confidential Treatment’, can be found on p.76 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

In accordance with EPA regulations at 40 C.F.R. sections 2.204 and 2.205, information will be entitled to confidential treatment if the manufacturer (1) asserts that the information is entitled to confidential treatment, and (2) has not waived or withdrawn that assertion. Inherent in assertion (1) are the following representations by the manufacturer: (a) they have maintained the information in confidence, (b) the information cannot be readily obtained by other legitimate means, and (c) disclosure of the information to the public both before and after model introduction would be likely to cause substantial harm to the manufacturer’s competitive position. [EPA-HQ-OAR-2014-0827-1269-A1 p.76][This section can also be found in section 14.4.12 of this comment summary]

EPA provides two alternative methods to certify engines used in locomotive applications. Such engines can be certified on an engine dynamometer or alternatively in the locomotive. In the latter case, it is necessary to know the notch-specific engine/alternator efficiencies to ensure that the engine is tested at the appropriate speed and load conditions. [EPA-HQ-OAR-2014-0827-1269-A1 p.76][This section can also be found in section 14.4.12 of this comment summary]

EMA believes that notch-specific engine/alternator efficiency clearly fits within the category “Technical Description Information” on Table 3 above. Accordingly, EMA believes that notch-specific engine/alternator efficiencies readily meets the criteria set forth in 40 CFR 2.204 and 2.205 and should be treated as confidential business information. [EPA-HQ-OAR-2014-0827-1269-A1 p.77][This section can also be found in section 14.4.12 of this comment summary]

Organization: Truck Renting and Leasing Association

We also are concerned that the Proposed Standards do not go far enough in protecting company proprietary information which could discourage innovation. Fuels maps and related data-rich information are closely held within our industry, yet the Proposed Standards seem to envision that such information will be made available to parties outside of the requisite company. [EPA-HQ-OAR-2014-0827-1140-A1 p.4-5]

Organization: Volvo Group

GEM Inputs Should be maintained as Confidential Business Information

As noted in the EMA comments, Volvo Group is concerned with proprietary data considered Confidential Business Information (CBI) becoming public domain if used in the certification of engines.
and vehicles. Fuel mapping strategies, transmission shift strategies, and other features that Volvo Group views as proprietary and confidential, and as providing a competitive edge in the constant race to lead the HHD market in fuel economy, would become available to competitors not only once that technology is released into production, but in the case of a competitor to whom we are also a supplier that information would need to be made available prior to their vehicle model year certification. Furthermore, since GEM inputs are not “emissions data”, they are not automatically subject to disclosure under CAA § 208(c), 42 U.S.C. § 7524(c). [EPA-HQ-OAR-2014-0827-1290-A1 p.32]

We do, however, recognize that it will be necessary for vehicle manufacturers to have access to required GEM inputs from suppliers, including engines, transmissions, axles, and tires. We believe such data, if considered proprietary, could be encrypted so that it could be read into the GEM tool without direct access to vehicle manufacturers who may also be competitors to these suppliers. Such encrypted data could be restricted only to OEM certification personnel via a confidentiality agreement. Another alternative is to use a third party contractor to run GEM simulations for vendor supplied engines so that fuel maps could be maintained as confidential. We also believe that data for tire rolling resistance should be publicly available so that vehicle owners can know which replacement tires will maintain the vehicle in its certified configuration. [EPA-HQ-OAR-2014-0827-1290-A1 p.32]

In addition, given the complexity of the Phase 2 rule making there is concern over this information being provided openly to a public that is not familiar with the technologies and derivation of the GEM inputs employed to certify to the Phase 2 regulation, as well as the data being misrepresented to competitively target customers with the same limited knowledge. [EPA-HQ-OAR-2014-0827-1290-A1 p.32]

For these reasons Volvo Group is requesting the Agencies consider this data as confidential business information, and treat it accordingly. [EPA-HQ-OAR-2014-0827-1290-A1 p.32]

Response:

The agencies received mixed comments regarding the question of whether GEM inputs should be made available to public. Some commenters supported making this information available, while others thought it should be protected as confidential business information (CBI). In accordance with Federal statutes, EPA does not release information from certification applications (or other compliance reports) that we determine to be CBI under 40 CFR part 2. Consistent with section 114 (c) of the CAA, EPA does not consider emission test results to be CBI after introduction into commerce of the certified engine or vehicle. (However, we have generally treated test results as protected before the introduction into commerce date). EPA has not yet made a final determination for Phase 1 or Phase 2 certification test results or other GEM inputs. Nevertheless, at this time we expect to continue this policy and consider it likely that we would not treat any test results or other GEM inputs as CBI after the introduction into commerce date as identified by the manufacturer.

In a broader context, the agencies agree with the principle that it would be helpful to make available to the public data and information that would enable the public to track trends in technology sales over time, as well as track company-specific compliance data. As described in the FRM Preamble, one approach would be to publish an annual compliance report for the Heavy-duty Phase 2 program. In the context of the light-duty vehicle GHG standards, EPA has already published four annual compliance reports which has made available to the public detailed information regarding both how individual light-
duty vehicle companies have been meeting their compliance obligations, as well as summary information at the light-duty fleet level. NHTSA makes information on the light-duty fuel economy program available through its CAFE Public Information Center (http://www.nhtsa.gov/CAFE_PIC/CAFE_PIC_Home.htm). Information includes manufacturer and overall fleet standards and CAFE performance, credit status, and civil penalty status. This information has been helpful to increase transparency to all stakeholders and to allow the public to see how companies are progressing from one year to the next with respect to their compliance requirements. Prior to issuing such compliance reports, EPA and NHTSA will work with regulated manufacturers to reconcile concerns over the release of claimed confidential business information, consistent with 40 CFR Part 2 and 49 CFR 512.

1.4.7 General ABT issues 197

Organization: American Automotive Policy Council

Credit Transfers

In the Preamble of the Phase 1 Heavy-Duty rule (76 Federal Register 57106, 57127-28) NHTSA stated that it was implementing “Program Flexibilities” in the form of different kinds of CAFE credits, and averaging, banking and trading (ABT) provisions. NHTSA also said that it’s important for manufacturers to plan for compliance using a multi-year time frame, consistent with normal business practice. NHTSA decided that it was prudent to start with a five-year carry-forward and three-year carry-back approach to credit usage, but in doing so NHTSA would have time thereafter “to learn about technical and other issues that can inform future rulemakings[, and that i]n the future, [NHTSA] intend[s] to consider whether additional cost savings could be realized through broader trading provisions and whether such provisions could be designed so as to address any other relevant concerns.” [EPA-HQ-OAR-2014-0827-1238-A1 p.15]

As raised during the interagency EO12866 review, AAPC agrees that the ability to transfer credits between fleets can offer a cost effective way to meet multiple regulatory compliance challenges. With limited product offerings and smaller fleet volumes, manufacturers of heavy-duty vehicles and engines have unique limitations compared to manufacturers of light-duty vehicles. [EPA-HQ-OAR-2014-0827-1238-A1 p.15]

AAPC requests that the Agencies provide heavy-duty manufacturers with all reasonable mechanisms to manage their fleet compliance. Current allowances for averaging, banking and trading that allow trading only between narrowly defined averaging sets are overly restrictive, providing very limited flexibility to large manufacturers and no flexibility to manufacturers who may only have a single product in a given averaging set. [EPA-HQ-OAR-2014-0827-1238-A1 p.15]

AAPC strongly encourages the Agencies to remove the restrictions for credit trading between engine and vehicle averaging sets as well as to allow for trading of credits between Class 2b/3 trucks and vans with vocational vehicles and engines on a “Megagrams of CO2” and “gallons” basis. [EPA-HQ-OAR-2014-0827-1238-A1 p.16]

Specifically, AAPC proposes trading across all medium- and heavy-duty compliance categories and light duty fleets and would work with the Agencies to define necessary adjustment factors to get all units into equivalent megagrams*. [EPA-HQ-OAR-2014-0827-1238-A1 p.16]
Oppose/Comment on Topic Where NPRM Requests Comment

Comment – Use of banked Phase 1 credits in Phase 2 program / Credit adjustment factors

The NPRM indicates that “positive market reception to Phase 1 technologies could lead to manufacturers accumulating credit surpluses that could be quite large at the beginning of the Phase 2 program” (pages 40157 and 40251 of the NPRM). The NPRM does not attempt to quantify the level of projected banked credits that could be available at the end of Phase 1. However, U.S. EPA and NHTSA believe, even at this early stage of Phase 1 implementation, that substantial credits will be available that will impact Phase 2 cost, technology readiness, and other key variables. The NPRM provides almost no analysis of, nor accounting for, the potential implications of a large number of banked Phase 1 credits. A large number of Phase 1 credits means that manufacturers have adopted CO2 reducing technologies much faster than originally anticipated. However, the NPRM baseline scenarios do not recognize that a large number of banked credits reflect technology advancement beyond Phase 1 standards: [EPA-HQ-OAR-2014-0827-1265-A1 p.78-79]

“In each of these proposed baseline configurations, the agencies have not applied any vehicle-level fuel saving or emission reduction technology beyond what is required to meet the Phase 1 standards. NHTSA and EPA reviewed available information regarding the likelihood that manufacturers of vocational vehicles would apply technology beyond what is required for Phase 1, and we concluded that the best approach was to analyze a reference case that maintains technology performance at the Phase 1 level.” (page 2-113 of the RIA). [EPA-HQ-OAR-2014-0827-1265-A1 p.79]

U.S. EPA and NHTSA propose that these credits be fully carried over into the Phase 2 regulations, without discounting. CARB staff has several concerns with this approach: [EPA-HQ-OAR-2014-0827-1265-A1 p.79]

1) Allowing banked Phase 1 credits in the Phase 2 program reduces the efficacy of the Phase 2 program and delays technology development progress. Generation of large volumes of credits in the Phase 1 program indicates that technology has progressed faster than anticipated during the Phase 1 rulemaking. This faster Phase 1 progress should not justify reduced progress during Phase 2. CARB staff believes sunsetting these credits with the Phase 1 program would still provide manufacturers the opportunity to utilize these credits during Phase 1 (although some manufacturers may not), while maintaining the technological momentum needed to cost-effectively meet more aggressive Phase 2 standards. CARB staff believes that, at most, the life of remaining Phase 1 credits should be limited to no more than three years or with MY 2020, whichever is sooner, such that they would be sunsetted after MY 2020. [EPA-HQ-OAR-2014-0827-1265-A1 p.79]

2) The cost and benefit assessments in the NPRM did not account for the potential of large quantities of banked Phase 1 credits in either of the “baseline” scenarios. If manufacturers have banked large numbers of credits at the beginning of the Phase 2 program, this suggests that the baseline for purposes of cost-benefit and feasibility analysis at the beginning of Phase 2 should reflect Phase 1 plus the technology advancement associated with the large numbers of banked credits. A large number of credits at the end of Phase 1 suggests the trajectory of technology advancement may be more rapid than utilized
for baseline scenario modeling, and a more dynamic baseline may be appropriate. [EPA-HQ-OAR-2014-0827-1265-A1 p.79]

3) Not only does the NPRM not discount the Phase 1 credits when carrying them over into Phase 2, it actually adjusts these credits upwards, reflecting an increase in the proposed useful life definition. CARB staff recommends against use of these proposed adjustment factors. U.S. EPA and NHTSA base the calculation of credits on factors such as the emission level compared to the standard and the useful life. Some of the useful life values in Phase 1 were substantially shorter than the actual typical useful life; U.S. EPA and NHTSA have proposed to increase the useful life period for these classes of vehicles. As a consequence of this increase, U.S. EPA and NHTSA propose to apply an adjustment factor relating the old useful life to the new useful life. U.S. EPA and NHTSA assert that CO2 deterioration is relatively flat and thus, one can presume that the certified CO2 levels will indeed continue to be met over the longer useful life. While CARB staff agrees that it is appropriate to adjust the useful life upwards to more closely represent the actual useful life, if the credit is multiplied by the ratio of new “actual” useful life to Phase 1 (shorter) useful life, an additional fractional credit will be generated for a benefit that already exists. Because this change in the useful life reflects a recognition of the actual useful life, rather than an increase in the anticipated useful life, CARB staff believes that it is not appropriate to apply a credit adjustment factor to these credits. Allowing the Phase 1 credits to be adjusted upward based on a new extended useful life, as proposed, would take benefits achieved by the Phase 1 program and -- instead of allowing them to benefit the environment -- would allow them to be used to reduce the potential benefits of the proposed Phase 2 program. [EPA-HQ-OAR-2014-0827-1265-A1 p.80]

CARB supports the use of ABT to enable manufacturers to meet Phase 1 and Phase 2 standards in the most efficient and cost-effective way. However, allowing excess Phase 1 credits into the Phase 2 program could result in slower technology advances than anticipated in the NPRM. CARB encourages U.S. EPA and NHTSA to consider sunsetting banked Phase 1 credits in the Phase 2 program to lock in the faster than anticipated technology adoption anticipated from Phase 1. CARB staff specifically suggests that the Phase 1 credits, which currently expire after 5 years, be set to expire in three years or with MY 2020, whichever is sooner. CARB staff further recommends that Phase 1 credits not be adjusted upwards to reflect the change in the useful life to more properly approximate actual useful life. Finally, CARB staff suggests a more dynamic baseline than U.S. EPA and NHTSA are proposing may be appropriate if U.S. EPA and NHTSA are correct in presuming the accumulation of large numbers of Phase 1 credits. [EPA-HQ-OAR-2014-0827-1265-A1 p.80]

Manufacturers are demonstrating their ability to utilize ABT to cost-effectively meet and exceed existing GHG standards. If U.S. EPA disagrees with CARB’s recommendation and maintains its proposal to allow Phase 1 credits in Phase 2, a significant number of Phase 1 credits in the early years of Phase 2 provides greater justification for adopting Alternative 4 over Alternative 3 (as is CARB staff’s recommendation discussed elsewhere in this comment package). [EPA-HQ-OAR-2014-0827-1265-A1 p.81]

**Oppose/Requested Change Comment**

**Comment – Retirement of emission reduction credits**

CARB staff recommends U.S. EPA and NHTSA consider the inclusion of a mechanism within the proposed Phase 2 rulemaking for manufacturers to quantify and then voluntarily forego/retire emission reduction credits (particularly for hybrid heavy-duty engines) in a way that is simple, real, transparent, and enforceable. CARB staff is currently developing innovative technology regulatory requirements that
could allow hybrid engine, vehicle and/or driveline manufacturers to meet more flexible CARB OBD and other certification requirements to facilitate market launch of key hybrid truck and bus technologies. The innovative technology regulations could also provide more limited certification flexibility for other innovative engine technologies, such as WHR, that have the ability to achieve even greater CO2 emission reductions. CARB staff anticipates that the innovative technology regulations could require manufacturers opting to receive this flexibility to demonstrate that the applicable hybrid or other innovative technology be surplus to all applicable rules, regulations, or other requirements. Further detailed discussion on these issues follows. [EPA-HQ-OAR-2014-0827-1265-A1 p.86]

CARB staff is exploring how a potential innovative technology surplus emission reduction compliance demonstration might be conducted in a transparent and efficient way. One potential approach might be to allow manufacturers to generate emission reduction credits from the hybrid or other innovative technology as part of their federal Phase 2 compliance demonstration, and then require the manufacturer to forego/retire these credits as part of their possible Phase 2 ABT reporting. This report would then be shared with CARB as part of the demonstration that the hybrid technology receiving certification flexibility via the innovative technology regulation is surplus to any Phase 2 requirement. The accounting involved with generation, quantification, and retirement of the applicable emission reduction credits would be critical for CARB to determine that the hybrid engines opting to participate in the innovative technology regulation are surplus to Phase 2. Such a mechanism could mirror the approach taken in the NPRM, 40 CFR 1039.710(h), which allows for quantification and retirement of emission reduction credits generated by off-road engines. We believe credit for hybrid engines not participating in the Innovative Technology Regulation should continue to be allowed. [EPA-HQ-OAR-2014-0827-1265-A1 p.86-87]

Another potential approach might be to allow manufacturers to voluntarily designate their credits to a third party, such as CARB (or other public agencies). Such an approach would provide CARB staff with assurance that a banked credit is permanently retired. [EPA-HQ-OAR-2014-0827-1265-A1 p.87]

Without a reporting mechanism to ensure a technology is (and remains) surplus to the proposed Phase 2 requirements in each compliance MY, a potential Innovative Technology Regulation may need to require manufacturers to supplement any adopted federal Phase 2 compliance demonstrations with a California-specific Phase 2 compliance demonstration (with and without the hybrid or other technology, weighted as appropriate by its anticipated California sales volume). Even in such circumstances, however, it may be challenging for CARB staff to track whether a manufacturer utilizes the “surplus” reduction associated with the hybrid or other technology in future year federal compliance demonstrations. A formal mechanism for manufacturers to demonstrate compliance with any adopted federal Phase 2 standard, generate the appropriate emission reduction credits associated with a specific technology, and then permanently forego/retire those credits could help align a potential CARB Innovative Technology Regulation with any adopted federal Phase 2 program, and provide a simple, real, transparent and enforceable mechanism to encourage key technologies in California that go beyond proposed Phase 2 standards. CARB staff looks forward to discussing such a potential approach with U.S. EPA and NHTSA over the coming months as CARB, U.S. EPA and NHTSA consider the adoption of these potential rulemakings. [EPA-HQ-OAR-2014-0827-1265-A1 p.87]

Comment on Topic Where NPRM Requests Comment

Comment – Foregoing emission credits; Expiration of credits

CARB staff fully supports the provisions in 40 CFR 1039.701(h) that allow manufacturers to voluntarily waive their rights to use banked emission credits. CARB staff’s only recommendation for amending this
proposal is that U.S. EPA and NHTSA should clarify that manufacturers choosing not to generate credits for an engine family certified to a FEL more stringent than the applicable standard, as described in 40 CFR 1039.701(h)(2), are permanently bound by that choice and cannot later decide to claim credits for that engine family retroactively in a subsequent MY. [EPA-HQ-OAR-2014-0827-1265-A1 p.128]

On a separate but related topic, CARB staff recommends that U.S. EPA and NHTSA adopt provisions to set a reasonable timeframe for the compulsory expiration of Tier 4 non-road compression ignition emission credits, and codify the terms for expiration in 40 CFR 1039.740. California is a participant in the federal ABT program and is therefore dependent on U.S. EPA and NHTSA for action regarding this request. Our concern is the delay in the full implementation of engines in California equipped with advanced exhaust aftertreatment controls for both PM and NOx. More manufacturers than anticipated are certifying off-road compression ignition engine families in California to Tier 4 final standards without simultaneously employing both PM and NOx aftertreatment devices, and this is due in part, we believe, to manufacturers’ use of banked emission credits. We recognize that other factors may contribute to this situation as well, but addressing the expiration of emission credits would help California to more quickly achieve its much needed PM and NOx emission reduction goals. [EPA-HQ-OAR-2014-0827-1265-A1 p.128]

Organization: Cummins, Inc.

Cummins considers ABT to be an important and necessary part of any regulatory program. ABT encourages earlier implementation of new technologies, allows manufacturers flexibility in planning their investments and managing product costs and provides relief for technical and lead-time issues. All contribute to the development of reliable products that meet the needs of customers. We support the inclusion of ABT provisions in this rulemaking. As described below, Cummins agrees with many aspects of the proposed Phase 2 ABT program for GHG/FE that assist in a successful implementation of the program without sacrificing the sought after environmental and fuel-saving benefits. [EPA-HQ-OAR-2014-0827-1298-A1 p.30]

Cummins supports maintaining the Phase 1 ABT averaging set restrictions [EPA-HQ-OAR-2014-0827-1298-A1 p.30]

In the Preamble (80 FR 40157), the Agencies are proposing to continue the Phase 1 averaging sets and restrictions in Phase 2. Cummins agrees with maintaining the Phase 1 averaging set and restrictions such as: [EPA-HQ-OAR-2014-0827-1298-A1 p.30]

- No credit exchange between gasoline, light heavy-duty (LHD), medium heavy-duty (MHD) and heavy heavy-duty (HHD) engines. [EPA-HQ-OAR-2014-0827-1298-A1 p.30]
- Credit exchange allowed between vocational and tractor engines within a service class. [EPA-HQ-OAR-2014-0827-1298-A1 p.30]

Cummins supports continuing the use of CO2-equivalent credits to comply with nitrous oxide (N2O) and methane (CH4) standards [EPA-HQ-OAR-2014-0827-1298-A1 p.31]
The Agencies are proposing the continued use of CO2-equivalent credits to comply with N2O and CH4 standards. Continuing this provision is appropriate in Phase 2, and Cummins supports it. The specified Global Warming Potentials (GWP) of N2O and CH4 are used to account for the equivalent CO2 credits needed to offset any standards exceedance. This flexibility has been applied by various manufacturers in Phase 1 and is necessary for Phase 2. [EPA-HQ-OAR-2014-0827-1298-A1 p.31]

**Cummins opposes a 90-day final reporting deadline for ABT** [EPA-HQ-OAR-2014-0827-1298-A1 p.31]

Cummins urges the Agencies to maintain Phase 1 ABT reporting deadlines where the final ABT report is due at 270 days after the end of the model year. Many engine/vehicle first point of sale information is not known for well over 90 days after the model year is over. Thus, without that location information the credits from those engines would not be allowed if the first point of sale was in the US and occurred on day 91. This is an unreasonable and punitive proposal due to the fact that the markets and customer demand fluctuates and not all first point of sales will occur within 90 days at the end of the model year. The current final reporting using first point of sale information up to 270 days needs to be maintained. [EPA-HQ-OAR-2014-0827-1298-A1 p.31]

**Organization:** Daimler Trucks North America LLC

- **Averaging, Banking & Trading (80 FR 40387 et seq.)** - The agencies propose to retain the 5-year carry-forward rule for all heavy-duty sectors. The agencies should instead allow a credit carry-forward period of more than 5 years, allowing Phase 1 credits generated in the model years 2014 to 2019 to be used in later model years up to 2027. EPA included a similar provision in the light-duty vehicle regulations. This provision would assist manufacturers in retaining their usual heavy-duty vehicle lifecycles (much longer than 10 years) and gaining additional compliance flexibility. By including such a provision, the agencies would allow an appropriate lead time that will enable the industry to comply with the Phase 2 regulations. As the costs for fuel-saving technologies are likely to decrease over time, future vehicle generations can be equipped with future technologies at lower costs. [EPA-HQ-OAR-2014-0827-1164-A1 p.113-114]

- **Credit Transfer Between Class 2b-3 Medium-Duty and Light-Duty Programs** Daimler encourages EPA and NHTSA to allow the transfer of credits between the medium-duty truck and van (Class 2b-3) program and the light-duty vehicle program. As EPA recognized in responding to similar comments made by Daimler on the light-duty Phase 2 proposed rule, EPA is authorized under the Clean Air Act to allow such transfer. See EPA Response to Comments, 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, at 10-13 (Aug. 2012). Previously, EPA indicated that such a step would require careful analysis and notice and comment, see 77 FR 62789 (Oct. 15, 2012), and committed to making such a proposal for broader credit transfers, including transfers between light- and heavy-duty vehicles, in the second phase of its heavy-duty GHG rulemaking. See 76 FR 57128 (Sept. 15, 2011) (“Through this public process, emphasizing the Administration’s strong preference for flexible approaches and maximizing the use of market tools, the agencies intend to fully consider whether broader credit trading is more appropriate in developing the next phase of heavy-duty regulations.”). Although the heavy-duty Phase 2 proposed rule has not specifically proposed allowing such a credit transfer, as the agencies committed, the agencies have requested comment on all aspects of their proposed medium-duty truck and van standards and on all aspects of their proposed Averaging, Banking, and Trading program. [EPA-HQ-OAR-2014-0827-1164-A1 p.114]

The agencies purposely structured the medium-duty truck and van program to be akin to the light-duty program. The program is attribute-based with the standards set pursuant to a mathematical function.
While the agencies added elements to the footprint-based attribute to account for the functionality of these vehicles, the agencies also made clear that the measured performance values for CO2 are generally equivalent to fuel consumption. Compliance with the light-duty and medium-duty standards is measured through similar dynamometer light-duty program. The agencies recognize all of these commonalities in the heavy-duty Phase 2 proposed rule. See 80 FR 40148 (recognizing similarities between medium-duty trucks and vans and light-duty vehicles), 40175 (same chassis dynamometer test procedure), 40331-32 (comparable weight range, manufacturing, and GHG/fuel economy technologies), 40365 (recognizing technology sharing and requesting comment on agency plans to analyze light-duty and medium-duty trucks and vans jointly). [EPA-HQ-OAR-2014-0827-1164-A1 p.114]

Daimler considers the standards established for medium-duty trucks and vans to be challenging and aggressive. For example, compliance with the Phase 1 standards required that many 6-cylinder diesel engines be downsized to 4-cylinder diesel engines. Far from creating “windfall” credits to apply to the light-duty program, any credits earned with regard to Class 2b-3 vehicle represent substantial emissions improvements, as well as real and measurable reductions in CO2. [EPA-HQ-OAR-2014-0827-1164-A1 p.114-115]

In the medium- and heavy-duty Phase 1 rule, the agencies effectively created three separate programs: one for tractor/trailers, one for vocational vehicles, and one for medium- and heavy-duty trucks and vans. While the first two programs involve vehicles where emissions regulation has in the past been focused exclusively on engines, the third program is vehicle-based—just as with the light duty GHG program—and in fact involves vehicles in the same weight ranges but subject to different use. Vehicles that meet certain criteria designed to identify “work trucks” are placed with the medium-duty truck and van program, while vehicles meeting certain criteria designed to identify “medium duty passenger vehicles” are placed within the light-duty program. Allowing credit transfers in this class between the light-duty and light heavy-duty vehicle fleets is consistent with the agency’s general structure to treat like vehicles alike. The basic programs categorize vehicles by general type, construction, and use. The ABT program recognizes that similarly weighted vehicles are likely to utilize the same engine, transmission, and after-treatment technologies to reach and exceed compliance. EPA established a system whereby similar vehicles using similar technologies could share credits across the various programs. Nothing in the Clean Air Act prohibits the agency from using its discretion to harmonize and promote its greenhouse gas program across similar vehicles and to promote more broadly the application of emissions reducing technology. EPA should exercise this discretion in a limited fashion to allow credits earned on Class 2b-3 vehicles in the medium-duty truck and van program to be applied in the light-duty program as well. [EPA-HQ-OAR-2014-0827-1164-A1 p.115]

NHTSA also has the legal authority to apply credits developed in its medium- and heavy-duty fuel consumption program. Although the legislation mandating NHTSA’s program did not expressly authorize a credit program, NHTSA nonetheless exercised its discretion in the heavy-duty Phase 1 rulemaking to adopt one and to harmonize its program with the EPA program. NHTSA also noted in the program that it has considerably more leeway within the medium- and heavy-duty program to establish flexibilities and to include consideration of credits within its standard setting than it does under the light-duty program. Allowing the transfer of Class 2b-3 vehicle credits between the medium-duty program and the light-duty program is an extension of the same discretion that led and authorized NHTSA to develop the medium-duty credit program initially. Daimler urges NHTSA to use the same authority to extend the credits in a limited fashion, and along the same lines as EPA, to allow credits generated on Class 2b-3 medium-duty trucks and vans to be applied in the light-duty CAFE program. [EPA-HQ-OAR-2014-0827-1164-A1 p.115]
**Technology neutral standards:** The EPA proposes technology neutral standards. We agree that this is the right approach. Prescribing technology to vehicle manufacturers is not the right role for the EPA. That said, the agencies should recognize that—although they purport to create technology neutral standards—in creating a separate engine standard alongside a vehicle standard, the agencies depart from technology neutrality, forcing technology onto the engine even if the same net emissions impact on-road could be achieved through vehicle-side technologies. We recommend that, upon a showing from a manufacturer that a vehicle-side technology creates extra emission reductions beyond those necessary for vehicle-side compliance, that the manufacturer be able to convert those extra emission reductions into an engine-side credit (and vice versa). Only with such an allowance will the agencies truly achieve the technology neutrality that they claim their regulations have. [EPA-HQ-OAR-2014-0827-1164-A1 p.116]

**Erroneous reference:** in ABT provisions, the EPA requires that a manufacturer account for a credit limitation at 1037.40(c), yet there is no such provision. The agency needs to clarify. 1037.40(c) [EPA-HQ-OAR-2014-0827-1164-A1 p.117]

**Organization:** Eaton Vehicle Group

The EPA requested comments on the life of Phase 1 credits in 2021. We are working with some OEMs to produce Phase 1 credits with advanced technology in the market today and are accelerating advanced technology development and deployment. Should Phase 1 credits carry over toward 2021 compliance, we would be further incentivized to accelerate new fuel saving technology as it would also generate compliance value and flexibility for our customers. [EPA-HQ-OAR-2014-0827-1194-A1 p.19]

**Organization:** General Motors

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 103.]

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, pp. 121-122.]

We have also had favorable experience with the extended carry forward time allowed in the light duty regulation, which has resulted in manufacturers achieving greater improvements sooner based on the understanding that they will not waste through expiration the surplus credits that they have earned through their early actions. This concept could also be applied to the medium and heavy duty segments.

**Organization:** Gentherm, Inc.

**Comment #1. Treat Tractor emissions at the Tractor level; provide a transparent mechanism for efficiency improvements trades between Powertrain and Engine technology areas.** [EPA-HQ-OAR-2014-0827-1133-A1 p.1]

**Background from Draft**

“We also propose not to allow trading between engines and chassis, even within the same vehicle class. Such trading would essentially result in double counting of emission credits, because the same engine technology would likely generate credits relative to both standards.” [EPA-HQ-OAR-2014-0827-1133-A1 p.1-2]
In the proposed draft the target for improvements of CO2 emissions for Engines is listed as 4% for diesel engines and 0% for gasoline engines. At the same time, the expected CO2 emission reduction resulting from powertrain improvements are listed at 24%. [EPA-HQ-OAR-2014-0827-1133-A1 p.2]

**Proposed change:** Gentherm recommends allowing for a mechanism to trade emission reductions between engine and chassis. In other words, we are proposing an implementation of mechanism which would encourage engine manufacturers to adopt advanced technologies which would reduce CO2 emissions beyond the level defined in this ruling. To achieve this we are proposing an ability to apply additional improvements at the tractor level. As an example, if an engine improvement in a gasoline engine (and associated technologies such as Waste Heat Recovery) of Class 7 vehicle can contribute to CO2 emissions reduction, this could be accounted towards the overall goal of efficiency improvement. Another example would be a case where improvement of diesel engine emission exceeds the stipulated 4%. The proposal would is to allow the improvements above the stipulated numbers to count towards overall tractor improvement efficiency, effectively allowing trading between the improvements from Engines and Powertrain. Instead of the concern of double-counting the credits, as indicated in the draft of the rule today, the allowance of trading would stimulate industry cooperation between engine and chassis/powertrain makers. [EPA-HQ-OAR-2014-0827-1133-A1 p.2]

**Organization:** National Automobile Dealers Association (NADA)

NADA/ATD fully supports the proposals allowance for averaging, banking, and trading, for small business accommodations, and for other flexibilities designed to enhance compliance and program effectiveness. [EPA-HQ-OAR-2014-0827-1309-A1 p.11]

**Organization:** Navistar, Inc.

Sections 1036.730 and 1037.730 of the NPRM propose to set the deadline for filing final ABT reports to March 31st following the model year, thus reducing total the period for filing final ABT reports. This is a significant reduction in the filing time frame from that in the current rule requirements of 90 days for an end of the year report and 270 days for a final report. Navistar opposes the reduced time frame for the final report. The rules as they exist already constitute a significant burden. This change also appears to reduce the time frame to correct errors, since the rules currently allow all errors to be corrected by the final report. The proposal effectively only allows the correction of an error if it is works against the manufacturer by reducing the number of credits. There is no reasonable basis for this change. Given the complexity of the rules, manufacturers ought to be able to correct any errors within 270 days as is presently the case. In addition, this proposed change coupled with significant cutting of the final report deadline will have an unnecessary and unwarranted effect of increasing the burden on the manufacturer. We also note that the 90 / 270 day timeframe has been in place for many years for other types of emissions such as NOx, and will remain in effect in that context. There is no reason a dual time frame should exist. Navistar would be in favor of eliminating the first report at March 31 as part of an alternative approach that allows a single report, but provides sufficient time in which to create that report. We also note, in this regard, that the Proposed Rule potentially significantly expands the number of separate families that must be tracked for ABT purposes. This only increases the burden and argues directly feasibility of allowing less time for report filing than is the case today. [EPA-HQ-OAR-2014-0827-1199-A1 p.14]

**Organization:** PACCAR, Inc.

**Retain the Existing ABT End of Year 270-day Reporting**
The proposal to reduce the time for end of year reporting for Averaging, Banking, and Trading (ABT) and for production volumes to 90 days after the end of the calendar year named in the model year is overly restrictive. This proposal comes too soon after production periods are completed and will add an unnecessary burden onto manufacturers as well as preventing EPA and NHTSA from receiving the most complete and thus more accurate data on the vehicle and engine configurations that are entering into operation. PACCAR recommends retaining the current 270 days from the end of the calendar year that is named in the model year for report submission. [EPA-HQ-OAR-2014-0827-1204-A1 p.29]

**Organization:** Tiffin Motorhomes, Inc.

IV. Compliance with the proposed regulations using ABT is not possible or feasible for Tiffin

After a studied reading of the proposed regulations, it is not possible or feasible for Tiffin to meet the proposed 2021, 2024 and 2027 standards using ABT. [NHTSA-2014-0132-0099-A1 p.3]

The ABT provisions are not a viable alternative for Tiffin for two reasons. First and foremost, Tiffin currently manufactures only two chassis models, one classified as a MHO, the other as an HHD. These chassis are produced only for motorhomes, and exclusively for Tiffin. This narrow range or products along with the low production volume provide a much lower level of compliance flexibility under the ABT provisions. The annual production volumes for these chassis are; MHO 300-500 units per year, and HHD 500-700 units per year. [NHTSA-2014-0132-0099-A1 p.3-4]

**Organization:** Truck & Engine Manufacturers Association (EMA)

AB&T Credit Life and Averaging

Allowing Phase 1 credits to carry-over into the Phase 2 program is critical to the feasibility and cost-effectiveness of the Proposed Phase 2 Standards for medium-duty and heavy-duty vehicles. Simply stated, if Phase 1 credits were to expire at the end of the Phase 1 program, the Phase 2 program, as proposed, would not be feasible for heavy-duty vehicles. In addition, the Agencies should clarify that manufacturers are not required to use current-year excess credits to balance a prior-year’s deficit. [EPA-HQ-OAR-2014-0827-1269-A1 p.47]

In particular, the Agencies will need to change the wording of proposed sections 1036.745(c) and 1037.745(c), which are carry-overs from the Phase 1 program. Currently, those provisions state as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.47]

(c) You may apply only surplus credits to your deficit. You may not apply credits to a deficit from an earlier model year if they were generated in a model year for which any of your engine families for that averaging set had an end-of-year credit deficit. (Emphasis added) [EPA-HQ-OAR-2014-0827-1269-A1 p.47]

While the Agencies’ intent in proposing this language may be to require manufacturers to reconcile an aggregate deficit within a given model year before carrying credits over to off-set a deficit in a different model year – with the net effect that only “surplus” credits from a model year can be used – the current regulatory language is not so limited. Manufacturers necessarily will have engine and vehicle families in a given model year that have deficit balances even though there is a net positive balance for the entire averaging set. That is the whole point of “averaging.” Consequently, the Agencies should revise the proposed regulatory sections at issue to state as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.47]
(c) You may apply only surplus credits to your deficit. You may not apply credits to a deficit from an earlier model year if they were generated in a model year for which your averaging set had an end-of-year credit deficit. (Emphasis added) [EPA-HQ-OAR-2014-0827-1269-A1 p.48]

End-Of-Year Reporting

EMA supports the Agencies’ proposal to have manufacturers submit one report at the end of the model year to track compliance with the Proposed Phase 2 Standards. However, given the time that it takes for many engines and vehicles (most especially from the most recent model year) to reach their final configuration and point of sale, the deadline for the submission of that one end-of-year report should be 270 days (not 90 days) after the close of the calendar year named in the model year. [EPA-HQ-OAR-2014-0827-1269-A1 p.48]

**Organization:** Volvo Group

**Engine Efficiency**

Recognizing that the Agencies have chosen to include a separate engine efficiency regulation, we encourage them not to increase stringency beyond the proposed levels. Maintaining engine stringency at these levels pushes the envelope of engine technology without forcing the many negative consequences we have outlined in these comments. Furthermore, we are very concerned that an engine manufacturer could generate significant credits (for example by selling alternatively fueled engines) so that they could avoid selling undesirable, complex, expensive engine technology, while competitors, lacking such credits, would be pushed out of the market. [EPA-HQ-OAR-2014-0827-1290-A1 p.19-20]

**Response:**

The Phase 1 ABT provisions were patterned on established EPA ABT programs that have proven to work well. In Phase 1, the agencies determined this flexibility would provide an opportunity for manufacturers to make necessary technological improvements and reduce the overall cost of the program without compromising overall environmental and fuel economy objectives. Commenters generally supported this approach for engines, pickups/vans, tractors, and vocational vehicles. Thus, we are generally continuing this Phase 1 approach with few revisions to the engine and vehicle segments. However, as described in Section 5, we are finalizing a much more limited averaging program for trailers that will not go into effect until 2027. The agencies see the overall ABT program as playing an important role in making the technology-advancing standards feasible, by helping to address many issues of technological challenges in the context of lead time and costs. It provides manufacturers flexibilities that assist the efficient development and implementation of new technologies and therefore enable new technologies to be implemented at a more aggressive pace than without ABT.

**Relation of ABT to Stringency**

Volvo commented that the ABT program should not be used to justify more stringent standards. However, ABT programs are more than just add-on provisions included to help reduce costs. They can be, as in EPA’s Title II programs generally, an integral part of the standard setting itself. A well-designed ABT program can also provide important environmental and energy security benefits by increasing the speed at which new technologies can be implemented (which means that more benefits accrue over time than with later-commencing standards) and at the same time increase flexibility for, and reduce costs to, the regulated industry and ultimately consumers. Without ABT provisions (and other related flexibilities), standards would typically have to be numerically less stringent since the
numerical standard would have to be adjusted to accommodate issues of feasibility and available lead time. See 75 FR 25412-25413. By offering ABT credits and additional flexibilities the agencies can offer progressively more stringent standards that help meet our fuel consumption reduction and GHG emission goals at a faster and more cost-effective pace.22

Volvo’s comments seemed to be primarily addressing the proposed vocational vehicle standards. They argued that “it is completely unacceptable that the Agencies promulgate a regulation where an entire class (regulatory subcategory) of vehicles is known and intentionally targeted beforehand to be incapable of meeting the standard for that subcategory when utilizing the full technology package and the expected penetration rates used to set the standard.” However, that is not what is being done in the final rule for vocational vehicles. As explained in Preamble Section V.C.(2) and RIA Chapter 2.9, the vocational vehicle standards for each of the subcategories (Regional, Multi-Purpose, Urban powered by LHD, MHD, and HHD engines) were developed as are all the other standards in the rule: reflecting achievable reductions based on the technology packages and penetration rates in the agencies’ designated potential compliance pathways. In particular, the agencies are not basing any of the vocational vehicle standards on either normalization of the baseline, or equalization of the standard stringencies. The standards being adopted thus would be achievable without averaging.

**Carryover of Phase 1 Credits and Credit Life**

The agencies proposed to continue the five-year credit life provisions from Phase 1, and not to adopt any general restriction on the use of banked Phase 1 credits in Phase 2. In other words, Phase 1 credits in MY2019 could be used in Phase 1 or in Phase 2 in MYs 2021-2024. CARB commented in support of a more restrictive approach for Phase 1 credits, based on the potential for manufacturers to delay implementation of technology in Phase 2 by using credits generated under Phase 1. We also received comments asking the agencies to provide a path for manufacturers to generate credits for applying technologies not explicitly included in the Phase 1 program. In response to these comments, the agencies have analyzed the potential impacts of Phase 1 credits on the Phase 2 program for each sector and made appropriate adjustments in the program. For example, as described in Section II of the FRM preamble, the agencies are adopting some restrictions on the carryover of windfall Phase 1 engine credits that result from certain test procedure aspects of the Phase 1 vocational engine standards. Also, as described in Section III of the FRM, the agencies are projecting that Phase 1 credit balances for tractor manufacturers will enable them to meet more stringent standards for MY2021-2023, so the agencies have increased the stringency of these standards accordingly.

In particular, CARB argued that the agencies had not analyzed the impacts of allowing carryover of Phase 1 credits into Phase 2. However, we have analyzed such impacts and have adjusted the MY 2021 tractor standard to be one percent more stringent based on projected Phase 1 credit balances for tractor manufacturers.23 Although not explicitly quantified in other cases, the likelihood of manufacturers having significant Phase 1 credits available in the Phase 2 timeframe has allowed us be less conservative in our projections of the availability and effectiveness of technologies. Just as important, CARB appears to be overlooking a very important benefit of allowing manufacturers to bank credits. It provides an incentive for manufacturers to develop new technologies and introduce them into the market as soon as possible. The effect of CARB changes would be to reduce this incentive, which appears to conflict with their comments regarding advanced technologies.

---

23 Memo to Docket, Phase 1 Credit Balance Analysis, August 2016.
Although, as we have already noted, the numerical values of Phase 2 standards are not directly comparable in an absolute sense to the existing Phase 1 standards (in other words, a given vehicle would have a different g/ton-mile emission rate when evaluated using Phase 1 GEM than it would when evaluated using Phase 2 GEM), we believe that the Phase 1 and Phase 2 credits are largely equivalent. Because the standards and emission levels are included in a relative sense (as a difference), it is not necessary for the Phase 1 and Phase 2 standards to be directly equivalent in an absolute sense in order for the credits to be equivalent.

This is best understood by examining the way in which credits are calculated. For example, the credit equations in 40 CFR 1037.705 and 49 CFR 535.7 calculate credits as the product of the difference between the standard and the vehicle’s emission level (g/ton-mile or gallon/1,000 ton-mile), the regulatory payload (tons), production volume, and regulatory useful life (miles). The Phase 2 payloads, production volumes, and useful lives for tractors, medium and heavy heavy-duty engines, or medium and heavy heavy-duty vocational vehicles are equivalent to those of Phase 1. However, EPA is changing the regulatory useful lives of HD pickups and vans, light heavy-duty vocational vehicles, spark-ignited engines, and light heavy-duty compression-ignition engines. Because useful life is a factor in determining the value of a credit, the agencies proposed to apply interim adjustment factors to ensure banked credits maintain their value in the transition from Phase 1 to Phase 2.

For Phase 1, EPA aligned the useful life for GHG emissions with the useful life already in place for criteria pollutants. After the Phase 1 rules were finalized, EPA updated the useful life for criteria pollutants as part of the Tier 3 rulemaking. The new useful life implemented for Tier 3 is 150,000 miles or 15 years, whichever occurs first. This same useful life is being adopted in Phase 2 for HD pickups and vans, light heavy-duty vocational vehicles, spark-ignited engines, and light heavy-duty compression-ignition engines. The numeric value of the adjustment factor for each of these regulatory categories depends on the Phase 1 useful life. These are described in detail in Sections II, V, and VI of the Preamble. Without these adjustment factors the changes in useful life would effectively result in a discount of banked credits that are carried forward from Phase 1 to Phase 2, which is not the intent of the changes in the useful life. With the relatively flat deterioration generally associated with CO2, EPA does not believe the changes in useful life will significantly affect the feasibility of the Phase 2 standards. CARB’s opposition to this adjustment appears to be the result of either its general opposition to allowing Phase 1 credits into Phase 2, or a mistaken belief that there will be an actual in-use difference between usage patterns for Phase 1 and Phase 2 vehicles. To the extent their comment reflects the former, we do not believe it would be appropriate to use this useful life difference to discount Phase 1 credits. If it is the latter, we do not believe there will an in-use durability difference for vehicles at the end of Phase 1 (e.g. MY2020) and vehicles at the start of Phase 2 (e.g. MY 2021).

We note that the primary purpose of allowing manufacturers to bank credits is to provide flexibility in managing transitions to new standards. The five-year credit life is substantial, and allows credits generated in either Phase 1 or early in Phase 2 to be used for the intended purpose. However, we believe that limited ability manufacturers have had to generate Phase 1 credits for Class 2b through 7 vocational vehicles, along with the sometimes narrow product line for some manufacturers, makes it more likely that the five-year credit life would be too short for these vocational vehicles. As described in Section I.C.(1)(b)(i) of the FRM Preamble, the agencies are extending the credit life for the Light and Medium heavy-duty vehicle averaging sets (typically vehicles in Classes 2b through 7) so that all credits generated in 2018 and later will last at least until 2027.

For other engines and vehicles, the agencies believe a credit life longer than five years is unnecessary to accomplish this transition. Restrictions on credit life serve to reduce the likelihood that any manufacturer will be able to use banked credits to disrupt the heavy-duty vehicle market in any given
year by effectively limiting the amount of credits that can be held. Without this limit, or other constraints, one manufacturer that saved enough credits over many years could achieve a significant cost advantage by using all the credits in a single year. The agencies believe that allowing a five-year credit life for all credits, and as a consequence allowing use of Phase 1 credits in Phase 2, creates appropriate flexibility and appropriately facilitates a smooth transition to each new level of standards.

Averaging Sets

EPA has historically restricted averaging to some extent for its HD emission standards to avoid creating unfair competitive advantages or environmental risks due to credits being inconsistent. It also helps to ensure a robust and manageable compliance program. Under Phase 1, averaging, banking and trading can only occur within and between specified “averaging sets” (with the exception of credits generated through use of specified advanced technologies). We proposed to continue this regime in Phase 2, retaining the existing vehicle and engine averaging sets, and creating new trailer averaging sets.

Comments were mixed, with some supporting the proposed restrictions, and others supporting relaxation of the restrictions.

We are not allowing trading between engines and chassis, even within the same vehicle class. Such trading would essentially result in double counting of emission credits, because the same engine technology would likely generate credits relative to both standards (and indeed, certain engine improvements are reflected exclusively in the vehicle standards the agencies are adopting). With respect to Gentherms’s comment, we believe the inclusion of fuel maps in GEM will provide sufficient additional incentive for engine improvements.

The agencies continue to believe that maintaining trading to be only within the classes listed above will provide adequate opportunities for manufacturers to make necessary technological improvements and to reduce the overall cost of the program without compromising overall environmental and fuel efficiency objectives, and it is therefore appropriate and reasonable to allow under the agencies’ respective statutory authorities. We do not expect emissions from engines and vehicles – when restricted by weight class – to be dissimilar. Similarly we expect complete HD pickups and vans to be more similar to one another than to other Class 2b-5 vehicles or to light-duty vehicles. We therefore expect that the lifetime vehicle performance and emissions levels will be very similar across these defined categories, and the credit calculations will fairly ensure the expected fuel consumption and GHG emission reductions.

These restrictions have generally worked well for Phase 1, and we continue to believe that these averaging sets create flexibility without creating an unfair advantage for manufacturers with erratically integrated portfolios, including engines and vehicles. See 76 FR 57240.

Credit Deficits

The Phase 1 regulations allow manufacturers to carry-forward deficits for up to three years. This is an important flexibility because the program is designed to address the diversity of the heavy-duty industry by allowing manufacturers to sell a mix of engines or vehicles that have very different emission levels and fuel efficiencies. Under this construct, manufacturers can offset sales of engines or vehicles not meeting the standards by selling others (within the same averaging set) that better than the standards. However, in any given year it is possible that the actual sales mix will not balance out, and the manufacturer may be short of credits for that model year. The three-year provision allows for this possibility and creates additional compliance flexibility to accommodate it.
EMA comments that “manufacturers necessarily will have engine and vehicle families in a given model year that have deficit balances even though there is a net positive balance for the entire averaging set.” However, EMA misunderstands what it means for a family to have an end-of-year deficit. An engine family is not actually considered to have an end-of-year deficit if the manufacturer has sufficient credits to achieve a zero-balance in the end-of-year report.

Voluntary Retirement of Credits

CARB recommended that the agencies include a mechanism within the proposed Phase 2 rulemaking for manufacturers to quantify and then voluntarily forego/retire emission reduction credits. The agencies proposed such a program and are finalizing it. See 40 CFR 1036.701(e) and 1037.701(e).

Reporting Requirements

Several commenters opposed the proposed change to the reporting deadlines and supported maintaining the Phase 1 ABT reporting deadlines where the final ABT report is due at 270 days after the end of the model year. Some noted that the required information may not be known for well over 90 days after the model year is over. The agencies have decided to not finalize the proposed changes and instead to largely continue the Phase 1 approach. However, we are changing the reporting deadlines slightly to make them dates certain rather than a number of days after the model year ends. Reports will now be due on March 31 and September 30. These are essentially the same deadlines, but will be easier to implement because neither manufacturers nor the agencies will be required to track small changes to the end dates of model years.

Other Issues

Daimler identified an incorrect reference a nonexistent §1037.40(c) in the proposed 40CFR 1037.730. This has been revised to refer to 1037.740(c)

1.4.8 Global Warming Potential Comments

Organization: American Automotive Policy Council

- **Global Warming Potential (GWP) change for non-CO2 GHGs** - EPA should refrain from having different GWP based on vehicle classifications. If EPA chooses to lower the N2O GWP from 298 to 268 and increase CH4 from 25 to 36 based on latest IPCC report, the cost-benefit analysis needs to be clearly outlined in the final RIA inclusive of the impact on flex fuel vehicle and CNG products. In addition, the effective impact on greenhouse gas stringency associated with offsetting exceedances of the N2O and CH4 cap standards must be evaluated. Furthermore, the draft RIA should also include a detailed analysis of the merits of using Global Temperature Potential (GTP) values in lieu of GWP for both N2O and CH4. As stated above, this change should be consistent across all vehicle classes, as well as, all regulations under EPA and NHTSA authority. [EPA-HQ-OAR-2014-0827-1238-A1 p.11]

Organization: American Gas Association (AGA) et al.

We Strongly Support Maintaining the Agency-wide Use of the 100-year Global Warming Potential of 25 for Methane that Was Established in the IPCC’s AR4
Establishing a global warming potential (GWP) is a critical issue in any GHG program. EPA has wisely adopted a single GWP that it uses consistently in all of its programs and reporting obligations. More specifically, EPA consistently uses a 100-year GWP of 25 for methane. This GWP was established in the IPCC’s Fourth Assessment Report (AR4), which was published in 2007.\footnote{P. Forster and V. Ramaswamy. “Changes in Atmospheric Constituents and in Radiative Forcing”. Chapter 2 of the IPCC’s Fourth Assessment Report, page 212. http://www.ipcc.ch/publicationsanddata/ar4/wg1/en/ch2s2-10-2.html.} We strongly support maintaining this approach for the Phase 2 Rule. [EPA-HQ-OAR-2014-0827-1223-A1 p.2]

Examples of EPA’s use of the AR4 GWP include:\footnote{We strongly support maintaining this approach for the Phase 2 Rule. [EPA-HQ-OAR-2014-0827-1223-A1 p.2]}

- The LD Phase 1 Rule, the LD Phase 2 Rule, and the HD Phase 1 Rule;\footnote{5 HD Phase 1 Rule, page 57188.} [EPA-HQ-OAR-2014-0827-1223-A1 p.2]

In addition to ensuring internal consistency among EPA’s many greenhouse gas programs, maintaining the use of the AR4 GWP also enables EPA to coordinate its data with the data collected by EPA pursuant to its obligations under the United Nations Framework Convention on Climate Change (UNFCCC). Doing so “improves EPA’s ability to analyze corporate, national, and sub-national GHG data consistently, enhances communication of GHG information between programs, and gives outside stakeholders a consistent, predictable set of GWPs to avoid confusion and additional burden.”\footnote{10 “The national inventory of GHG emissions and sinks.” [EPA-HQ-OAR-2014-0827-1223-A1 p.3]}

We strongly support the continued use of the AR4 GWP in this Proposal. Furthermore, we believe that changing the GWP should be an agency-wide decision, and not an outcome of any particular sector-specific rule. Anything else could result in a patchwork of inconsistent metrics being used across the array of EPA programs. [EPA-HQ-OAR-2014-0827-1223-A1 p.3]
Organization:  Center for Biological Diversity

The Methane GWP Used for Analysis and Trading Must be the 20-year GWP from AR5

The EPA has requested input regarding what methane global warming potential (“GWP”) is appropriate for the purposes of these standards. As we have strenuously urged in previous comments to the EPA, the only reasonable source is the Intergovernmental Panel on Climate Change (“IPCC”) most recent assessment. At present, this is the Fifth Assessment Report (“AR5”), but GWP values should be updated each time a new Assessment Report becomes available. [EPA-HQ-OAR-2014-0827-1460-A1 p.16-17]

As noted in the call for comments within the Proposed Rule, there are several GWP values from which to choose, depending on both carbon cycle feedbacks and time frame for climate impacts. With regard to carbon cycle feedbacks, it is essential to employ the GWP that includes carbon cycle feedbacks. The groundbreaking realization by the contributors to AR5 was that carbon cycle feedbacks are an inherent part of the warming caused by CO2. Yet, until the most recent Assessment, they were omitted from GWP values for other greenhouse gases. Thus, until AR5, the GWP conversion was actually comparing apples to oranges. The only way to accurately compare among greenhouse gases – the entire purpose of a GWP – is to include carbon cycle feedbacks. This amounts to a 100-year methane GWP of 36. [EPA-HQ-OAR-2014-0827-1460-A1 p.17]

The second choice with regard to the GWP for methane is time horizon: 20 years or 100 years. We urge the EPA to analyze the effects of the rule using both, but to use the 20-year GWP for trading purposes as this is the most accurate reflection of the time scale for this rule. [EPA-HQ-OAR-2014-0827-1460-A1 p.17]

The selection of a particular time horizon for GWPs influences the policy focus because the analysis and comparison occurs only at the selected time frame. Many policy analysts and decision makers, believe that a 100-year focus is important for long-term climate stabilization, while a near-term (20 years or less) focus is equally crucial because the next few decades will determine whether catastrophic and irreversible damage can be avoided before tipping points are crossed. Decision makers and the public should be presented with the 20-year effects of greenhouse gases to focus attention on short-term
solutions that may abate immediate harm sufficiently to allow us to reach climate stability on a 100-year and beyond time scale. [EPA-HQ-OAR-2014-0827-1460-A1 p.17]

The time-based distinction between GWPs is of key importance for a greenhouse gas such as methane. Methane is a short-lived greenhouse gas that remains in the atmosphere a little over a decade; by contrast, CO2 has an atmospheric lifetime of a century and beyond. Methane has exerted the second largest warming influence since the Industrial Revolution, behind only CO2.85 And crucially, the AR5 value for its 20-year GWP (87) is nearly 2.5 times higher than its 100-year GWP (36). The implications of this difference for responsive action are enormous. [EPA-HQ-OAR-2014-0827-1460-A1 p.17]

85 Myhre 2013, supra note 69, IPCC Figure 8.17 at 69.

Organization: Clean Energy

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 248-249, 250-251.]

Specifically, we appreciate the continued allowance of cross-pollutant trading of CH4, N2O, and CO2.

The rule also provides consistency. Continued utilization of the 100-year global warming potential of 25 for CH4 provides a standard metric across the full array of light-, medium-, and heavy-duty vehicles as well as other agency rules governing greenhouse gas emissions.

Organization: NGVAmerica

J. GWP Values for Methane (CH4) and N2O. EPA has proposed using the GWP values identified in the IPCC Fourth Assessment [EPA-HQ-OAR-2014-0827-1270-A1 p.8]

NGVAmerica strongly supports the continued use of the GWP values used under the Phase 1 rules. These GWP values have long-standing acceptance and are used for purposes of the greenhouse gas regulations covering light and medium duty passenger cars, and also for numerous other EPA rules. Using these values provides consistency and uniformity across a number of regulatory programs and allows efficient comparisons across these regulatory programs. Therefore, we strongly urge EPA to continue to use the GWP values adopted under Phase 1. [EPA-HQ-OAR-2014-0827-1270-A1 p.8]

Organization: Optimus Technologies

GWP Values for CH4 and N20

Concerning the Request for Comment on Changing Global Warming Potential Values in the Credit Program for CH4 and N2O at 80 FR 40206 (Column 1, Paragraphs 1-2): “Therefore, we not only request comment on whether to update the GWP for methane and nitrous oxide to that of the Fifth Assessment Report, but also on which value to use from this report.” The IPCC states on page 44 of its Synthesis Report1 that global concentrations of N2O (as well as CO2 and CH4) have been steadily
increasing despite efforts and regulations to curb and decrease its concentration. As such, Optimus Technologies believes the higher value for nitrous oxide should be used. In regards to methane, Optimus Technologies believes the EPA should consider using the 20-year GWP value, stated in the report as 86, given the shorter lifetime of methane. The harmful effects of methane should be mitigated by increasing the GWP of methane (and thus reducing the number of vehicles/engines with excess methane emissions on the road). Methane emissions are especially prevalent with natural gas (CNG or LNG) vehicles. In a recent Pennsylvania State University Study, researchers state that “the CH4 emissions are nearly 100 times higher for CNG” and that the “CH4 emissions from the CNG vehicle lead to CO2 equivalent emissions of 1890 g/mi, compared to the 1785 g/mi of CO2 emitted by the diesel vehicle.” [EPA-HQ-OAR-2014-0827-1276-A1 p.1]

Organization: Securing America's Future Energy

We support maintaining key structural components established in the Phase 1 Rule, which provide for a fair and consistent Phase 2 Proposal. Specifically, SAFE is agrees with the continuance of the compliance pathway flexibility for cross-pollutant trading of methane and the 100-year global warming potential factor for methane. [EPA-HQ-OAR-2014-0827-1462-A1 p.2]

Response:

The Phase 1 GHG rule included a compliance alternative allowing heavy-duty manufacturers and conversion companies to comply with the respective methane or nitrous oxide standards by means of over-complying with CO2 standards (40 CFR 85.525). More specially, EPA allows manufacturers to use CO2 credits (generated from the same averaging set) to comply with the methane and nitrous oxide requirements after adjusting the CO2 emission credits based on the relative GHG equivalents. To establish the GHG equivalents used by the CO2 credits program, the Phase 1 heavy-duty vehicle rulemaking incorporated the IPCC Fourth Assessment Report GWP values of 25 for CH4 and 298 for N2O, which are assessed over a 100 year lifetime. EPA is largely continuing this allowance for Phase 2.

Since the Phase 1 rule was finalized, a new IPCC report has been released with new GWP estimates. EPA asked for comment on whether the methane GWP used to establish the GHG equivalency value for the CO2 Credit program should be updated to those established by IPCC in its Fifth Assessment Report (AR5). The IPCC AR5 presents four different potential values for the GWP of methane over a 100 year lifetime, ranging from 28 to 36. These values are the result of slightly different calculation methods. Therefore, we not only requested comment on whether to update the GWP for methane to that of the AR5, but also on which value to use from this report. The GWPs of 28 and 30 are both a result of using a carbon cycle approach consistent with that used in the Fourth Assessment Report. This carbon cycle approach included a climate-carbon feedback when calculating the lifetime of a pulse of carbon dioxide emissions, but did not include any climate-carbon feedback when calculating the impacts of a pulse of non-CO2 greenhouse gas emissions. As the GWP is the ratio of the impact of a pulse of non-CO2 GHG
emissions relative to a pulse of carbon dioxide emissions, a second approach was presented where the non-CO$_2$ GHG pulse also included climate-carbon feedbacks. This second approach yields GWP values of 34 or 36. For the purposes of this rule, EPA is choosing the approach that includes climate-carbon feedbacks for both non-CO$_2$ and CO$_2$ pulses, as the agency considers this the approach most likely to be adopted by the international scientific community in future assessments on the timescale of this rule. The IPCC presents the value of 34 as the default value for the methane GWP, but also reports a value of 36 for “fossil” methane to take into account the atmospheric CO$_2$ that would result from the oxidation of methane in the atmosphere.

We received a number of comments on this issue. For the most part, the environmental community favored using the more recent GWP value and even some commented that EPA should use a methane GWP based on a 20 year timeframe. On the other hand, the natural gas industry and natural gas truck manufacturers commented that EPA should not update to the newer GWP values but continue to use the methane GWP value from the AR4 IPCC report because EPA is still using the methane GWP from the AR4 today in other contexts. Although EPA is currently using AR4 values in other contexts, it is unlikely that EPA will still be using AR4 values in 2021 when the Phase 2 requirements begin. Thus, commenters opposing the use the methane GWP from the later IPCC report are not persuasive. EPA will continue to base the credit adjustment on a 100 year timescale because it seems to best balance short-term versus long-term effects of climate change.

Of the possible 100 year methane GWP values presented in the IPCC AR5 report, EPA is choosing to use the value of 34 because it is the primary value presented by the IPCC and because the approach of not accounting for the CO$_2$ oxidation product within the GWP for methane is consistent with prior IPCC practice. The use of this GWP for credit adjustments will not begin until 2021, when the Phase 2 engine standards go into effect. The choice of this GWP value for future rules on this timescale does not prejudice the choice of other GWP values for use in regulations and other purposes in the near term.

1.5 Lead Time 216

Organization: Advanced Engine System Institute (AESI)

There appears to be ample evidence to indicate that, of the options considered by the agencies, Alternative 4’s timeline comes closest to striking the right balance though it does appear greater reductions than the 4.2% in the proposal could well be feasible now and still be quite cost-effective. There are now a multitude of technologies, including waste heat recovery, turbo-compounding, advanced downspeeding, hybridization, etc. that can be ready to deploy in the Alternative 4 timeframe or sooner at still reasonable cost, provided the right policy or market signal and some combination of incentives or credits. EPA may want to consider whether such incentives or credits, particularly in an era of low fuel prices, might expedite the development and commercialization of these technologies and promote earlier and more cost-effective achievement of the program goals. If the Agency chooses not to adopt a technology-driving engine standard in this rulemaking cycle, it may make sense to incorporate a Mid-term Review or evaluation of engine related technologies in the not too distant future so the standards can be adjusted and updated to keep pace with innovation and the growing need to reduce carbon emissions. [EPA-HQ-OAR-2014-0827-1152-A1 p.2 [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.290-291.]]]

Organization: American Bus Association et al.

---

24 The corresponding N2O value from the AR5 report is 298, which is the same as the value used in Phase 1.
We, the 16 undersigned trade associations, represent a diverse cross-section of industries that have a strong interest in the joint U.S. Environmental Protection Agency and National Highway Traffic Safety Administration proposed rule “Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles - Phase 2.” Our combined 240,000 members rely on a strong, vibrant U.S. commercial motor vehicle industry to safely and cost-effectively transport goods and people, provide high quality direct and indirect job opportunities, and make meaningful contributions to cleaner air and safer roads. Given we are already very concerned over the proposed Phase 2 “Alternative 3” efficiency targets, we ask EPA and NHTSA to reject what is defined in the NPRM as “Alternative 4” to avoid serious negative economic implications for fleets, truck manufacturers, suppliers, dealers, and the nation’s economy as a whole. [EPA-HQ-OAR-2014-0827-1293-A1 p.1]

Equipment acquisition costs are a top consideration for all fleets. New and increasingly more stringent emissions and safety regulations have required extensive changes to engines and vehicles, including the addition of expensive technologies such as exhaust after-treatment systems. As a result, vehicle and operation costs have risen significantly over the past 10 years. [EPA-HQ-OAR-2014-0827-1293-A1 p.2]

Fleets can better absorb cost increases associated with the purchase of fuel efficient technologies if they deliver reasonable payback periods and return on investment. We are concerned that the actual costs of Phase 2 technologies for model year 2017-2027 vehicles and trailers will greatly exceed the agencies’ estimates. Fleets look at the total cost of ownership—acquisition and operation costs, fuel, personnel, maintenance, overhead, road charges, insurance, residual values, and taxes. If the incremental investment and operating costs of trucks and trailers manufactured to comply with the Phase 2 regulations are not met by corresponding fuel savings and reliability benefits, it is likely that fleets will avoid buying them. [EPA-HQ-OAR-2014-0827-1293-A1 p.2]

For suppliers to the heavy-duty commercial vehicle industry, “pre-buys” and “low-buys” of Phase 2 technologies have serious economic implications. When EPA mandated new engine technologies effective in 2007, fleets held off buying new vehicles and jobs at U.S. heavy-duty commercial vehicle manufacturers, suppliers, and dealers suffered significantly. We are very concerned that the Phase 2 Rule “Alternative 4” is not achievable and could, as a result, seriously impact fleet operations and have a downward effect on U.S. jobs and the economy. [EPA-HQ-OAR-2014-0827-1293-A1 p.2]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Standards in 2027 must drive advanced technologies.

If the program is extended to 2027, those standards must go well beyond what is currently proposed to meet the agencies’ requirements for appropriate and maximum feasible standards. A crucial function of motor vehicle emissions standards is to promote the further development and accelerate the deployment of promising technologies whose pathway to market acceptance is less clear. EPA has the authority to set technology-forcing standards under the Clean Air Act; it is especially important that the agency exercise that authority in a rule, such as this one, that has a long time horizon. [EPA-HQ-OAR-2014-0827-1280-A1 p.6]

The proposed rule recognizes this, and includes technologies such as advanced aerodynamics and vocational hybrids in the compliance scenario for this reason. However, given that the proposed standards can be met without drawing on those technologies, it is necessary to substantially strengthen the 2027 standards to ensure the program does in fact promote the development of these and other
advanced technologies and point the way to further, major gains for heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1280-A1 p.6]

- Adopt standards for 2024 that are comparable or superior in fuel consumption reductions to the 2027 standards. [EPA-HQ-OAR-2014-0827-1280-A1 p.29]

For 2027, adopt technology-forcing standards that will help drive advanced technologies into the market and reduce overall fuel consumption by 31% beyond Phase 1 levels. [EPA-HQ-OAR-2014-0827-1280-A1 p.29]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The proposed 2027 standards – and more – can cost-effectively and feasibly be achieved by model year 2024.

As discussed in detail below, the fuel consumption reduction achieved by 2027 in the preferred alternative (Alternative 3) can and should be reached or exceeded by 2024. However, the agencies’ compliance package for Alternative 4 represents only one pathway to reach those reductions, and it is unlikely to be the lowest cost option to do so. In particular, we find that an overall fuel consumption reduction of 24% relative to 2017 levels could be achieved cost-effectively in 2024 without the use of advanced technologies, as described later in these comments. [EPA-HQ-OAR-2014-0827-1280-A1 p.6]

Other Issues

Acceleration of Standards to 2024 and ensuring 2027 standards promote adoption of advanced technology

As noted above, ACEEE finds that the overall stringency of the standards proposed in Alternative 4, and more, is readily achievable. That is, the fuel consumption reduction achieved by 2027 in the preferred alternative (Alternative 3), can and should be reached or exceeded by 2024. [EPA-HQ-OAR-2014-0827-1280-A1 p.27]

The majority of improvements beyond Phase 1 would come from fuel consumption reduction in tractor trailers, followed by heavy-duty pickups and vans, and vocational vehicles. Table 9 replicates the agencies’ proposed improvement for heavy-duty vehicles and engines and the overall reductions in 2024 and 2027. [EPA-HQ-OAR-2014-0827-1280-A1 p.27]

[Table 9 can be found on p.27-28 of docket number EPA-HQ-OAR-2014-0827-1280-A1]

Greater reductions can be achieved in all vehicle and engine classes, however, even without accelerating or increasing reliance on advanced technologies such as waste heat recovery (Rankine cycle/turbo-compounding), hybrids, or advanced aerodynamics. By adopting higher effectiveness values from the SwRI study for some incremental engine, transmission, and vehicle technologies, as explained in the previous sections, we can achieve 26% and 31% reductions in overall fuel consumption in 2024 and 2027, respectively, substantially more than the 23.5% reduction from the proposed 2027 standard. [EPA-HQ-OAR-2014-0827-1280-A1 p.28]
Moreover, given concerns that have been raised about the cost, performance and/or durability of some advanced technologies, it is worth noting that similar results can be achieved in 2024 without any adoption of waste heat recovery, advanced aero for tractors and trailers, level 3 tires, start/stop systems or strong hybrids. If we exclude these technologies from our 2024 package and keep the agency penetration rates for all other technologies, we can still attain 24% reduction in 2024, as shown in table 10. This shows that the manufacturers can comply with stronger standards than those proposed with existing technologies in the market. [EPA-HQ-OAR-2014-0827-1280-A1 p.28]

[Table 10 can be found on p.28 of docket number EPA-HQ-OAR-2014-0827-1280-A1]

However, it is important that the standards in fact help to draw new technology into the market, especially if they are set out to 2027. The package mentioned above, delivering an overall fuel consumption reduction of 31% in 2027 using the agencies’ assumptions for adoption and effectiveness of advanced technologies would be an appropriate target for that year. [EPA-HQ-OAR-2014-0827-1280-A1 p.28]

Figure 3 shows the fuel consumption reductions in 2024 or 2027 for the three scenarios discussed, and compares them with the Phase 2 proposal for 2027. [EPA-HQ-OAR-2014-0827-1280-A1 p.29]

[Figure 3 can be found on p.29 of docket number EPA-HQ-OAR-2014-0827-1280-A1]

- Adopt standards for 2024 that are comparable or superior in fuel consumption reductions to the 2027 standards. [EPA-HQ-OAR-2014-0827-1280-A1 p.29]
- For 2027, adopt technology-forcing standards that will help drive advanced technologies into the market and reduce overall fuel consumption by 31% beyond Phase 1 levels. [EPA-HQ-OAR-2014-0827-1280-A1 p.29]

**Organization:** American Lung Association

The American Lung Association offers the following recommendations to strengthen the stringency and timing of the proposal and address several key elements of California’s commitment to protecting public health and air quality. [NHTSA-2014-0132-0087-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.143-144]]

The American Lung Association recommends adopting the most aggressive implementation schedule, Alternative 4, bringing the rule online by 2024, and requiring much stronger fuel efficiency to achieve a 40 percent fuel reduction savings. These changes will help to drive down emissions sooner and help move us further down the path to clean, healthy air by cutting significantly more carbon dioxide emissions, cuts that are crucial to fighting climate change. The urgency of climate change and the air pollution challenges in California indicate that we need all emission reductions possible in the near term. Analysis by the Union of Concerned Scientists shows that a greater reduction in fuel use is possible. ¹ Their analysis showed that by going to 10.7 mpg from 6.3 mpg, the standards could achieve a 40 percent reduction in fuel use by 2025. A stronger fuel efficiency standard will reduce petroleum consumption more rapidly and reduce emission of greenhouse gases. There is no reason to delay-action now will also help to spur further action to reduce emissions from the truck sector. [NHTSA-2014-0132-0087-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.144.]]
ATA Opposes Alternative 4

Phase 2 will only be successful if projected future technology patterns are wholly recognized. Making the best predictions on what the trucking sector will look like in over a decade from now is an extremely difficult undertaking. Factors such as the state of technology development, fleet buying patterns, future industry-wide purchasing estimates, the strength of the national and global economies, along with fuel and equipment pricing, will determine whether the agencies’ proposed targets can be achieved. Given this multitude of variables, ATA strongly urges the agencies to adopt Alternative 3 as the chosen pathway subject to addressing various concerns contained in our comments. Current cost projections and efficiency improvements do not, and should not, warrant pulling-ahead the 2027 targets to 2024 as proposed under Alternative 4. Such approach would result in serious market disruptions and force unproven technologies into the market before being fully tested and verified – a dire result the industry seeks to avoid given the recent history fleets experienced involving the regulation of particulate matter (‘PM’) and nitrogen oxides (‘NOx’) emissions. [EPA-HQ-OAR-2014-0827-1243-A1 p.5]

Organization: Autocar, LLC

4.6 Additional lead time would not provide sufficient relief. Although Autocar appreciates the Agencies’ willingness to consider providing additional lead time for compliance by small custom chassis manufacturers, the Company believes that additional lead time would not remedy the difficulties faced by such manufacturers in meeting the proposed standards or the negative consequences for the industry. For example, the manufacturers would still have limited ability to benefit from averaging and to spread compliance costs across many vehicles. We would still suffer from the shortage of technical compliance expertise, and customers would still experience disruption to their businesses due to production delays, upfront cost increases and increased continuing maintenance costs.[EPA-HQ-OAR-2014-0827-1233-A1 p.16]

Organization: Barcode Technology Solutions

Please do not delay in enacting this important regulatory policy. [EPA-HQ-OAR-2014-0827-0764 p.2]

Organization: Bay Area Air Quality Management District (BAAQMD)

The proposed EPA/DOT Phase 2 rule-making can help us pursue both our air quality and GHG emission reduction goals. To ensure the maximum benefits are achieved from this joint-rule-making effort, we would like to offer the following suggestions. [EPA-HQ-OAR-2014-0827-1136-A1 p.2]

Adopt the schedule proposed in Alternative 4 to accelerate the roll-out of the Phase 2 standards so full implementation is reached by 2024 instead of 2027. This option will result in greater overall reductions in fuel use and GHGs. [EPA-HQ-OAR-2014-0827-1136-A1 p.2]
The agencies are requesting comment on the alternatives described in Section X below. The agencies seek comment on the feasibility of Alternative 4, whether for some or for all segments, including empirical data on its appropriateness, cost effectiveness, and technological feasibility. [EPA-HQ-OAR-2014-0827-1241-A1 p.2]

Bendix believes that Alternative 3 – 2027 proposed standard should be adopted rather than Alternative 4 - 2024 which is also under consideration. Alternative 3 will be more feasible by providing more time for development of technologies required to meet the stringencies proposed by the agencies. In addition, many of the technology adoption rates have significant uncertainty associated with them. We must avoid situations where fleets and smaller customers experience increases in vehicle downtime due to component failures or vehicle acquisition and operating cost increases that diminish the profitability of their businesses. The fleets will create a market pull for technologies that save them operating costs with payback times between 18 and 48 months. A well risk-managed adoption of new technologies is more feasible with Alternative 3 for all regulatory categories. [EPA-HQ-OAR-2014-0827-1241-A1 p.2]

BYD would also support more aggressive implementation of the stringency levels, such as Alternative 4, which would accelerate the stringency levels by 3 years to 2024. This change would cause fleet operators to more seriously consider advanced technologies. It would also allow the agencies the flexibility to evaluate the appropriateness for the inclusion of advanced technologies for future phases and the ability to implement those changes sooner. [EPA-HQ-OAR-2014-0827-1182-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.228.]]

CARB strongly recommends that the federal agencies strengthen the overall proposal and adopt the Alternative 4 timeline, rather than adopt the proposed Alternative 3. While the two alternatives are nearly identical in terms of technological feasibility and payback periods for fuel efficient technologies, Alternative 4 accelerates full program phase-in by three years, from 2027 to 2024, and as discussed below, can be strengthened in overall stringency. [EPA-HQ-OAR-2014-0827-1265-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.21-22.]]

By 2030, Alternative 4 as proposed would provide about four million metric tons more cumulative greenhouse gas benefits in California than Alternative 3, and together with Phase 1 would reduce petroleum use from the medium- and heavy-duty sector by about 22 percent. Yet, this still is not enough, and even more needs to be done to strengthen the federal Phase 2 proposal, such as including an increase in the engine-only standard, as described in our next recommendation. Overall, a strengthened Alternative 4 would provide an important step toward reaching Governor Brown's climate goals and 50 percent petroleum reduction target for the transportation sector. [EPA-HQ-OAR-2014-0827-1265-A1 p.2]

Adopting Alternative 4 standards across all vehicle categories would also result in the Phase 2 program being fully phased in by 2024 (by 2025 for pickups and vans), three years earlier than if Alternative 3
standards are adopted. This would allow manufacturers to take action on reducing NOx emissions from
the heavy-duty vehicles addressed in this rulemaking in a timelier manner. This is especially important
since heavy-duty vehicles are responsible today for one-third of California’s NOx emissions. The South
Coast Air Basin will need nearly a 90 percent reduction in heavy-duty vehicle NOx emissions by 2031
from 2010 levels to attain the 2008 National Ambient Air Quality Standards (NAAQS) for ozone.
Additionally, on November 25, 2014, U.S. EPA issued a proposal to strengthen the ozone NAAQS. If a
change to the ozone NAAQS is finalized, California and other areas of the country will need to identify
and implement measures to reduce NOx as needed to complement federal emission reduction measures.

In this rulemaking action, Alternative 4 provides manufacturers of heavy-duty engines and heavy-duty
vehicles approximately eight years of lead-time to develop and apply technologies needed to comply
with the most stringent greenhouse emission standards. This time frame is 60 percent longer than the
time frame considered by the NRDC court, and in light of the extensive information discussed in this
NPRM regarding the numerous control technologies that manufacturers are anticipated to utilize to
comply with the proposed standards, their capability of reducing GHG emissions, current states of
development, and identification of the major steps needed to refine those technologies for
implementation in MY 2024 engines and vehicles, it is clear that Alternative 4 is consistent with the
lead time requirements of section 202(a)(2) of the CAA (42 U.S.C. 7521 (a)(2)). [EPA-HQ-OAR-2014-
0827-1265-A1 p.25-26]

Comment on Topic Where NPRM Requests Comment

Comment – Lead time

The NPRM requests comment on the lead time for the proposed rulemaking and market disruption.
CARB staff suggests that U.S. EPA and NHTSA conduct additional research on the market impact of
the proposed rulemaking, including an ex post (retrospective) analysis of the market impacts resulting
from existing GHG and criteria pollutant engine and vehicle regulations. [EPA-HQ-OAR-2014-0827-
1265-A1 p.187]

Organization: Caterpillar Inc, et al.

Expected technologies must be appropriately demonstrated

A core principle of the Clean Air Act is that expected technologies must be feasible, including
accounting for cost and development lead-time. Given the complexity of modern technology, unique
customer duty cycles, and the myriad of federal, state, and local regulations under which commercial
vehicles operate, it is not enough to presume a technology will be available and gain market acceptance
unless it has been adequately demonstrated in commercial service. An effective “technology
demonstration” must include a substantial amount of successful testing (meaning it is reliable, durable,
efficient, and cost effective) within a commercial fleet in revenue-generating applications. It is
insufficient to rely on demonstration of a few vehicles operating in carefully selected applications or
routes tailored to their design. It is even less appropriate to rely on promises of future technology from
suppliers who wish to ensure a market for the technologies in their development plans. There is a very
long history of failed technologies in both of these categories. A number of key technologies within the
Phase 2 rule expectations fail to meet the hurdle of adequate demonstration, including for example:
Rankine waste heat recovery; tractor aerodynamics (within the proposed regulatory context); future
levels of tire rolling resistance; “deep integration” of vocational powertrains; stop-start for heavy-duty
diesels; and vocational hybridization. It is unacceptable to base stringency targets on such unproven technologies. [EPA-HQ-OAR-2014-0827-1215-A1 p.5]

One thing we are certain of is that we could not achieve, and therefore cannot support, the pull-ahead of these standards according to the plan identified as “Alternative 4” in the proposed rule. [EPA-HQ-OAR-2014-0827-1215-A1 p.7]

One key factor is the cost of an increase in both reliability and durability failures due to forcing technology that is immature or inadequate for all applications within the defined regulatory subcategories and their associated duty cycles (e.g. increased warranty surcharges, repair costs after the warranty period, increased downtime and the resultant loss of income, and penalties for missing delivery on time-sensitive loads). [EPA-HQ-OAR-2014-0827-1215-A1 p.7]

The Agencies have also proposed to revise certain provisions of the Phase 1 protocols. These revisions have the effect of increasing the stringency of the Phase 1 requirements already in the implementation phase. We oppose any such changes because the requisite lead time is not provided to comply. [EPA-HQ-OAR-2014-0827-1215-A1 p.8]

**Organization:** Center for Biological Diversity

**Accelerated Implementation**

As explained in the Proposed Rule, an accelerated schedule for implementation is part of the “maximum feasible and appropriate” alternative. The proposed rule refers to “Alternative 4” as an option to speed implementation by 2 to 3 years. The Center strongly urges the Agencies to adopt this earlier implementation schedule for greenhouse gas standards. Earlier implementation will allow for 13 percent greater cumulative emissions reductions, given the same engine and vehicle standards. As noted in the Proposed Rule, this accelerated implementation schedule would extend the payback period for most commercial trucks by only about 3 months and appears to be “very cost effective.” Earlier implementation is a key component of meeting the technology-forcing mandate of the governing statutes. [EPA-HQ-OAR-2014-0827-1460-A1 p.12]

Besides greater lifetime emissions reductions and fuel savings, an earlier implementation schedule would provide an earlier date to revisit the standards and adjust as necessary. As proposed, the standards would cover nearly 10 years. This is an exceedingly long period in which there is much opportunity for innovation and more advanced technology to come to the fore. Even over the short period of the Phase 1 standards, it has become clear that technology implementation is outpacing the standards. An accelerated implementation schedule for Phase 2 that ends with model year 2024/2025 would allow the Agencies to re-analyze at an earlier date the level of fuel savings and emissions reductions that are feasible and appropriate, with the potential for the next phase of fuel savings to begin sooner. [EPA-HQ-OAR-2014-0827-1460-A1 p.12]

The available data indicate that manufacturers have easily complied with Phase 1 standards, which had a shorter implementation time. For instance, the Proposed Rule indicates that “credit surpluses could be quite large at the beginning of the proposed Phase 2 program.” The accumulation of such excess credits is a clear indicator that the Phase 1 standards were not stringent enough, and by extension, necessitates more stringent Phase 2 standards than what the Agencies are currently proposing. Another indicator that compliance with Phase 1 standards has been nearly effortless is the fact that some technologies assumed for Phase 1 standards have not been used at all to comply with 2014 standards, as is the case with automatic engine shutdown and idle reduction technology on Class 8 tractors. This is particularly
Another factor that must be considered is the high cost of the total delay in meaningful emissions reductions between both the lenient Phase 1 standards and the currently-proposed decade-long delay until full implementation of the Phase 2 standards. In light of the fact that, under optimistic assumptions, only a few decades remain to achieve sharp greenhouse gas emission reductions to avoid exceeding the 2°C warming increase that is the internationally-agreed target, scheduling full compliance with the Proposed Rule’s targets over ten years from now is unreasonable and unjustifiable. As the Administration’s laudable recent report on the cost of delaying action on climate change demonstrates, the cost of delay is extremely steep as well as irreversible, and it rises exponentially as delay continues. Based even on this recent report’s highly conservative assumptions (omitting, for example, the effects of crucial tipping points such as methane release from melting permafrost), the report values the cost of delay alone as at least $150 billion for every year of delayed action if the delay results in overshooting the increase of temperatures over pre-industrial levels by just one degree Celsius, and sharply higher annual amounts for every degree of warming thereafter. [EPA-HQ-OAR-2014-0827-1460-A1 p.12-13]

At present, global emissions continue to increase and are on a path leading to a projected total warming above pre-industrial temperatures of some 4.5°C Celsius, resulting in annual costs exponentially higher than those examined by the Cost of Delay report. Plainly, every year of unnecessary delay in implementing the maximal technological feasible reductions in the face of steeply rising, persistent, and irreversible costs – including the acknowledged possibility that mitigation will be too late altogether – is unreasonable and unjustifiable. The final rule should accelerate the implementation timeline to at least 2024. [EPA-HQ-OAR-2014-0827-1460-A1 p.13]

In sum, the Proposed Rule does not embody a reasonable balance between the statutory factors to reach standards that are technology-forcing under the Clean Air Act or that represent the maximum feasible improvement under EISA. This is a result of underestimations of technology availability and effectiveness, market penetration, and overestimation of the time needed to implement the Phase 2 standards. [EPA-HQ-OAR-2014-0827-1460-A1 p.13-14]

56 Draft RIA at 5-47.

57 Id. at 10-29.

59 Implementation times: Final rule for Phase 1 was promulgated in 2011, with CO2 standards in effect beginning in 2014; fuel standards were not mandatory until 2016. In the Proposed Rule, the earliest start of standards would be 2021, with final stringency not reached until 2027.

62 Phase 1 Final Rule, supra note 11 at 57,207.

**Organization:** Ceres

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 200, 202.]

We urge the agencies to strengthen the proposed phase 2 standard under consideration today by adopting a standard requiring a 40 percent reduction in fuel consumption by 2025. Alternative 4 comes closest to that standard.

Ceres agrees with the California Air Resources Board, which recommends the adoption of the Alternative 4 standards at a minimum, stating this option is both technology forcing and technologically feasible.

**Organization:** Coalition for Clean Air/California Cleaner Freight Coalition

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 217.]

EPA should adopt the 2014 alternative 4 because it is urgent we get the emissions reductions.

**Organization:** Cummins, Inc.

*Cummins supports the timeline of the proposed Alternative 3 standards* [EPA-HQ-OAR-2014-0827-1298-A1 p.18]
Lead-time and stability are critical to achieving the goals of the proposal. The three steps proposed in 2021, 2024 and 2027 give adequate lead-time and stability for manufacturers to develop and implement the technology needed to meet the standards. The long-term certainty of known reductions through 2027 benefits component suppliers, manufacturers and end users who will invest in fuel-saving technologies. Therefore, Cummins supports the proposed timeline of the Alternative 3 standards. [EPA-HQ-OAR-2014-0827-1298-A1 p.18-19] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.49.]]

The Alternative 3 timing proposed by the Agencies, with a final step in 2027, should be maintained in the Final Rule in order to provide the lead time, stability and certainty necessary for manufacturers to invest in and develop reliable technologies. [EPA-HQ-OAR-2014-0827-1298-A1 p.42]

**Organization:** Curl, Tilden

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 185.]

While the agencies' proposal of alternative 3 mostly pushes for technology which is largely of use today, there are some concerns to be recognized. If the agencies pursue alternative 4, there are many more concerns about, again, thrusting unproven technology into the marketplace. This would result in more truckers choosing to keep their current trucks on the road even longer. I want to stress the agencies' approach must allow for ample time for the OEMs to develop the new technology.

**Organization:** Daimler Trucks North America LLC

**Regulatory paradigm of 4 year lead-time and 3 year stability** - The regulatory paradigm of 4 years lead-time and 3 years stability needs to be revisited given the complexities of today’s powertrain technologies as required to meet multiple regulations and heightened customer expectations. We believe that a three year cadence of tightened standards is too fast, as our experience has shown us that the three year criteria pollutant emission periods caused significant instability. Moreover, as the agencies press manufacturers for further improvements in fuel efficiency--which we at DTNA have been pursuing for decades--the changes become more difficult and more time-consuming to implement. Development of a new engine or a new cab takes on the order of a decade. Implementing new aftertreatment device requirements or, if it is necessary, waste heat recovery systems on all chassis takes more than three years from the time that we know what the technology will be. OBD calibration development must be performed on final calibrations, so its development is time shifted to later in the timeline and more time is needed overall. Plus, the workload has to be prioritized as cab redesigns, implementing aftertreatment devices, etc. cannot all be done at once; we have a limited engineering staff and a vast array of HDV products. In contrast to simple mechanical emissions controls utilized in engines at the onset of regulations, when 4 year lead-time and 3 year stability was conceived, the process for fuel economy optimization now involves development and integration of highly complex electronically controlled engine systems, transmissions, aftertreatment systems with DPF and SCR based NOx control systems, development of sophisticated diagnostics, and integration with vehicle system. [EPA-HQ-OAR-2014-0827-1164-A1 p.111]

HDV operators rely on higher levels of reliability and durability to prevent downtime that would compromise their investment in increasingly expensive technologies. Even if there is a warranty, HDV operators lose money whenever their vehicle is stranded by the side of the road; they may default on contracts; they may lose future business. HDV operators, therefore, have become very wary of new
technologies released prematurely. For the sake of HDV operators, the agencies should regulate with achievable lead-time and stability. [EPA-HQ-OAR-2014-0827-1164-A1 p.111]

Therefore, as stringency of the regulations increases, and with it the complexity of technologies required to meet new regulations, the agencies should commensurately provide both additional lead-time for new technology introduction and increase the stability period between regulatory steps. In short, tightening standards every three years is too rapid, both for vehicle and for engine standards. We recommend standards in 2021 based on a lower penetration rate of new technologies and a subsequent round of standards no sooner than (say) [redacted]. [EPA-HQ-OAR-2014-0827-1164-A1 p.111-112]

**Organization:** Diesel Technology Forum

We believe these are also important considerations for EPA in developing a final Phase 2 rules, as follows: [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

- **That ample lead time and stability are provided:** This is important because the number of commercial trucks made and sold each year (several hundred thousand) is a tiny fraction of the 11-17 million cars made. The significant diversity in the marketplace will require many hundreds if not thousands of different approaches depending on the type of vehicle. Manufacturers must have adequate lead time to make changes in technology for this diverse vehicle population along with regulatory stability so that they can recoup their investments over the longer sales and turnover cycles common in this segment. [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

**Organization:** Eaton Vehicle Group

Eaton believes the NPRM proposes performance-based standards that ensure that the fuel savings certified by the test procedures deliver fuel cost savings to truckers and fleets on the road. Eaton is also encouraged by the potential of a long term rule of 10 years. We believe regulatory certainty will help focus R&D efforts of companies like Eaton that are investing heavily in advanced technologies aimed at significant fuel savings. Clarity provided to the market with the proposed 10 year length of the rule allows Eaton to work with our customers in the near, mid and long term on solutions to meet the prescribed standards. [EPA-HQ-OAR-2014-0827-1194-A1 p.5]

The EPA requested the technology readiness for alternative 4. Eaton supports the preferred Alternative 3. While some of the powertrain technologies discussed are already entering the market, there is significant work ahead of us to ensure the product reliability and its extensions and impact in larger segments. Furthermore, as we show in our remarks on hybrids, we do not see the right market or regulatory conditions for progress in the near future. As the objectives of Phase 2 are dependent on a more significant hybrid adoption, we support MY2027 to target full implementation. [EPA-HQ-OAR-2014-0827-1194-A1 p.19]

**Organization:** Environmental Defense Fund (EDF)

**Overarching principles**

Our technical comments support two overarching recommendations: [EPA-HQ-OAR-2014-0827-1312-A1 p.26]
The proposed 2027 standards—and more—should be accelerated to model year 2024

We recommend that the proposed 2027 standards be strengthened and accelerated to 2024. More protective standards can be met in 2024 by technologies that are already proven and mature—no advanced technologies are needed to go meaningfully beyond the proposed standards. Moreover, the technologies needed are already in use today and manufacturers have indicated that they plan to further deploy them to meet anticipated standards. In addition, these technologies are extremely cost effective and have short payback periods that present a very attractive market proposition for truckers. Nine years provides a feasible lead-time for manufacturers to adopt these available technologies. [EPA-HQ-OAR-2014-0827-1312-A1 p.26]

[The following comments were submitted as testimony at the Chicago, Illinois public hearing held on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 33.]

The second recommendation is to accelerate the timing of the most stringent standards to 2024. The compliance timeline in alternative four is consistent with our assessment of the appropriate timeframe for implementing the most stringent standards. Nearly a decade away, it provides sufficient lead time for manufacturers to cost-effectively scale fuel saving solutions. It also better reflects the urgent need to reduce climate disrupting emissions.

123 See ACEEE comments submitted to this docket; EPA-HQ-OAR-2014-0827-1280-A1

124 See ICCT comments submitted to this docket; EPA-HQ-OAR-2014-0827-1180-A4

Organization: FedEx Corporation

Provide Regulatory Certainty to Ensure Advanced Technology Investments: Longer time frames and enough lead time to develop, mature and deploy advanced technology will provide regulatory certainty and pull through advanced solutions that will provide significant GHG and fuel consumption reduction in an economically sustainable fashion. This is necessary for both manufacturers to make long-term investments that would support the new standards, as well as for fleets that need a high level of reliability and cost effective solutions in order to deploy new technology. [EPA-HQ-OAR-2014-0827-1302-A1 p.2-3]

Organization: First Industries Corporation

(3) EPA must not adopt Alternative 4 [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

EPA's Must Not Adopt Alternative 4

EPA's proposal for GHG phase 2, known as Alternative 3, is very aggressive and will force technology into the marketplace that does not yet exist. This creates significant risk of a pre-buy/no-buy. Indeed, it is not apparent how OEM's will meet the challenge of Alternative 3. It is very clear, however, that
accelerating the timeline for those technologies by way of Alternative 4, will lead to a pre-buy/no-buy similar to 2007. This is bad for the trucking industry, bad for the US economy and bad for the environment as delayed purchases delay environmental benefits under the rule. Accordingly, we urge EPA to not even consider adopting Alternative 4. [EPA-HQ-OAR-2014-0827-1145-A2 p.5]

**Organization:** Ford Motor Company

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 28.]

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 158.]

It is of critical importance to provide manufacturers with adequate lead time to meet the requirements.

**Organization:** Honeywell Transportation System (HTS)

Honeywell also appreciates the proposed rule’s ten year timeline through 2027 and the three-phased approach because it provides the industry with clear milestones that support long-term investment in the development of enabling technologies. [EPA-HQ-OAR-2014-0827-1230-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.256.]]

**Organization:** Institute for Policy Integrity at NYU School of Law

**Stringency:** The agencies have proposed a technology-forcing standard with compelling net social benefits. However, Alternative 4 would generate even higher net social benefits than the agencies’ preferred alternative. And, for most vehicle classes and under most methodological assumptions, Alternative 5 would generate even greater net benefits. Unless the agencies have good reason to believe that their estimates of costs and benefits for these alternatives are wrong, they are under-regulating by failing to select Alternative 4 or Alternative 5. [EPA-HQ-OAR-2014-0827-1195-A1 p.3]

**Organization:** International Council on Clean Transportation (ICCT)

Advancing the proposed 2027 standards by three years would achieve the agencies’ requirements for appropriate and maximum feasible standards. Advancing the timing for the standards is based on three fundamental reasons: (1) that the applicable technologies to comply with the proposed standards are already mature, (2) that these technologies are the ones that manufacturers are already planning to deploy, and (3) that these technologies offer a very attractive market proposition for heavy-duty vehicle owners. The rationale and references for these reasons are provided below. [EPA-HQ-OAR-2014-0827-1180-A4 p.4]

**Technology maturity:** The proposed stringency of the Phase 2 standards is predicated on well-understood and proven technologies. Given that the proposed stringency falls short of the demonstrated technology potential in the rule’s timeframe, the required technology can be deployed between 2016 and 2024. In many cases the required technology is commercially available. Here are several examples that put the required technology penetration in the context of the full known technical potential: [EPA-HQ-OAR-2014-0827-1180-A4 p.4]
• **Diesel engines** – The engine standards are based on modest incremental improvements including engine friction, air handling, and combustion/controls, which are part of every engine/vehicle manufacturers existing technology portfolio and therefore allow for accelerated deployment before 2024. For context, the agencies proposed standards require less than half of the known technology potential for diesel tractor engines (e.g., see Eckerle, 2015; Thiruvengadam et al, 2014; Reinhart, 2015). The proposed standards (Phase 1 and 2 together from a 2010 baseline) also fall well short of SuperTrucks’ engine technologies (i.e., 10% versus SuperTrucks’ 15%, over the SET cycle) that have already been physically demonstrated in Peterbilt and Daimler tractors (Lutsey, 2015a). [EPA-HQ-OAR-2014-0827-1180-A4 p.4]

• **Transmissions** – Advanced integrated transmissions, including automated manual transmissions that enable downspeeding and optimal engine operation, by leading companies like Eaton and Volvo, have already been introduced (Stoltz and Dorobantu, 2014; Greszler, 2014). Automatic transmissions are the norm in Europe, and increasingly advanced dual-clutch transmissions are being introduced there. The agencies considered this technology as part of their stringency determination, but more advanced versions of this technology have been demonstrated in SuperTruck (Delgado and Lutsey, 2014). [EPA-HQ-OAR-2014-0827-1180-A4 p.4]

• **Trailers** – The trailer technologies upon which the stringency is determined embrace the already commercialized technologies that have been spurred by EPA’s SmartWay program and California’s in-use regulation. These technologies are already being adopted in increasing numbers by leading SmartWay Elite fleets and as part of the California regulation (Sharpe and Roeth, 2014). Asking trailer manufacturers and tractor fleets to move toward 2015’s leading technologies by 2024 provides sufficient lead time. [EPA-HQ-OAR-2014-0827-1180-A4 p.5]

• **Tractor-trailers** – Overall for tractors, the technologies included in the stringency determination are far short of the full technology potential. Applying the available incremental technologies for engines, transmissions, and aerodynamics can achieve technology potential far greater than agencies’ proposed 8 miles-per-gallon tractor-trailer standards before 2025 (See Delgado and Lutsey, 2015). SuperTruck teams are achieving 10.7 mpg (Peterbilt) and 12.2 mpg (Daimler/Freightliner) in real-world testing (Buchholz, 2014; Daimler, 2015) with combinations of engine, tractor, and trailer technologies that greatly surpass the proposed 2027 standard analysis. After correcting for test cycle differences, the SuperTruck technologies demonstrated by manufacturers would achieve up to 10 miles per gallon (Lutsey, 2015b); because the proposed 2027 stringency levels do not approach these stringency levels, the standards can be advanced by at least several years. [EPA-HQ-OAR-2014-0827-1180-A4 p.5]

**Industries’ expected technology roadmap:** The agencies chose technologies, with input from extensive industry discussions, based on the technologies that the various companies are prepared to, and plan to, deploy in much larger numbers in the rules’ timeframe. Based on publicly available data, the technologies in the engine, powertrain, aerodynamics, and tire areas are exactly the ones that suppliers and vehicle manufacturers have been discussing for the rules’ timeframe (Lutsey, Langer, Khan, 2014; Greszler, 2014; Salemme, 2014; Stoltz and Dorobantu, 2014). All of the major companies (e.g., Peterbilt/Cummins, Daimler, Navistar, Volvo) have participated in the U.S. Department of Energy (DOE) SuperTruck program, which has the explicit goal of using over $140 million in public funding to demonstrate and help transition the efficiency technologies to the commercial marketplace over time (Delgado and Lutsey, 2014). Manufacturers and suppliers have already begun commercializing many of the technologies (Bloch-Rubin and Gallo, 2014), and therefore moving toward SuperTruck technologies considerably faster than the agencies are projecting. The fact that the technologies are already squarely in the plans of the several major manufacturing companies suggests that the agencies’ proposed timeframe to allow 12 years for implementing the standards is substantially more time than necessary and do not meet the statutory criteria of maximum feasible and appropriate. [EPA-HQ-OAR-2014-0827-1180-A4 p.5]
**Market-ready technologies.** Not only are the technologies mature, but they are well vetted and market-ready due to their attractive fuel-saving proposition for truck owners. At the proposed stringency levels, the standards can be met almost entirely with commercialized technologies that are available today in the marketplace and that have already been embraced by early adopters. Efficiency technologies, though highly cost-effective, are held back by prevailing market barriers (Vernon and Meier, 2012; Roeth et al, 2013). The proposed regulations remove many of these barriers. The applicable technologies, based on the latest analyses, are highly cost-effective – allowing average tractor-trailer owners to return their technology investments in fuel savings in 6 months to 2 years, even if diesel fuel prices are low (Meszler et al, 2015). Similarly, looking just at trailers, the cost-to-fuel saving proposition is even more attractive (See Sharpe et al, 2014). Because the efficiency technologies offer the rapid payback periods as desired by truck owners, the regulated fleet can easily take them up within the nine years between 2015 and 2024. [EPA-HQ-OAR-2014-0827-1180-A4 p.5-6]

---

1. *Per the Clean Air Act, EPA has broad discretion to give appropriate consideration and weight to the statutory factors of emission reductions, cost, and lead time and allows EPA to adopt technology-forcing standards.*

2. *Per the Energy Independence and Security Act, NHTSA is instructed to set standards that “achieve the maximum feasible improvement”, previously defined as including factors of appropriateness, cost-effectiveness, and technological feasibility.*

**Organization:** International Foodservice Distributors Association

IFDA is particularly concerned that the proposal’s Alternative 4 would accelerate the timetable well beyond what is feasible both in terms of the ability of manufacturers to comply and adoption by the industry. [EPA-HQ-OAR-2014-0827-1258-A1 p.1]

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

The UAW supports standards with sufficient lead time allowing for research and development of cost effective and reliable technology that will be accepted by the fleets and other customers. [EPA-HQ-OAR-2014-0827-1248-A2 p.2]

In this vain, we strongly oppose Alternative Four which pulls stringency requirements forward from 2027 to 2024. Pulling the 2027 requirements forward may not only force unreliable and unproven technology to market, it is a de-facto increase in stringency requirements. Alternative Three is highly ambitious but could reach the proper balance if important modifications are made. Our concerns and recommendations are detailed in our comments. [EPA-HQ-OAR-2014-0827-1248-A2 p.3]

**Organization:** Manufacturers of Emission Controls Association (MECA)

MECA supports the EPA proposed reductions in greenhouse gas emissions for the heavy-duty truck segment, and believes that the proposed reductions are technically feasible using technologies that are ready for deployment on trucks today. Numerous analyses have estimated greater potential reductions of CO2 than will be achieved by this proposal suggesting that EPA’s Alternative 4 may be the more realistic scenario. EPA’s own analysis shows that the faster Alternative 4 implementation timeline
provides nearly the same payback periods as the longer Alternative 3 implementation timeline. The Department of Energy’s SuperTruck program has demonstrated the magnitude of reductions that engine and vehicle technologies can deliver. A 2024 final implementation date, under Alternative 4, would allow developmental technologies to be optimized and ready for deployment under future, Phase 3 heavy-duty GHG standards to achieve the full potential reductions that exist from this transportation sector. We urge EPA to finalize a set of stringent Phase 2 standards that would incentivize the deployment of the full spectrum of cost effective technologies developed for engines and vehicles to guide industry investment and maximize environmental benefits. At a minimum, MECA is supportive of a final rule with a 2024 final phase-in date. [EPA-HQ-OAR-2014-0827-1210-A3 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.211.]]

**Organization:**  Mass Comment Campaign sponsored by Center for Biological Diversity (web) - (4,429)

To that end I support the timeline for implementation as currently set out in 'Alternative 4.' But I also urge you to opt for an alternative that will actually drive innovation by requiring greater reductions in fuel usage over this time. An analysis from the International Council on Clean Transportation has developed a roadmap for achieving up to 30 percent greater reductions in CO2 emissions by 2040 than would be achieved under your currently proposed standards. [EPA-HQ-OAR-2014-0827-1167-A1 p.1]

**Organization:**  NAFA Fleet Management Association

Given we are already very concerned over the proposed Phase 2 “Alternative 3” efficiency targets, we ask EPA and NHTSA to reject what is defined in the proposal as “Alternative 4” to avoid serious negative economic implications for fleets and truck manufacturers. Alternative 4 would “pull-- ahead” the 2027 greenhouse gas/fuel efficiency target dates for engines, vehicles, and trailers by three years to accomplish all such milestones in 2024. [NHTSA-2014-0132-0111-A1 p.4]

**Organization:**  National Association of Clean Air Agencies (NACAA)

With respect to timing, NACAA strongly supports EPA’s proposed Alternative 4, under which the standards would be fully implemented by 2024. This implementation deadline is entirely feasible and vitally important to spur much-needed near-term emissions reductions and technological innovation. Further, Alternative 4 would provide manufacturers of heavy-duty engines and vehicles nearly eight years of lead-time to develop and apply technologies needed to comply with the most stringent GHG emissions standards and is consistent with the lead-time requirements of section 202(a)(2) of the Clean AirAct. NACAA urges EPA to finalize Alternative 4 rather than Alternative 3, which would unnecessarily extend full implementation by three years to 2027, particularly when all of the technologies/approaches required already exist, with many already deployed on today’s trucks. [EPA-HQ-OAR-2014-0827-1157-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.53-54.]]

We believe, in general, that the Phase 2 proposal is overly pessimistic regarding the implementation outlook for advanced technologies nationwide. The proposal also underestimates the ability of engine and truck manufacturers to incorporate longer-term technical solutions now for meeting global climate goals. As such, we recommend that EPA take a more assertive stance in challenging industry to accelerate technology innovation by adopting Alternative 4. EPA includes the projected compliance costs for the proposed emission standards under Alternatives 3 and 4 in the proposal. Even the projected higher compliance costs for Alternative 4 – which constitute only a fraction of the base costs of new
engines and vehicles – are more than offset by the cost savings from reduced fuel consumption within two to six years. With respect to fuel efficiency and emission reductions, the proposal indicates that, on a nationwide basis, Alternative 4 overall would save 10 billion more gallons of fuel and provide about 130 more million metric tons of GHG reductions by 2030 than Alternative 3. These are important improvements that can and should be realized. [EPA-HQ-OAR-2014-0827-1157-A1 p.3]

In addition to early climate benefits, federal action on our recommendation to adopt Alternative 4 (full implementation by 2024) would also provide manufacturers the ability to incorporate technologies to significantly reduce NOx emissions from heavy-duty vehicles in a more timely manner. While already crucial for a number of areas, NOx reductions from the heavy-duty sector will become increasingly important to additional areas under strengthened National Ambient Air Quality Standards for ozone, which are expected imminently. We urge that EPA include in the final Phase 2 rule a clear and comprehensive discussion of the need for very substantial additional NOx reductions from heavy-duty vehicles and engines and, even more critically, an explicit commitment to begin immediately a separate rulemaking initiative to capture those reductions. [EPA-HQ-OAR-2014-0827-1157-A1 p.4] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.54.]]

**Organization:** National Association of Manufacturers (NAM)

Finally, the NAM strongly encourages the EPA and NHTSA not to adopt the pull-forward of the vehicle standards from MY2027 to MY2024 under Alternative 4. Manufacturers want and need regulatory certainty, and the vehicle standards pull-forward in Alternative 4 would jeopardize this certainty by creating early deadlines that manufacturers may not be able to meet. [EPA-HQ-OAR-2014-0827-1323-A2 p.2]

**Organization:** National Automobile Dealers Association (NADA)

However, unlike Phase 1 which largely involves currently available technologies, the Phase 2 proposal focuses on many that are not yet fully developed or deployed. For each vehicle group, the proposal suggests that fuel savings should offset the up-front and ongoing costs of new technologies, but fails to adequately recognize how those technologies inevitably will make vehicle ownership and operations more complex. Since commercial truck purchasers are very risk averse, any higher costs, reduced performance, or increased complexities associated with the Phase 2 program could undermine its potential benefits. [EPA-HQ-OAR-2014-0827-1309-A1 p.5]

NADA/ATD categorically objects to Alternative 4, which would effectively impose MY 2027 targets in MY 2024. [EPA-HQ-OAR-2014-0827-1309-A1 p.11]

**Organization:** Natural Resources Defense Council (NRDC)

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372 pp. 42-43.]

First, the compliance timeline should be moved up. The environmental community conducted conservative analysis showing that the new fleet fuel consumption and greenhouse gas emissions can be reduced by at least 40 percent from 2010 levels by 25. Within the proposal alternative four, which achieves full compliance in 2024, is the closest to meeting our target. When it comes to cutting carbon and reducing our dangerous dependence on oil, every year counts.]
The agencies’ own analysis shows that alternative four is technically feasible and cost effective. NRDC believes that the 2024 compliance timeline is also appropriate. Compared to the proposal, alternative four reduces oil consumption and carbon pollution by an additional 13 percent, and increases net benefits by over $24 billion. NRDC urges the agencies to accelerate the compliance timeline.

**Organization:** Navistar, Inc.

In the NPRM the agencies have offered several alternatives and asked for comments on Alternative 4 in particular. This proposal would compress the timeline for adoption from a three-stage process to a two-stage process, with completion of implementation scheduled in 2024 instead of 2027. The administration believes this alternative is the maximum feasible and appropriate alternative but they have outstanding questions about the relative risks and benefits and are seeking comments. [EPA-HQ-OAR-2014-0827-1199-A1 p.17]

In preparing comments for this Proposed Rule, Navistar devoted significant engineering time to provide a detailed analysis of the rule and the company has already commented extensively on the fundamental problems with Alternative 3, which is the agencies’ preferred option. Alternative 4, which would pull the implementation date forward by three model years, would significantly increase the technological risk and in some cases would make compliance with the final rule impossible. [EPA-HQ-OAR-2014-0827-1199-A1 p.17]

The most significant examples of the risk this alternative introduces relate to engine emission standards and the aerodynamics component of the Proposed Rule. The four truck OEM’s and the US Department of Energy have spent over $250 million on the SuperTruck program to develop highly advanced Class 8 line haul tractor-trailers. In these Comments Navistar discusses in detail how the 2027 aerodynamics standard are unachievable even utilizing the tractors developed for the SuperTruck program. Pulling an unachievable standard forward by three years would merely accelerate the problem. [EPA-HQ-OAR-2014-0827-1199-A1 p.17-18]

The impact on the engine would be at least as severe, since one of the critical technologies is waste heat recovery, which is not yet commercially viable and will not be viable by 2024. Alternative 4 does not provide enough lead time for this technology and the NPRM has not shown that any technologies are feasible in the Alternative 4 time frame. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

Alternative 3 also presumes extremely aggressive technology adoption rates. This is particularly the case for the use of hybrid powertrains in the vocational vehicle sector. The NPRM is based on 18% of urban and 18% of multi-purpose vocational vehicles utilizing hybrid powertrains by 2027. As we note in our discussion on hybrids, this is not likely to be feasible. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

The adoption rate for hybrid vocational vehicles is essentially zero today because of low fuel prices and the significant regulatory burden that hybridization faces in the commercial vehicle space. As one of the first companies to market commercial hybrid vehicles, we know there is little evidence to suggest our customers will be willing to buy vocational hybrids in sufficient numbers to meet the standard in 2027. In fact, at its highest, the penetration rate for hybrids never exceeded 1%. Predicating this alternative on the assumption that hybrid adoption rates will reach 18% by 2024, instead of 2027 will inject significant risk into the technology path that the NPRM lays out for vocational vehicles to achieve compliance. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

The NPRM also has an aggressive adoption rate for low rolling resistance drive and steer tires in both vocational and line haul trucks. While low rolling resistance tires offer clear benefits to some
commercial vehicle operators, there is a trade-off in adopting lower rolling resistance tires, which will impact traction and durability in negative ways. This is a tradeoff that many of Navistar’s customers will be unwilling to make given the capabilities of low rolling resistance tires today. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

While Alternative 3 has substantial problems, Alternative 4 compounds those problems by shortening the timeframe for compliance. Navistar therefore strongly believes that Alternative 4 would cause massive disruptions in the industry and lead to a significant pre-buy/no-buy in 2023MY-2024MY as customers seek to avoid additional costs and complexity. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

Navistar feels the following are key areas the agencies must address: [NHTSA-2014-0132-0094-A1 p.2]

• The accelerated option of Alternative 4 is not achievable. [NHTSA-2014-0132-0094-A1 p.3]

**Organization:** North American Die Casting Association (NADCA)

NADCA does support comments made by a number of groups that Alternative 4 is not feasible at this time and regulators should reject pressure to adopt these standards. [EPA-HQ-OAR-2014-0827-1283-A1 p.3]

**Organization:** Northeast States for Coordinated Air Use Management (NESCAUM)

The agencies should adopt the timeline proposed in Alternative #4.

Given that the proposed technologies are already mature or have been successfully demonstrated, and given our states’ need for significant GHG reductions in the near term, the timeline proposed in Alternative #4 is both reasonable and appropriate. Based on the assessments of the California Air Resources Board (CARB) and the International Council on Clean Transportation (ICCT), a full phase-in of the rules by 2024 is technologically feasible. Given the scope of needed GHG reductions, and the compelling benefits to freight industries and their consumers from reduced fuel expenditures, 2027 is too long to wait to realize the full potential of this rule. [EPA-HQ-OAR-2014-0827-1221-A1 p.2]

[[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.136-137.]]

As ICCT¹ and CARB² have noted, existing technologies are already available to provide the proposed reductions in the 2024 timeframe. Moreover, manufacturers have expressed their intentions to further increase the deployment of these technologies in the near term. These technologies are cost-effective and have been shown to provide strong return on investment for operators. [EPA-HQ-OAR-2014-0827-1221-A1 p.2]

---

Targeting incremental improvements by 2027 may be slower than achievable. [EPA-HQ-OAR-2014-0827-1135-A1 p.1]

**Organization:** Owner-Operator Independent Drivers Association (OOIDA)

**Lead Time**

A crucial aspect of this rulemaking is the amount of time which the manufacturers will be given in order to comply with the new standards. OOIDA members are concerned that if there is not sufficient lead time to develop and test new technologies, that trucking companies will be forced to purchase, at an extra cost, unreliable equipment which is susceptible to frequent repairs – further increasing the truck owners costs. [EPA-HQ-OAR-2014-0827-1244-A1 p.15]

For the past decade, the trucking industry has been flooded with emission reduction regulations including EPA 2007, EPA 2010, Onboard Diagnostic (OBD) in 2013, GHG14, OBD in 2016, and GHG17. The rapid succession of regulations has not given the manufactures time to work to reduce the costs of new vehicles, therefore, these forced regulations will dramatically increase the cost of medium-and-heavy-duty trucks. A study published in 2012 entitled A Look Back at EPA’s Cost and Other Impact Projections For MY 2004-2010 Heavy-Duty Truck Emissions Standards, detailed EPA’s significant underestimation of real-world vehicle costs. [EPA-HQ-OAR-2014-0827-1244-A1 p.15]

[Chart 1 can be found on p.16 of docket number EPA-HQ-OAR-2014-0827-1244-A1]

Further, the decreased reliability of EPA compliant truck and engine models has been well documented. A 2011 J.D. Power and Associates study suggested that, “With the new technology required to meet emissions standards, today’s engines simply are more problematic than the previous generation. So, while it’s possible that manufactures can continue to improve the quality of the engines, it’s unlikely that they’ll quickly get back to the pre-2004 levels.” In addition, Daimler Trucks North America has stated that vehicle efficiency improvements reduce real-world NOx emission benefits in proportion to power demand reduction. The combustion fundamentals state that any increase in stringency of NOx standards will compromise the ability to optimize for minimum CO2 emissions and maximum fuel efficiency. While EPA admits that there were some problems with the Phase I trucks, the agency fails to recognize that similar problems could develop with Phase II. [EPA-HQ-OAR-2014-0827-1244-A1 p.16]

For example, the MaxxForce engine produced by Navistar was labeled as an “approved engine.” As Navistar attempted to perfect its exhaust gas recirculation (EGR) technology, many trucking companies with MaxxForce powered trucks experienced repeated breakdowns and engine failure between 2010 and 2012, many of which were directly related to the EGR system. [EPA-HQ-OAR-2014-0827-1244-A1 p.17]

Problems with components such as EGR valves, EGR coolers, EGR inlet tubes, EGR sensors, and defective ECM modules were being experienced by trucking companies throughout the United States. Not surprisingly, both Navistar's International trucks and MaxxForce engines experienced numerous recalls and dozens of service bulletins related to the EGR system. These problems led to increased breakdowns, downtime, repair costs, and lost profits for the companies operating these trucks. [EPA-HQ-OAR-2014-0827-1244-A1 p.17]
Without proper lead time, the OEMs will not have sufficient time to produce proven and reliable trucks, which could create a pre-buy scenario in which the agencies have hoped to avoid. OOIDA’s preferred option is Alternative 1. This Alternative will allow the market to drive fuel efficient technologies at a pace that is conducive to healthy growth and actual consumer costs, which will assist the agencies in reaching their objectives that much sooner by avoiding pre-buys, risky technology, and negative outlooks on any future rulemakings. [EPA-HQ-OAR-2014-0827-1244-A1 p.17]

OOIDA proposes that agencies’ preferred alternative, Alternative 3, as well as Alternatives 4 and 5, are unrealistic and if adopted as part of this rulemaking process, will severely compromise the agencies’ praiseworthy objectives to increase the fuel efficiency of medium-and heavy-duty trucks and reduce GHG emissions. Truck drivers certainly desire fuel efficient trucks and appreciate cleaner air to breathe. While various governmental agencies and environmental groups tend to paint owner-operators as individuals who do not care about the environment, nothing could be further from the truth. It is crucial to understand that owner-operators are not only hardworking Americans who help to move our economy, but that they also spend a majority of their life around tractor-trailers. Therefore, it is in their best interest, as well as in the interest of the public, to operate clean and efficient trucks. [EPA-HQ-OAR-2014-0827-1244-A1 p.36-37]

Alternatives 3 or 4 very well could put many owner-operators out of business, and thus would have a major unintended consequence on the nation’s economy, as 70 percent of all freight is moved by a truck. [EPA-HQ-OAR-2014-0827-1244-A1 p.38]

---

Organization: PACCAR, Inc.

Stringency of Standards: EPA and NHTSA Should Adopt Alternative 3 Standards with Appropriate Revisions Because these Offer the Optimum Combination of GHG Reductions and Lead-Time for Manufacturers [EPA-HQ-OAR-2014-0827-1204-A1 p.1]

PACCAR has worked closely with EPA and NHTSA in the development of the proposal, providing feedback and data points on many technical aspects of the rule. PACCAR strongly urges the Agencies to adopt Alternative 3, which if appropriately modified, is the best combination of standards and compliance deadlines to achieve environmental protection goals, as well as ensure that consumer demands and expectations are met. Alternative 3 will, without question, require significant technological development and widespread implementation of new technologies. In Section II below, we outline the issues that make compliance with Alternative 3 standards challenging and should be addressed by the Agencies before promulgation of final standards. The lead-time provided in Alternative 3 will minimize disruptions to our customer base while achieving significant improvements in fuel efficiency and GHG emission reductions. [EPA-HQ-OAR-2014-0827-1204-A1 p.2]

Alternative 4 Pulls Ahead Compliance with more Stringent Standards but Will Not Result in Significant Additional GHG Reductions or Fuel Efficiency Improvements in the Long Run

In contrast to Alternative 3, Alternative 4 would require greater emission reductions on an accelerated basis. This combination may have the counterproductive effect of causing truck owners to either pre-
buy less-efficient models or delay the purchase of more efficient, yet more expensive and technically complex, new trucks and engines, leaving older, less-efficient trucks on the road for longer. Overall, PACCAR believes that Alternative 3 will achieve the same emission-reduction and fuel-efficiency goals as Alternative 4, but without the market disruption and customer dissatisfaction that Alternative 4 would create. [EPA-HQ-OAR-2014-0827-1204-A1 p.4]

**Organization:** Recreational Vehicle Industry Association (RVIA)

Further, while Alternative 3 in the Proposed Rules would be highly problematic for the motorhome sector for the reasons stated below, EPA should not choose an even more restrictive option, Alternative 4. [EPA-HQ-OAR-2014-0827-1261-A1 p.4]

In no event should EPA choose Alternative 4 for its overall standards. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

**Organization:** Rubber Manufacturers Association (RMA)

**Lead time**

Both the NPRM and the DOT draft Environmental Impact Statement (EIS) propose lead time of not less than 4 model years, consistent with the requirements of the Energy Independence and Security Act of 2007 (EISA) at 49 U.S.C. § 32902(k)(3)(A). Although RMA recognizes that the Clean Air Act does not provide similar guidance to EPA on lead time for its rulemaking, RMA encourages both Agencies to recognize the significant challenges associated with redesigning certain tires (e.g., drive tires for vocational vehicles and tires for non-aero vans and non-box trailers) to meet aggressive rolling resistance targets. As discussed above regarding tires for non-aero vans and non-box trailers, significant lead time is needed to design lower rolling resistance tires for these applications, due to the specialized performance needs of these tires and the fact that SmartWay tires are not appropriate fitments for non-aero vans and non-box trailers. [EPA-HQ-OAR-2014-0827-1304-A1 p.34]

RMA has stated in previous discussions with EPA, DOT/NHTSA, the National Academy of Sciences (NAS) committees that have studied these areas and the California Air Resource Board (CARB), a 5 year lead time is necessary to effect changes to tire technological advances, e.g. design, development, testing, validation, and commercialization. This lead time is critical to assuring the development of new tires that meet the myriad needs of customers in the areas of tire performance, including durability, load carrying capacity, tread wear, traction, rolling resistance and retreadability. [EPA-HQ-OAR-2014-0827-1304-A1 p.34]

Continuous rolling resistance improvements will require an evaluation of available technologies and materials, the development of new technologies and materials, as well as reasonable lead times. [EPA-HQ-OAR-2014-0827-1304-A1 p.34]

**Organization:** Schneider National Inc

Schneider is an early adopter of fuel efficiency technologies and is constantly evaluating options for improving overall freight efficiency. New technologies, however, take time to develop in order to ensure the products are reliable, safe and provide real world benefits. Accordingly, Schneider opposes EPA's Alternative 4, which seeks to move already aggressive targets from 2027 to 2024. Such a proposal creates the risk of forcing technology into the market before it is ready. The increased risk of
such action will likely lead to a pre-buy of existing technologies (as occurred when EPA pulled forward 2004 engine emission standards to October 2002), with the net effect that anticipated air quality benefits were not realized. [EPA-HQ-OAR-2014-0827-1201-A1 p.3-4]

**Organization:** School Bus Manufacturers Technical Council

The SBMTC would also like to comment that we feel that the proposed Alternative 3 implementation timeline (years 2021, 2024, and 2027) is reasonable and gives adequate time for manufacturers to implement reliable technologies and designs to meet end users requirements and to be compliant. We support retaining this timeline in the Final Rule. [EPA-HQ-OAR-2014-0827-1287-A1 p.2]

**Organization:** Sierra Club

**Accelerate the timeline of efficiency improvements**

While the proposed standards would decrease fuel consumption by 36% by 2027, analysis by the Union of Concerned Scientists, Natural Resource Defense Council, Environmental Defense Fund, and American Council for an Energy-Efficient Economy has shown we can reduce new truck fuel consumption 40% by 2025, compared to 2010 vehicles. [EPA-HQ-OAR-2014-0827-1277-A1 p.2]

Indeed, in the proposed rule, the agencies consider Alternative 4, in which full compliance is achieved by 2024 and find that this alternative is both technically feasible and cost-effective. Not only would this alternative reduce oil consumption and carbon pollution by an additional 13 percent, it would increase net benefits by more than $24 billion. We urge the agencies to adopt the timeline and stringency of Alternative 4. [EPA-HQ-OAR-2014-0827-1277-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.188-189.]]

**Organization:** South Coast Air Quality Management District (SCAQMD)

The SCAQMD staff strongly believes that tighter greenhouse gas emission standards should be established and the timeframe for full implementation be shortened relative to U.S. EPA’s recommended standards and timeframe. As such, we strongly support adoption of Alternative 4 rather than Alternative 3 to achieve full implementation by 2024. [EPA-HQ-OAR-2014-0827-1181-A1 p.2]

In summary, the SCAQMD staff urges U.S. EPA to finalize the proposed Phase 2 greenhouse gas emissions and fuels standards rule as early as possible with the inclusion of proposed revisions from CARB and NACAA along with the comments provided above.[EPA-HQ-OAR-2014-0827-1181-A1 p.8] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.34.]]

**Organization:** Truck & Engine Manufacturers Association (EMA)

Phase 1 has required vehicle manufacturers to undertake significant IT investments and complex process upgrades in order to generate and organize the data needed for GHG/FE compliance reporting to EPA and NHTSA. For each vehicle manufacturer, the necessary IT upgrades have involved millions of dollars and multiple years of development effort to generate and finalize all of the required data elements. The IT solution for GHG/FE tracking and reporting has had to be integrated into existing
systems to deliver the required compliance data. In that regard, manufacturers’ systems need to interrogate the listing of materials for each vehicle (i.e., each VIN) to identify the relevant vehicle subcategory, aerodynamics, tires, weight, AES/VSL, engine, and other operative GHG/FE factors. That information is then used to calculate the required inputs for “GEM” (the Agencies’ greenhouse gas emissions model) and to generate the unique complex vehicle label. GEM is run for each vehicle to find the VIN’s predicted CO2. All of those data are required for the compliance reports submitted to EPA and NHTSA. In addition to the IT infrastructure and programming, significant resources also have been required to maintain and secure the information necessary for compliance with Phase 1. [EPA-HQ-OAR-2014-0827-1269-A1 p.2-

For Phase 2, significant additional IT investments will be needed to develop and input engine fuel maps, transmissions (including powertrain test data), rear axles, and other vehicle attributes for the revised and more complex Phase 2 GEM calculations. Consequently, the IT investment for Phase 2 is expected to be even more significant than for Phase 1, which, as noted, was itself very substantial. [EPA-HQ-OAR-2014-0827-1269-A1 p.3]

Infeasibility of “Alternative 4”

Leadtime and stability are critical to achieving the goals of the Phase 2 proposal. The Agencies have proposed three steps of standards for engines and vehicles – in 2021, 2024, and 2027. The long-term certainty of knowing the required reductions through 2027 provides benefits to component suppliers and manufacturers, who need to invest in, develop, and validate reliable fuel-saving technologies, and to the end-users who will ultimately depend on those technologies in the market. Pulling ahead the 2027 standards by three years reduces the necessary certainty for manufacturers and results in less reliable technologies. [EPA-HQ-OAR-2014-0827-1269-A1 p.55]

In that regard, the Agencies have asked for comment on the feasibility of “Alternative 4,” which would pull ahead by three years the proposed effective dates of the Phase 2 Standards as laid out under Alternative 3. Simply stated, Alternative 4 is not feasible for medium-duty and heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.55]

Proponents of Alternative 4 may opine that it is feasible based on assumed “pay-back” periods, and based on assertions that the potential pay-back periods would be, by and large, the same under either Alternative 3 or Alternative 4. But that argument is irrelevant. [EPA-HQ-OAR-2014-0827-1269-A1 p.55]

The stringency of the Proposed Phase 2 vehicle standards is premised on assumptions (albeit overestimated assumptions) about technological developments and on the market penetration rates for those to-be-developed vehicle technologies, not on assumed “pay-back” periods. Neither the timeline for the necessary technological developments nor the realistic market penetration rates for those vehicle technologies would allow Alternative 4 to be feasible, let alone cost-effective. In that regard, the presumed penetration rates for the higher-bin aerodynamic packages, as well as for stop-start technologies, single tires, hybrid powertrains, and “6x2” axle systems, among other technologies, are all overstated. [EPA-HQ-OAR-2014-0827-1269-A1 p.55]

For example, “6x2” axle systems cannot be implemented as the Agencies have assumed, since they are not allowed in all localities. Local and state laws pertaining to bridge loads, per-axle weights and tire-patch requirements simply make it impractical to implement “6x2” axle configurations at the rate of penetration that the Agencies have forecast. There are similar impracticalities with respect to the Agencies’ other forecasted penetration rates as well. As a result, a three-year pull-ahead of already
overstated penetration rates would only serve to exacerbate the infeasibility of the proposed vehicle program, cause significant market disruptions, and would result in disproportionately costly and delayed reductions in GHG emissions. [EPA-HQ-OAR-2014-0827-1269-A1 p.55]

Accordingly, Alternative 4 should not be the basis for the Proposed Phase 2 Standards. The Alternative 3 timeframe (assuming the Agencies make the required revisions, as noted in EMA’s comments) will be challenging enough. [EPA-HQ-OAR-2014-0827-1269-A1 p.55]

Potential Pre-Buy/Low-Buy Concerns

Other issues exacerbate the problems associated with adopting Alternative 4 for medium-duty and heavy-duty vehicles. As the Agencies well know, there is significant elasticity in the demand for the commercial vehicles at issue in this rulemaking. The Agencies only regulate the manufacturing of new engines and vehicles. There is no obligation for customers to buy the new products – and certainly not at the time of implementation of a new regulation. Moreover, experience has shown that adverse economics, globally or affecting key market segments, have resulted in customers delaying vehicle purchases. Similarly, experience has shown that actual or perceived concerns about the cost, performance, durability, serviceability, or overall efficacy of new-tier vehicle technologies have also resulted in customer “pre-buys” of current-tier technologies and/or the delayed purchase of new-tier technologies. Neither manufacturers (who wish to start recovering their investment in new-tier engine and vehicle technologies as soon as possible) or regulators or the public (who wish to realize the benefits of new regulations as soon as possible) want to experience a pre-buy/low-buy response to the Phase 2 Standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.56]

Alternative 4 increases the risk for such a potential response since it likely would result in significantly higher per-vehicle cost increases (compared to Alternative 3), and could produce real or perceived concerns for product durability, reliability and maintenance issues. Those possible circumstances – necessarily more likely under Alternative 4 – could induce vehicle and fleet owners to revise their scheduled purchases of new Phase 2 vehicles. In that regard, and as the Agencies expressly acknowledge, Alternative 4 would deprive manufacturers of three-years of learning time and therefore would decrease the “learning-benefit” savings otherwise available under Alternative 3. [EPA-HQ-OAR-2014-0827-1269-A1 p.56]

The net result could be that manufacturers will be unable to recoup their capital investments in the time period projected in the NPRM. Worse, the very marginal GHG emission benefits ascribed to Alternative 4 might not be realized, even if the three-year pull-ahead could be accomplished, if the Alternative 4 standards proved in the market to be perceived as problematic by customers. The higher costs and potential reliability issues associated with Alternative 4 could be enough to cause vehicle and fleet owners to keep their Phase 1 vehicles longer than otherwise. Consequently, Alternative 4 might actually result in higher aggregate GHG emissions than under Alternative 3, not marginally lower emissions. This is another reason why the Agencies should not implement Alternative 4. [EPA-HQ-OAR-2014-0827-1269-A1 p.56]

Overall Feasibility Of The Proposed Phase 2 Vehicle Standards

As noted above, many of the Agencies’ Proposed Phase 2 Standards for heavy-duty and medium-duty vehicles are based on a series of very aggressive assumptions regarding the development of efficiency-enhancing technologies and regarding the market penetration rates of those technologies out to the year 2027. In that regard, EPA and NHTSA have developed a number of tables summarizing the Agencies’ key assumptions that led to the development of the Proposed Phase 2 Standards for Class 7 and 8 heavy-
duty tractors, heavy-haul tractors, trailers, and vocational vehicles. Each of those tables (including Table III-10, Table III-18, Table IV-4, Table IV-13, Table IV-14, Table V-15, Table V-19, and Table VIII-3) contains assumptions that are incorrect or over-estimated, and that call into question the feasibility of the Proposed Phase 2 Standards for the heavy-duty vehicles at issue. Included among those flawed or over-estimated assumptions are the following: [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

- The assumptions that Class 7 and Class 8 high-roof vehicles will achieve a 35% penetration rate into Bin V, a 20% penetration rate into Bin VI, and a 5% penetration rate into Bin VII are grossly over-stated and unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71][This section can also be found in section 4.3 of this comment summary]
- The assumed aerodynamic performance improvements to be achieved by daycab and mid and low-roof vehicles are over-estimated by at least one Bin, and so are inherently unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71][This section can also be found in section 4.3 of this comment summary]
- The assumptions that 90% of Class 8 sleeper caps and 90% of long-haul tractor trailers will utilize APUs to achieve extended idle emission reductions is based on grossly underestimated cost estimates and is unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71][This section can also be found in section 4.3 of this comment summary]
- The assumption that 40% of all Class 7 and 8 vehicles will utilize automated tire inflation systems lacks any factual basis, overlooks the prevalence of tire inflation monitoring systems, and is unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71][This section can also be found in section 4.3 of this comment summary]

The Agencies will need to correct all of the foregoing unreasonable assumptions, along with the others noted in these comments, before finalizing the Phase 2 Standards. Otherwise the Phase 2 Standards will likely prove to be infeasible for medium-duty and heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.72]

Organization: Truck Renting and Leasing Association

However, TRALA has several concerns about the Proposed Standards, which we have set forth below: (5) TRALA strongly opposes Alternative 4. [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

**TRALA Opposes Alternative 4**

For the reasons stated above, TRALA believes that the Proposed Standards already go too far in imposing burdensome costs and technology-forcing mandates that industry and its customers are not equipped to bear. Making the Proposed Standards even more stringent by, for example, moving up the full implementation date to MY2024 from MY2027 would run the risk of resulting in a largely unworkable regulatory program that would have to be later revised to enable compliance in the years ahead. [EPA-HQ-OAR-2014-0827-1140-A1 p.6]

Organization: Truck Trailer Manufacturers Association (TTMA)

**The Problem with Technology Forcing and Long-Duration Regulations:**

This proposed regulation postulates an aggressive schedule of technological development for a long period into the future. While we appreciate the experience the agencies have brought forward in making these predictions, and that the regulation is crafted with the intent of bringing a certain degree of
stability to regulation by laying out a roadmap until MY 2027, facts often fly contrary to the best predictions. Moreover, other voices are calling on the agencies to pursue a more aggressive schedule, one that would require an even faster technological development and deployment schedule. Therefore, we request that the regulation have built into it a mid-course review. For areas where there have been unexpected delays, say due to intellectual property rules creating a monopoly for a critical item such as a trailer boat-tail, then this could be addressed. If the rule posited the boat tails would be developed for trailers equipped with roll-up doors despite that no such devices exist today, only to find out that the technical challenges of creating a viable device precluded one, the rule could be revisited. Similarly, if a new device came along that offered improvements beyond what the Agencies envisioned, then the rule’s goals could be pushed forward to include that. [EPA-HQ-OAR-2014-0827-1172-A1 p.18]

Organization: Union of Concerned Scientists (UCS)

As the agencies move to finalize the standards, we urge you to adopt Alternative 4, with modifications to strengthen the standards for tractor engines, vocational vehicles, and heavy-duty pick-ups. The stringency and timing of this proposal would maximize the overall environmental, economic, and energy security benefits of the standards. [EPA-HQ-OAR-2014-0827-1329-A2 p.1-2]

We would support the timing and stringency of Alternative 4 with the following modifications: [EPA-HQ-OAR-2014-0827-1329-A2 p.4]

- Increasing tractor engine stringency up to 9.0 percent by 2024, compared to the current baseline;
- Increasing vocational vehicle stringency by at least 5 percent;
- Increasing the stringency of gasoline-powered pick-ups and vans by more than 7 percent; and
- Moving to SmartWay Elite levels for van trailers in the timeframe of this rule. [EPA-HQ-OAR-2014-0827-1329-A2 p.5]

The agencies' proposal must be 'technology-forcing' and achieve the 'maximum feasible' reductions in the timeframe of the rule. To do this, the agencies must strengthen Alternative 4 by: [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

- Increasing the stringency of the engine standard in 2024 to at least 9 percent from the current baseline to ensure real-world reductions over the lifetime of the vehicles; [EPA-HQ-OAR-2014-0827-1329-A2 p.27][This comment can also be found in section 3.3 of this comment summary]
- Increasing the stringency for tractors by 6 percent in 2024 to reflect the full range of improvements to the powertrain; [EPA-HQ-OAR-2014-0827-1329-A2 p.27][This comment can also be found in section 4.2 of this comment summary]
- Increasing the stringency for gasoline-powered vocational vehicles by 7.8 percent and those for diesel-powered vocational vehicles by 3.6 percent in 2024 to fully reflect the ability for conventional technologies to reduce fuel use from this sector, while incentivizing the adoption of more advanced technologies where appropriate; [EPA-HQ-OAR-2014-0827-1329-A2 p.27][This comment can also be found in section 6.2 of this comment summary]
- Ensuring that light- and heavy-duty pick-up and van standards are more closely aligned by acknowledging the full complement of applicable technologies - this would reduce consumption from gasoline-powered pick-ups and vans by 8.8 percent and diesel-powered pick-ups and vans by 2.1 percent in 2024; and [EPA-HQ-OAR-2014-0827-1329-A2 p.27][This comment can also be found in section 7.2 of this comment summary]
- Proposing guidelines for the inclusion of upstream emissions in these regulations to ensure that as the fuels powering these vehicles become more diverse, the emissions benefits of alternative-
fuel powertrains are appropriately credited and accurately reflect real world performance [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

In making these modifications to the proposal, the agencies will have ensured the further reduction of tens of millions of barrels of oil each year and avoided greenhouse gas emissions equivalent to shutting down 10 coal-fired power plants. In doing so, they will have also saved truckers hundreds of millions of dollars in fuel, costs which are inevitably borne by consumers.

Should the agencies extend the timeframe of the rule to 2027, these modifications must go further. EPA and NHTSA have the opportunity to put heavy-duty trucks on a more sustainable path, and they have an obligation to strengthen the proposed regulation in order to get us there.

**Organization:** United Parcel Service (UPS)

Opposition to Alternative 4

UPS supports Alternative 3, and opposes alternative 4, which would move the targets for 2027 earlier to 2024. In addition to our comments above about forcing premature technologies, and after looking at the state of our suppliers' readiness, we do not see any basis for such acceleration. The trucking industry is already challenged, as perhaps never before, by alternative fuel options, new impending emission requirements from multiple quarters, and unpredictable fuel prices. [EPA-HQ-OAR-2014-0827-1262-A1 p.3]

**Organization:** Volvo Group

**Timeframe of the Rule**

The extended timeframe of the proposed rule stretches beyond our visibility range for technology development and other influences on trucking operations.

The proposed rule would first impose new requirements as early as 2020 (when many manufacturers release their MY 2021 vehicles), and then extend additional requirements out to model years 2027 and beyond. Under this timeline, manufacturers will be stripped of the necessary lead-time contemplated by the Clean Air Act at the front end, while simultaneously faced with the considerable uncertainty created by imposing vastly more stringent requirements in the future based on the assumption that new, unproven technologies will emerge. We are very concerned that the feasibility and costs of technology are unknown 12 years into the future. And this concern is supported by the track record for regulators predicting the efficacy of emissions control technology in heavy-duty vehicles far in advance of their use. For example, in 2000 EPA promulgated a rule regulating NOx and particulate emissions from heavy-duty vehicles, which became fully effective in 2010. At the time of promulgation, the presumed technology for NOx control was NOx adsorbers (or NOx trap). The cost of the rule was then projected by EPA based on this technology: “We project that the emission reductions and the resulting significant public health and environmental benefits of this program will come at an average cost increase of about $1,200 to $1,900 per new vehicle, depending on the vehicle size.” Similarly, the Agency predicted it would cost up to $368 per vehicle for the EGR systems to be deployed in 2004. By the time these rules were fully implemented in 2010, the actual cost increase for a Class 8 truck was approximately $20,000 (this figure does not include significant increases in operating and maintenance costs), and not one heavy-duty manufacturer was successful in industrializing a NOx adsorber. Instead, all heavy-duty diesel manufacturers deployed selective catalytic reduction; a technology originally dismissed by EPA.
("SCR has significant NOx control potential, but it has many roadblocks to marketability in this country. These roadblocks include infrastructure issues that we believe would prove exceedingly difficult and potentially costly to overcome. Because of that, we believe that the NOx adsorber is the best technology for delivering significant diesel NOx reductions, while also providing market and operating characteristics necessary for the U.S. market.") [EPA-HQ-OAR-2014-0827-1290-A1 p.16-17]

Apart from the fact that vehicle technology appropriate for meeting 2027 emissions standards is unknown, there are also a host of other potential influencing factors that may change substantially before then. These include the availability and GHG impact of alternative fuels, vehicle size and weight limits, highway congestion, vehicle connectivity and autonomy, engine NOx limits, mandatory road speed limits, and others. These factors will influence vehicle duty cycles (payload, speed profiles, cruise power) and the optimum specifications for efficiency. But manufacturers will be constrained by fixed regulatory duty cycles and protocols, limiting their capacity to react to the changing environment and potentially forcing the introduction of technologies with limited real-world benefits that customers will not want to purchase. [EPA-HQ-OAR-2014-0827-1290-A1 p.17]

It is also possible that new novel concepts may be deployed in this time frame. The advent of connected or autonomous vehicles could significantly change vehicle duty cycles, for example: reducing idle time or modifying vehicle speeds. [EPA-HQ-OAR-2014-0827-1290-A1 p.17]

Given the history of the 2000 emissions regulations (effective in 2010) and the uncertainty of evolution in how vehicles are used, manufacturers are rightfully concerned that this long timeframe will introduce the risk of unpredictable and unintended consequences. In their Regulatory Impact Analysis, the Agencies outline the expected vehicle and engine technology areas and penetration rates for the stringency steps associated with model years 2021, 2024, and 2027. As stated herein, however, this outline remains speculative at best, as it is difficult to know how and whether the potential design changes will deliver the efficiencies predicted in each technology area. [EPA-HQ-OAR-2014-0827-1290-A1 p.17]

We also note that pulling the MY 2027 standard forward (alternative 4) is not a solution to this issue. As discussed below, the alternative 3 stringencies are already infeasible. [EPA-HQ-OAR-2014-0827-1290-A1 p.17]

**Organization:** Waste Management (WM)

**WM Supports a Regulatory Compliance Schedule with Full Implementation in MY 2027**

EPA and NHTSA have proposed a compliance schedule for fuel efficiency improvements and GHG reductions from trucks to occur over a period beginning in MY 2021, with further reductions required in MY 2024 and final implementation in MY 2027. Although the Agencies have proposed this schedule, they are also taking comment on an expedited schedule with full implementation of required reductions in MY 2024. WM believes this would be an unwise approach. Both equipment manufacturers and purchasers need sufficient lead-time to test new technologies or new applications of existing technologies in the field to understand how they will operate in real world circumstances. Expediting the compliance schedule by three years would significantly curtail valuable field-testing that is so necessary to assess the real world GHG reductions and fuel efficiency enhancements that may be achieved by new technologies. [EPA-HQ-OAR-2014-0827-1214-A2 p.6]

WM has significant experience testing new technologies on our vocational refuse vehicles in the field. We have learned a great deal from those road tests, where we can evaluate equipment while operating in
the various duty cycles that we use in serving our customers. Refuse vehicles are not typical of most vocational fleet vehicles. They are extremely heavy and have difficult duty cycles that place substantial demands on the vehicle. We have found that it is often necessary to test new technologies using a typical refuse duty cycle to assess whether they can achieve the advertised fuel or GHG reductions, or even operate properly in our work environment. We are very concerned that expediting the compliance schedule by three years would preclude much of the valuable field-testing time that we need to assure ourselves that we are purchasing vehicles and equipment that can serve our and our customer’s needs. [EPA-HQ-OAR-2014-0827-1214-A2 p.6]

Response:

The agencies noted in the proposal that the Phase 2 standards represent a more technology-forcing approach than the Phase 1 approach, predicated on use of both off-the-shelf technologies and emerging technologies that are not yet in widespread use. 80 FR 40154. As such, we recognized that assuring proper lead time would be very important and requested comment on this issue. Many commenters, including most non-governmental organizations, supported more stringent standards with less lead time.

Vehicle manufacturers did not support more stringent standards and emphasized the importance of lead time. Although some technology and component suppliers supported more stringent standards, they also supported the proposed lead time.

To the extent these commenters provided technical information to support their comments on stringency and lead time, it is discussed in Sections II through VI of the Preamble, and in Chapter 2 of the RIA. However, the vast majority of the comments summarized here addressed the issue of lead time from a broader view. This section primarily addresses these broader comments.

Need for Lead Time

The standards being adopted provide approximately ten years of lead time for manufacturers to meet these 2027 standards, which the agencies believe is appropriate to implement the technologies industry could use to meet these standards. For some of the more advanced technologies, production prototype parts are not yet available, though they are in the research stage with some demonstrations in actual vehicles. Additionally, even for the more developed technologies, phasing in more stringent standards over a longer timeframe will help manufacturers to ensure better reliability of the technology and to develop packages to work in a wide range of applications. For example, consider the one extreme of technologies that are currently available for some but not all vehicles. These may represent the easiest technologies to develop. Yet even for these technologies, manufacturers will need to spend some time and resources to complete such tasks as:

- Packaging the technology for each vehicle model, including physically fitting the technology within the available space.
- Evaluating and optimizing the effectiveness of the technology across the range of in-use operation.
- Identifying and remedying failure modes for unique or severe duty cycles.
- Retooling facilities.

As noted in the NPRM, providing additional lead time can often enable manufacturers to resolve technological challenges or to find lower cost means of meeting new regulatory standards, effectively making them more feasible in either case. See generally NRDC v. EPA, 655 F. 2d 318, 329 (D.C. Cir. 1981). On the other hand, manufacturers and/or operators may incur additional costs if regulations
require them to make changes to their products with less lead time than manufacturers would normally have when bringing a new technology to the market or expanding the application of existing technologies. After developing a new technology, manufacturers typically conduct extensive field tests to ensure its durability and reliability in actual use. Standards that accelerate technology deployment can lead to manufacturers incurring additional costs to accelerate this development work, or can lead to manufacturers beginning production before such testing can be completed. See RIA Chapter 2.3.9. Some commenters identified the introduction of diesel particulate filters and/or SCR in response to the 2007 heavy-duty engine standards as an example of durability problems that can occur. While it is unclear whether the problems occurred because of insufficient lead time or because of other factors, it is clear that manufacturers did not perform sufficient product development validation, and that led to additional costs for operators when the technologies required repairs or resulted in other operational issues in use.

Daimler noted that the combination of greater product diversity and lower sales volumes than light-duty, makes lead time a more critical issue for heavy-duty. The agencies have considered these factors.

Another issue raised by commenters was the possibility of disrupting the market if compliance required application of new technologies too suddenly. Some noted that expectations of reduced reliability, increased operating costs, reduced residual value, or of large increases in purchase prices can lead the fleets to pull-ahead by several months planned future vehicle purchases by pre-buying vehicles without the newer technology. In the context of the Class 8 tractor market, where a relatively small number of large fleets typically purchase very large volumes of tractors, such actions by a small number of firms can result in large swings in sales volumes. We agree with commenters that, to the extent such market impacts occur, they could be followed by some period of reduced purchases that can lead to temporary layoffs at the factories producing the engines and vehicles, as well as at supplier factories, and disruptions at dealerships. Such market impacts also could also reduce the overall environmental and fuel consumption benefits of the standards by delaying the rate at which the fleet turns over. See International Harvester v. EPA, 478 F. 2d 615, 634 (D.C. Cir. 1973).

While the agencies do not agree with commenters that argue the proposed lead time will cause such problems, we do agree with the points raised that these things could have resulted if we had provided insufficient lead time. The agencies have taken steps in the design of the program to avoid such these potential disruptions, including:

- Providing ten years of lead time for full implementation of Phase 2
- Adopting standards that will result in significantly lower operating costs for vehicle owners (unlike the 2007 standard, which increased operating costs)
- Phasing in the standards
- Structuring the program so the industry will have a significant range of technology choices to be considered for compliance, rather than the one or two new technologies the OEMs pursued to comply with EPA’s 2007 criteria pollutant standard
- Allowing manufacturers to use emissions averaging, banking and trading to phase in the technology even further

Statutory Requirements for Lead Time

EISA requires that NHTSA provide four model years of lead time (and three years of stability) for heavy-duty fuel consumption regulations. Beyond that, NHTSA has the broad discretion to weigh and balance lead time with the other applicable factors in order to accomplish EISA’s mandate of determining
maximum feasible standards. The fact that the factors may often be at odds gives NHTSA significant discretion to decide what weight to give each of the competing factors, policies and concerns and then determine how to balance them—as long as NHTSA’s balancing does not undermine the fundamental purpose of the EISA: energy conservation, and as long as that balancing reasonably accommodates “conflicting policies that were committed to the agency’s care by the statute.”

EPA also has significant discretion in assessing, weighing, and balancing the relevant statutory criteria. Section 202(a)(2) of the Clean Air Act requires that the standards “take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period.” This language affords EPA considerable discretion in how to weight the critical statutory factors of emission reductions, cost, and lead time (76 FR 57129-57130). Section 202 (a) also allows (although it does not compel) EPA to adopt technology-forcing standards. Id. at 57130; see also responses in Section 1.7 below.

Is the Final Lead Time Sufficient?

Comments on the sufficiency of the proposed lead time were mixed and somewhat nuanced. Many commenters stated that the proposed lead time was more than sufficient. These comments supporting less lead time are discussed in the next subsection. On the other hand, many other commenters supported the lead time as being appropriate, although some did so while arguing for less stringent standards. Commenters who believe (or appear to believe) that the proposed lead time is insufficient, generally expressed the concern in the context of less stringent standards rather than additional lead time. Comments addressing the stringency of the standards, as well as those regarding the lead time necessary to address specific technologies, are addressed in Sections 3 through 7 of this RTC.

Although the agencies are finalizing the proposed implementation schedule that will provide at least four years of lead time for most standards, we have also revised many aspects of the proposal including providing additional lead time to address concerns raised in the comments.

Daimler commented that “a three year cadence of tightened standards is too fast” and should be revisited. We disagree. Most of the projected technologies can be introduced incrementally and would not need to be tied to vehicle redesign cycles. Also manufacturers may use the averaging provisions to provide additional flexibility. Where product introduction is closely tied to design cycles (e.g. introduction of WHR), the agencies have carefully accounted for projected redesigns. See, e.g. RIA section 2.7. 5.

RMA commented that tires require five years of lead time. Although we do not necessarily agree with this comment, we note that tire manufacturers could provide themselves this amount of lead time if they so choose. The standards that take effect before model year 2024 can be met with tires already on the market. To the extent that the standards require new tire designs in 2024, industry will have eight years of lead time.

Finally, we do not believe comments related to the implementation of the 2007/2010 standards are directly relevant here (other than to highlight the importance of considering reliability when adopting new technologies). In discussions with EPA outside of the context of this rulemaking, manufacturers have acknowledged that their internal processes were not adequate when they implemented the 2007/2010 standards. However, they have also indicated that they have improved these internal processes to ensure similar problems do not occur for other new technologies.

Are the Agencies Providing Too Much Lead Time?
Comments on lead time overlapped with comments on the overall stringency of the proposed Phase 2 program. Many commenters, including most non-governmental organizations, supported more stringent standards with less lead time. They generally supported the proposed Alternative 4. However, many technology and component suppliers supported more stringent standards but with the proposed lead time. Vehicle manufacturers strongly opposed the reduced lead time of Alternative 4. To the extent any of these commenters provided technical information to support their comments on stringency and lead time, it is discussed in Sections II through VI of the FRM Preamble. Comments regarding the lead time necessary to address specific technologies, are also addressed in Sections 3 through 7 of this RTC.

Many of the comments supporting the Alternative 4 standards stated that they would be “cost-effective”. In general, however, we did not find costs or cost-effectiveness to be a significantly limiting factor in determining the stringency of the standards. Rather, we found that actual technological feasibility and lead time to be the more limiting factors. Manufacturers and suppliers have limited research and development capacities, and although they have some ability to expand, the process of developing and applying new technologies is inherently constrained by time. This limits the extent to which they can bring new technologies to market. EMA also commented that even the IT system improvements will require substantial lead time.

While the agencies agree that many cost effective technologies exist, and indeed, we reflect the potential for many of those technologies to be applied in our analysis for today’s final rule, commenters who focused on the cost-effectiveness of technologies did not consistently recognize certain real-world constraints on technology implementation. Adequate lead time is also necessary to complete durability, reliability, and safety testing and ramp up production to levels that might be necessary to meet future standards. If the agencies fail to account for lead time needs in determining the stringency of the standards, we could create unintended consequences, such as technologies that are applied before they are ready and lead to maintenance and repair problems. In addition to cost-effectiveness, then, lead time constraints can also be highly relevant to feasibility of more stringent standards.

In response to CARB’s comment that the lead time we are providing “is 60 percent longer than the time frame considered by the NRDC court”, we note that this is not relevant. The requirements for lead time do not require any fixed length of time, or any other formulaic value. Rather, the statutes require that we provide the lead time “necessary to permit the development and application of the requisite technology”.

Lead Time for Engine Standards

Many commenters specifically cited the engine technologies as an area for which the agencies had proposed too much lead time. They generally supported the Alternative 4 lead time with more stringent standards. We agree partially with these commenters. We have reanalyzed the technological feasibility of engine improvements and are now projecting manufacturers will be able to largely achieve the Alternative 4 engine improvements in 2024.

Additional Lead Time for Small Manufacturers

Autocar commented that providing an additional year of lead time was not sufficient to address the concerns of small custom chassis manufacturers. In response, the agencies note that we are also finalizing other relief for these manufacturers including the optional custom chassis program.

Need for Market Research
CARB suggested that the agencies “conduct additional research on the market impact of the proposed rulemaking, including an ex post (retrospective) analysis of the market impacts resulting from existing GHG and criteria pollutant engine and vehicle regulations.” We do not believe this is necessary. Our goal was to provide enough lead time to allow manufacturers to develop the applicable technologies and complete the necessary durability testing before widespread use of the technology is required to meet the standards.

Lead Time for Phase 1 Changes

Caterpillar commented that the agencies have not provided sufficient lead time for changes to Phase 1. However, the changes applicable to Phase 1 are all minor and do not require substantial lead time (and EPA is providing additional lead time to accommodate additional paperwork possibly needed for the revised delegated assembly provisions). Nevertheless, we also note that 40 CFR 1068.40 allows for manufacturers to request additional time (up to 12 months) to comply with newly adopted changes to existing regulations.

Standards beyond 2024

Several commenters expressed support for setting standards for MY 2027 because they believe it will provide valuable certainty for OEMs and technology manufacturers. However, Volvo expressed concern about the ability to project technology development so far into the future. While we understand Volvo’s concern, we believe the value of longer-term standards offsets this concern.

TTMA supports a “mid-course review” of the standards. While the agencies are not finalizing a formal process for such a review, we note that we expect to do so informally. In addition, manufacturers (and other stakeholders) retain the ability to formally petition us for a reconsideration of some or all of the Phase 2 program based on new information.

Impact of GHG Lead Time on Potential NOx Standards

Some commenters argued that pulling ahead the Phase 2 standards under the Alternative 4 time frame would allow manufacturers to adopt NOx improvements sooner. However, EPA believes the opposite would be true. If we provided less lead time for Phase 2, it would make it harder for manufacturers to devote resources to improving NOx emissions. As noted in Section 15, EPA believes that the lead time being provided for Phase 2 will allow manufacturers to simultaneously work to reduce NOx emissions by the 2024 model year.

1.6 Alternative Refrigerants

1.6.1 Requests for Credit/Incentive for Alternative Refrigerants

Organization: Daimler Trucks North America LLC

AC refrigerant changes: DTNA agrees with EPA that a change to refrigerants for heavy vehicles should not be assumed. The heavy vehicle industry, with its lower volumes, follows the passenger vehicle industry in this regard and cannot be expected to change refrigerants until several years after the light-duty vehicle industry does. That said, the agencies should consider giving GHG credits for low GWP

**Organization:**  Environmental Defense Fund (EDF)

At the same time, the final provisions should incentive the use of lower GWP refrigerants. Shifting the heavy-duty sector to low GWP refrigerants will result in far greater emissions reductions than leakage reductions alone. The light-duty sector has already begun such a shift, proving that the technology and refrigerants are available, cost-effective and successful. The Phase 2 rule should drive the heavy-duty sector toward lower GWP refrigerants. [EPA-HQ-OAR-2014-0827-1312-A1 p.52]

Instead, EPA states in the Preamble that it is not making any attempts to incentivize or require the use of lower GWP refrigerants because, “there is great uncertainty about when significant adoption of alternative refrigerants for HD vehicles might begin, on what timeline adoption might become widespread, and which refrigerants might be involved.” By waiting for industry members to take action, EPA is failing to fulfill its duty under the CAA. Indeed, EPA has authority, and the duty, to drive technology and promote the adoption of cleaner refrigerants. It is not necessary for EPA to “attempted to project any specific hypothetical scenarios of transition.” EPA’s job is to protect human health by adopting provisions that reduce harmful emissions from the heavy-duty sector. [EPA-HQ-OAR-2014-0827-1312-A1 p.52]

We urge EPA to accelerate the SNAP approval process for additional lower GWP refrigerants for use in heavy-duty applications. Simultaneously, EPA should finalize a rule prohibiting the use of HFC-134a in heavy-duty A/C systems. In the interim, EPA should take steps in this final rule to incentivize the adoption of low GWP refrigerants before high GWP ones are prohibited. [EPA-HQ-OAR-2014-0827-1312-A1 p.52]

These actions would support the Obama Administration’s Climate Action Plan call for EPA to use its authority under the Significant New Alternatives Policy (SNAP) Program to encourage alternatives and prohibiting the use of the most harmful chemical alternatives.220

**Organization:**  Honeywell Fluorine Products

We support EPA’s approach to use the established processes to expand the pool of qualified low GWP refrigerants to replace HFC-134a. While EPA has not yet approved HFO-1234yf under SNAP for use in HD, MD and VV, we believe that the crediting methodology in 40 CFR 86.1867-12(e) offers an appropriate approach to leak crediting/scoring once EPA grants SNAP approval for these applications. [EPA-HQ-OAR-2014-0827-1191-A1 p.5]

**Organization:**  FCA US, LLC

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 62.]
[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 134.]
As far as A/C system improvements, we believe there is value in recognize the greenhouse gas and fuel consumption contributions from reducing the energy demand of the A/C systems. We also believe there's additional opportunity to further harmonize with the Light Duty Program and recognize the added greenhouse gas emission benefit beyond leak reduction. That's switching to a lower global warming potential a refrigerant can provide.

Organization: American Automotive Policy Council

Light-Duty MAC Refrigerant/Leakage

The table above documents the rapid reduction in refrigerant leakage resulting from the direct MAC credit program. Leakage reduction improvements increased 69% to 10.3 million megagrams in only three years, from 2009 to 2012. The increase on a per vehicle basis was from approximately 3.5 grams per mile of CO₂ per vehicle in 2009 to approximately 4.0 grams per mile in 2012 (EPA Manufacturer Performance Report for the 2012 Model Year, p. 29). [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

Although industry-wide statistics have not yet been published beyond 2012, production capacity for the new low-global-warming refrigerant R-1234yf has increased. Following its introduction on a few models in 2013, R-1234yf has been implemented on many important vehicle platforms totaling millions of vehicles. The incentive created by pre-defined MAC credits has accelerated the U.S. HFC reduction program into a leading position worldwide, laying the groundwork for eventual phase-out or dramatic phase-down of high GWP automotive refrigerants. [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

Class 2b/3 Pre-Defined Refrigerant Credit List

The experience from the Light-Duty vehicle program shows that a pre-defined list of credits for refrigerant improvements on heavy-duty vehicles would accelerate these improvements. Credits for low leak air conditioner systems and credits for low-global-warming refrigerants should both play a role, laying the basis for eventual industry-wide refrigerant replacements in systems with high refrigerant containment integrity. By using an incentive approach, rather than mandates, companies move as quickly as they can, according to their various constraints and capabilities, with the result that the most eager early actors break down barriers and reduce costs to smooth the path for an eventual industry-wide switchover. [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

The current rulemaking is an appropriate time to create this incentive structure in heavy-duty vehicles. At a minimum, given the similarities in the air conditioning systems between Class 2b/3 trucks and many light-duty trucks, as well as the experience of the light-duty vehicle manufacturers with these provisions of the Light-Duty regulation, a pre-defined credit list for refrigerants should be created for Class 2b/3 trucks. The credit levels and other provisions should be identical to the credit provisions for light-duty trucks in the same time period, through 2025 model year, including acknowledging further improving leakage and moving R-134a systems to low-GWP refrigerants. [EPA-HQ-OAR-2014-0827-1238-A1 p.20]

Organization: Chemours Company FC, LLC

Chemours recognizes the need for concerted action to avoid significant future growth in greenhouse gas emissions. That is why we are bringing low global warming potential (GWP), energy efficient products to market across various end uses. We also believe it is critical that emissions are reduced in a manner that ensures that we are able to deliver the critical societal benefits that HFCs provide today including safe and energy efficient air conditioning. [EPA-HQ-OAR-2014-0827-1231-A1 p.1]
The proposed regulation includes two options for reducing greenhouse gas emissions related to HFC refrigerants. Under EPA’s current proposal manufacturers could continue to meet the leak-tight A/C systems requirements or could choose to comply by installing systems that use a low GWP SNAP-listed MVAC refrigerant. While this is a good proposal, it may not offer credit to those manufacturers who have already complied. [EPA-HQ-OAR-2014-0827-1231-A1 p.1]

Therefore, Chemours suggests that an opportunity to secure CO2 credits be offered in addition to the current “leak-tight” requirements. In addition to these credits, Chemours recommends that credits for early adoption should also be given. These early adopter credits could motivate manufacturers to transition to low GWP solutions sooner further reducing greenhouse gases than might be emitted under the current proposed standard. The value of these credits should be set at a sufficiently high value to incentivize vehicle manufacturers to absorb the higher cost of the low GWP refrigerant option. The successful credit structure in the 2017-2025 EPA/NHTSA CAFE/Greenhouse Gas Final Rule for Light Duty Vehicles provides a template that should also work for medium- and heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1231-A1 p.1]

EPA specifically requested comments on ways to prevent or discourage manufacturers that transition to an alternative low GWP refrigerant from discontinuing existing, low-leak A/C system components and instead reverting to higher-leakage components. Incentives or credits could be provided to manufacturers who elect to convert to a low GWP refrigerant and utilize leak-tight A/C systems concurrently as a means of encouraging the continued use of low-leak A/C system components. [EPA-HQ-OAR-2014-0827-1231-A1 p.1]

Response

A transition to lower-GWP A/C refrigerants by HD vehicle manufacturers, although not specifically required or incentivized in this rule, may already be underway. LD vehicle manufacturers are currently making investments in systems designed for lower-GWP refrigerants, both domestically and on a global basis. In support of the LD GHG rule, EPA projected a full transition of LD vehicles to lower-GWP alternatives in the United States by MY 2021. We expect the costs of transitioning to decrease over time as alternative refrigerants are adopted across all LD vehicles and trucks, in part due to increased availability of components and the continuing increases in refrigerant production capacity, as well as knowledge gained through experience. As lower-GWP alternatives become widely used in LD vehicles, some HD vehicle manufacturers may wish to also transition their vehicles. Transitioning could be advantageous for a variety of reasons, including platform standardization and company environmental stewardship policies. Also, the recently-proposed EPA action under the SNAP program to list HFO-1234yf as acceptable for some HD vehicles (subject to use conditions) could affect future plans, depending on what EPA ultimately finalizes. (See the response to Section 1.7.2 below).

Because the Phase 1 HD A/C refrigerant leakage standards are separate from the CO2 standards (unlike the LD leakage standards), and because the Phase 2 program is not changing these standards or their structure, the program does not have a mechanism for providing credit for lower-GWP refrigerants.

1.6.2 Requests for EPA Action on Status of Current or Alternative Refrigerant

Organization: Natural Resources Defense Council (NRDC)

Encourage the rapid adoption of alternative refrigerants with low global warming potentials. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]
Encourage Rapid Transition to Alternative Refrigerants

Using energy-efficient, low global warming potential (GWP) refrigerants in medium- and heavy-duty motor vehicle air conditioning systems is an important part of reducing the overall greenhouse gas impact of the sector. NRDC recommends approaches to facilitate a smooth transition to low-GWP refrigerants as they become available for heavy-duty vehicles in comments filed separately from these with partners at the Institute for Governance and Sustainable Development. Please refer to those comments for details. [EPA-HQ-OAR-2014-0827-1220-A1 p.10]

Organization: Natural Resources Defense Council (NRDC) and the Institute for Governance and Sustainable Development (IGSD)

As EPA recognizes, transitioning to energy-efficient, low-GWP refrigerants in medium- and heavy-duty motor vehicle air conditioning systems is an important part of reducing the overall greenhouse gas impact of the sector. The most important way in which EPA can achieve this result is by promptly using its Significant New Alternatives Policy Program (SNAP) authority to approve low-GWP alternative refrigerants for use in medium- and heavy-duty vehicles and to prohibit use of the high-GWP refrigerants currently in use. We understand that EPA is currently considering a low-GWP candidate, HFO-1234yf, in certain types of medium- and heavy-duty vehicles. As EPA approves low-GWP replacements for use in medium- and heavy-duty vehicles, EPA should also move forward as quickly as possible to phase out use of high-GWP HFC-134a. [EPA-HQ-OAR-2014-0827-1305-A1 p.1]

Organization: California Air Resources Board (CARB)

Include requirement for low-GWP refrigerants once commercially available

The NPRM requests comment on industry development and other aspects of low-GWP refrigerants for heavy-duty vehicles. CARB staff supports U.S. EPA and NHTSA’s intent to consider and evaluate alternative, low-GWP, refrigerants for use in heavy-duty AC systems. Using low-GWP refrigerants would significantly reduce the climate impact from the direct refrigerant emissions from heavy-duty vehicles. R-744 (CO2) and HFC-152a have already been approved by U.S. EPA Significant New Alternatives Policy (SNAP) program for use in all (including heavy-duty) AC applications. One chemical manufacturer, Chemours, is preparing an application to U.S. EPA SNAP program to qualify HFO-1234yf (another low-GWP refrigerant which is SNAP approved for light-duty use) for heavy-duty applications. In general, however, industry development and adoption of low-GWP refrigerants in heavy-duty subsectors has been relatively slow compared to light-duty applications, despite the substantial similarity between the AC systems for light-duty and for heavy-duty. [EPA-HQ-OAR-2014-0827-1265-A1 p.144-145]

CARB staff believes that regulatory requirements or incentives can motivate those research and development activities, and speed up the transition to low-GWP refrigerants for heavy-duty applications. Therefore, CARB staff is considering developing regulations to prohibit the use of high-GWP refrigerants for these applications, as a part of CARB strategies to reduce short-lived climate pollutants. For the same reason, CARB staff urges U.S. EPA and NHTSA to expedite the review and determination process for the incoming HFO-1234yf SNAP application for heavy-duty. Furthermore, CARB staff recommends that U.S. EPA and NHTSA include in the Phase 2 standards a requirement of using low-GWP refrigerants, starting as early as legally and technologically possible. (For example: “Starting in Model Year 2021, or the model year commencing four years after this provision is promulgated, or the model year commencing three years after a low-GWP refrigerant for this end-use becomes commercially available, whichever comes last, the GWP of Motor Vehicle AC refrigerants used by manufacturers in new heavy-duty vehicles be equal to or less than 150. Being ‘Commercially Available’ in this provision means having been approved for the concerned end-use by the SNAP
program, having been determined to be acceptable for adoption by at least one vehicle manufacturer, and being produced at commercial quantities. This provision must stay in effect till the end of the current regulation, and no less than three model years.” The three-year lead time is based on a stakeholder (Honeywell) comment on CARB Short-Lived Climate Pollutant Concept Paper that manufacturers would need two to three years to implement a transition to a low-GWP alternative once the refrigerant has been evaluated. [EPA-HQ-OAR-2014-0827-1265-A1 p.145]

Organization: Chemours Company FC, LLC

EPA has requested comment on the possible change of status of HFC-134a for use in Medium- and Heavy-Duty vehicles. Chemours supports a change of status of HFC-134a to unacceptable for use in Medium- and Heavy-Duty vehicles after equipment manufacturers have had sufficient time to finalize designs to utilize the new refrigerants and after low GWP replacements have been approved and listed under the SNAP program. [EPA-HQ-OAR-2014-0827-1231-A1 p.1-2]

Organization: Honeywell Fluorine Products

Honeywell is a strong supporter of EPA’s commitment to reducing the use of substances with a high global warming potential (GWP) and the use of its Significant New Alternatives Policy (SNAP) program and motor vehicle related rules to transition the automotive industry to low-GWP alternatives. We have been working diligently to develop and commercialize products and technologies to further those goals. [EPA-HQ-OAR-2014-0827-1191-A1 p.1-2]

Honeywell appreciates EPA’s continued recognition that low GWP refrigerants can contribute significantly to the reduction of GHG emissions from the transportation sector, including from heavy duty (HD), medium duty (MD), and now, through this Proposed Rule, in vocational vehicles (VV). (Also referred to collectively throughout as HD) [EPA-HQ-OAR-2014-0827-1191-A1 p.2]

In response to EPA’s request in the Proposed Rule for “comment on all aspects of our proposed approach to HD vehicle refrigerant leakage and the potential future use of alternative refrigerants for HD applications,” Honeywell offers the following: [EPA-HQ-OAR-2014-0827-1191-A1 p.2]

1. Low GWP Refrigerants Are Poised to Make Significant Contribution to a Reduction of GHG emissions from HD Vehicles Without Compromising Performance or Safety [EPA-HQ-OAR-2014-0827-1191-A1 p.2] HFO-1234yf has been proven effective in light duty vehicles. We estimate that approximately five million light duty vehicles using HFO-1234yf will be on the road by the end of this year. European Union regulations require the phase out of R-134a in all new light duty vehicles by January 1, 2017 and the vast majority of European auto manufacturers intend to use HFO-1234yf. In the United States, many manufacturers are adopting voluntarily HFO-1234yf as part of their strategy to comply with EPA’s stringent CO2 emission requirements. [EPA-HQ-OAR-2014-0827-1191-A1 p.2]

As EPA recognizes in the Proposed Rule, air conditioning systems in HD vehicles are very similar in design to light duty vehicles, only with bigger equipment that holds a significantly larger charge of refrigerant. Many of the same Tier 1 manufacturers make the air conditioning systems for both light and HD vehicles, and Honeywell believes that HFO-1234yf would work well in HD and MD vehicles as well. [EPA-HQ-OAR-2014-0827-1191-A1 p.2]

As EPA notes, “most manufacturers of LD vehicles have identified HFO–1234yf as the most likely refrigerant to be used in that application. For that reason, EPA would anticipate that HFO–1234yf could
be a primary candidate for refrigerant substitution in the HD market in the future if it is listed as an acceptable substitute under SNAP for HD A/C applications.” [EPA-HQ-OAR-2014-0827-1191-A1 p.2]

Honeywell agrees with EPA that low GWP refrigerants such as HFO-1234yf will offer similar performance and safety in HD vehicles as they have demonstrated in light duty vehicles. Compared to 134a, HFO-1234yf demonstrates comparable energy efficiency over the complete operating range and good life cycle performance in all climates. After extensively studying the use of HFO-1234yf for light duty vehicles, SAE concluded that HFO-1234yf has the best environmental performance and judges it to be safe in use through extensive risk assessments. [EPA-HQ-OAR-2014-0827-1191-A1 p.3]

Honeywell is committed to working with EPA, NHTSA and industry to address any issues regarding the safe and effective adoption of 1234yf. Parallel to this effort, Honeywell will seek SNAP approval for HFO-1234yf in HD, MD and vocational vehicles. [EPA-HQ-OAR-2014-0827-1191-A1 p.3]

Organization: FCA US, LLC

As far as A/C system improvements, we believe there is value in recognize the greenhouse gas and fuel consumption contributions from reducing the energy demand of the A/C systems. We also believe there's additional opportunity to further harmonize with the Light Duty Program and recognize the added greenhouse gas emission benefit beyond leak reduction that switching to a lower global warming potential a refrigerant can provide.

Organization: American Automotive Policy Council

Light-Duty SNAP Program

Based on the early start and clear incentives provided by the MAC provisions in the Light-Duty greenhouse gas regulation, EPA recently published a final rule (80 Federal Register 42870) under its Significant New Alternatives Program (SNAP) which will remove high-GWP R-134a entirely from use as an air conditioner refrigerant in new light-duty vehicles by the 2021 model year. AAPC recommends that EPA approve R-1234yf and other low GWP refrigerants for use in heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

Response:

Under EPA’s Significant New Alternatives Policy (SNAP) Program, EPA has found acceptable, subject to use conditions, three alternative refrigerants that have significantly lower GWP s than HFC-134a for use in A/C systems in newly manufactured light-duty vehicles: HFC-152a, CO$_2$ (R-744), and HFO-1234yf. HFC-152a has a GWP of 124, HFO-1234yf has a GWP of 4, and CO$_2$ (by definition) has a GWP of 1, as compared to HFC-134a which has a GWP of 1,430. CO$_2$ is nonflammable, while HFO-1234yf and HFC-152a are flammable. All three are subject to use conditions requiring labeling and the use of unique fittings, and where appropriate, mitigating flammability and toxicity. Currently, the SNAP listing for HFO-1234yf is limited to newly manufactured A/C systems in light-duty vehicles, whereas HFC-152a and CO$_2$ have been found acceptable for all motor vehicle air conditioning applications for new equipment, including heavy-duty vehicles.

A change in A/C refrigerants requires significant engineering, planning, and manufacturing investments. EPA is not aware of any significant development of A/C systems designed to use alternative refrigerants in heavy-duty vehicles. However, all three lower GWP alternatives are in use or under various stages of development for use in LD vehicles. Of these three refrigerants, most manufacturers of LD vehicles
have identified HFO-1234yf as the most likely refrigerant to be used in that application. For that reason, EPA anticipates that HFO-1234yf will be a primary candidate for refrigerant substitution in the HD market in the future if it is listed as an acceptable substitute under SNAP for HD A/C applications.

As mentioned above, EPA has listed as acceptable, subject to use conditions, two lower-GWP refrigerants, R-744 (CO\textsubscript{2}) and HFC-152a, for use in new HD vehicles. On April 18, 2016, EPA also proposed to list HFO-1234yf as acceptable, subject to use conditions, in A/C systems for newly manufactured MDPVs, HD pickup trucks, and complete HD vans (81 FR 22810). In that action, EPA proposed to list HFO-1234yf as acceptable, subject to use conditions, for those vehicle types for which human health and environmental risk could be assessed using the currently available risk assessments and analysis on LD vehicles. Also in that action, EPA requested “information on development of HFO-1234yf MVAC systems for other HD vehicle types or off-road vehicles, or plans to develop these systems in the future.” EPA also stated “This information may be used to inform a future listing” (81 FR 22868).

In another rulemaking action under the SNAP program, on July 20, 2015, EPA published a final rule (80 FR 42870) that will change the listing status of HFC–134a to unacceptable for use in newly manufactured LD motor vehicles beginning in MY 2021 (except as allowed under a narrowed use limit for use in newly manufactured LD vehicles destined for use in countries that do not have infrastructure in place for servicing with other acceptable refrigerants through MY 2025). In that same rule, EPA listed the refrigerant blends SP-34E, R-426A, R-416A, R-406A, R-414A, R-414B, HCFC Blend Delta, Freeze 12, GHG-X5, and HCFC Blend Lambda as unacceptable for use in newly manufactured light-duty vehicles beginning in MY 2017. EPA’s decisions were based on the availability of other substitutes that pose less overall risk to human health and the environment, when used in accordance with required use conditions. Neither the April 2016 proposed rule nor the July 2015 final rule consider a change of listing status for HFC-134a in HD vehicles.

Overall, EPA acknowledges commenters’ perspectives about alternative refrigerants and will consider the comments as it evaluates possible future status change rules under the SNAP program. These comments support the Agency’s understanding that HFO–1234yf could be a primary candidate as an alternative refrigerant for certain heavy-duty vehicles in the future if it is listed as an acceptable substitute under the SNAP program.

1.6.3 Comments Relating to Alternative Refrigerants and Compliance with Leakage Standards

Organization: Natural Resources Defense Council (NRDC) and the Institute for Governance and Sustainable Development (IGSD)

EPA also seeks comment on whether manufacturers using low-GWP refrigerants would be likely to revert to more leak-prone systems if EPA were to no longer require maximum leak rates. We expect that manufacturers are not likely to do so. HFO-1234yf is more costly than HFC-134a and we expect that manufacturers will want to continue to use the same systems that are currently required in order avoid more expensive refrigerant recharges. Even if some greater leakage did occur, the environmental effect of leaking HFO-1234yf is of course not nearly as harmful as leaks of HFC-134a. Thus, if EPA believes that it can encourage a transition to low-GWP systems early by exempting the leak provisions, then such a strategy is likely to reduce greenhouse gas emissions. If such an exemption is provided for low-GWP systems, EPA should require that the system be recharged only with low-GWP refrigerants. [EPA-HQ-OAR-2014-0827-1305-A1 p.2}
Organization: Environmental Defense Fund (EDF)

We encourage EPA to ensure that the proposed new “deemed to comply” provision does not result in backsliding of HFC emissions. EPA is proposing that if a manufacturer switches to a lower GWP refrigerant listed as acceptable under the SNAP program, it will be “deemed to comply” with the low leak standard – meaning that A/C system will not have to employ low leakage components as finalized in the Phase 1 rule. Without requirements for continued in-use compliance with a lower GWP refrigerant, we are concerned this proposed provision would allow manufacturers who choose a lower GWP refrigerant to switch back to higher leakage components at the time of manufacture and compliance. Subsequently, the consumer could immediately, or at the time of replacement, switch back to a high GWP refrigerant, seriously undercutting the benefits and flouting the intent of the program. We strongly encourage EPA to put in place in-use protocols to ensure that high GWP refrigerants are not used for recharge. If this cannot be ensured, we recommend EPA maintain the low leak requirement for all heavy-duty A/C systems at least until the SNAP listing for HFC-134a is changed to “unacceptable” for use in new heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.52]

Organization: California Air Resources Board (CARB)

Not appropriate to allow manufacturers to be “deemed to comply” with Air Conditioning (AC) leakage standard by using an alternative refrigerant

U.S. EPA and NHTSA are proposing to allow a manufacturer to be “deemed to comply” with the leakage standard by using a lower global warming potential (GWP) alternative refrigerant. [EPA-HQ-OAR-2014-0827-1265-A1 p.139] Although CARB supports the promotion of the development and use of lower-GWP refrigerants for heavy-duty vehicle air conditioning, CARB staff has significant concerns regarding the proposed “deemed to comply” provisions, because CARB staff believes that maintaining a low leak rate is important, regardless of the refrigerant in use, for the reasons discussed below. [EPA-HQ-OAR-2014-0827-1265-A1 p.139] First, having a low leak rate helps realize the full direct refrigerant emission benefits of a transition to a low-GWP refrigerant by reducing the need for AC service, and hence reducing the potential for consumers to recharge their low-GWP AC systems with hydrofluorocarbon (HFC)-134a (a high-GWP refrigerant), as HFO-1234yf (a low-GWP refrigerant) is more expensive than HFC-134a. Due to similar thermodynamic properties between HFO-1234yf and HFC-134a, it is possible that an HFO-1234yf AC system can have satisfactory performance when recharged with HFC-134a. A leak-tight system will reduce this possibility, simply because the AC system is less likely to need recharging. [EPA-HQ-OAR-2014-0827-1265-A1 p.140] Second, having a low leak rate also reduces the possibility of loss of cooling performance and energy efficiency due to undercharging. Experimental and modeling studies have shown that as an AC system loses refrigerant charge, its cooling performance generally decreases, and its energy efficiency (Coefficient of Performance, or COP) first remains constant or increases slightly, then decreases markedly after the charge drops below a certain level, usually about half the nominal charge. When significant charge loss occurs, vehicle drivers or operators would have to either endure compromised performance and efficiency, or have the AC recharged, in many cases more frequently than necessary, hence incurring emissions and cost associated with service. The most efficient and cost-effective means to tackle the undercharging issue is to use better refrigerant containment technologies to make the AC leak rate low. [EPA-HQ-OAR-2014-0827-1265-A1 p.140] Therefore, having a low leak rate complements using a low-GWP refrigerant, and ensures that the optimal benefits of the use of a low-GWP refrigerant would be achieved. Such rationale also applies to light-duty vehicle AC systems, and formed the basis for a “high-leak disincentive” term in the AC

CARB staff further believes that retaining a leakage standard separate from a low-GWP requirement is necessary to maintain low leak rates. Such a separate leakage standard would apply to existing manufacturers to ensure that they continue to use good refrigerant containment technologies after the Phase 1 implementation period ends. The leakage standard would also apply to new entrants to the market to hold them to the same requirements. A “deemed to comply” provision would result in the use of either low-leak technologies or low-GWP refrigerants, but likely not both, hence losing the benefits that can only be realized when a leakage standard and a low-GWP requirement work in tandem. [EPA-HQ-OAR-2014-0827-1265-A1 p.141]

Therefore, CARB staff recommends that U.S. EPA and NHTSA not include such a “deemed to comply” mechanism, but rather develop a provisional requirement for the use of low-GWP refrigerants (see CARB comment regarding alternative refrigerants) while retaining the leakage standard. [EPA-HQ-OAR-2014-0827-1265-A1 p.141]

Organization: Honeywell Fluorine Products

eeee Honeywell supports EPA’s decision to ease “the burden associated with complying with the lower-leakage requirements when a lower-GWP refrigerant is used instead of HFC–134a. These provisions would recognize that leakage of refrigerants would be relatively less damaging from a climate perspective if one of the lower-GWP alternatives is used. Specifically, EPA is proposing to allow a manufacturer to be “deemed to comply” with the leakage standard by using a lower-GWP alternative refrigerant.” P. 40172. [EPA-HQ-OAR-2014-0827-1191-A1 p.4]

Honeywell supports EPA’s approach to deem manufacturers in compliance with the AC leakage requirements for any vehicle that uses approved low GWP refrigerants. Such an approach will provides certainty that a proper incentive is in place as the market transitions to lower GWP refrigerants. We agree that the environmentally friendly aspect of refrigerants such as HFO-1234yf eliminates concern for extensive procedures and technologies to assure compliance with the leakage rates offered in the Proposed Rule. [EPA-HQ-OAR-2014-0827-1191-A1 p.4]

“In order to be “deemed to comply” the vehicle manufacturer would need to use a refrigerant other than HFC-134a that is listed as an acceptable substitute refrigerant for heavy-duty A/C systems under SNAP, and defined under the LD GHG regulations at 40 CFR 86.1867-12(e). The refrigerants currently defined at 40 CFR 86.1867-12(e), besides HFC-134a, are HFC-152a, HFO-1234yf, and CO2. If a manufacturer chooses to use a lower-GWP refrigerant that is listed in the future as acceptable in 40 CFR part 82, subpart G, but that is not identified in 40 CFR 86.1867-12(e), then the manufacturer could contact EPA about how to appropriately determine compliance with the leakage standard.” [EPA-HQ-OAR-2014-0827-1191-A1 p.4-5]

4. Honeywell Agrees that EPA Must Establish and Implement Appropriate Measures to Assure Compliance with the Proposed Rule, including compliance with Leakage Rates and to Protect Against Backsliding [EPA-HQ-OAR-2014-0827-1191-A1 p.5]

As EPA is well aware, even the best designed regulatory program will not achieve its objectives unless there are high levels of compliance with the rules. [EPA-HQ-OAR-2014-0827-1191-A1 p.5]
“We specifically request comment on whether there should be additional provisions that could prevent or discourage manufacturers that transition to an alternative refrigerant from discontinuing existing, low-leak A/C system components and instead reverting to higher-leakage components.” [EPA-HQ-OAR-2014-0827-1191-A1 p.5]

Honeywell encourages EPA to consider ways to better promote, monitor and assure compliance with all standards that EPA adopts with regards to the use of refrigerants in HD vehicles. This is important both with regards to assuring that new vehicles contain a proper mix of equipment from EPA’s A/C menu to comply with maximum leakage rates, as well as to assuring that vehicles which utilize low GWP refrigerants do not backslide to higher GWP refrigerants upon recharge without detection. Given that lack of existing legal mechanisms to prevent against backsliding to higher GWP refrigerants during retrofit and recharge, we support regulatory measures that protect against reverting to higher GHG emissions over the life of a vehicle. We recommend that EPA provide incentives for the aftermarket industry to assure use of compliant, low GWP refrigerants. One option is for EPA to consider a credit based system similar to the effective light duty CO2 credit program as a way to accelerate the transition away from R-134a in HD vehicles. [EPA-HQ-OAR-2014-0827-1191-A1 p.5]

We support requirements for manufacturers to attest to the durability of components and systems used to meet the maximum refrigerant leakage standards, however we believe that independent, real world testing is the preferred method that EPA should adopt. Independent, real world testing on refrigerant leakage rates of HD vehicles will promote transparency and best ensure data accuracy. [EPA-HQ-OAR-2014-0827-1191-A1 p.5]

Honeywell appreciates EPA’s and NHTSA’s recognition of the meaningful contribution that low GWP refrigerants offer to reducing the GHG emissions from HD, MD and vocational vehicles. Assuring a rapid and smooth transition to low GWP refrigerants will deliver comparable cooling in all climates, while saving time, costs, and environmental impact for years to come. [EPA-HQ-OAR-2014-0827-1191-A1 p.6]

We respectfully request EPA to continue to work with all stakeholders to establish a regulatory program that fairly accounts for GHG emissions from air conditioning in HD vehicles and establishes mechanisms to assure compliance with all aspects of the proposed rule in advancing our nation’s clean energy and environmental objectives. [EPA-HQ-OAR-2014-0827-1191-A1 p.6]

4 Compare Establishment of Leakage Rates of Mobile Air Conditioners in Heavy Duty Vehicles: Part 1 Trucks (ENV.C.1/SER/2005/0091r), Prepared for the European Commissions (DG Environment) by Winfried Schwarz (Öko-Recherche) (27 January, 2007) with Minnesota Pollution Control Agency, MY 2015 Mobile Air Conditioner Leakage Rates. See also, A. Burnette and R. Baker, CARB. Contract No. 06-342 (showing very high leakage rates in HD vehicles. Study involved approximately 65-70 vehicles, measured initial charge in vehicle, sent into field for a few months, re-measured charge for comparison).

5 The SAE J2727 that EPA recommends does take into account variation in components. For example, a single o-ring connection will have a higher leak rate than seal washer connection for two reasons: 1) average leak rate through properly installed o-ring is higher than average leak rate through properly installed seal washer, and 2) o-ring is more likely to be mis-assembled (i.e. pinched/cut upon assembly) which leads to even higher leak rates. J2727 was based upon study of assembly of many connections and some of the o-ring connections were less than optimal (pinched/cut, etc). However, there is no
additional variation added for things like road damage, accidents, service failures, etc. It only considers
variation from “normal wear and tear” of system during operation.

Response:

EPA proposed to allow a manufacturer to be “deemed to comply” with the leakage standard if its A/C
system used a refrigerant other than HFC-134a that was both listed as an acceptable substitute
refrigerant for heavy-duty A/C systems under SNAP, and was identified in the LD GHG regulations at
40 CFR 86.1867-12(e). 80 FR 40172.

For several reasons, EPA has reconsidered the proposed “deemed to comply” provision for this rule, and
instead, the Phase 2 program retains the Phase 1 requirement that manufacturers attest that they are
using low-leak components, regardless of the refrigerant they use. In general, we expect that the
progress LD vehicle manufacturers are making toward more leak-tight A/C systems will continue and
that this progress will transfer to HD A/C systems. Still, we agree that continued improvements in low-
leak performance HD vehicles is an important goal, and that continuing the Phase 1 leakage
requirements in the Phase 2 program should discourage manufacturers from reverting to higher-leak and
potentially less expensive components. It is also important to note that there is no “deemed to comply”
option in the parallel LD-GHG program – manufacturers must attest to meeting the leakage standard.
There is no compelling reason to have a different regime for heavy duty applications.

At the same time, EPA does not believe that finalizing the “deemed to comply” provision would have an
impact on any future transition of the HD industry to alternative refrigerants. As discussed above, two
lower-GWP refrigerants are already acceptable for use in HD vehicles, and EPA has proposed to list
HFO-1234yf as acceptable, subject to use conditions, for limited HD vehicle types. As also discussed
above, and especially in light of the rapid expansion of alternative refrigerants that has been occurring in
the LD vehicle market, similar trends may develop in the HD vehicle market, regardless of EPA’s action
regarding leakage of alternative refrigerants in this final rule.

Although leakage of lower-GWP refrigerants is of less concern from a climate perspective than leakage
of higher GWP refrigerants, we also agree with the concern related to the servicing of lower-GWP
systems with higher-GWP refrigerants in the aftermarket. We agree that this could result due to factors
such as price differentials between aftermarket refrigerants. However, as is the case for Phase 1, as a
part of certification, HD manufacturers will attest both to the use of low-leak components as well as to
the specific refrigerant used. Thus, in the future, a manufacturer wishing to certify a vehicle with an
A/C system designed for an alternative refrigerant will attest to the use of that specific refrigerant. In
that situation, any end-user servicing and recharging that A/C system with any other refrigerant would
be considered tampering with an emission-related component under Title II of the CAA. For example,
recharging an A/C system certified to use a lower-GWP refrigerant, such as HFO-1234yf, with any
other refrigerant, including but not limited to HFC-134a, would be considered a violation of Title II
tampering provisions.

1.6.4 Additional Issues

Organization: Structural Composites, Inc. and Compsys, Inc.

Our preliminary research indicates that approximately one-tenth of the HFC-134a used in our composite
preforming process is released into the atmosphere. Our polyurethane foam is sprayed into a mold that
is completely encapsulated in a composite coating. Because of the size of the HFC-134a molecule, it
cannot pass through the composite coating. Thus, any HFC-134a that reaches the atmosphere occurs
during the spray process. Once the foam is enclosed and fully encapsulated, any HFC-134a retained in
the foam will be permanently enclosed. [EPA-HQ-OAR-2014-0827-1205-A1 p.2]

As a result, the GHG emissions and overall global warming potential associated with HFC-134a use in
composite preforming are extremely low. Moreover, such GHG emissions are non-recurring and are
negligible in comparison to the overall GHG reductions that will be achieved by improving boat and
vehicle fuel economy. Our calculations indicate that use of Prisma preform technology in refrigerated
trailers can reduce GHG emissions by approximately 25 tons of CO2-equivalent per year and 650,000
lbs. of CO2-equivalent over the useful life of the trailer. Also associated with use of lightweight Prisma
products would be hundreds of thousands of gallons of fuel savings. [EPA-HQ-OAR-2014-0827-1205-
A1 p.2]

**EPA Should Coordinate Internally to Ensure that the Agency’s SNAP Rule Does Not
Prevent Significant GHG Reductions under the Heavy-Duty Engine and Vehicle GHG Program.**

Our technology has the potential to offer significant overall GHG reductions and fuel savings for this
transportation sector. However, in a final rule issued at 80 Fed. Reg. 42,870 (July 20, 2015), entitled
“Protection of Stratospheric Ozone: Change of Listing Status for Certain Substitutes Under the
Significant New Alternatives Policy Program,” EPA appears to have eliminated Compsys’ ability to
produce our Prisma product in the U.S. after 2020. We therefore urge EPA to carefully consider the
relationship between the SNAP program and the heavy-duty GHG rule. Due to the great potential for
longer-term GHG reductions at the cost of de minimis emissions of HFC-134a from the foam blowing
process, Compsys and Structural Composites urge EPA to continue to allow unrestricted use of HFC-
134a as a blowing agent for composite preforming. If the SNAP rule limits or prohibits the use of HFC-
134a as a foam blowing agent for our process, EPA will have eliminated a potential avenue for
achieving even greater GHG reductions from the on-road transportation sector. [EPA-HQ-OAR-2014-
0827-1205-A1 p.2]

Compsys and Structural Composites have requested that EPA reconsider the final SNAP rule and clarify
that the use restrictions placed on HFC-134a as of January 1, 2020 do not apply to our product or
process. Compsys and Structural Composites have researched, and continue to investigate, whether
alternatives to HFC-134a can be used in our process. We previously phased out HCFC-22 and replaced
that substance with HFC-134a. However, we have not yet identified a substitute for HFC-134a. We
continue to examine alternatives but urge EPA’s Office of Transportation and Air Quality and Office of
Stratospheric Protection to work together to ensure that the SNAP rule does not prevent the achievement
of significant lifetime GHG reductions under the heavy-duty vehicle and engine GHG program. [EPA-
HQ-OAR-2014-0827-1205-A1 p.2]

The SNAP rule also would permit the importation of refrigerated trailers and other products produced
outside of the U.S., even if those items are produced using foam blowing agents such as HFC-134a that
would be prohibited for use within the U.S. Any reductions in GHG emissions that EPA expects to
achieve under the SNAP rule may easily be offset by companies moving production of foam blowing
operations outside of the U.S. Even leaving aside environmental considerations, EPA’s decision to
continue to allow imported foam products while prohibiting the same manufacturing processes within
the U.S. has massive financial and competitive consequences for the foam blowing industry. Companies
with operations located solely within the U.S.—including small businesses such as Compsys and
Structural Composites—that contribute to the growth and prosperity of the U.S. economy will be put out
of business. Compsys respectfully requests that OTAQ and the Office of Stratospheric Protection
coordinate efforts to ensure that on-road trucking products manufactured within the U.S. are protected to
avoid bankrupting successful, innovative American small business. [EPA-HQ-OAR-2014-0827-1205-
A1 p.2-3]
Response:

EPA appreciates the comments by Compsys and Structural Composites; however, these comments go beyond the scope of the current rulemaking. The commenter has also raised these comments in connection with the SNAP program, and EPA will address them through that process.

Organization: EOS Climate

Our comment is focused on the flexibility that is proposed for use of alternative (nonhydrofluorocarbon, HFC) under Section 1037.115(e)(2). Under the proposal, an alternative refrigerant is defined as a refrigerant other than HFC-134a that is listed as an acceptable substitute under EPA’s Significant New Alternatives Policy (SNAP) program. Manufacturers using an alternative refrigerant are exempt from reporting on their vehicles’ air conditioning leakage rate. [EPA-HQ-OAR-2014-0827-1170-A1 p.1]

We recommend the Agency consider expanding the definition of alternative refrigerant to include HFC-134a that has been reclaimed. Reclaimed HFC is refrigerant that has been previously used, recovered from equipment (typically at equipment end-of-life), and processed to remove contaminants (e.g., oil, water, other refrigerants) and restored to virgin-grade purity for re-use in other equipment by an EPA-certified refrigerant reclaimer. In contrast to HCFC-22 which is being phased out of production in the United States, there is no economic incentive to recover and reclaim HFC refrigerant today. Even under the most conservative assumptions, the best estimate is that less than 5-10% of HFC refrigerant is being reclaimed for re-use. By using reclaimed HFC-134a, vehicle manufacturers would be displacing new production of virgin HFC-134a and thereby preventing additional greenhouse gas (GHG) emissions. [EPA-HQ-OAR-2014-0827-1170-A1 p.1]

The reduced GHG emissions associated with use of reclaimed HFC refrigerant is quantified and verified under a new protocol under the American Carbon Registry (ACR). Our company, EOSClimate, originated the protocol, in conformance with the International Standards Organization (ISO) Standard 14064-2. The protocol relies on data and modeling from the U.S. EPA, the International Panel on Climate Change (IPCC), the Montreal Protocol Technology and Economic Assessment Panel (TEAP), the California Air Resources Board, and other technical literature, and has been peer reviewed by industry and government experts, and the public. The protocol establishes baseline scenarios, emission factors, monitoring and reporting requirements, regulatory parameters, project eligibility criteria, and the other elements involved in generating GHG emission reductions that are then verified by certified 3rd parties. [EPA-HQ-OAR-2014-0827-1170-A1 p.1]

As an example, using the quantification methodology in the new ACR protocol, if a heavy-duty truck has an air conditioning system with a 3 pound refrigerant charge of HFC-134a, using reclaimed HFC-134a would prevent the equivalent of 1.35 metric tons of CO₂ over 10 years (the crediting period under the protocol, accounting for normal system leaks and the baseline reclamation rate in the United States). Alternatively, the manufacturer could achieve the same greenhouse gas reduction by purchase of 1.95 verified credits (representing the equivalent of 1.95 metric tons of CO₂) which would correspond to the reclamation of 3 additional lbs of HFC-134a refrigerant for re-use in the United States. [EPA-HQ-OAR-2014-0827-1170-A1 p.1-2]

We encourage EPA, and your colleagues at the Department of Transportation to consider reclaimed HFCs and reclaimed HFC credits as part of a comprehensive approach to reduce GHG emissions across multiple components of trucks and automobiles, including for example, use of re-refined motor oil. By using reclaimed HFC refrigerant, or alternatively, by purchase of the verified GHG credits generated by reclaiming HFC refrigerant, vehicle manufacturers would be reducing the GHG footprint of their new
vehicles. Prior to full market availability of new low-GWP alternatives, use of reclaimed HFC or purchase of verified, reclaimed HFC credits delivers immediate GHG reductions associated with vehicle air conditioning systems and gives the industry a market-ready tool to promote EPA’s goals, as highlighted in the President’s Climate Action Plan, of expanding reclamation of fluorochemical refrigerants across the United States and driving down HFC emissions. [EPA-HQ-OAR-2014-0827-1170-A1 p.2]

Response:

EPA does not believe the definition of alternative refrigerant should be revised to include reclaimed R-134a. EPA has defined “reclaim” refrigerant at 40 CFR 82.152 to mean “to reprocess refrigerant to all of the specifications in appendix A to 40 CFR part 82, subpart F (based on ARI Standard 700–1995, Specification for Fluorocarbons and Other Refrigerants) that are applicable to that refrigerant and to verify that the refrigerant meets these specifications using the analytical methodology prescribed in section 5 of appendix A of 40 CFR part 82, subpart F.” Additionally, EPA does not differentiate between virgin and reclaimed refrigerants based on the difficulty in determining whether refrigerant that is undergoing a phase-out for certain end-uses in the United States (e.g., R-134a) is virgin refrigerant or is used refrigerant that has been reclaimed. This is especially true for appliances and components that are produced and pre-charged abroad and imported into the United States. It would not be possible for EPA to determine whether such imported pre-charged appliances and components were manufactured with reclaimed refrigerant.

Organization: Chemours Company FC, LLC

To make this a lasting environmental improvement, Chemours strongly encourages the EPA to pursue additional efforts to prevent both intentional and unintentional improper service (servicing vehicles with low GWP refrigerant based A/C systems with R-134a). Further, Chemours suggests that EPA clearly state on the SNAP website that any low GWP MVAC refrigerant system only be serviced with the OEM refrigerant listed in the vehicle A/C manual and A/C system label and require that all HFC-134a MVAC service containers be clearly marked that it is a violation to use the product for servicing vehicles other than those that were originally charged with HFC-134a or CFC-12. [EPA-HQ-OAR-2014-0827-1231-A1 p.2]

In addition, EPA requirements for Certification for Refrigerant Handling Equipment and Technician Training and Certification are one-time events, and such training and certification can at this point be decades old. Much has changed in the world of MVAC, including transitioning from non-flammable to mildly flammable refrigerants, and new compressor certification standards. Refresher training is commonly applied in many fields to both ensure technicians are reminded of basic requirements and to update technician knowledge with more recent developments. Chemours recommends mandatory technician training and certification be required every five years to ensure technicians are current on regulatory requirements, including use conditions, and appropriate industry standards. This requirement could be phased in such that any technician whose training and certification was more than five years old as of the date the final rule goes into effect would have a period of time (such as 12 months) to complete the training and certification. [EPA-HQ-OAR-2014-0827-1231-A1 p.2]
Response:

These comments go beyond the scope of the current rulemaking as they concern CAA section 609, which directs EPA to establish standards and requirements regarding the servicing of MVACs. However, EPA appreciates receiving this information and will consider the comments as it evaluates possible future actions.

In the SNAP July 2015 final rule (80 FR 42953), EPA listed R-134a as unacceptable for newly manufactured light-duty vehicles beginning in Model Year 2021, except where allowed under narrowed use limits. In this rule, we stated that “HFC-134a is listed, and will remain listed, as an acceptable refrigerant for retrofit of existing systems designed to use CFC-12, but because of the use restrictions for refrigerants listed as acceptable, it cannot be used as a retrofit for MVAC systems using other alternatives. EPA did not propose to revise the listing decision for use of HFC-134a as a retrofit and thus did not establish a new use condition as part of the final rule. See section V.B.6.e of that SNAP final rule for a response to several comments on servicing CFC-12, HFC-134a, and the lower-GWP alternative refrigerant MVAC systems. EPA understands that Chemours and/or other refrigerant manufacturers may be interested in voluntarily providing information to customers on permitted uses of their products and EPA sees no barriers to such communication. EPA will consider updating the information on our website, as appropriate.

EPA agrees on the importance of technician training on safe handling of refrigerants, and notes that EPA has received additional requests to establish recertification requirements for technicians outside of this rulemaking process. The Agency is currently working with the approved CAA section 609 technician training and certification programs to update training material to focus on HFC-134a and the new climate-friendly alternatives that technicians will encounter in the coming years. The goal of this update is to ensure that technicians entering the field today are aware of the growing use of additional MVAC refrigerants and their unique properties, current regulatory requirements for MVAC under CAA section 609, section 612 (SNAP), and section 608, and relevant industry standards. EPA has also made an effort to update the information available on our website.

1.7 General Comments on Regulatory Framework and Rule Principles

Organization: American Automotive Policy Council

Need for Customer Acceptance - AAPC strongly believes that the Phase 2 program must continue to recognize the unique functionality and utility needs of the trucking industry, and that this regulation must preserve the performance integrity of these work trucks. [EPA-HQ-OAR-2014-0827-1238-A1 p.2]

Organization: American Gas Association (AGA) et al.

We Strongly Support the Preservation of the Conversion Factor between CO2 and Fuel Consumption

The agencies’ three previous rulemakings (the LD Phase 1 Rule,\textsuperscript{13} the LD Phase 2 Rule,\textsuperscript{14} and the HD Phase 1 Rule\textsuperscript{15}) established a “one-to-one” relationship between CO2 emissions and fuel consumption. This relationship converts measured CO2 emissions into fuel consumption by using gasoline- and diesel-specific conversion factors. [EPA-HQ-OAR-2014-0827-1223-A1 p.3]

We support the preservation of this approach in the Phase 2 Proposal because it maintains a “uniform approach to rulemaking”\textsuperscript{16} across the range of GHG and fuel consumption rules in the transportation...
sector and continues the approach of calculating fuel consumption according to measured levels of CO2, regardless of fuel type. [EPA-HQ-OAR-2014-0827-1223-A1 p.4]

We commend your efforts to propose an equitable Phase 2 Rule that will deliver significant environmental and fiscal benefits to 2027 and beyond. [EPA-HQ-OAR-2014-0827-1223-A1 p.14]

**Organization:** Behrendt, Diane

We are as small as a small business can be. We operate one tractor and one trailer and have done so for the last 23 years. My husband has been a professional driver for the last 36+ years. So our experience with 'big trucks' goes back decades. [EPA-HQ-OAR-2014-0827-0949-A1 p.1]

The EPA and the NHTSA need to realize trucking is not a one size fits all industry. We live in a country with lots of variables, such as the weather. A truck cannot have automatic engine shut off, when temps are below fuel gelling conditions. The 2010 International had a maximum run time of 90 minutes, this does not work when you live in central Minnesota and do not have a heated garage. Let alone when your job takes you through the harshest conditions in the country. Engine idling wastes fuel, but are necessary if you don't want to freeze to death, or suffer heat stroke. Idling also clogs up the DPF. [EPA-HQ-OAR-2014-0827-0949-A1 p.2]

The government should not mandate technology that does not exist at this time. Society will pay a heavy price for goods and services if this failed “technology” continue to bankrupt an industry that has been financially strained for years. When you pay 140-160 thousand dollars for a truck, it needs to be reliable and last far longer than 5 years or 435,000 miles that the EPA proposes in its GHG Phase 2 plan. [EPA-HQ-OAR-2014-0827-0949-A1 p.2-3]

**Organization:** Bendix Commercial Vehicle Systems, LLC

In summary, the market should have choices and options to achieve the goals of the regulation. Through choice, optimum flexibility is enabled, providing multiple options to achieve the intent of the regulation and deliver the results expected. Bendix is committed to policies that enable the introduction of new technologies needed to support sustainable mobility. The interconnectedness of the industry drives the need for consistent, long-term policies, regulations and standards so that all stakeholders can more effectively incorporate technologies into the nation’s fleet. Suppliers are a key part to producing the results outlined by the Administration. Bendix urges the agencies to consider all of these comments as the final rule is developed. [EPA-HQ-OAR-2014-0827-1241-A1 p.8]

**Organization:** Caterpillar Inc, et al.

**Expected technology penetration rates must align with market needs and legal restrictions**

EPA and NHTSA must ensure that their assumptions about various technologies match with market reality and that their cost estimates are comprehensive and accurate so that environmental benefits and efficiency gains are realized in a logical and cost-effective manner. Stringency of the standards should be based on products customers can actually afford to purchase and that do not interfere with operations. Customers will not buy technologies in order to meet a regulatory target. [EPA-HQ-OAR-2014-0827-1215-A1 p.5]
The following proposed penetration rates are a few examples of overly aggressive targets and in our estimation must be adjusted downward: [EPA-HQ-OAR-2014-0827-1215-A1 p.5]

**Organization:** Center for Biological Diversity

We also note that there has been a call from various organizations for fuel neutral standards (i.e., a single standard for both gasoline and diesel engines) since the Phase 1 rulemaking.\(^\text{30}\) The principal reason for moving to fuel neutral standards is that a single standard allows all engines to compete in the same market, thus driving selection and innovation further. Many international standards are fuel neutral, as are the large light-duty pickup and van CAFE standards. The market is already largely segregated between gasoline and diesel engines depending on work capacity such that the largest overlap would be in the pickup and van classes where there are abundant technologies being developed for large light-duty pickups and vans that could easily be applied to heavy-duty pickup and van engines. [EPA-HQ-OAR-2014-0827-1460-A1 p.8]

\(^{30}\) See, e.g., summary contained in ICCT Pickup Report, *supra* note 27 at 11.

**Organization:** Cummins, Inc.

Through these avenues and our comments here, Cummins supports continuation of the Phase 1 regulatory framework as the foundation for the Phase 2 program. Key elements include separate engine and vehicle standards, clear enforceability to ensure real world benefits, adequate lead-time and stability and regulatory flexibilities for manufacturers. Phase 2 should also strive for performance-based standards that are fuel neutral. [EPA-HQ-OAR-2014-0827-1298-A1 p.5-6]

**Organization:** Caterpillar, Daimler, Navistar, PACCAR, and the Volvo Group

Careful execution of fuel efficiency standards for this industry will enable the classic win-win scenario. As manufacturers, we support a practical, achievable greenhouse gas and fuel efficiency regulation that does not disrupt the market due to over-reaching demands, while allowing the flexibility to offer each customer the features they need in their specific operation. [EPA-HQ-OAR-2014-0827-1215-A1 p.2]

It’s imperative that our ability to deliver on these fundamental customer expectations is preserved by this regulation. Said another way, correctly finalizing the certification and compliance protocols in this rule and the associated standards is essential to maintaining customer demand for these work tools, and thereby critical to successfully achieving the environmental goals of the program. [EPA-HQ-OAR-2014-0827-1215-A1 p.2]

To assure this success, the Phase 2 regulation must be finalized with seven basic principles in mind: [EPA-HQ-OAR-2014-0827-1215-A1 p.3]

- Regulation must appropriately reflect real-world reductions

- There must be a single, national GHG regulation adopted by EPA, NHTSA and CARB

- Expected technologies must be appropriately demonstrated
-Expected technology penetration rates must align with market needs and legal restrictions

-Regulation must take into account total cost of ownership

-Protocols must be clearly defined, and accommodate production and test variability

-Regulation must recognize the trade-off of NOx and CO2 reduction targets [EPA-HQ-OAR-2014-0827-1215-A1 p.3]

We believe that if these principles are fulfilled in the crafting of the final version of this regulation, the stage will be set to deploy a new fleet of highly efficient, low-emitting medium-and heavy-duty vehicles fully capable of fulfilling the mission for which they were purchased, with minimal risk of unintended consequences. [EPA-HQ-OAR-2014-0827-1215-A1 p.3]

**Organization:** Daimler Trucks North America LLC

**The agencies should not require powertrain testing nor premise standards on a significant amount of powertrain testing** – The agencies request comment regarding EPA requiring broad use of powertrain testing (80 FR 40179). DTNA believes that complete vehicle simulation be established in Phase 2 as the preferred method of certification. Complementing GEM simulation with selectable dropdown fuel efficiency features that represent benefits of specific powertrain controls is a reasonable, efficient, and cost effective way to include benefits of integration features. EPA should go no further than to offer powertrain testing as an option for manufacturers and should not consider powertrain testing more broadly. 80 FR 40179 [EPA-HQ-OAR-2014-0827-1164-A1 p.66-67]

**Organization:** Diesel Technology Forum

We believe these are also important considerations for EPA in developing a final Phase 2 rules, as follows: [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

**The program must be fuel neutral in nature.** Through the adoption of emissions standards, testing procedures and other provisions, the proposed rule must ensure that one fuel or technology is not directly or indirectly favored over others, for any of the categories of vehicles covered. Manufacturers and their customers are best suited to select the technology that makes the most sense for their specific needs. [EPA-HQ-OAR-2014-0827-1171-A2 p.5] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.111-112.]]

**Organization:** Eaton Vehicle Group

As we did in Phase 1, Eaton supports the push for a new generation of clean, fuel-efficient commercial vehicles that will reduce greenhouse gas emissions and strengthen the U.S. economy. Phase 1 has been successful in that it put together a sound regulatory framework that is aligned with market forces. The separate engine and vehicle standards reflect the reality of the commercial vehicle. Also, Phase 1 was a nationally harmonized 50-state solution which is essential for commercial and compliance purposes. We are encouraged by the EPA’s preference to keep in place the Phase 1 regulatory structure that minimized market disruption and compliance burdens. [EPA-HQ-OAR-2014-0827-1194-A1 p.4]

We believe that the framework outlined in the NPRM for Phase 2 is a good step toward a final regulation that will drive innovation, foster both technology and competition, while maintaining fleet
diversity and incentivizing over-compliance with emissions and fuel economy targets. By following the structure in Phase 1, the agencies are relying upon an established regulatory structure, testing and processes that are efficient and fair. [EPA-HQ-OAR-2014-0827-1194-A1 p.4-5]

The NPRM sets forth clear, achievable objectives that spur innovation and deployment, while avoiding negative impact on the economy and promoting leadership in commercial vehicle fuel efficiency. We believe that many of the technologies needed to achieve the proposed standards are available. Some are in low volume production, and others need a path into a market that values their contributions to emissions reduction and fuel efficiency. Phase 2 will provide clear and realistic targets for industry and will accelerate adoption of these technologies. [EPA-HQ-OAR-2014-0827-1194-A1 p.5]

Eaton was a founding member of The Heavy Duty Fuel Efficiency Leadership Group; we believe the Phase 2 NPRM generally reflects the Statement of Principles put forward by the Leadership Group, as follows [EPA-HQ-OAR-2014-0827-1194-A1 p.5]

1. The Phase 2 rule should maintain market, fleet and technology choice by allowing OEMs and component suppliers to continue to produce vehicles that perform the work required of them [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

- The EPA Phase 2 regulations should ensure continued investment in advanced powertrain technology to maintain market dynamic and fleet technology choice.

- The EPA should not promulgate standards that would prohibit, either directly or indirectly, the continued production of specialized commercial vehicles

- The EPA should expand the list of current exempt vehicles to include highly specialized, low volume vehicles

2. The EPA should ensure that all testing and certification requirements are cost-effective, straightforward, and they accurately measure fuel efficiency and GHG reductions. [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

Powertrain testing should remain an optional requirement that can measure the real world performance differentiation among drivetrains; GEM should be refined in order to accurately capture the benefits of closely integrated engines and transmission.

The EPA should provide a method to protect intellectual property of component suppliers

3. If the EPA includes different transmission architectures in GEM, they must be fully supported with data and technical analysis. [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

Phase 2 Rule should ensure that no transmission architecture is unduly favored in GEM

They must reflect real world driving conditions.
They must incorporate substantially more transient operation than Phase 1 standards for vocational vehicle sector.

5. The EPA should maintain current responsibilities in Phase 1 regarding certificates of conformity in the Phase 2 rule. [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

6. Vocational vehicles should be further subcategorized to reflect usage. [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

7. The EPA should continue advanced and innovative technology credits in Phase 2. [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

-The EPA should allow for certification using full vehicle, powertrain or component testing.

8. A long-term Phase 2 rule would provide certainty to drive investments in technology development. [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

Organization: Enovation Controls (ENC)

EPA/NHTSA Phase 2 Heavy-Duty Greenhouse Gas Regulations are of particular interest to ENC because our company’s Class 6, 7 and 8 on-highway products directly enable lower tailpipe emissions using natural gas. We believe a fuel-agnostic approach must be taken to any emissions regulation in order to provide a level playing field for traditional and alternative forms of energy. The proposed regulation must result in lower greenhouse gases to effectively result in cleaner air and increasing energy independence. [EPA-HQ-OAR-2014-0827-1203-A1 p.1]

1.1 Continuation of Phase 1 Approach - ENC agrees with the general direction presented to adopt the Phase 1 approach to calculated fuel consumption based on tailpipe emissions. However, the wording should be unified between petroleum consumption and CO2 emissions in order to specifically highlight the overarching goal for the legislation. It is our opinion that CO2 emission limits properly and accurately address concerns regarding both greenhouse gas environmental impact and petroleum consumption. A lack of clarity between fuel / petroleum consumption and CO2 emissions is likely to create areas of misalignment. [EPA-HQ-OAR-2014-0827-1203-A1 p.1]

Organization: Environmental Defense Fund (EDF)

The Proposed Rule: an Important First Step

EDF fully supports a comprehensive and robust heavy-duty program.

The Phase 1 rule established an effective structure and many key components to a successful program that have been carried over to the Phase 2 proposal, and in some cases improved upon. While we believe the final standards should go much farther in driving technology and providing benefits to our families and communities, the Agencies’ proposed structure can help secure these reductions. [EPA-HQ-OAR-2014-0827-1312-A1 p.15]

Standards in 2027 must drive advanced technologies
If the program is extended to 2027, those standards must go well beyond what is currently proposed to truly force technology development. Doing so would be consistent with EPA’s CAA technology-forcing authority and NHTSA’s maximum feasible mandate in EISA. A crucial function of motor vehicle emissions standards is to promote the further development and foster the deployment of promising technologies whose pathway to market acceptance is less clear. The proposed rule recognizes this, and includes technologies such as advanced aerodynamics and vocational hybrids in the compliance scenario for this reason. However, the proposed standards can be met without even drawing on these technologies; to promote the development of these and other advanced technologies the 2027 standards must be substantially strengthened. With many previous rulemakings, EPA has set a precedent for establishing standards based on a reasonable projection that technology still in the research stages of development when the rules were adopted would be available at the time the standard went into effect. 

A. A stronger rule is necessary for broader climate and health benefits

A rigorous Phase 2 program could fundamentally alter the path of medium- and heavy-duty GHG emissions – reducing fuel consumed by the entire on-road truck fleet to below today’s levels, while helping the freight economy grow. To achieve this, however, the Phase 2 program must fully mobilize all existing modern technologies and drive the development and deployment of advanced technologies. A joint analysis by EDF, NRDC, UCS, ACEEE and the Sierra Club in 2014 found that by 2025, the first and second phases of standards together could cut fuel consumption of new trucks by at least 40 percent compared to 2010 levels. The analysis – based on a broad set of analyses by the National Research Council, research by Southwest Research Institute (“SwRI”) and results from the Department of Energy (“DOE”)’s SuperTruck program – also found that the technologies to improve fuel efficiency are cost-effective in the 2025 timeframe. While the proposal is an important step in this direction, it does not drive these technologies to their full potential. The Agencies estimate that the proposed standards would cut climate pollution by 1 billion tons and reduce fuel consumption by 1.8 billion barrels of oil over the life of the vehicles subject to the rule. These are necessary and significant reductions. However, finalizing standards that are consistent with a 40 percent reduction in fuel consumption by 2015, as outlined by EDF and others, would save an additional 200,000 barrels of oil per day in 2035 and reduce 40 million addition tons of GHG emissions annually. A more protective rule would also hasten and possibly enhance NOx reductions – 2.4 million tons reduced over the life of the program. Our comments in Section VI below provide more detailed recommendations on how these improvements can be achieved.

C. Comprehensive, rigorous program is needed to address market barriers

Robust Phase 2 standards are needed to deliver the full benefits available from existing and developing efficiency technology. There is clear evidence, as summarized in the proposal, that market barriers exist preventing consumers from investing in efficiency technology that will save them money in the long term. For example, consumers may not have complete or reliable information about the effectiveness and durability of the technology or vehicle they are interested in – both in the new vehicle market and the resale market. An additional barrier in the heavy-duty market is a split incentive where the party paying the upfront cost may be different from the party realizing the fuel cost savings. These barriers impede the development and uptake of the full array of modern technologies. As the Agencies stated in the Preamble, “a significant number of fuel efficiency improving technologies would remain far less
widely adopted in the absence of these proposed standards.” This is true. However, a weak final rule would also leave certain advanced technologies on table. Therefore, it is imperative that the agencies finalize more robust fuel economy and greenhouse gas standards to realize the full potential of efficiency improvements from the heavy-duty sector. Doing so “would provide regulatory certainty and generate important economic benefits in addition to reducing externalities.” [EPA-HQ-OAR-2014-0827-1312-A1 p.18-19]

**EPA and NHTSA Must Finalize Standards that Reflect the Full Range of Existing and Advanced Technologies**

EDF provides extensive comments and recommendations below on how the Agencies can improve and strengthen the final standards to reflect today’s available technologies and drive adoption of more advanced technologies. Making these important improvements to the final standards will deliver additional emissions reductions and fuel savings while saving customers and businesses money and providing certainty for manufacturers investing in innovative solutions. As examined in detail below, the Agencies’ proposed engine standards are unlawful in failing to carry out the Agencies’ delegated statutory responsibilities, in proposing standards that are unreasonable in light of the body of evidence indicating that far more protective standards are available, and in proposing resulting emission standards that are fundamentally irrational in relying on decision criteria and conclusions that break the bond of reasoned decision-making, severing the facts available in the record before the Agencies from the proposed choices made by the agencies. This is contrary to law. See Motor Veh. Mfrs. Ass’n v. State Farm Ins., 463 U.S. 29 (1983). [EPA-HQ-OAR-2014-0827-1312-A1 p.26]

---

5 EIA, Annual Energy Outlook (2015), Table 19.

77 Assumes Class 8 truck VMT of 120,000 miles and average fuel economy of 6.1 MPG, and sedan VMT of 11,318 and average fuel economy of 31 MPG. Energy Information Agency (EIA), Annual Energy Outlook 2014, Table 68; Freight Transportation Energy Use. Heavy Duty Fuel Efficiency,
Existing Trucks by Size Class. University of Michigan Eco-Driving Index available at www.umich.edu/~umtriswt/data/UMTRI_sales-weighted-CAFE_April-2015.xls; and Federal Highway Administration, Table VM-1 American Public Transit Association's Public Transportation Fact Book Tables 8, 16, and 21.

126 Walsh and Charlton, Feasibility Assessment of Future Efficiency Improvement for Class 8 Diesel Tractor Engines, Consultant Report, (September 2015). See also ICCT comments submitted to this docket, UCS comments submitted to this docket and ACEEE comments submitted to this docket.

127 For example, the 2007/10 heavy-duty NOx and PM standards that EPA finalized in 2001 required the application of both NOx and PM aftertreatment to HD trucks for the first time. These aftertreatment technologies had existed in research laboratories before the rule was finalized, but system- and component-level development and demonstration had not taken place. EPA projected that with 6 to 9 years lead-time manufacturers could continue the development of these technologies and successfully deploy them commercially beginning in 2007. In fact, the industry was able to successfully deploy PM aftertreatment (traps) to their entire 2007 truck fleet. Again in 2010, the industry successfully deployed NOx aftertreatment (selective reduction catalysts (SCR)) to their entire fleet. The Agency had projected NOx adsorbers would be the system of choice for 2010, but instead the industry utilized SCR, a technology not even relied upon by EPA. This rule demonstrates the successful application of the CAA technology forcing authority and the ingenuity of industry in meeting those requirements.

Organization: FedEx Corporation

Achieve Significant Environmental, Economic and Energy Security Benefits: Phase 1 has begun reducing U.S. oil consumption, cutting GHG emissions and producing fuel costs savings for fleets. Phase 2 should also drive GHG reductions and fuel savings while achieving important economic and energy security benefits. [EPA-HQ-OAR-2014-0827-1302-A1 p.2]

Maintain Market, Fleet and Technology Choices: Fleets are necessarily diverse in weight, size and capability to perform specific work tasks. Phase 2 should achieve significant GHG/Fuel Efficiency gains without restricting fleet choice of product specifications and GHG/Fuel Efficiency technologies needed for different applications. [EPA-HQ-OAR-2014-0827-1302-A1 p.2]

Build on Success of Phase 1: Phase 1 utilized proven testing/certification protocols while establishing incentives to drive adoption of advanced and innovative technologies. Additionally, it minimized compliance burdens by relying heavily on the existing emissions protocols. Phase 2 should not impose requirements that shift compliance burdens to end-users. The Phase 1 framework, which minimized market disruption and compliance burdens, should be maintained and improved for Phase 2. [EPA-HQ-OAR-2014-0827-1302-A1 p.2]

Organization: Honeywell Transportation System (HTS)
Honeywell believes the goals of the proposed rule can be best achieved through a technology/fuel neutral approach. [EPA-HQ-OAR-2014-0827-1230-A1 p.1]

Whenever possible, government should set regulatory standards, and industry innovation should be allowed to meet those standards in the most economical and consumer friendly manner. [EPA-HQ-OAR-2014-0827-1230-A1 p.1]

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

We believe it is possible to craft a regulation that sets reasonable standards while promoting good jobs and protecting the environment. [EPA-HQ-OAR-2014-0827-1248-A2 p.1-2]

The medium and heavy duty truck industry is already working to comply with the Phase 1 Greenhouse Gas Emission and Fuel Efficiency Standard that is projected to save 530 million barrels of oil and reduce carbon emissions by 270 million metric tons. In fact, we do not know the full impact of prior regulations as comprehensive data is only now being gathered and analyzed for the 2014 model year. The new data should be carefully evaluated and compared to the estimates and assumptions used to formulate both Phase 1 and the proposed Phase 2 of the heavy duty regulations. [EPA-HQ-OAR-2014-0827-1248-A2 p.7]

We urge EPA, NHTSA and other regulatory agencies to refrain from altering intersecting regulations in a way that affects Phase 2 standards outside of existing timelines and benchmarks. This is a major concern in light of the numerous initiatives the Administration has undertaken to combat climate change. [EPA-HQ-OAR-2014-0827-1248-A2 p.7] The SNAP program impacted the agreement reached by the EPA, NHTSA, and UAW, automakers, environmentalists and CARB. Clearly a similar scenario can occur in the future in conjunction with this proposed regulation, all the more reason why the final rules should be flexible and designed with caution. [EPA-HQ-OAR-2014-0827-1248-A2 p.7-8]

Manufacturers need flexibility to meet stringency standards via a mix of different technologies and paths based on competitive advantages, market position, brand, customer demands and product cadence. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]

Medium and heavy truck manufacturers have overcome challenges meeting Phase 1 stringency requirements that were developed assuming market adoption of existing off the shelf technology. Phase 2, in contrast is technology forcing. [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

The UAW supports developing and bringing new technology to the fleet as long as the technology is reliable, cost effective and manufacturers have more than one technology path to comply with stringency requirements. [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

We strongly agree with the EPA and NHTSA’s warning that poorly crafted regulations forcing unproven technology can lead to: [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

Expectations of reduced reliability, increased operating costs, reduced residual value, or of large increases in purchase prices can lead the fleets to pull-ahead by several months planned future vehicle purchases by pre-buying vehicles without the newer technology. Such market impacts would be followed by some period of reduced purchases that can lead to temporary layoffs at the factories
producing the engines and vehicles, as well as at supplier factories, and disruptions at dealerships. [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

The stringency of the Phase 2 standards must be crafted with the realities of the market in mind. As we have seen, regulations requiring customers to buy technology that are not proven or cost-effective lead to unintended consequences as customers often keep their vehicles longer or pre-buy vehicles in advance of new standards. [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

Stringency requirements must recognize customer expectations, vehicle work and functionality requirements, product cadence, lower volumes and cost structure of the market. Final regulations should not be overly prescriptive. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]

**Organization:** Mannix, Brian

**Impact on Competition**

The RIA does not include an analysis of the impact of the proposed standards on competition. Generally it is a good idea to explore such impacts, particularly to counteract the tendency of a benefit-cost analysis to point to one apparently “optimum” solution to a given problem. Such a calculated solution is rarely optimal, and never optimal for very long, so it is important not to lock it in. Moreover, competition remains the most effective overall regulator of economic performance and efficiency, and by-the-book regulators need to be very careful, while pursuing their own missions, not to inflict a greater harm by impairing competition. The proposed standards appear to have been developed in close consultation with industry incumbents, and incorporate prescriptive requirements that are likely to create barriers to entry. Rather than encouraging innovation, the standards are likely to make innovation very difficult. Even the exemptions for small manufacturers incorporate caps and grandfather features that appear to be designed to suppress competition. [EPA-HQ-OAR-2014-0827-1222-A1 p.7]

The danger of impaired competition is even greater when regulations require the use of proprietary technologies. Complying with the proposed Phase 2 standards will require vehicle manufacturers to use a range of advanced technologies, discussed in detail in Chapter 2 of the RIA. In many cases these technologies appear to be proprietary. For example, the RIA discusses the effectiveness of SABIC Roof Fairing Technology\(^{16}\) in reducing drag, but does not discuss the potential costs that can result when a regulation effectively requires the use of patented technologies, leaving manufacturers at the mercy of the patent holder. The agencies seem unconcerned about the danger of creating mandated monopolies: “We are currently coordinating with SABIC [Saudi Arabia Basic Industries Corporation] on future efforts to determine feasibility and capability of this concept on additional areas of the tractor (e.g., bumper, hood, fuel tank/chassis skirt fairings, cab side extenders).”\(^{18}\) The proposed standards appear to be dramatically increasing our dependence on proprietary intellectual property, even “as we take another big step to grow our economy and reduce America’s dependence on foreign oil.”\(^{19}\) [EPA-HQ-OAR-2014-0827-1222-A1 p.7-8]

\(^{16}\) RIA, p. 2-19.

\(^{17}\) “Saudi Basic Industries Corporation (SABIC) has passed the milestone of having more than 10,000 patents either issued or pending approval, making it the largest owner of intellectual property in the Middle East.” Arab News, “SABIC becomes region’s largest patent developer,” 13 June 2014. http://www.arabnews.com/news/585811
Technology development has a 15-20 year cycle from the lab to commercialization. This is why stringent standards are a critical signal to industry to make investments today for technologies that will be needed in the future. MECA members are engaged in developing a large portfolio of efficiency technologies that will directly or indirectly impact CO2 emissions. These technologies include advanced SCR catalysts, passive NOx adsorbers (PNA) and substrates, waste heat recovery, turbochargers, turbo-compounding, EGR coolers, EGR valves and other air management technologies, thermal management strategies including insulated dual wall manifolds and exhaust systems, active thermal management approaches, advanced fuel injection and ignition systems. Technologies, like turbo-compounding and advanced air management strategies are already being commercialized in Europe whereas others such as Rankine cycle systems and advanced high pressure injection, are under demonstration and technologies with still longer term horizons, such as thermoelectric generators are still in the laboratory. MECA members estimate that using the proposed Alternative 3, 2027 engine efficiency standards, some of these technologies, such as waste heat recovery, will fall significantly short of the penetration rates forecasted in the proposal. [EPA-HQ-OAR-2014-0827-1210-A3 p.2]

Maintain Broad Regulatory Framework - Nationally and Internationally

Meritor supports the proposed nationwide regulatory framework as demonstrated in Phase 1 and proposed for Phase 2. We encourage the agencies to resolve any open issues with state regulatory bodies to ensure a unified, national regulation. As a global company, we also encourage the agencies to take a leadership role and collaborate internationally so that the final regulation may harmonize with global actions that are proposed or already completed. Addressing the global issue of reducing greenhouse gas on a state-by-state or a country-by country level will contribute to proliferation which increases cost and requires that limited resources be dedicated to compliance rather than the pursuit of technologies that will further drive greenhouse gas reduction. Although we recognize the feasibility limitations of global regulatory standards, we encourage the agencies to continue efforts to commonize global regulation where possible. [EPA-HQ-OAR-2014-0827-1254-A1 p.2]

As noted in the April 2015 white paper from the International Council on Clean Transportation, “Heavy-Duty Vehicle Fuel Efficiency Simulation: A Comparison of U.S. and EU Tools,” a key area for harmonization is the alignment of test procedures to quantify a technology’s performance or efficiency benefit. For example, it would be ideal to conduct a single axle-efficiency test to create an input map for both the U.S. and EU regulatory models. [EPA-HQ-OAR-2014-0827-1254-A1 p.2]

Ensure Technology-Neutral, Performance-Based Standards [EPA-HQ-OAR-2014-0827-1274-A1 p.3]

MEMA maintains that instituting technology-neutral, performance-based standards are the best way to ensure that the compliance targets are achieved by utilizing application-appropriate technologies and
concurrently preserving choice and avoiding unintended market shifts. In this manner, then the overall objectives of the Phase 2 program are not unintentionally compromised. Ultimately, the end goal of this regulation is to reduce emissions and to take the nation to a new level of clean air and energy independence. We believe that a technology-neutral approach is the ideal way to approach the standards. [EPA-HQ-OAR-2014-0827-1274-A1 p.3]

Not only would a technology- and performance-based approach be fair and equitable, but also it would establish regulatory consistency with elements of other emissions standards, enable the industry to develop the best available GHG emission reduction technologies and provide the intended CO2 reduction in the most cost-effective, customer-friendly, and technology-neutral way. [EPA-HQ-OAR-2014-0827-1274-A1 p.4]

MEMA and the supplier industry are committed to policies that enable the introduction of new technologies needed to support sustainable mobility. The interconnectedness of the industry drives the need for consistent, long-term policies, regulations and standards so that all stakeholders can more effectively incorporate technologies into the nation’s fleet. [EPA-HQ-OAR-2014-0827-1274-A1 p.12]

**Organization:** National Automobile Dealers Association (NADA)

The Phase 2 technology-forcing proposal does not fully recognize the complex and varied nature of commercial vehicle manufacturing, sales and ownership. For example, commercial purchasers often do not spec and purchase truck bodies and trailers from tractor and truck chassis manufacturers and their dealers, but rather from body and trailer manufacturers and dealers. Moreover, vehicle purchasers often spec engines and other major components from a variety of manufacturers with no single manufacturer having complete dominion over the finished product. Also, due to the prevalence of leasing (35-40 percent) and other commercial realities, operators often do not own and control the trucks, tractors, and trailers they operate. [EPA-HQ-OAR-2014-0827-1309-A1 p.5-6]

**Organization:** Schneider National Inc

Schneider strongly supports all efforts to improve the fuel efficiency of our vehicles. Our experience has shown this can best be done in a free market where customers and suppliers can work together to define the most fuel efficient vehicles available which meet the needs of the driver and the end customer. A realistic improvement goal for the supplier of equipment, with flexibility to deploy specific components where the overall total business benefit is positive, is strongly preferred. Regulations should promote adoption of cost-beneficial technologies, maintained by users, and that continue to generate positive environmental and total business results. Forcing technologies into industry applications for which there is no benefit will simply add to costs and the technology will not be sustained/maintained for its life. If the cost and operating risks are severe enough, purchasing cycles could be impacted with pre-buys to avoid unfavorable mandates. No one in the industry wants to alter purchasing cycles to postpone the consequences of a poor regulation, and we believe this should be avoided by promoting improvement with the flexibility to obtain efficient new vehicles which meet the many diverse and unique requirements of end users of the equipment. [EPA-HQ-OAR-2014-0827-1201-A1 p.4]

**Organization:** Truck & Engine Manufacturers Association (EMA)

While implementing the Phase 1 standards has been a formidable task, the Proposed Phase 2 Standards are more challenging in very fundamental ways. Phasing-in between 2021 and 2027 (starting in 2018 for trailers), the Proposed Standards for heavy-duty vehicles are truly “technology-forcing,” relying on
technological advancements and improvements that have yet to be fully developed, demonstrated or commercialized. Consequently, there are many assumptions based on unproven technological advancements in fuel efficiency, and on uncertain adoption rates for those technological advancements, that form the foundation for the Proposed Phase 2 Standards. To the extent that those assumptions are wrong or over-estimated, compliance with certain of the Proposed Standards for heavy-duty vehicles will be infeasible. As a result, the GHG/FE Standards that EPA and NHTSA are proposing in Phase 2, which in their present form are infeasible and impractical for many categories of heavy-duty vehicles, are fundamentally different from what the many key stakeholders negotiated and consensed around in Phase 1. [EPA-HQ-OAR-2014-0827-1269-A1 p.3]

It is very important, therefore, that EPA and NHTSA recognize and acknowledge that the pending Phase 2 rulemaking is not simply a continuation of the Phase 1 rulemaking. More specifically, the Agencies will need to make significant and, in some cases, fundamental changes to their Phase 2 proposal in order to avoid the adoption of a number of infeasible and cost-prohibitive heavy-duty vehicle standards. Indeed, as explained below, without certain fundamental changes to the Phase 2 proposal, many of the projected improvements in vehicle fuel efficiency could remain theoretical only, and the primary outcome of this rulemaking could be significant disruptions in the manufacture and sale of medium-duty and heavy-duty on-highway vehicles, products that are quite literally the driving force behind this nation’s economic welfare. That said, and as was the case with the development of the Phase 1 standards, EMA remains willing to work diligently with EPA and NHTSA to craft the revisions necessary to ensure a viable and successful Phase 2 program. [EPA-HQ-OAR-2014-0827-1269-A1 p.3]

**Organization:** Truck Trailer Manufacturers Association (TTMA)

The existing proposal is overly complex and in our “Ways to Simplify/Streamline” section (9), we discuss a few ideas to modify it. [EPA-HQ-OAR-2014-0827-1172-A1 p.2]

**Organization:** Volvo Group

All, or nearly all, heavy-duty vehicles are purchased by businesses to perform services that support the business and enhance profits. In the largest market segment, Class 8 tractor-trailer rigs, fuel costs are a high percentage of the operating cost, creating a strong commercial incentive to minimize fuel use. Heavy-duty on-road vehicles cover a vast range of size, load capacity, and function. Examples include tractor-trailer rigs, dump trucks, concrete mixers, urban delivery, refuse collection, street sweepers, urban buses, motor coaches, and utility trucks. Vehicles are specified by customers, working with manufacturers, to serve the target application efficiently and cost-effectively. Tractor-trailers use the majority of fuel and deserve the greatest attention, but even in this segment there is huge variety with tractors designed to haul single box vans, multiple trailers, tankers, flatbeds, etc., and with load capacity ranging up to 120,000 lbs. and more. Purchasers often target their vehicles to operate in specific regions, accounting for terrain, speed, loading, and other variables in their specifications. Vehicles may need to get in and out of construction sites, mines, dumps, oil drilling sites, or other off-road situations. Manufacturers offer an enormous number of options to accommodate this vast array of customer requirements, including many engine ratings, transmission types, gearing options, axle ratios, axle combinations, tires, aerodynamic treatments, weight ratings, sleeper cabs, etc. All of these options impact fuel consumption and GHG emissions. [EPA-HQ-OAR-2014-0827-1290-A1 p.8]

No regulation can accommodate all these variables without considerable complexity. An enforceable regulation requires each vehicle to be assigned to a regulatory category or market segment that defines its regulatory duty cycle including load, speeds, road grades, trailer type (if applicable) and other operating parameters to assess performance. Proliferation of vehicle categories and duty cycles
increases the burden to determine which category is appropriate for any vehicle, to develop a representative duty cycle, and to establish regulatory targets based on appropriate technologies and penetration rates. In some cases a vehicle manufacturer builds a chassis for a body builder without knowing what the application will be, further frustrating the ability to segment vehicles into finer categories. [EPA-HQ-OAR-2014-0827-1290-A1 p.8]

Well-chosen regulatory duty cycles and load factors can approximate actual in-use performance for an average vehicle in a particular category, but cannot account for performance in any specific application. This creates two key issues. First, accurate characterization of duty cycles requires a large number of vehicle measurements in each vehicle category over an extended time period, a difficult task during an expedited rulemaking. Second, there must be adequate flexibility to design and specify vehicles for the intended function rather than the regulatory duty cycle. If these factors are not considered and accounted for, in-use operational efficiency and fuel consumption will be compromised, not improved. Ideally, the rule should be carefully crafted and tested to ensure that regulatory requirements translate to real world efficiency, and avoid unintended consequences. Volvo Group is concerned that the compressed schedule for adopting the GHG Phase 2 regulation has not allowed sufficient time to fully consider all of the factors at play in this rulemaking. In Europe, regulators are proposing to test their heavy-duty CO2 rule by requiring efficiency labelling for several years. This preliminary step offers manufacturers and regulators the opportunity to evaluate the testing and evaluation protocols, and to gain an understanding of the market efficiency baseline before setting limit levels. Unfortunately, it appears that the Environmental Protection Agency (EPA) and the National Highway Traffic Safety Administration (NHTSA) will move ahead on an arbitrary, compressed schedule, without market testing. [EPA-HQ-OAR-2014-0827-1290-A1 p.8]

It should be noted that the current (Phase 1) rule provides little guidance toward the Phase 2 rule. The Phase 1 rule governs only a few of the design parameters that impact efficiency, using an EPA devised “generic” engine and powertrain for each vehicle category rather than the components actually installed by the manufacturer. For vocational vehicles, the only variable considered in Phase 1 is rolling resistance of the tires. Even if there is a modicum of guidance available from Phase 1, it only became mandatory in 2014, which means that the August 2015 final reports for this first year were not available to inform the proposed rulemaking. [EPA-HQ-OAR-2014-0827-1290-A1 p.9]

Given the requirement for regulation enforceability, the expedited rulemaking schedule (although there may be some delay, President Obama announced a final rule to be completed by March, 2016), limited Agency resources and data, and the need to avoid an impossibly complex rule, the only practical way to avoid negative unintended consequences under the current rulemaking schedule is to set reasonable stringency targets that provide averaging margin to allow the best specification for each vehicle’s application, while still achieving the average target for the vehicle category. Appropriately, the EPA and NHTSA have attempted to do this by evaluating the effectiveness and optimal penetration level for each efficiency technology in each vehicle category. Even so, the effectiveness and market acceptance of many of these technologies as far as 15 years into the future is speculative and therefore unknown, and many of the targeted technology penetration rates are unrealistically high. [EPA-HQ-OAR-2014-0827-1290-A1 p.9]

The 2300 page draft NPRM and Regulatory Impact Analysis (RIA) underscores the huge complexity of the heavy-duty vehicle market and the difficulty in creating an appropriate regulation while avoiding unintended consequences that could actually degrade efficiency. EPA and NHTSA have made great effort to create effective measurements for GHG emissions and vehicle efficiency and to set stringency targets that force development and deployment of available technologies at a rate and cost that the
market will accept. There remain, however, many problematic elements that demand resolution if this rule is to be workable and effective. [EPA-HQ-OAR-2014-0827-1290-A1 p.9]

UNINTENDED CONSEQUENCES

Manufacturers Need Flexibility to Meet Application Requirements

A truck, tractor, or bus is only useful if it can efficiently perform its work at an acceptable cost. Efficient performance is not only measured in fuel consumption, but in time and cost to complete its mission, including all costs of ownership. If a vehicle does not have the features needed for efficient performance, it will not be purchased. Breakdowns, equipment damage, inadequate traction for any part of a mission, reduced load capacity, inadequate torque or power, inadequate ground clearance, poor drivability, and a host of other concerns must be considered when specifying each vehicle. Rule makers have the luxury to focus on a single desired outcome, but manufacturers must have flexibility to meet all requirements. This means many vehicles will not be able to utilize fuel efficiency features that the Agencies expect in a given vehicle segment. This is anticipated by the Agencies and AB&T (Averaging, Banking, and Trading) is provided to accommodate this need. But this is only effectual if target stringencies are based on realistic technology effectiveness and penetration rates that markets will accept while still meeting all operational requirements. If technology penetration rates exceed market acceptance due to mission requirements or cost, the customers will opt to maintain and rebuild existing vehicles to the detriment of regulator’s objectives while causing potentially severe market and economic disruptions. [EPA-HQ-OAR-2014-0827-1290-A1 p.30]

Overly stringent expectations can actually lead to greater in-use fuel consumption if we are forced to specify vehicles optimized to Agencies’ duty cycles rather than customer’s requirements. For example, a truck set up with a lower axle ratio that is efficient at 65 mph may actually run a gear down if the customer typically runs at lower speed or sets his road speed limit at 62 mph, resulting in more fuel consumption than if the appropriate axle was specified. This issue is even more acute if the regulatory duty cycles do not match the typical in-use duty cycles, an issue further discussed in these comments. [EPA-HQ-OAR-2014-0827-1290-A1 p.30]

Compromising Vehicle Utility

Given the previously stated concerns regarding inability to meet the standards with the Agencies assumed technology packages and penetration rates, the far reaching timeframe for the Phase 2 regulation, the uncertainty in the feasibility of the proposed technologies and their penetrations, and the expected increases in fuel economy and GHG performance measured on non-representative duty cycles that are still under revision, Volvo Group is concerned that the proposed regulation will force technologies that are not suited for the specific intended applications and duty cycles. One such example is expected penetration of Waste Heat Recovery on a highway tractor which could serve to limit aerodynamic performance due to increased cooling package size, as well as suitability for weight sensitive applications. If, forced to introduce this technology, OEMs could likely face pre-buy, no-buy, or delayed-buy effects, all of which would result in continued operation of old trucks and large scale rebuilding of older vehicles and engines. This again renders the proposal uncertain to accomplish its intended purpose. [EPA-HQ-OAR-2014-0827-1290-A1 p.31-32]

Organization: Walsh, Michael and Charlton, Stephen

A stated goal of the Phase 2 GHG rule for Medium and Heavy-Duty Engines and Vehicles is to be ‘technology advancing’ over the lifetime of the rule, i.e. through 2027 – in response to the President’s
directive on February 18, 2014 [13]. Such a goal makes sense in light of the climate crisis we are facing and is consistent with the technology forcing nature of the Clean Air Act. [NHTSA-2014-0132-0102-A1 p.10]

This analysis finds the agencies to be overly conservative in their assessment of technology effectiveness, cost / retail price and adoption rates, which is reflected in the very modest HD tractor engine standards proposed. [NHTSA-2014-0132-0102-A1 p.10]

Organization: Waste Management (WM)

In particular, we support the Agencies developing a Phase 2 rule that builds on the success of the Phase 1 rule, which minimized compliance burdens on end-users and provided compliance flexibilities for regulated original equipment manufacturers (OEMs). WM also strongly supports a final Phase 2 rule that maintains market, fleet, fuel and technology choices for end users. Phase 2 can provide advances in GHG reductions and fuel efficiency without restricting our choice of product specifications or technologies needed to conduct our refuse collection services. [EPA-HQ-OAR-2014-0827-1214-A2 p.2]

EPA and NHSTA have Appropriately Proposed a Fuel-Neutral Vehicle Emission Program

The regulatory framework adopted by EPA and NHTSA establishes a vehicle emission program that is fuel-neutral. In EPA’s Denial of the Petition To Reconsider the Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles (77 FR 51705), EPA discusses the fundamental premise of a fuel-neutral vehicle standard. [EPA-HQ-OAR-2014-0827-1214-A2 p.3-4]

“The Phase 1 rules comprise a coordinated and comprehensive Heavy-Duty National Program designed to address the urgent and closely intertwined challenges of reduction of dependence on oil, achievement of energy security, and amelioration of global climate change.” EPA further explained, “A further reason this heavy-duty rule does not regulate GHG emissions from a lifecycle perspective, ... is that it would no longer be possible to establish harmonized, performance-based tailpipe GHG emissions standards (EPA) and fuel efficiency standards (NHTSA). [EPA-HQ-OAR-2014-0827-1214-A2 p.4]

Organization: Werner Enterprises

Additional concerns within the proposal include the technology-forcing standards for both the engine and the vehicle that affect 2021, 2024, and 2027 model year vehicles and engines. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

There are several key areas the Agencies need to address: [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

- Unproven technologies with too many associated unknowns should not be included in this rule. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]
- Accurately reflect operators’ total cost of ownership, and provide realistic targets in a realistic timeframe. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

Ultimately, the manner in which Phase 2 is implemented will decide the success and failure of this rule. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

Response:

The commenters make numerous suggestions as to the regulatory framework and guiding principles that a final Phase 2 program should follow. As discussed in Section I of the Preamble, the agencies set standards based on our respective authorities and have certain statutory considerations to take into account when determining feasibility of the final program. EPA’s HD Phase 2 GHG emission standards are authorized under the Clean Air Act, and NHTSA’s HD Phase 2 fuel consumption standards are authorized under the Energy Independence and Security Act of 2007. The agencies are adopting these standards because, based on the information available at this time and careful consideration of all comments, we believe they best fulfill our respective statutory authorities when considered in the context of available technology, feasible reductions of emissions and fuel consumption, costs, lead time, safety, and other relevant factors.

We agree with the commenters on the importance of basing the structure of the Phase 2 program on the existing Phase 1 standards, and we have continued to do so for the final standards. The Phase 2 standards will maintain the underlying regulatory structure developed in the Phase 1 program, such as the general categorization of MDVs and HDVs and the separate standards for vehicles and engines. Also like the Phase 1 program, we are applying the Phase 2 standards in a manner that is fuel neutral (See Preamble Section I for further discussion).

The Diesel Technology Forum commented that the “program must be fuel neutral in nature.” Although we see many positive features of fuel-neutrality, we recognize that they must be balanced against other important market factors. We believe that continuing the Phase 1 approach appropriately balances these factors.

Many commenters stressed the importance of flexibility. The Phase 2 standards are performance-based, meaning that the industry will have a significant range of technology choices to be considered for compliance, rather than the one or two new technologies the OEMs pursued to comply with EPA’s 2007 criteria pollutant standard. It is important to emphasize here that the agencies are generally not mandating the use of a specific technology to meet the Phase 2 standards, rather manufacturers would be able to choose the technologies, or combinations of technologies, that are best for them in achieving the standards. In emphasizing the need for flexibility, commenters raised concerns about market disruptions. As discussed further in Preamble Section I, the agencies have considered the possibility of market disruptions (e.g., we understand the potential impact that fleets pulling ahead purchases can have on American manufacturing and labor, dealerships, truck purchasers, and on the program’s environmental and fuel savings goals), and we have taken steps in the design of the program to avoid such disruption. These steps include the following:

- Providing considerable lead time
- Adopting standards that will result in significantly lower operating costs for vehicle owners (unlike the 2007 standard, which increased operating costs)
- Phasing in the standards

The one exception to this general rule is the category of non-box trailers which have simple design standards.
Structuring the program so the industry will have a significant range of technology choices to be considered for compliance

Allowing manufacturers to use emissions averaging, banking and trading to phase in the technology even further

Commenters have varying views about how technology-advancing (or technology-forcing) the standards should be: some commenters arguing that the standards go to far and rely too much on “unproven” technologies, while others argue that the standards do not go far enough and should further “force” more advanced technology. As discussed in Preamble Section I, the Phase 2 standards represent a more technology-forcing approach than the Phase 1 approach, predicated on use of both off-the-shelf technologies and emerging technologies that are not yet in widespread use. The agencies are adopting standards for MY 2027 that we project will require manufacturers to make extensive use of these technologies. The standards increase in stringency incrementally beginning in MY 2018 for trailers and in MY 2021 for other segments, ensuring steady improvement to the MY 2027 stringency levels. For existing technologies and technologies in the final stages of development, we project that manufacturers will likely apply them to nearly all vehicles, excluding those specific vehicles with applications or uses that prevent the technology from functioning properly. We also project as one possible compliance pathway that manufacturers could apply other more advanced technologies such as hybrids and waste engine heat recovery systems, although at lower application rates than the more conventional technologies. To the extent that commenters provided technical information on their specific technologies, we address these comments in the appropriate sections of the Preamble, the RIA, and this Response to Comment document.

With respect the Daimler’s comment that we “should not require powertrain testing nor premise standards on a significant amount of powertrain testing” we note that the final standards are premised on less powertrain testing than the proposed standards. Nevertheless, we do not agree that “selectable dropdown fuel efficiency features” are inherently preferable to powertrain testing.

Finally, Volvo identified many issues to emphasize the complexity of the HD Phase 2 program and underscore the potential for unintended consequences. We have considered these factors, most of which were discussed in the NPRM or are addressed in more detail in other sections of this RTC. Nevertheless, the agencies will monitor the implementation of this program and would take appropriate action that would be necessary to avoid these unintended consequences.

1.8 Basing Standards on Life Cycle Analysis

Organization: American Iron and Steel Institute

In this regard, AISI has previously filed comments with respect to the Model Year ('MY') 2012-2016 Light-Duty Vehicle Greenhouse Gas Rule and the MY 2017 and Later Light -Duty Vehicle Greenhouse Gas Rule. Our comments concerning this Proposed Rule center on some of the same concerns that we have previously expressed, namely that the Environmental Protection Agency ('EPA') and the National Highway Traffic Safety Administration ('NHTSA') more accurately take into account the greenhouse gas ('GHG') emissions associated with vehicles and engines, specifically life cycle emissions associated with the use of various materials in vehicle and engine manufacturing. Our comments with respect to the Proposed Rule, however, take on added importance regarding the agencies’ new effort to promulgate medium- and heavy-duty standards, which will be implemented over the next decade. EPA and NHTSA must make every effort in such a long-term rule to address important structural issues in how GHG emissions and fuel efficiency are measured. We do not believe that EPA and NHTSA can maintain a ‘wait and see’ approach to life cycle analysis. Doing so undermines both the accuracy and legal basis for this rulemaking. [EPA-HQ-OAR-2014-0827-1275-A1 p.1-2]
A. Life Cycle Analysis of Materials Will Provide More Accurate Assessment of Vehicle GHG Impacts and Improve GHG Benefits of Final Rule

The Proposed Rule represents a 'more technology-forcing approach' than Phase I standards. Specifically, it 'will effectively require manufacturers to develop new technologies (or to significantly improve technologies) from standards that can be met using off-the-shelf technology alone.' According to EPA analysis, fully-phased in standards will result in 24 percent lower carbon dioxide (CO2) emissions for Class 7 and 8 combination tractors and a 16 percent CO2 reduction from Phase I for vocational vehicles. Total GHG reductions from the program are estimated at 1 billion metric tons. [EPA-HQ-OAR-2014-0827-1275-A1 p.9]

Emissions from steel manufacturing are substantially lower than alternative materials used in motor vehicles. Within the context of the Proposed Rule - which contains interim standards in MY 2021 and MY 2024 and extends through MY 2027 - EPA must incorporate life cycle analysis and not 'lock in' vehicle material choices for the next decade. While current vehicle CO2 emissions are dominated by the utilization of the vehicle, as GHG and fuel efficiency standards for medium- and heavy-duty vehicles are implemented with increasing stringency, the balance between emissions associated with materials versus driving will shift and selection of materials will become increasingly important. EPA should not ignore this evolving opportunity to increase, and not unintentionally decrease, the projected benefits of the final rule. [EPA-HQ-OAR-2014-0827-1275-A1 p.9-10]

Within the LDV sector, production phase GHG emissions can account for about 40% of total CO2 emissions from a vehicle. It has also been estimated that the percentage of such emissions could rise to 50% by 2020. Since the LDV sector is defined in terms of 8,500 lbs. Gross Vehicle Weight Rating ('GVWR') and below, the relative GHG emission reductions associated with vehicles in medium- and heavy-duty sector, with range from 8,500 to over 60,000 GVWR will be comparatively greater based on weight. Even accounting for the greater utilization of commercial versus personal LDVs, significant reductions in GHGs could be expected by influencing the selection of materials in vehicle construction. [EPA-HQ-OAR-2014-0827-1275-A1 p.10]

In general, heavy-duty trucks are limited with respect to payload because of road restrictions. Therefore, if a truck weighs less, it is able to carry additional payload (in most situations), while the total weight of the vehicle remains the same. Since more payload is able to be transported per vehicle, benefits are created with respect to reducing the number of trips that are required to engage in the same commercial activity. This results in a direct benefit in terms of overall GHG emissions. The resulting benefit is correspondingly greater in city driving and stop/start performance. Since reduction in mass is central to this benefit, EPA and NHTSA must more accurately assess the GHG emissions associated with the reduction in mass, namely through utilization of life cycle analysis. [EPA-HQ-OAR-2014-0827-1275-A1 p.10]

Methodologies to incorporate life cycle emissions into the regulatory structure of this rulemaking are available and would improve the accuracy of EPA's assessment of a vehicle's GHG emissions. In this regard, Ricardo has examined the feasibility of considering a vehicle's entire life cycle to be able to compare the impact of different LDVs. While this assessment recognized that there are indeed strengths to the current system of testing and certifying vehicles over a defined drive cycle, the report noted multiple limitations to this regulatory system, including the lack of measurement of emissions upstream of vehicle use where the strong influence of the carbon intensity of material can be quantified. [EPA-HQ-OAR-2014-0827-1275-A1 p.11]

**Organization:** American Iron and Steel Institute

EPA and NHTSA have statutory authority to incorporate life cycle analysis into GHG emission and fuel efficiency standards. To the extent either agency may believe it is legally constrained in this area, past practice would allow either agency to ‘conform’ its final standards to those promulgated by the other agency. [EPA-HQ-OAR-2014-0827-1275-A1 p.2]

If EPA and NHTSA believe that there is insufficient information in the Proposed Rule to incorporate life cycle analysis in a final rule, there are several administrative alternatives to correct this situation. The agencies have authority to issue supplemental rules or a Notice of Data Availability (‘NODA’). In the alternative, a ‘look-back’ mechanism could be incorporated into the final rule that would allow for future integration of such analysis. [EPA-HQ-OAR-2014-0827-1275-A1 p.3]

**III. EPA and NHTSA Should Incorporate Life cycle Analysis into Phase 2 HD Standards**

AISI has previously submitted comments and detailed information with respect to life cycle analysis in EPA/NHTSA vehicle rulemakings and other agency interactions. Some of this information is attached and submitted to the docket for the agencies’ further consideration in this rulemaking, including recent WorldAutoSteel studies. We respectfully request that the agencies thoroughly review this information and engage AISI if there are questions concerning study methods or results. [EPA-HQ-OAR-2014-0827-1275-A1 p.7]

To date, however, the agencies have only provided summary responses to AISI's comments in this area and, within the Proposed Rule, EPA and NHTSA are now specifying 'that Phase 2 standards apply exclusively at the vehicle tailpipe . . . compliance is based on vehicle fuel consumption and GHG emission reductions, and does not reflect so-called life cycle emission properties.' EPA and NHTSA, however, should reconsider this course of action for several legal and policy reasons, including improving the accuracy and reliability of its regulation in this area and the opportunity to secure additional improvements in GHG emissions and fuel efficiency. Indeed, given the lengthy phase-in of new medium- and heavy-duty regulations over the next 12 years, the Proposed Rule provides a perfect opportunity for the agencies to incorporate life cycle analysis into the final standards. The long timeframe of the rule would allow the market to respond and better incorporate material selection into their compliance strategies. Moreover, there are existing GHG emissions measurement models and several different regulatory methods that can be utilized, including phase-in of such analysis or supplementary rulemaking that would provide additional adjustment to the GEM utilized in this rulemaking. [EPA-HQ-OAR-2014-0827-1275-A1 p.7-8]
The National Research Council has recognized that EPA and NHTSA should address 'well to wheel GHG and petroleum reduction benefits' with respect to light duty alternative-fueled vehicles. In its report regarding light-duty vehicle technologies, the council noted that starting in MY 2020, EPA and NHTSA will utilize data with respect to the actual use of alternative fuel in such vehicles. The intent of this change in regulatory policy is abundantly clear: emission benefits in alternative-fueled vehicles are only achieved if the vehicles are utilizing fuel which contains fewer upstream GHG emissions, i.e., the GHG emissions associated with the production of alternative fuels versus 'conventional' fuels such as gasoline and diesel. The same concept applies with respect to vehicle materials: the benefit of weight reductions can only be accurately measured if the full life cycle of the materials are considered. Without consideration of such upstream GHG emissions, EPA and NHTSA estimates of the resulting benefits of this rulemaking will be inaccurate as well as any standards premised on such estimates.

Similarly, the Department of Energy (DOE) has considered the relevance of 'well to wheels' assessment related to different types of fuel as part of its 21st Century Truck Partnership. Particularly regarding natural gas vehicles, DOE noted that 'Natural gas based fuels for heavy-duty vehicle applications are of importance to the [21st Century Truck Partnership]. Several recent U.S. studies have examined the impacts of shale gas and conventional [natural gas] production, so any effort to examine these fuels should build on this work.' Again, since the focus of this analysis is with respect to upstream production of fuel utilized in vehicles, there is no logical distinction between considering such emissions and those associated with the life cycle emissions attributable to the materials utilized in vehicle production.

The agencies' discussion of life cycle analysis in the Preamble along with the review and solicitation of comment on using such analysis with respect to natural gas vehicles forms a basis under which the agencies could finalize a broader use of life cycle analysis for materials in the final rule. In the alternative, the agencies could solicit additional comment on the broader use of life cycle analysis of vehicle materials and components, either in a supplemental rule or NODA to this rule. If this course is taken, we would request that this procedure occur in a timeframe so as to allow incorporation of life cycle analysis prior to the implementation of the new GHG and fuel efficiency standards established by this rulemaking.

AISI previously submitted draft regulatory language to create a life cycle assessment report in the context of the LDV rule. Regarding this rulemaking, EPA and NHTSA should incorporate a regulatory provision that creates an advisory board to assess current information on life cycle analysis of materials and then require subsequent action to revise the GHG and fuel efficiency standards applicable to in-use heavy duty vehicles beginning in MY 2021 and 2024. Draft regulatory language to accomplish this result is attached to these comments.

The long-term nature of this rulemaking means that accuracy of GHG emission reduction estimates and the mechanisms by which the agencies seek to achieve GHG reductions and improvements in fuel efficiency must be improved. This rulemaking is the appropriate time to incorporate life cycle analysis since it would improve the data utilized in GEM to project vehicle emissions and to certify vehicles. As EPA and NHTSA seek to reduce emissions and improve fuel efficiency, the relative amount of materials-related emissions will grow. It would be arbitrary and capricious for EPA to ignore such a long-term condition, which threatens the accuracy of its estimates of the benefits of this rulemaking as well as the accuracy of its compliance mechanism. While the agencies have broad statutory criteria under which to establish final standards, administrative discretion is not unlimited. Continuing to ignore...
life cycle analysis or delay its consideration could undermine the rational basis of this rulemaking and lead to the unintended consequence of increasing emissions. [EPA-HQ-OAR-2014-0827-1275-A1 p.19]

15 See Attachment A.

16 While EPA, like other parts of the Executive Branch, is not required to 'discuss every item of fact or opinion included in the submissions is receives in response to a Notice of Proposed Rulemaking, it must respond to those comments which, if true, would require a change in [the] proposed rule. Louisiana Federal Land Back Association, FCLA v. Farm Credit Administration, 336 F. 3d 1075, 1080 (D.C. Cir. 2003). See also Delaware Department of Natural Resources and Environmental Control v. EPA, Slip op. 13-1093 (D.C. Cir. 2015). 'Naturally, an agency need not 'discuss every item of fact or opinion included in the submissions made to it.' Pub. Citizen, Inc. v. FAA, 988 F. 2d 186, 197 (D.C. Cir 1993) . . . But an agency must respond sufficiently to 'enable us to see what major issues of policy were ventilated . . . and why the agency reacted to them as it did.' Id. at 24.

21 To the extent EPA and NHTSA might treat such emissions as a 'credit' versus a direct part of the calculation of emission standards applicable to vehicles is of no matter. The consideration of weight based on different material use serves as a compliance mechanism for the standards and is integral to the implementation of the final heavy-duty GHG requirements. Thus, if this credit is inaccurately measured due to the failure to consider the life cycle impact of various materials, the regulatory requirements of the final rule are negatively affected.

57 See Attachment K; EPA-HQ-OAR-2014-0827-1275-A12 In the event that EPA and NHTSA do not directly incorporate life cycle analysis into the final rule, we request that EPA and NHTSA incorporate this review mechanism into the rule

Organization: American Iron and Steel Institute

The Clean Air Act Allows for Life Cycle Analysis

EPA cites Clean Air Act ('CAA') Sections 202(a), 203 and 207 as authority for this rulemaking. Under CAA Section 202(a), EPA is required to promulgate regulatory standards for 'any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines' which are considered to cause or contribute to air pollution that 'may reasonably be anticipated to endanger public health or welfare.' EPA has previously taken an expansive view of this authority. In this rulemaking, EPA addresses arguments that it cannot regulate trailers since they do not emit pollutants and therefore cannot be subject to emission standards. EPA considers this argument 'without legal predicate' and states that '[t]here is no requirement that pollutants be emitted from a specified part of the motor vehicle or engine.' This interpretation of its authority applies equally to life cycle analysis. [EPA-HQ-OAR-2014-0827-1275-A1 p.3-4]
Historically, EPA has not considered itself to be constrained to one particular regulatory approach in addressing engine and vehicle emissions. For example, EPA's current Light-Duty Vehicle ('LDV') rules utilize a mathematical curve-based computer modeling of 'feasible' levels of emissions relative to the footprint of a vehicle. Many other engine and vehicle programs allow for fleet averaging and emission credits to be generated and used, rather than standards applied solely on the basis of contemporaneous emissions. Therefore, it is abundantly clear that EPA does not believe the CAA limits the agency to promulgate only traditional 'tailpipe' standards that rely on the direct measurement of air pollution. [EPA-HQ-OAR-2014-0827-1275-A1 p.4]

EPA has, in fact, made previous statements that it does possess the authority to utilize life cycle emissions as part of engine and vehicle regulations. Within the Response to Comments document for the MY 2012-2016 LDV rule, EPA indicated that the agency ‘agree[d] that the issue of life cycle emissions accounting may be appropriate to consider for subsequent rulemakings.’ In addition, EPA believes it can advance different policy objectives through its engine and vehicle rulemakings. In the MY 2012-2014 LDV rulemaking, for example, EPA indicated using a vehicle's footprint as part of its regulatory standard would minimize incentives to 'downsize' vehicles as a compliance strategy. Thus, it would be reasonable to conclude that EPA considers the authority Congress granted to it within Title II of the CAA and CAA Section 202 specifically, to encompass an ability to incorporate life cycle analysis into motor vehicle regulatory standards. [EPA-HQ-OAR-2014-0827-1275-A1 p.4]

C. EPA's Denial of Petition for Reconsideration on Fuels Does Not Impact Life Cycle Analysis Based on Materials

In support of its decision to utilize tailpipe standards and not to propose standards that 'reflect any so-called life cycle emission properties,' EPA cites its denial of a petition for reconsideration from POP Diesel with respect to the MY 2014-2018 medium- and heavy-duty GHG rule. But EPA's rationale in denying the POP Diesel petition has no bearing on the use of life cycle analysis with respect to materials in this rulemaking. Instead, EPA's denial was focused on the existence of other programs that already control GHGs from fuels, i.e., the renewable fuel standard contained in CAA Section 211(o). Clearly, there is no corollary program regarding the life cycle analysis of materials within the statutory authorities cited for this rulemaking. Otherwise, EPA's denial of the POP Diesel petition was largely on procedural grounds - on that the basis of their petition for reconsideration did not, in fact, occur after the period for public comment had closed. Since we are currently in the rulemaking process itself, this rationale is also inapplicable to incorporating life cycle analysis of materials. [EPA-HQ-OAR-2014-0827-1275-A1 p.14]

4 For example, in the proposed rule for light-duty greenhouse gas standards for MY 2012-2016 EPA stated that Title II of the CAA provides for 'comprehensive regulation of mobile sources' and that the title offers 'sweeping grants of authority' that allow the Agency to consider numerous factors including technological effectiveness, the impact of standards on oil conservation and energy security and other energy impacts. 79 Fed. Reg. at 49,454.

Organization: California Air Resources Board (CARB)

Support/Comment on Topic Where NPRM Requests Comment
Comment – Upstream emissions/deemed zero language for BEVs

Like the Phase 1 standards, Phase 2 standards are based on tailpipe emissions. Because the expected penetration of BEVs is low, U.S. EPA and NHTSA propose to continue to treat BEVs as if they have zero emissions of CO2, methane, and nitrous oxide (N2O) without accounting for upstream emissions from charging. The NPRM specifically requests comment on this continued use of deemed zero language for EVs. While there are clearly emissions associated with power production to charge medium-and heavy-duty EVs, emissions associated with producing a kW of power are declining, and medium- and heavy-duty BEVs currently comprise a small portion of the fleet that the emissions associated with charging the vehicles is comparatively insignificant. [EPA-HQ-OAR-2014-0827-1265-A1 p.99]

The 2017 to 2025 MY light-duty vehicle GHG rule includes a cap whereby upstream NHTSA believe such a cap is not needed for medium- and heavy-duty BEVs due to their anticipated low likelihood of significant production volumes in the Phase 2 timeframe. CARB staff agrees such a cap need not be included in this regulation at this time. CARB staff believes a different regulatory structure for the likely small number of anticipated vehicles would put an extra burden on manufacturers and would not result in significant emission reductions. [EPA-HQ-OAR-2014-0827-1265-A1 p.99-100]

Organization: Cummins, Inc.

Cummins supports the Agencies’ proposal for GHG/FE compliance based on tailpipe emissions, not lifecycle emissions [EPA-HQ-OAR-2014-0827-1298-A1 p.41]

Cummins supports the proposal that Phase 2 GHG/FE compliance is based on tailpipe emissions. As stated in the Preamble (80 FR 40503), this approach allows for fuel neutral standards and maintains a unified program between EPA and NHTSA, so the tailpipe approach should continue in Phase 2. [EPA-HQ-OAR-2014-0827-1298-A1 p.41]

Organization: National Biodiesel Board

EPA and NHTSA are proposing that the Phase 2 standards apply exclusively at the vehicle tailpipe. 80 Fed. Reg. at 40,158-40,159. In other words, “compliance is based on vehicle fuel consumption and GHG emission reductions, and does not reflect any so-called lifecycle emission properties.” Id. at 40,159. NBB agrees that the agencies should not seek to undertake a separate analysis of lifecycle emissions here. 77 Fed. Reg. at 62,823. Indeed, the lifecycle analysis utilized by EPA for the RFS cannot assess actual emissions and should not be applied here.13 [EPA-HQ-OAR-2014-0827-1240-A1 p.11]

As discussed throughout the final rule, close coordination in this first heavy-duty rule enabled EPA and NHTSA to promulgate complementary standards that appropriately allow manufacturers to build one set of vehicles to comply with both agencies’ regulations. WM, therefore, strongly recommends the Agencies abstain from incorporating lifecycle GHG emissions accounting in the Phase 2 rule. [EPA-HQ-OAR-2014-0827-1214-A2 p.4]

WM Supports the Adoption of Tailpipe-based GHG and Fuel Efficiency Standards

I. Executive Summary

Electricity as a transportation fuel offers significant long-term environmental benefits. Increased deployment of medium- and heavy-duty PEVs will both increase fuel efficiency and reduce emissions of GHGs and criteria pollutants from the transportation sector. These environmental benefits will only be multiplied by the continued reductions in upstream emissions of both GHGs and criteria pollutants related to the generation of electricity that will fuel the PEVs. [EPA-HQ-OAR-2014-0827-1327-A2 p.3-4]

EEI strongly supports the EPA’s and NHTSA’s decision to apply the proposed Phase 2 standards exclusively at the tailpipe. Consistent with Phase 1, the agencies correctly recognize that EVs emit 0.0 g/mile, for both GHG emissions and criteria pollutants, and therefore assess emissions and fuel economy appropriately. For purposes of compliance with vehicle emissions or fuel efficiency standards, any assessment of emissions should continue to be confined to the tailpipe and should not include estimated upstream emissions. However, should EPA and NHTSA determine that a review of upstream emissions for the Phase 2 Program, or in other future rulemakings, any such assessment must be fair, assessing the upstream national and/or international emissions of all transportation fuels (conventional and PEVs), and it must be based on current data with a clear recognition of regulatory developments that address and limit those stationary emissions sources. [EPA-HQ-OAR-2014-0827-1327-A2 p.4]

A. Tailpipe Emissions From Electric Vehicles Are Zero and the Phase 2 Program Correctly Focuses on Tailpipe Emissions

As a preliminary matter, EEI strongly supports the EPA’s and NHTSA’s decision to apply the proposed Phase 2 Program standards for medium- and heavy-duty engines and vehicles exclusively at the vehicle tailpipe. As proposed, the Phase 2 Program standards correctly focus compliance on vehicle fuel consumption and GHG emission reductions. Similar to the Phase 1 Program, the agencies appropriately recognize that EVs emit 0.0 g/mile, for both GHG emissions and criteria pollutant emissions. For purposes of compliance with vehicle emissions or fuel economy standards, any assessment of emissions should continue to be confined to tailpipe emissions (consistent with past EPA practice under Title II of the Clean Air Act) and should not include estimated upstream emissions. [EPA-HQ-OAR-2014-0827-1327-A2 p.7-8]

Consistent with the Phase 1 Program, and unlike the 2017-2025 light-duty standards, the agencies appropriately do not propose a “cap” for the technically accurate application of the 0.0 g/mile standard for heavy duty EVs. In the proposed rule, however, EPA and NHTSA state that this is “because of the small likelihood of significant production of EV technologies in the Phase 2 timeframe.” All EVs should be judged on their actual tailpipe emissions, which are 0.0 g/mile. [EPA-HQ-OAR-2014-0827-1327-A2 p.8]
B. If Assessed At All, Estimated Upstream Emissions Should Be Calculated Using Recent, Accurate Data and Should Recognize Current and Future Regulations that Limit These Emissions

While EPA and NHTSA propose to measure compliance with the proposed Phase 2 Program standards at the tailpipe, the agencies have specifically requested comment on this issue. This request appears to be aimed at concerns relating to upstream emissions—those emissions related to the production and delivery of transportation fuels. As a general matter, and consistent with the approach proposed for the Phase 2 Program, vehicle emissions standards should focus on actual vehicle emissions. However, should EPA and NHTSA determine that it is appropriate to assess upstream emissions for EVs, this assessment must be fair—it must assess the upstream impacts of all transportation fuels—and its must be based on current data (national and international) and recognize regulatory developments that address and limit upstream emissions. [EPA-HQ-OAR-2014-0827-1327-A2 p.8]

With respect to EVs, the agencies have not included any analysis or discussion of the upstream emissions related to electricity as a transportation fuel. However, the proposed Phase 2 Program makes unsubstantiated statements about the environmental benefits of EVs that appear to be related to concerns about estimated upstream emissions from electricity production. For example, in discussing possible compliance flexibilities and incentives for heavy duty (HD) pickups and vans, EPA states that incentives for EVs “would result in reduced benefits in terms of CO2 emissions...due to the Phase 2 Program.” As EV deployment would reduce emissions from vehicle tailpipes, it can only be assumed that this statement reflects concerns about upstream electricity emissions. [EPA-HQ-OAR-2014-0827-1327-A2 p.9]

As discussed in the proposed rule, back in 2010, NHTSA and EPA issued a joint final rule that established CAFE and GHG standards for passenger cars and light trucks for MY 2017-2025. As part of that rule, EPA conducted an assessment of upstream emissions from electricity generation and determined that it would only use the technically correct emissions value of 0.0 grams/mile for a limited number of EVs sold per manufacturer. In support of this position, and based on outdated data from 2005, EPA calculated a nationwide average electricity upstream GHG emissions rate. Using this national annualized average, EPA came to the spurious conclusion that “actual” GHG emissions attributable to EVs exceed the GHG emission of conventional fuel vehicles. [EPA-HQ-OAR-2014-0827-1327-A2 p.9]

As the agencies have not provided any discussion related to upstream electricity emissions in this docket, EPA and NHTSA may be continuing to rely on this outdated analysis. However, in the draft EIS for the vehicle standards for passenger vehicles and trucks for model years 2022-2025, which was released in 2012, NHTSA found that “even in modeled scenarios in which EVs charge from a carbon-intensive grid mix (i.e., electricity generated mostly from coal plants), the vehicle life-cycle emissions from EVs are less than conventional gasoline vehicles.” Draft EIS at 6-22. At a minimum, it is unclear why the agencies are not using their own, more recent assessments of upstream emissions from EVs and the potential for EVs to reduce emissions. Moreover, it is inappropriate to rely on EPA’s 2010 analysis of upstream emissions related to electricity production because it is flawed, outdated and does not consider significant regulatory developments that will further reduce both GHG and criteria pollutant emissions from the electric sector. [EPA-HQ-OAR-2014-0827-1327-A2 p.10]

First, EPA’s creation and use of a national annualized average electricity upstream GHG emissions rate fails to account for significant regional differences in electricity generation. National averages cannot help the agencies estimate any localized or regional impacts of potential increased penetration of PEVs. Emissions associated with generation of electricity vary significantly from utility to utility—with nuclear, wind, solar, geothermal, and hydroelectric powered sources emitting very low or no GHGs or...
criteria air pollutants in varying degrees across the country. Any meaningful estimates of upstream emissions associated with electricity as a transportation fuel would need to be tailored not only to reflect regional variations in current electricity baseload generation and expectations for marginal electricity generation mix, but also assumptions about usage and recharging of the vehicle as well as state/regional/federal electric generation policies (such as state Renewable Electricity Standard (RES) requirements) and state/regional/federal GHG emissions limits and reductions programs (e.g., California’s A.B. 32, the New England Regional Greenhouse Gas Initiative, and the federal CAA). For example, the timing of recharging patterns is highly significant because if, as expected, PEVs are largely charged at night, they will be charged at a time when nuclear, wind, and other clean sources provide perhaps the highest contribution to our electricity generation mix, depending on the region. Appropriate consideration of these regional variations and usage rates represent an integral step in producing a full and fair analysis of the upstream emissions for PEVs. [EPA-HQ-OAR-2014-0827-1327-A2 p.10]

Another significant flaw in the prior analysis lies in the utilization of historic and not projected data on power plant emissions. For example, according to the Energy Information Agency (EIA), total carbon dioxide emissions from electric generation were 10.8 percent lower in 2009 and 14.6 percent lower in 2013 respectively, when compared to the 2005 data relied upon for standards that will be in effect through 2025. As a result, historic data cannot be viewed as a reasonable proxy for expected emissions 10 plus years into the future. Any analysis that fails to use projected data would be inaccurate at best and most likely highly misleading. Given that any future standard would have to rely on these projections, the agencies should document all assumptions and allow for public review and comment on any estimates related to future electricity supply and demand. [EPA-HQ-OAR-2014-0827-1327-A2 p.11]

Most importantly, however, analysis of upstream emissions that relies on 2010 data fails to consider significant regulatory developments that have and will continue to reduce both GHG and criteria pollutant emissions. In particular, this means that EPA and NHTSA have failed to account for the implementation of the Mercury and Air Toxics Standards (MATS), which began in April 2015. It also means that neither agency considered the long-term GHG reductions that will be associated with the final Clean Power Plan, which the EPA Administrator signed on August 3, 2015. This program, by EPA’s own estimates, will reduce power sector GHG emissions by 32 percent below 2005 levels by 2030. The final Clean Power Plan also includes incentives for early—2016-2021—deployment of renewables and certain end-use efficiency programs. As EIA noted in its analysis of the proposed Clean Power Plan, which was projected to achieve lesser reductions, “the Clean Power Plan has a significant effect on projected retirements and additions of electric generating capacity. Projected coal plant retirements over the 2014-40 period, which are 40 GW in the AEO2015 Reference case (most before 2017), increase to 90 GW (nearly all by 2020)... [and] the Clean Power Plan increases projected renewable capacity additions in all cases.” The agencies cannot assert that increased EV deployment will undermine the GHG emissions reduction goals of the Phase 2 Program (or of any vehicle standards) because of potential increases in upstream emissions without assessing the impacts of the final MATS and Clean Power Plan. [EPA-HQ-OAR-2014-0827-1327-A2 p.11-12]

If the agencies chose to include upstream GHG or criteria pollutant emissions in the final Phase 2 Program or in other future rulemakings, the analysis must be fuel neutral, assessing the upstream national and/or international emissions of all fuels, conventional and alternative, and all vehicles, conventional and PEV. Moreover, the agencies must recognize the significant changes to the emissions profile of electricity generation that are occurring as a result of other regulatory programs aimed at stationary sources. [EPA-HQ-OAR-2014-0827-1327-A2 p.12]

19 Id.

20 In past vehicle standards rulemakings, NHTSA has failed to provide upstream analyses addressing petroleum or natural gas. EEI notes that NHTSA’s Draft EIS in support of the proposed Phase 2 Program contains a discussion of the upstream emissions related to the production and transmission of natural gas and some discussion of the upstream emissions related to petroleum production and transportation. This Draft EIS, unlike those for standards for passenger cars and trucks, does not address upstream emissions related to electricity production and transmission, likely because NHTSA does not rely on EVs as the basis for any of the proposed Phase 2 Program standards and does not expect many EVs to be deployed in these vehicle classes. Similarly, the Preamble to the proposed Phase 2 Program
discusses lifecycle emissions for natural gas and diesel vehicles, as does the draft Regulatory Impacts Analysis. See 80 Fed. Reg. at 40,503-10.

22 See 80 Fed. Reg. at 40,158; see also, 75 Fed. Reg. 25,324, (May 7, 2010).

27 Further, failure to acknowledge and account for the reductions associated with regulations that address electricity generation is inconsistent with the approach that EPA and NHTSA have taken with respect to regulations addressing fuels. In the Preamble, the agencies note that it is appropriate to focus on tailpipe emissions because of the existence of “Clean Air Act programs that encourage the use of renewable fuels.” 80 Fed. Reg. at 40,189. The Clean Power Plan does not just encourage GHG emissions reductions from electric generating units, but will require them during the MYs covered by the proposed Phase 2 Program.

Organization: Electric Drive Transportation Association (EDTA)

We support the proposed rule’s tail-pipe focus and zero emission status for electric vehicles as appropriate for this rulemaking.3 We reiterate our support as provided in comments on the most recent light duty rule, 2017 and Later Model Year Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, that any future regulatory regimes that seek to incorporate upstream emissions associated with vehicles should apply upstream metrics to all fuels.4 Regarding electricity, upstream modeling must be sufficiently granular to recognize regional variations in power profile and sufficiently dynamic to measure and project the rapidly evolving regulation and operations of the nation’s power sector. [EPA-HQ-OAR-2014-0827-1217-A1 p.2]

3 80 Federal Register 40158, July 13, 2015

4 See EDTA Comment #80fb45ce at http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0799-9449

Response

We are applying the Phase 2 standards at the vehicle tailpipe. That is, compliance is based on vehicle fuel consumption and GHG emission reductions, and does not reflect any so-called lifecycle emission properties. The agencies have explained why it is reasonable that the heavy duty standards be fuel neutral in this manner and adhere to this reasoning here. See 76 FR 57123; see also 77 FR 51705 (August 24, 2012) and 77 FR 51500 (August 27, 2012).
NHTSA notes that the fuel efficiency standards are necessarily tailpipe-based, and that a lifecycle approach would likely render it impossible to harmonize the fuel efficiency and GHG emission standards, to the great detriment of our goal of achieving a coordinated program. 76 FR 57125/1-2; (similar finding by EPA); see also Sections I.F. (1) (a) and XI of the FRM preamble.

The agencies received mixed comments on this issue. Many commenters supported the proposed approach, generally agreeing with the agencies’ arguments. However, some other commenters opposed this approach. Opposing commenters generally fell into three categories:

- Commenters concerned that tailpipe-only standards ignore the GHG benefits of using renewable fuels.
- Commenters concerned that upstream emissions of methane occurring during the production and distribution of natural gas would offset some or all of the GHG emission reductions observed at the tailpipe.
- Commenters concerned that ignoring upstream emissions overstates benefits for certain technologies.

These and other factors are discussed below. These factors were considered in the context of EPA’s engine and vehicle emission standards and NHTSA’s vehicle fuel consumption standards (including those for light-duty vehicles), which have been in place for decades as tailpipe standards. The agencies find no reasonable basis in the comments or elsewhere to change fundamentally from this longstanding approach.

Although the final standards do not account for life cycle emissions, the agencies have estimated the upstream emission impact of reducing fuel consumption for heavy-duty vehicles. As shown in Sections VII and VIII of the Preamble to the final rule, these upstream emission reductions are significant and worth estimating, even with some uncertainty. In addition, NHTSA has conducted a life-cycle impact assessment as part of its final environmental impact statement, including an assessment of an examination of medium- and heavy-duty vehicle materials and technologies.[1] Because the standards in today’s final rule are performance-based and not attribute-based standards, NHTSA’s analysis features a literature synthesis of existing credible scientific information relevant to evaluating the potential environmental impacts from some of the fuels, materials, and technologies that may be used to comply with the standards. However, while the agencies considered life-cycle impacts during the rulemaking process, the inability to quantify those impacts limits the agencies’ ability to incorporate life-cycle considerations into the standards themselves.

**Renewable Fuels**

With respect to fuel effects, EPA notes that there is a separate, statutorily-mandated program under the Clean Air Act which encourages use of renewable fuels in transportation fuels, including renewable fuel used in heavy-duty diesel engines. This program considers lifecycle greenhouse gas emissions compared to petroleum fuel. The agencies are not issuing rules that effectively would turn the Phase 2 rules into a fuel program, rather than an emissions reduction and fuel efficiency program, and thus will continue to measure compliance at the tailpipe, for the reasons just stated. See also response to POP Diesel in Section 1.3 above.

**Methane Emissions**

Issues relating to whether to consider in the emission standards upstream emissions related to natural gas exploration and production are addressed in detail in Section XI of the FRM and in Section 12 of
this RTC. It is sufficient to state here that the agencies carefully investigated the potential use of natural gas in the heavy-duty sector and the impacts of such use. We do not believe that natural gas is likely to become a major fuel source for heavy-duty vehicles during the Phase 2 time frame. Thus, since we project natural gas vehicles to have little impact on both overall GHG emissions and fuel consumption during the Phase 2 time frame, the agencies see no need to make fundamental changes to the Phase 1 approach for natural gas engines and vehicles.

EPA further notes that it is directly addressing the issue of methane emissions relating to production, transport and distribution activities upstream of vehicular applications. The EPA-promulgated 2012 New Source Performance Standards (NSPS) will reduce emissions of ozone precursors from natural gas facilities and have methane and hazardous air pollutant reduction co-benefits. The NSPS standards require that emissions from natural gas wells that are hydraulically fractured be controlled using flaring or reduced emission completion (REC) technology from completions and workovers starting in 2012. RECs used by natural gas well drillers capture the natural gas emissions that occur during well completion, instead of venting or flaring the emissions. Starting in January 2015, RECs are required for natural gas well completions and workovers. The NSPS also regulates the emissions from certain new natural gas production equipment, including dehydrator vents and condensate tanks. EPA is taking additional steps to reduce the emissions of methane from natural gas and oil production facilities. On May 12, 2016, EPA finalized regulations (2016 NSPS) which, among other things, include methane standards for oil and gas equipment used across the oil and gas sources currently only regulated for VOCs, and require the use of reduced emissions completions at hydraulically fractured oil wells. In March of 2016, the U.S. EPA and Canadian ECCC announced plans to regulate emissions from existing oil and gas sources. The goal of these various actions is to achieve an aggregated 40 to 45 percent reduction in methane emissions relative to methane emissions in 2012. The lifecycle analysis presented here and in RIA Chapter 13 does not take into account the 2016 NSPS, or a future action that would address existing sources, thus, it likely overestimates methane emissions from natural gas facilities. EPA believes that is the more reasonable approach than to use the vehicle program to indirectly seek to affect upstream emissions.

Technology-Specific Life Cycle Emissions

In a very practical sense, the agencies cannot accurately address life-cycle emissions on a technology specific basis at this time for two reasons:

1. We lack data to address each technology, and see no path to selectively apply a life cycle analysis to some technologies, but not to others.
2. Actual life cycle emissions are dependent on factors outside the scope of the rulemaking that may change in the future.

With respect to the first reason, even if we were to accept the AISI comments, this would not allow us to address life cycle emissions for other technologies. For example, how would the agencies address potential differences in life cycle emissions for shifting from a manual transmission to and AMT, or the life cycle emissions of aerodynamic fairings? If we cannot factor in life cycle impacts for all technologies, how would we do it for weight reductions? Given the complexity of these rules and the number of different technologies involved, we see no way to treat the technologies equitably.

26 Oil and Natural Gas Sector: Emission Standards for New and Modified Sources; 40CFR 60, May 12, 2016.
Commenters do not provide the information necessary to address this challenge, nor are the agencies aware of such information.

The second reason is potentially more problematic. This rulemaking is setting standards for vehicles under specific statutory provisions. It is not regulating manufacturing processes, distribution practices, or the locations of manufacturing facilities. And yet each of these factors could impact lifecycle emissions. So while we could take a snapshot of lifecycle emissions at this point in time for specific manufacturers, it may or may not have any relation to lifecycle emissions in 2027, or for other manufacturers. Consider, for example, two component manufacturers: one that produces its components near the vehicle assembly plant, and relies on natural gas to power its factory; and a second that is located overseas and relies on coal-fired power. How would the agencies equitably factor in these differences without regulating these processes? AISI, in its comments, does not address the issue much less offer potential solutions.

Given these challenges, as well as the other factors already mentioned, the agencies are not adopting lifecycle-based standards in this rulemaking.

Electric Vehicles

The agencies note further that a consequence of the tailpipe-based approach is that the agencies will treat vehicles powered by electricity the same as in Phase 1. In Phase 1, EPA treated all electric vehicles as having zero emissions of CO\textsubscript{2}, CH\textsubscript{4}, and N\textsubscript{2}O (see 40 CFR 1037.150(f)). Similarly, NHTSA adopted regulations in Phase 1 that set the fuel consumption standards based on the fuel consumed by the vehicle. The agencies also did not require emission testing for electric vehicles in Phase 1. The agencies considered the potential unintended consequence of not accounting for upstream emissions from the charging of heavy-duty electric vehicles. In our reassessment for Phase 2, we have found only one all-electric heavy-duty vehicle manufacturer that has certified through 2016. As we look to the future, we project limited adoption of all-electric vehicles into the heavy duty market. Therefore, we believe that this Phase 1 provision is still appropriate. Unlike the 2017-2025 light-duty rule, which included a cap whereby upstream emissions would be counted after a certain volume of sales (see 77 FR 62816-62822), we believe there is no need to establish a cap for heavy-duty vehicles because of the small likelihood of significant production of EV technologies in the Phase 2 timeframe. Commenters specifically addressing electric vehicles generally supported the agencies’ proposal. However, some commenters did support accounting for emissions from the generation of electricity in the broader context of supporting full lifecycle analysis.
2 Vehicle Simulation Model

2.1 General Comments

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Vehicle Simulation, Engine Standards and Test Procedures

As in the Phase 1, the output files of the GEM executable distributed with the Phase 2 proposal display only the composite fuel consumption and emissions results and not the individual cycle results. Basing the fuel efficiency standard on a weighted average of cycle-specific fuel consumption results makes sense. However, there is no justification for not providing these cycle-specific results to the GEM user, for whom the individual cycle results clearly constitute valuable information about vehicle performance. [EPA-HQ-OAR-2014-0827-1280-A1 p.6]

Furthermore, the individual cycle results for each model should be reported in a publicly accessible electronic database. The variation in duty cycles experienced by heavy-duty vehicles, even within a vehicle category, is among the challenges to creating a sound and equitable program of standards. Knowing how vehicles compare on individual cycles can be much more valuable information than the composite results for some purchasers, especially those for whom the relevant duty cycle involves much more or much less transient and idle operation than is reflected in the weighting assumed for purposes of the standards. [EPA-HQ-OAR-2014-0827-1280-A1 p.6]

- The GEM executable should be revised to report sufficient fuel efficiency performance data to permit buyers to assess fuel consumption over customized duty cycles. In particular, outputs should include fuel efficiency results over each discrete test cycle. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]

- Full vehicle integration. The proposal takes very important steps toward making the standards full-vehicle standards. In Phase 2, tractor and vocational vehicle certification levels will reflect the efficiency of the engine sold with the vehicle, rather than a default engine, and how that engine operates in the vehicle. Transmission efficiency, which allows for several additional percentage points savings, will be recognized and credited for the first time. Integration of engine and transmission can be captured through a powertrain test, an important option introduced in the proposal. The greenhouse gas emissions model (GEM), which is used to calculate vehicles’ fuel efficiency, will become more sophisticated and allow many more technologies to contribute to certified fuel efficiency. The vehicle certification protocols will promote integration of engine, transmission, and vehicle components. [EPA-HQ-OAR-2014-0827-1280-A1 p.5] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.54-55.]]

Improved functionality
In the MATLAB version of the model, it is possible to obtain detailed outputs for the 55-mph, 65-mph, and transient modes that include average engine speed and torque; crankshaft, transmission, and axle work; number of shifts; and grams fuel, grams CO2, and grams CO2 per ton-mile. This “detailed output” option is a change noted in the documentation for GEM P2v2.1, and we expect this functionality to be available in the final, executable version of GEM. We support this addition to GEM output options. The ability to view these results for individual modes will allow end users to better understand the benefits of technologies for their own duty cycles, which may be better represented by weighting the three drive cycles differently than they are weighted for certification purposes. [EPA-HQ-OAR-2014-0827-1896-A1 p.4]

**Organization:** Autocar, LLC

**GEM**

The GEM program comprises a complex emissions simulation tool, which heretofore Autocar has not utilized. However, to identify and address any potential issues with GEM P2v2.1, EPA and DOT must allow stakeholders a sufficient opportunity to perform their own simulations. Yet EPA has not posted the new version for download from the Web, instead requiring that people request a copy on a CD, thereby delaying receipt of the updated (version 2) model with the known bugs removed. [EPA-HQ-OAR-2014-0827-1869-A1 p.2]

Only through these simulations can interested parties such as Autocar assess whether EPA’s claims about the effectiveness of various compliance measures matches what data from the field shows, and provide the agencies appropriate commentary on its proposed rule. This is especially true for small manufacturers such as Autocar that were exempt from Phase 1 and have no prior experience with GEM modeling. To further the agencies’ efforts at developing an appropriate compliance model, Autocar requests an extension to run full and simplified GEM simulations (as contemplated by the Memorandum referenced in Section 2 below) with the goal of identifying any issues with, or limitations of, the model. That “simplified model” is not yet available for parties to use and review, making commentary on that approach even more difficult. [EPA-HQ-OAR-2014-0827-1869-A1 p.2]

**Organization:** California Air Resources Board (CARB)

**Neutral/Provide Additional Information Comment**

**Comment – Overall Phase 2 GEM**

The GEM was developed by U.S. EPA for demonstrating compliance with U.S. EPA’s GHG emissions and NHTSA’s fuel consumption vehicle standards, applicable to class 7 and 8 combination tractors, trailers, and class 2b-8 vocational vehicles. In Phase 1 GEM, most of the simulation parameters were predefined and there were only very limited number of user input parameters. The proposed Phase 2 GEM (GEM P2v1.0) was substantially improved to better model real-world impacts of various fuel efficiency technologies. GEM P2 allows more user input simulation parameters including engine-specific fuel maps, transmissions, and drive axle ratios, which will increase accuracy. The model was validated using approximately 130 vehicle variants, using both chassis and powertrain dynamometer tests. [EPA-HQ-OAR-2014-0827-1265-A1 p.122]
CARB staff commends U.S. EPA for taking significant steps to improve the model. [EPA-HQ-OAR-2014-0827-1265-A1 p.122]

Organization: Caterpillar Inc, et al.

The GEM simulation, fed by appropriately representative vehicle and component characteristics and operational duty cycles, is the best way to compare real-world performance of vehicles. We fully support this approach, but remain concerned that the regulatory measurements and duty cycles must be firmly grounded in engineering principles and a thorough survey of how these vehicles are used. Otherwise, the assessments of technology impacts will not match real-world results. Our assessment is that the proposed rule needs significant improvements to aerodynamic measurement and analysis, audit margins, duty cycles, and other areas in order to meet this objective. Indeed, the provisions as proposed have the effect of increasing real-world stringency requirements by as much as 50% beyond the intended improvements. [EPA-HQ-OAR-2014-0827-1215-A1 p.4]

Organization: Cummins, Inc.

The Greenhouse Gas Emissions Model (GEM) is applied to demonstrate compliance for vocational vehicles and combination tractors. GEM is a more practical solution compared to chassis dynamometer testing for the abundant variations of vehicles in this market segment. Full vehicle testing is costly considering test facilities and the large proliferation of vehicles that would need to be tested. However, the agencies must recognize that a vehicle modeling approach significantly impairs the ability of the agencies to verify and enforce emissions control at the vehicle level in use. Engine standards are based on direct, experimental measurement and verification of performance, unlike model-based vehicle standards. Hence, it is imperative that use of GEM at the vehicle level is complemented with a separate engine standard to ensure compliance and real-world CO2 reductions. [EPA-HQ-OAR-2014-0827-1298-A1 p.7]

Organization: Daimler Trucks North America LLC

Regulations are correct in not requiring GEM inputs be finalized before vehicle build - Although no portion of the regulation requires a GEM number in advance of the vehicle build, 1037.520(a)(2)(ii) with its reference to the calibration identifier (an item not associated with a vehicle until the engine is installed, at the vehicle build) might lead someone to mistakenly think that all of the GEM inputs including engine inputs will be known prior to building a vehicle. That is not the case. Engines are pulled from inventory and may have calibrations that are a few weeks or months old. The engines may be in inventory with newer engines usable in the same vehicles but with newer calibrations. To vehicle manufacturers, either calibration is acceptable. Only after the vehicle manufacturer pulls the engine from the inventory does the vehicle's engine calibration get decided: was the engine the older one or a newer one? Plus, engines fuel maps can be reflashed during vehicle manufacturing, if an engine's programming (e.g., selection of map and torque curve) contains inconsistencies. As a result, the EPA cannot expect us to have an exact GEM value until the vehicle and its engine are united. This should not matter to the EPA, and the EPA's regulations do not require a priori knowledge of the calibration. But we wish to make clear, in order to avoid any misunderstanding, that a priori knowledge of the calibration that will be associated with a vehicle is not possible. 1037.520(a)(2)(ii). [EPA-HQ-OAR-2014-0827-1164-A1 p.108]

Organization: Eaton Vehicle Group
Ensure the standards are performance-based: The EPA has adopted a computer model simulation approach to vehicle certification that in principle drives performance-based standards. However, we recognize that it is impossible to simulate all technologies that contribute to fuel efficiency and that at some point, a limit is reached between the accuracy of physics-based models coded in GEM, their fundamental modeling assumptions, and the quality of measured data in the lab. We believe the powertrain test can be used to quantify the benefits of many technologies. In rare cases, such as predictive powertrain management [Verma 2015], post-processing the GEM results is appropriate with a “slightly conservative” offset based on industry best practice (sometimes referred to as “Drop-down menus”) is recommended. However, these should be used conservatively so they do not compete unfairly with technologies that should be recognized through a powertrain test. [EPA-HQ-OAR-2014-0827-1194-A1 p.4]

**Organization:** Environmental Defense Fund (EDF)

D. Modify the engine inputs in GEM to reflect all GHG emissions; not just CO2

As it is currently designed, the engine inputs into GEM only reflect emissions of carbon dioxide. This is a significant oversight when certifying alternative fueled vehicles. Methane emissions from natural gas trucks greatly exceed the proposed methane standard. As EPA noted in the proposed rule, “for the initial natural gas engine certifications that EPA received for 2014, the truck manufacturers chose to continue to emit high levels of methane.” The final standard must ensure GEM engine inputs accurately reflect emissions from NGVs and other vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.42]

**Organization:** Ford Motor Company

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, pp. 29-30.]

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, pp. 159-160.]

Ford has some concerns with the accuracy of the greenhouse gas emissions model used to determine compliance for vocational vehicles, particularly in the case of vehicles with heavy duty gasoline and light heavy duty diesel engines. Ford recommends that data is used to validate the model for these engines and vehicles. Ford will provide detailed written comments on this subject once we have fully evaluated the model. We’ll continue to cooperate with EPA and NHTSA requests for data to support the refinement of the GEM model.

**Organization:** International Council on Clean Transportation (ICCT)

*Data sharing.* We commend the agencies for continuing to conduct rigorous analysis and share detailed data that underpins their regulatory development work. The level of testing, analysis, and data sharing by regulatory agencies within the regulatory process, as exemplified in the NODA, is commendable. For example, the data on the engine maps, model development, powertrain procedures, aerodynamics testing
is all very helpful in describing important underlying factors related to the agencies’ movement from the proposal and final rule. [EPA-HQ-OAR-2014-0827-1876-A1 p.2]

**Organization:**  Motor & Equipment Manufacturers Association (MEMA)

MEMA recognizes the scope and scale of the agencies’ endeavors to conduct a significant amount of research and data to offer a proposal that is more representative of real-world applications. Suppliers are the key innovators, developers and manufacturers of many of the technologies and systems recognized in the GEM program (e.g. lightweight materials, automatic tire inflation systems, advanced cruise control systems, improved aerodynamics, workday idle reduction systems, integrated drivetrains and transmissions). As such, MEMA supports the proposed expansion and modification of the Phase 2 greenhouse gas emissions model (GEM) because it recognizes a wider variety of systems and technologies in its menus and calculations compared to Phase 1. That notwithstanding, once the technology choices in GEM are finalized, they are essentially locked-in and making changes will be difficult. The result is the consequence of creating technology “winners and losers” unless a mechanism is created to assure the GEM remains a robust tool throughout the length of the standard. Therefore, MEMA proposes the agencies consider an approach to make the GEM a “living and breathing” tool to measure, include and credit future technologies that have quantifiable efficiency benefits. Such a process would be a streamlined, efficient and cost-effective way to drive adoption of fuel efficient technologies via the GEM. [EPA-HQ-OAR-2014-0827-1274-A1 p.8-9] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.195.]]

Certainly MEMA supports and appreciates the need for long-term certainty in these standards for investments, product planning and research and development. Yet, over the length of the standards, it is plausible and inevitable that breakthroughs in technologies will happen; some breakthroughs are on the horizon but not yet commercialized and some are not yet discovered. Future developments in current technologies or creation of new ones, would be essentially locked-out of the GEM menus once this rule is finalized. Adding technologies that approach commercialization during the course of Phase 2 to the credit menu allows for adjustment of an existing credit if evidence emerges to better quantify benefits. [EPA-HQ-OAR-2014-0827-1274-A1 p.9]

Therefore, as technologies evolve and become commercially available, MEMA asks the agencies to consider a streamlined mechanism as part of the rule’s structure that would also allow for GEM to evolve. Such an approach would allow for the future inclusion of technologies that have verifiable benefits at defined/designated milestones. [EPA-HQ-OAR-2014-0827-1274-A1 p.9]

It is important that such a process be public, transparent, data driven and have defined milestones. Perhaps this process could take the form of public government-industry workshops or forums announced in the Federal Register, in a manner similar to those held by the California Air Resources Board. Here industry stakeholders – including suppliers – can petition to amend the GEM either with new technology additions or modifications to existing GEM values. The petitioners’ evidence must be robust with data to support amendments to the GEM. It will further allow the GEM to account for adjustments if evidence emerges that there are quantifiable, verified improved benefits. Such a process would have to be demonstrable, rigorous, transparent and well-managed (i.e. accurate tracked changes and GEM version control). This proposed process offers an approach not only for industry stakeholders, but also government entities to benefit from having as robust a model as possible that reflects what is
available and of benefit in the marketplace that can be properly accounted for during the length of the rule. [EPA-HQ-OAR-2014-0827-1274-A1 p.9]

Consequently, a “living, breathing” and flexible GEM will increase market penetration and commercialization of these important technologies as well as drive continuous innovation and improvements. OEMs and engine manufacturers will be incentivized to always look beyond the horizon. Suppliers will be encouraged to continue to innovate new and creative technologies to take the next generation of commercial vehicles to another level of efficiency and performance. [EPA-HQ-OAR-2014-0827-1274-A1 p.9]

**Address Technical Problems with Phase 2 GEM Executable File** [EPA-HQ-OAR-2014-0827-1274-A1 p.9]

Certainly such a complex compliance tool must be ensured to be accurate, consistent and reliable. Unfortunately, some of our members that have been running the publicly released GEM executable file have encountered some problems (e.g. errors with coding and algorithms). Other stakeholders testified in the public hearings that they have experienced problems running the GEM executable files and expressed serious concerns. MEMA urges the agency to resolve these “bugs” before issuing a final rule and to utilize the administrative law tools available to ensure that this compliance mechanism is failsafe. [EPA-HQ-OAR-2014-0827-1274-A1 p.9-10]

**Organization:** Navistar, Inc.

Navistar feels the following are key areas the agencies must address: [NHTSA-2014-0132-0094-A1 p.2]

- The Greenhouse Gas Emission Model (GEM) must be accurate, flexible and fully developed. [NHTSA-2014-0132-0094-A1 p.2]

**Organization:** PACCAR, Inc.

**Greenhouse Gas Emissions Model (GEM) Issues**

EPA and NHTSA have acknowledged that there are a number of issues with the GEM model as it currently configured, and therefore have outlined some revisions during the public comment period. PACCAR and EMA have worked with staff from the agencies after GEM revisions were made public. The EMA comments reflect these discussions. Furthermore, PACCAR has performed substantial testing with the GEM tool and have encountered a number of issues that remain unaddressed. A discussion of each of these remaining issues follows. [EPA-HQ-OAR-2014-0827-1204-A1 p.17]

**Organization:** SABIC Innovative Plastics US LLC

SABIC also encourages EPA to release a 32-bit version of the software, in addition to the currently available 64-bit version, so that more users may evaluate the software. SABIC urges the agencies to resolve any technical issues before issuing the final rule. SABIC also points out the need to keep the software current to reflect changes in the truck marketplace in coming years. [EPA-HQ-OAR-2014-0827-1207-A1 p.6]
However, SABIC notes the critical need to improve the publicly released GEM software and respectfully requests that technical issues be resolved prior to the final rule. [EPA-HQ-OAR-2014-0827-1207-A1 p.7]

**Organization:** Truck Renting and Leasing Association

We also support: (1) the use of more robust models to more accurately simulate the work done by vocational vehicles; (2) greater weighting of emission benefits from currently available and commercially viable components and technologies in the GEM model [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

**Organization:** Volvo Group

Volvo Group was pleased to be an early test site for the GEM simulation and we have fed back findings that have been corrected or are in process of being corrected. Unfortunately every change in GEM has potential to impact the outputs for vehicle GHG emissions and fuel consumption. Combining GEM changes with other regulatory changes (aerodynamic method, duty cycles, vocational vehicle segmentation, alternative engine certification, highway grades, etc.) we are working against a constantly moving target in trying to assess where our technology plans put us against the proposed standards that are also subject to change. None-the-less, we offer our input on changes still needed in GEM. [EPA-HQ-OAR-2014-0827-1290-A1 p.50]

The NoDA proposes an updated version of the Greenhouse Gas Efficiency Model (“GEM”) and associated protocol for determining inputs. Many of the changes represent important improvements to earlier versions of GEM. There are, however, some critical elements that are not representative and risk driving designs and specifications that do not align with real world gains. We have provided details in our comments, and will continue to support effective resolution, though we are very concerned about the ability to appropriately resolve these matters within the agencies’ rulemaking timeline. [EPA-HQ-OAR-2014-0827-1928-A1 p.2-3]

**Organization:** Waste Management (WM)

However, EPA asked us to provide our thoughts on the assumptions used in the GEM model 2.0 relating to heavy-duty refuse trucks in the vocational category, and we have included comments on those assumptions as well. [EPA-HQ-OAR-2014-0827-1214-A2 p.2]

**WM Supports a Vehicle Testing Approach that Best Measures Real World Vehicle Performance**

We understand that EPA is continuing to evaluate alternative engine mapping tools to assess vehicle fuel efficiency and GHG emissions performance. Our primary concern as a major fleet operator and
purchaser is that the investments we make in new vehicles will continue to allow us to meet our customers’ needs and our operational requirements. Towards that end, we support engine and vehicle assessment tools and approaches that most accurately reflect the fuel efficiency and emission reduction performance achievable by a refuse vehicle operating in real world scenarios. [EPA-HQ-OAR-2014-0827-1214-A2 p.7]

**WM Urges Further Review of the Handling of Natural Gas Engines in GEM**

Based on our discussions with vehicle and engine OEM partners, we are concerned that GEM does not account for the lower carbon content of natural gas when calculating GHG emissions rates. We strongly urge the agencies to review this aspect of the GEM model and make the appropriate corrections to the model. [EPA-HQ-OAR-2014-0827-1214-A2 p.7]

**Response:**

While the agencies received many comments supporting the Phase 2 improvements to GEM, we also received comments supporting additional changes to GEM. The more general comments are addressed here, while the more specific comments are addressed in Sections 2.2 through 2.6 below.

We have made significant marginal improvements to GEM based on comments. For example, we have revised the way in which GEM treats natural gas and other alternative fuels.

**Technical Accuracy of GEM**

Some commenters stressed the importance of the technical accuracy of GEM. The more specific comments are addressed in Section 2.3 below. See Chapter 4 of the RIA for a broader discussion of GEM’s accuracy.

While we share the goal to have GEM accurately simulate overall vehicle performance in an absolute sense, it is actually more important that GEM is accurate in relative comparisons. This is because the agencies used the same version of GEM to calculate the stringency of the standards as was used to evaluate baseline performance for this rulemaking. The ultimate purpose of the FRM version of GEM will be to evaluate changes or additions in technology, and compliance is demonstrated on a relative basis to the numerical standards that were also derived from GEM. The importance of relative comparisons can be further explained with the following simplified example.

Assume you have two simulation models: one that says a baseline vehicle with Bin 3 aerodynamics and a conventional automatic transmission would be 90 g/ton-mile, and another that said the same vehicle would be 95 g/ton-mile. Assume also that there was a similar vehicle that was the basis of the new standards that had Bin 4 aerodynamics and a dual-clutch transmission. If both models simulated the second vehicle as being 10 g/ton-mile better than the baseline vehicle, then the models would work equally well for compliance as long as they were also used to set the standards. With the first model, we would set the standard at 80 g/ton-mile. And with the second, we would set the standard at 85 g/ton-mile. In both cases, manufacturers adding Bin 4 aerodynamics and dual-clutch transmissions would meet the standard. In other words, the two models would be equivalent in terms of measuring the effect of the change in technology on emissions, even though the absolute values were significantly different.

We largely agree with Eaton’s comment that it is appropriate in some cases for GEM to be conservative, especially where manufacturers have the option to more accurately reflect the technology by performing
powertrain testing. Nevertheless, we have done sparingly, and generally avoid intentionally introducing significant inaccuracy into the model to be overly conservative.

Usefulness of GEM

Some commenters, such as ACEEE, suggested ways to broaden the usefulness of GEM. While we have tried to make the FRM version of GEM relatively user-friendly, we note that the purpose of GEM is as a compliance tool. Thus, our focus to date has been on making GEM both technically sound and equitable, so that it will accurately and fairly represent the various technologies. We believe the FRM version of GEM meets these criteria. Having said that, we understand the comments supporting the broader perspective, and we may consider developing more user-friendly versions for broader purposes in the future. Should we do so, we would intend maintain the same numerical outputs as the FRM GEM so as to not create issues related to stringency.

Using GEM to Estimate Methane Emissions

EDF supported modifying GEM to simulate methane emissions and factor those emissions into the vehicle standards. We are not doing so for several reasons:

- The FTP-based controls are adequate.
- The Phase 1 and Phase methane standards are anti-backsliding or cap standards. Thus, a more complicated treatment is not warranted.
- Since measuring methane is somewhat more challenging than for most other exhaust pollutants, requiring methane measurements for all fuel maps would increase test burden, without significant additional benefit
- GEM is used for both EPA’s standards and NHTSA’s fuel consumption standards. Addressing methane in the vehicle standards would create disharmony between the programs.

Future changes to GEM

The purpose of this rulemaking is to achieve in-use emission and fuel consumption reductions by requiring manufacturers to demonstrate that they meet the promulgated emission standards. Thus, it is important that GEM simulations be reasonably representative of in-use operation. Testing that is unrepresentative of actual in-use operation does not necessarily tell us anything about whether any emission reductions occur. However, we recognize that certain simplifications are necessary for practical simulations. In the past, EPA has addressed this issue by including in our testing regulations a process by which EPA can work with manufacturers to adjust test procedures to make them more representative of in-use operation. For engine testing, this provision is in 40 CFR 1065.10(c)(1), where EPA requires manufacturers to notify us in cases in which they determine that the specified test procedures would result in measurements that do not represent in-use operation. That provision states:

The objective of the procedures in this part is to produce emission measurements equivalent to those that would result from measuring emissions during in-use operation using the same engine configuration as installed in a vehicle. However, in unusual circumstances these procedures may result in measurements that do not represent in-use operation. You must notify us if good engineering judgment indicates that the specified procedures cause unrepresentative emission measurements for your engines. Note that you need not notify us of unrepresentative aspects of the test procedure if measured emissions are equivalent to in-use emissions. If you notify us of unrepresentative procedures under this paragraph (c)(1), we will cooperate with you to establish whether and how the procedures should be appropriately changed to result in more representative measurements. While the provisions of this paragraph (c)(1) allow us to be
responsive to issues as they arise, we would generally work toward making these testing changes generally applicable through rulemaking. We will allow reasonable lead time for compliance with any resulting change in procedures.

Although we are not adopting an equivalent provision for GEM at this time, we expect similar principles to apply. To the extent that GEM fails to represent in-use emission, we would expect to work with manufacturers to address the issue – under the existing regulations where possible, or by promulgating a new rulemaking.

In some respects, powertrain testing can be considered to be a reference method for this rulemaking. Because manufacturers have the option to perform powertrain testing instead of engine-only fuel mapping, the stringency of the final standards can be traced to powertrain testing. In other words, methods that can be shown to be equivalent to powertrain testing can be considered to be consistent with the testing that was used as the basis of the final Phase 2 standards. Thus, it may be useful in the future to consider equivalency to powertrain testing as an appropriate criterion for evaluating changes to GEM to address new technologies. Consider, for example, a new technology that is not represented in GEM, but that is reflected in powertrain testing. The agencies could determine that it would be appropriate to modify GEM to reflect the technology rather than to require manufacturers to perform powertrain testing. In such a case, the agencies would not consider the modification to GEM to impact the effective stringency of the Phase 2 standards because the new version of GEM would be equivalent to performing powertrain testing.

Similarly, the agencies may revise GEM in the future to reflect technologies otherwise being recognized as off-cycle technologies. In other words, the agencies could determine that it would be appropriate to modify GEM to reflect the technology rather than to require manufacturers to go through the off-cycle process, and could do so without impacting the effective stringency of the Phase 2 standards because the new version of GEM would be equivalent to the off-cycle approach.

**Opportunity to Comment on Phase 2 GEM**

Some commenters maintain that they did not receive sufficient notice to provide informed comment on the GEM. The agencies disagree. As described in Section II.C of the Preamble and Section 15.5 of this RTC, the agencies have provided numerous opportunities for comment on GEM, and its iterative development. Even at proposal, Phase 2 GEM provided nearly all of the essential features of the version we are promulgating in final form. These include: (1) the reconfiguration of the engine, transmission, and axle sub-models to reflect additional designs and to receive manufacturer inputs; and (2) the addition of road grade and idle cycles for vocational vehicles, along with revised weighting factors. Moreover, the changes the agencies have made to GEM in response to public comment indicate that those comments were highly informed by the proposal. The agencies thus do not accept the contention that commenters were not afforded sufficient information to provide meaningful comment on GEM.

**2.2 Proposed Modifications to GEM**

**Organization:** Alcoa

As it is currently written, the proposed GEM methodology creates two lightweighting categories. The first category is unloaded and partially loaded. In lightweighting, this equates to the emissions reduction benefit. On trucks and trailers, the GEM assumes a light weighted vehicle will realize an emissions reduction for 66% of the vehicle usage. On vocational vehicles, the GEM assumes a light weighted
vehicle will realize an emissions reduction for 50% of vehicle usage. [EPA-HQ-OAR-2014-0827-1216-A1 p.1]

The second category is when the vehicle is fully loaded. In lightweighting, this is the emissions avoidance benefit. The GEM calculates trucks and trailers run fully loaded for 34% of their usage and that vocational vehicles run fully loaded for 50% of their usage. [EPA-HQ-OAR-2014-0827-1216-A1 p.1]

Currently, the GEM only recognizes benefits in the first category, emissions reductions, while disregarding the benefits in the second category, emissions avoidance. [EPA-HQ-OAR-2014-0827-1216-A1 p.2]

Alcoa believes this is a serious oversight. Although emissions reduction is a critical component in an overall emissions strategy, it can never fully ameliorate the problem of greenhouse gases and environmental particulate matter. Rather, the only realistic path to a goal of zero emissions is through emissions avoidance. [EPA-HQ-OAR-2014-0827-1216-A1 p.2]

Alcoa appreciates the difficulty in measuring real world benefits of some emissions avoidance technologies like logistics Improvements. However, Alcoa hopes this difficulty will not impede the agencies from recognizing easily calculated emissions avoidance benefits of technologies like lightweighting. [EPA-HQ-OAR-2014-0827-1216-A1 p.2]

For example, if an OEM reduces the weight of their vocational vehicles by 1,000 lbs, the fleets will be able to use that weight to increase the payload, reducing the total number of needed trips in fully loaded applications. Since vocational applications run fully loaded for 50% of their usage, we can see that the 1000 lbs weight reduction results in emissions avoidance of 3.3% through reduced trips by simply dividing the weight reduction by the baseline payload, then multiplying by the duty cycle (For vocational applications, this would be 0.5 * [weight reduction / 15,000]). [EPA-HQ-OAR-2014-0827-1216-A1 p.2]

Fleets can see similar emissions avoidance benefits on their trucks. According to research conducted by Ricardo Consulting Engineers, fleets can realize 3,300 lbs of light weighting benefits on 'aluminum intensive' class 8 tractor trailers. Using the EPA's assumption that tractors and trailers run fully loaded for 34% of their usage, an 'aluminum intensive' class 8 tractor trailer will realize an emissions avoidance benefit of almost 3% through reduced trips. [EPA-HQ-OAR-2014-0827-1216-A1 p.2]

Every day, fleets and OEMs work to maximize their efficiency. One very real benefit of these efficiency efforts is the avoidance of emissions In the first place. In addition to maintaining the current lightweighting credits for emissions reductions, Alcoa requests the agencies make adjustments to the final rule that will incorporate an appropriate recognition of the role of lightweighting plays in fleet efficiency, allowing fleets and OEMs to be credited for a portion of their activities which avoid the generation of emissions. [EPA-HQ-OAR-2014-0827-1216-A1 p.2]

Response:

The commenter misunderstands the functioning of lightweighting in GEM and the metric of the standards. Because the metric is grams (or gallons) per ton-mile, both types of benefits described by the commenter – emissions reductions and emissions avoidance -- are applied. When a user enters a positive value in the GEM input field for weight reduction, GEM allocates this reduced weight as described by
the commenter both ways: both increased payload and avoided emissions. In this way, manufacturers get full credit for every pound they certify as being reduced.

**Organization:** Allison Transmission, Inc.

The Greenhouse Gas Emission Model ("GEM") used in this rulemaking has been improved from Phase 1, but still requires several changes in order to properly credit emission reduction technology such as Neutral-Idle and Stop-Start technologies. To the extent GEM is revised, the agencies must allow for sufficient public review and comment. Some of the areas that need to be addressed include: [EPA-HQ-OAR-2014-0827-1284-A1 p.2]

- Automatic Neutral at Stop should be included in GEM for tractors. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]
- Drive cycles used in GEM should be reweighted to include additional transient operation. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]
- Variable Power Accessory Load should be included in GEM. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]
- Road grades should be better represented to reflect real-world highway conditions. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]

EPA and NHTSA should not include DCTs within GEM or through post simulation adjustment. There is not a sufficient basis in the record for this rulemaking to support crediting DCTs. Moreover, recent testing indicates that transient and idle operation of DCTs utilize more fuel than an Allison 2000 Series™ transmission. [EPA-HQ-OAR-2014-0827-1284-A1 p.3]

**VI. GEM Should Account for Differences in Vehicle Configurations That Cannot Meet Required Drive Cycles**

After reviewing the Proposed Rule and the NODA, it is apparent that EPA and NHTSA have not addressed an underlying issue in GEM’s modeling of emission results. That is, GEM does account for engine/transmission/vehicle configurations that cannot meet duty cycles utilized. This means that vehicles configurations that cannot maintain the prescribed vehicle speed during the GEM cycle will receive a GHG benefit from GEM since aero drag decreases along with decreasing speed. [EPA-HQ-OAR-2014-0827-1892-A1 p.10]

To simulate the effects of underperformance over an entire cycle, one can build a family of engines of different HP and Torque ratings to simulate a range of vehicle performance in GEM. Using this family of curves, a general approximation of aero drag benefit can be determined. For example, using the GEM 455 HP heavy duty engine to build a family of curves from 455 HP down to 215 HP, a series of identical vehicle (Sleeper Cab, High Roof, Tractor) configurations with the following torque curves were simulated to judge the impact on meeting the cycle and creating a GHG measure. [EPA-HQ-OAR-2014-0827-1892-A1 p.10]

[Chart of torque curves can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1892-A1]
Using these torque curves, as expected, Allison simulations show that lower rated engines were less likely to track the cycle. See the chart below. [EPA-HQ-OAR-2014-0827-1892-A1 p.10]

[Chart of simulations can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1892-A1]

The grams of CO2/ton-mile generated for each segment of the GEM run is plotted on the next graph. For lower rated engines that cannot maintain the drive trace, a benefit is seen from GEM, and the overall GEM measure of grams of CO2/ton-mile closely tracks with the benefit seen on the 65 MPH segment of the cycle where the underperformance is most. Based on this result, Allison believes the bulk of the benefit is from reduced aero drag due to the lower speeds on the high speed cycles. [EPA-HQ-OAR-2014-0827-1892-A1 p.11]

[Chart of CO2/ton-mile can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1892-A1]

Unless the aero benefit from underperformance is captured and compensated, vehicles that cannot maintain the vehicle speed trace could receive GHG benefits from GEM. Allison suggests that EPA track the difference in speed between the trace and the simulated configuration vehicle speed during each phase of the test cycle, and then compensate for underperformance to the trace by applying an offset to the CO2 emissions result during that underperformance period. [EPA-HQ-OAR-2014-0827-1892-A1 p.11]

In addition to technical accuracy, there are policy concerns which should also drive this result. If this matter is not addressed, manufacturers may build vehicles that cannot meet HD performance requirements for the work required (as evidenced by not meeting the cycle). In an extreme case, an end user fleet may need to purchase additional vehicles to get jobs done because the original purchased vehicles could not meet the performance requirements. More vehicles means more CO2 emitted. In a less extreme case, an end user fleet would have the underperforming vehicles on the road more hours per day to get the same amount of work done as vehicles that can meet the prescribed cycles. This again would result in additional GHG emissions. [EPA-HQ-OAR-2014-0827-1892-A1 p.12]

EPA and NHTSA Must Include Road Grade in Certification Duty Cycles

EPA and NHTSA have proposed to revise the urban and rural highway duty cycles to incorporate changes in road grade. The agencies rely on various analyses to derive road grade profiles, including profiles recommended by the National Renewable Energy Laboratory (“NREL”). A memorandum supporting the proposed incorporation has been placed into the docket as has the NREL Analysis. As the agencies note, utilizing flat road grade profiles over constant speed tests not only does not reflect real world operation of vehicles, but also may result in unjustified crediting of underpowered vehicles or excessively downsped drivetrains. [EPA-HQ-OAR-2014-0827-1284-A1 p.31]

Allison supports incorporation of road grade profiles into the certification process. We agree with the agencies that incorporation of road grades into the 55 mph and 65 mph cycles is needed to better represent the actual use of vehicles and to account for differences in vehicle performance, emissions and fuel efficiency. Based on testing at Oakridge National Laboratory (“ORNL”) with the TC10 (represented by the chart below), the 55 and 65 mph cycles result in an engine being forced to operate over a wide torque band and speeds, from zero to full torque; the transmission is forced to downshift and upshift to maintain cycle speed. This better represents actual vehicle operation. [EPA-HQ-OAR-2014-0827-1284-A1 p.31]

[Chart, 'Datalog showing 65 mph drive cycle (with EPA proposed grades)' can be found on p.32 of docket number EPA-HQ-OAR-2014-0827-1284-A1]
Indeed, if EPA and NHTSA seek to make changes to road grade profiles in the final rule, Allison would only support increasing grades from the currently proposed grades. The proposed grade profile in GEM favors lower grades than the national average. Ideally, the grades should reflect the national average. The proposed alternate grades being developed by EPA for the 55 and 65 mph cycles are constructed from a series of mathematical “half hill” elevations. The half hills all have the same shape and are simply scaled vertically and horizontally. Thus, the grades simply do not look like grade profiles that would be encountered in the real world and the synthetic shapes may impact the transmission shifting algorithm in a manner which does not reflect real world use. The synthetic grades only achieve max grade for a short period of time, where real world grades have a longer duration at a grade which allows the transmission time to obtain the desired gear, stabilize and maintain acceptable performance. While we recognize that part of the agencies’ evaluation and purpose is to “compress[] a large, real-world, drive cycle dataset into a single, statistically representative cycle,” the current GEM profile favors lower grades than the national average. Allison therefore believes that a more aggressive grade profile should be incorporated into the final rule which would ideally reflect the U.S. average grade. [EPA-HQ-OAR-2014-0827-1284-A1 p.32]

The agencies are also specifically seeking comment on whether or not these duty cycles should also simulate driver behavior in response to varying traffic patterns. Allison’s analysis of TC10 testing at ORNL indicates that the addition of grade causes sufficient changes in throttle as to induce upshifts and downshifts. Given the difficulty in obtaining a representative driver model, Allison believes that the currently proposed grades are sufficient to utilize a full range of engine torques and thus largely achieves the intended testing result. Allison would note, however, that GEM P2v1.0 does not downshift correctly on grade; correcting this defect is necessary to ensure that GEM has proper shifting when grade profiles are applied. Specifically, Allison has observed this defect in GEM simulations, particularly with lower numerical axles, in which engine speeds dipped as low as 768 rpm at 100% throttle on positive grades. Meanwhile, the vehicle lagged behind the 55 mph duty cycle. Even with real world fuel economy type shift schedules, this degree of downshift reluctance is unrealistic. [EPA-HQ-OAR-2014-0827-1284-A1 p.33]

On Page 9 of Memo to Docket- GEM new release (GEM P2v1_1).docx (which accompanied the latest GEM release), the agency acknowledged this defect as follows: [EPA-HQ-OAR-2014-0827-1284-A1 p.33]

Issue: Late downshift after losing speed on cruise cycles with high grade and vehicles with low torque to weight ratios. [EPA-HQ-OAR-2014-0827-1284-A1 p.33]

Workaround: None, needs to be addressed as a calibration change to the shift schedule. [EPA-HQ-OAR-2014-0827-1284-A1 p.33]

Notes: Several solutions are available, we just need to pick one and implement it for the FRM. [EPA-HQ-OAR-2014-0827-1284-A1 p.33]

This matter should be addressed in the final rule after allowing for public comment. [EPA-HQ-OAR-2014-0827-1284-A1 p.33]

We are pleased that EPA and NHTSA agreed with our public testimony and provided the opportunity for additional review of the GEM in this NODA. We also appreciate the willingness of both agencies to
work with affected industry to refine the GEM and to address lingering technical issues with the operation of the model. The additional material and analysis placed in the docket for the NODA is also helpful in understanding the direction of EPA and NHTSA’s thinking regarding several other important aspects of the Phase 2 program. [EPA-HQ-OAR-2014-0827-1892-A1 p.1]

At the same time, Allison believes that additional improvements and alterations to GEM, as well as additional technical information, must be reviewed by staff prior to issuance of a final rule. Specifically, EPA and NHTSA should: [EPA-HQ-OAR-2014-0827-1892-A1 p.1]

• Revise the engine stop-start delay time downward to better reflect the actual operation of existing and planned systems. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

• Correct certain aspects of the Southwest Research Institute (“SwRI”) report, including its assessment of hybrid vehicle manufacturing and barriers to market entry. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

• Revise GEM’s methodology to estimate transmission losses which unduly favors some transmission types over others. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

• Address issues in GEM related to vehicle configurations that cannot meet duty cycle speeds. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

• Correct calculations concerning maximum engine speed. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

Allison looks forward to continuing to work with EPA and NHTSA as the final rule moves forward. As we indicated in Chicago, to the extent possible, GEM must reflect real world vehicles and their operation. While no model will ever be perfect, EPA and NHTSA must strive to improve the accuracy of the current model and continue to review relevant data. As we indicated in our testimony - since GEM affects the stringency of the standards and largely provides the compliance mechanism for the Phase 2 rules - any inaccuracies in GEM could result in unjustified benefits and detriments to different transmission architectures as well as counter-productive effects in the marketplace. Further improvements are therefore needed. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

---

50 Development of an Alternative, Nationally Representative, Activity Weighted Road Grade Profile for Use in EPA GHG Certification of Medium- and Heavy-Duty Vehicles, May 13, 2015.

52 Data from Oak Ridge National Lab test cell, Cummins ISX15 engine, Allison TC10 10-speed transmission, weight 67,000 lb, July 2015. A larger version of this chart is also provided as Attachment 5.

Response:

We have made significant improvements on GEM based on many constructive and helpful comments from public. Those major changes can be summarized as follows:

• Modified road grade profile for 55- and 65-mph cruise cycles

• Revised idle cycles within the vocational vehicle duty cycles, and new vocational cycle weightings
• Made significant changes on the input file structures. Examples includes additions of columns for axle configuration (“6x2”, “6x4”, “6x4D”, “4x2”), and additions of a few more technology improvement inputs, such as “Neutral Idle and Start/Stop.”

• Made significant changes on output file structures. Examples include an option to allow the user to output detailed results on average speed, average work before and after transmissions, and the numbers of shift for each phase (55 and 65mph cycles and ARB cycle).

• Added input file for axle power losses (function of axle output speed and torque) and replaced single axle efficiency in model with lookup table of torque loss

• Added simulation of engine torque response with fast response region defined by engine displacement, and slower torque increase in boosted region with fast falloff on available torque

• Added regression models for all certification cycles to allow the user to simulate vehicle with cycle average approach

• Added different fuel properties according to 1036.530.

• Significantly improved shift strategy based on testing data

• Adjusted transmission loss & inertia scale factors per regulatory subcategory

• Added optional input table for transmission power loss data

• Added minimum torque converter lock-up gear input for AT

• Retuned the default transmission mechanical efficiency based on the testing data

• Added neutral idle and start/stop features during simulation

• Adjusted shift and torque converter lockup strategy

• Added neutral idle as a technology for tractors.

The agencies agree with the comment from Allison that DCT should not be explicitly modeled in GEM at this time. Instead automated manual transmission can be selected for vehicles with DCTs, if good engineering judgment indicates that the DCT can be accurately represented in GEM as an automated manual transmission. See 40 CFR 1037.520 (g).

The agencies agree with the comments from Allison that the road grade profile should be nationally representative. Due to this the agencies have used the data from the NREL analysis along with in-use vehicle and engine data from manufacturers in creating the final road grade profile. See chapter 3.4.2.1 of the RIA for the detailed description of the process the agencies took in creating the road grade profile. However, we do not agree that we should penalize vehicles that cannot maintain the GEM speed cycles. Allison expressed the concern that “manufacturers may build vehicles that cannot meet HD performance requirements for the work required,” but we do not share this concern. Any benefit over the GEM cycle is likely to be too small to justify producing vehicles with insufficient power to perform the work. To the extent that this aspect of GEM has any impact on the vehicles, it is more likely to provide a small disincentive to design vehicles with significantly more power than needed, which could provide an in-use benefit.

The agencies agree with the comments from Allison on not including traffic in the cycles, and have finalized the rule without including traffic in the drive cycles.

In regard to the following comment from Allison:

“Revise the engine stop-start delay time downward to better reflect the actual operation of existing and planned systems.”

Engine stop-start is recognized in two of the five duty cycles in GEM for vocational vehicles. The first is in the transient cycle where the engine will shut down, 5 seconds after the vehicle speed has reached zero mph. Since the amount of drive idle time is not fully represented in the transient cycle the agencies
have finalized a separate cycle. If stop-start is selected, GEM determines the fueling for this cycle by assuming the engine is running for 10% of the time and is off for the remaining 90%. The assumptions for both of these cycles was determined, to account for not just the time the vehicles is in drive and at zero speed, but to also account for the overrides that are allowed in 40 CFR part 1037. If a manufacture designs a system that shuts down in less than 5 seconds after reaching zero speed or is operational during some of the exclusions defined in 40 CFR part 1037 the manufacturer can use the off cycle provisions to get credit for the system.

**Organization:** American Automotive Policy Council

**Vocational Vehicles and GEM Model** – AAPC supports the intended direction of the Phase 2 GEM approach. However, the execution of Phase 2 GEM is not complete and does not accurately reflect vocational vehicle performance and physical characteristics. AAPC has numerous recommendations related to these concerns and recommends establishing an industry/agency working group to address them. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

Phase 2 GEM Road Grade

EPA has proposed (EPA-HQ-OAR-2014-0827-1032) changing the GEM 55 mph road grade profile to include additional road grades up to 5%. While AAPC supports the inclusion of road grades in Phase 2 GEM, the VMT traveled on grades as well as the duration and frequency of the grades proposed for the Phase 2 GEM cycle is disproportionate to actual in-use operation. AAPC recommends lengthening or modifying the cycle to reflect the correct proportion and frequency of positive and negative road grades relative to VMT traveled. [EPA-HQ-OAR-2014-0827-1238-A1 p.32-33]

§ 1037.560 BASF EMGARD FE 75W-90 Fuel Efficient Synthetic Lubricant

While AAPC agrees with the agencies intent to incentivize advanced low friction lubricants in Phase 2 GEM, the reference to the BASF EMGARD FE 75W-90 specification in its entirety and comments about reducing frictional losses at every test point relative to EMGARD are too specific and should be generalized. 1037.510 should be revised to include a generic Viscosity Index Specification per ATSM D2270 and Viscosity cSt requirements per ASTMD-445 that meet or exceed the BASF EMGARD FE 75W-90 specifications. Furthermore the requirement about exceeding the EMGARD FE 75-90 at every test point should be removed and replaced by a cycle average friction reduction requirement. As proposed, a new lubricant could exceed the BASF EMGARD lubricant at every test point except one and manufacturers would be denied a GEM credit. [EPA-HQ-OAR-2014-0827-1238-A1 p.34]

Additionally, the agencies should incentivize other technologies that accomplish the same friction reduction vs. other mechanisms. For example, active axle lubricant heating with a standard mineral oil base lubricant and/or perhaps active axle cooling with a very low transmission oil type lubricant could achieve the same results. [EPA-HQ-OAR-2014-0827-1238-A1 p.34]

AAPC suggests technical corrections to various aspects of GEM:

- **Fuel property adjustments and reference fuels:** Gasoline test fuel adjustments per 1036.530 and 1036.535 introduce a significant new source of unneeded variability in the phase 2 HD FTP and GEM measurement requirements. With adoption of Tier 3 fuels into this segment in 2021MY, these adjustments are no longer required. The gasoline ethanol blending specification
required by 1065.710 tightly controls the test fuel heating value and carbon weight fraction and renders the 1036.530 and 1036.535 post-test corrections an unneeded source of variation. AAPC recommends removing the 1036.503 and 1036.535 criteria for gasoline engines tested with Tier 3 1065.710 fuel.

- **Fuel mapping adjustments to account for engines that run negative brake torques:** GEM fuel mapping requires fuel flow to be measured at 0 n-m brake torque and various engine speeds. GEM then uses this value to linearly interpolate 0 n-m brake torque fuel rates to zero as determined by operating point relative to the motoring friction curve. While this approach will work to assess light load and near motoring fuel flow conditions, AAPC recommends that OEMs be optionally allowed to map engines at conditions less than 0 nm brake torque to minimize interpolation errors.

AAPC suggests technical corrections to various aspects of GEM, including: [EPA-HQ-OAR-2014-0827-1898-A1 p.2]
- Fuel property adjustments and reference fuels; and
- Fuel mapping adjustments to account for engines that run negative brake torques.

- **Gem 2 road grade assumptions are not aligned with U.S. road grade profiles and could drive manufacturers to implement technologies with adverse on-road CO2 impacts.** [EPA-HQ-OAR-2014-0827-1898-A1 p.2]
- AAPC suggests improvements to various procedures and methods associated with GEM inputs including: [EPA-HQ-OAR-2014-0827-1898-A1 p.2]
  - Neutral/light load fuel measurements;
  - Fuel mapping procedures; and
  - Accounting for measurement variability.

**Response:**

We have made significant improvements to GEM based on many constructive and helpful comments from the public, which improvements should address their concerns.

Based on AAPC’s comments and others like it, the agencies are finalizing 40 CFR 1037.560 (“axle efficiency test”) which provision recognizes improvements to the axle or the lubricant or both instead of a fixed improvement based just on the lubricant. Using a procedure that tests the full axle system allows GEM to weight the losses across the axles operation for the vehicle that the axle is installed in. In addition to having a more complete way of looking at the axle as a whole by bringing the loss table into GEM ties the cycle average losses to the vehicle the axle is installed in. Lastly by testing the full axle system, there is a robust way recognize improvements to lubricants beyond BASF EMGARD FE 75W-90 Fuel Efficient Synthetic Lubricant.

Regarding fuel property adjustments and reference fuels, the agencies have performed testing at Southwest Research Institute utilizing both Tier 2 and Tier 3 certification test fuels. These results show that post-test correction of the \( e_{\text{CO2}} \) results back to the reference fuel as required in 40 CFR 1036.530 does not result in a statistically significant difference in the Tier 2 and Tier 3 fuel results. In other words, the specified correction adequately accounts for test fuel effects. Thus there is no effect on stringency and the agencies will not be developing a Tier 3 E10 gasoline factor for Tier 3 certification fuels.

Regarding fuel mapping adjustments the agencies can see the value in adding additional points to the fuel map and would be interested in discussing with AAPC how 40 CFR 1036.535 could be modified to achieve this.
We also made adjustments relating to road grade, which are more representative to the real world driving routes. This was achieved by limiting the change in grade versus change in distance to rates of change seen in-use. In addition to this we also added additional distance with grade between ±0.5 percent to better align engine operation in GEM with engine operation in-use. See Chapter 3.4.2.1 of the RIA for the detailed description of the process the agencies took in creating the road grade profile.

Updates to the Greenhouse Gas Emissions Model (GEM P2v2.1)

Significant changes have been made to the GEM model release that accompanies the NODA. These improvements enable more accurate modeling of the behavior of heavy-duty trucks and therefore can more readily capture technology improvements that were left on the table in the proposal. We support the changes to the GEM model and recommend that the standards be strengthened to reflect the additional fuel savings opportunities captured by the improved GEM. [EPA-HQ-OAR-2014-0827-1896-A1 p.3]

New drive cycle weightings

As noted in the vocational vehicle section of these comments, the updated certification cycles both are more representative of vocational vehicle duty cycles and highlight further opportunities for fuel consumption reduction at high-speed (e.g., from aerodynamic improvements) and at low-speed through idle reduction (including automatic shut-down for parked idle). [EPA-HQ-OAR-2014-0827-1896-A1 p.3]

Cycle-average map

Perhaps the biggest change to GEM is the replacement of the transient cycle modeling with the cycle-average mapping procedure to assess a vehicle’s fuel consumption over the transient cycle. Most importantly, this replaces the “transient adjustment factor” of 1.05 with a value that more accurately captures the vehicle’s transient behavior. [EPA-HQ-OAR-2014-0827-1896-A1 p.4]

Impact on the proposal

The agencies used a transient adjustment factor of 1.05 so that leading engines with better transient response on a powertrain test would not receive undue advantage as a result of the test procedure. However, eliminating this factor would appropriately reward manufacturers who can prove better real world transient response. Replacing the transient adjustment factor may result in slightly higher baseline fuel consumption if the baseline reflects average performance, but it should allow the standards to drive leading-edge transient operation in the later years, creating a greater transient performance improvement from 2018 to 2027 than in the proposal. [EPA-HQ-OAR-2014-0827-1896-A1 p.4]

Response:

We appreciate ACEEE’s positive comments on GEM, drive cycle, and cycle average mapping. Regarding the transient correction, the agencies have removed the fixed 1.05 correction now that the cycle average engine test procedure has been finalized as part of the engine fuel map. One of the main advantages of the cycle average mapping procedure is that transient engine fueling is measured during the test, so improvements to transient fueling can be recognized in GEM without performing powertrain testing. The agencies believe that using the 1.05 multiplier to define the baseline and requiring the cycle average fuel map will give the proper recognition to technologies that improve transient engine fuel efficiency.

Organization: American Gas Association (AGA) et al.

We Recommend that the Agencies Include Additional Inputs to the Greenhouse Gas Emissions Model (GEM)
We commend the agencies’ efforts to modify the GEM in the Phase 2 Proposal by requiring that tractor and vocational chassis manufacturers provide their own engine, transmission, drive axle(s) and tire radius inputs.\textsuperscript{32} This expands the GEM to better account for a wide range of technological improvements. We support the expansion of GEM to enable certain advanced technologies that are not yet widely used and that are not otherwise incorporated into the GEM to generate off-cycle credits, such as improvements to the driver controller, engines, transmissions, and axles; lightweight thermoplastic materials; automatic tire inflation systems; advanced cruise control systems; engine stop-start idle reduction systems; and axle configurations that decrease the number of drive axles.\textsuperscript{33} [EPA-HQ-OAR-2014-0827-1223-A1 p.8-9]

However, we are concerned that the GEM assessment of natural gas-fueled vocational trucks may be overestimating the CO\textsubscript{2} emissions of natural gas due to the GEM treatment of the relative carbon content of diesel and natural gas fuels and other GEM components. We encourage EPA and NHTSA to investigate this further, and correct any shortcomings that are found, and request opportunities to discuss these issues further with the agencies before the Rule is finalized. [EPA-HQ-OAR-2014-0827-1223-A1 p.9]

In addition to the carbon content issue, we disagree with the Proposal’s assignment of a fixed weight increase to natural gas-fueled vehicles.\textsuperscript{34} While we agree with the Proposal’s assertion that natural gas fuel tanks are heavier than diesel and gasoline tanks, we raise two concerns with the Proposal as written: [EPA-HQ-OAR-2014-0827-1223-A1 p.9]

- The Proposal does not include weight penalties for other weight-increasing technologies, such as hybrids, Rankine cycle engines, and non-engine technologies that add weight. [EPA-HQ-OAR-2014-0827-1223-A1 p.9]
- The proposed weight increases that are assigned to natural gas vehicles do not take into account the real-world weight differences among natural gas fuel systems.\textsuperscript{35} [EPA-HQ-OAR-2014-0827-1223-A1 p.9]

With respect to our first concern, we request that the agencies assign weight increases to hybrid and Rankine cycle engines and non-engine technologies that add weight. There are numerous technologies used by both conventional and alternative fuel vehicles that will increase the weight of the vehicle. For instance, auxiliary power units, waste heat recovery systems, and refrigerated trailer units (“reefers”) add weight to the overall system. However, these technologies do not receive weight penalties in the GEM. We appreciate that all-electric and fuel cell vehicles generate zero GHG tailpipe emissions and are thus not requesting weight penalties for these specific alternative fuel types. [EPA-HQ-OAR-2014-0827-1223-A1 p.9]

With respect to our second concern, we request that the agencies decrease the proposed weight increases that apply to natural gas-fueled vocational vehicles. We believe that the agencies’ proposed use of a fixed weight increase for both tractors and vocational vehicles fueled by natural gas does not reflect the weight differences between the fuel tanks in these vehicles, and thus unfairly penalizes vocational vehicles. [EPA-HQ-OAR-2014-0827-1223-A1 p.9]

The amount of fuel storage required varies considerably with the class and type of the vehicle. As a result, natural gas fuel storage systems installed on vocational vehicles typically are smaller and weigh less than those installed on Class 7 and 8 tractors. This is because vocational vehicles themselves weigh less and often run less mileage, thus requiring less fuel. Class 5 vocational vehicles may be fitted with as little as 25 – 32 gasoline gallon equivalent (GGE) natural gas fuel storage systems.\textsuperscript{36,37} Refuse trucks (a type of vocational vehicle) may operate with a 60 – 80 diesel gallon equivalent (DGE) natural gas fuel
By comparison, Class 8 tractors may occasionally operate with a natural gas fuel storage system of up to 120 DGE. These examples demonstrate the need for differentiated weight increases among the various classes of natural gas vocational vehicles and tractors. [EPA-HQ-OAR-2014-0827-1223-A1 p.10]

The need to decrease the proposed weight increases for natural gas-fueled vocational vehicles also plays out in the GEM’s payload calculations. For the tractor-trailer calculation in the GEM, one-third of the weight reduction (or increase) is added (or subtracted) to the available payload number in the denominator while two-thirds of the weight reduction (or increase) is subtracted (or added) to the overall weight of the vehicle. However, the calculation for vocational vehicles is different: one-half of the weight reduction (or increase) is added (or subtracted) to the available payload number in the denominator while the other one-half of the weight reduction (or increase) is subtracted (or added) to the overall weight of the vehicle. This difference in calculation means that the weight increase is much more significant for natural gas-fueled vocational vehicles because it assigns a larger tank weight relative to the size of the vehicle. [EPA-HQ-OAR-2014-0827-1223-A1 p.10]

In sum, we commend the agencies’ efforts to update the GEM to better reflect real-world driving conditions and technologies. We believe that the recommendations listed above further advance those efforts. [EPA-HQ-OAR-2014-0827-1223-A1 p.10]

Response:

With regard to natural gas fuel properties, GEM contains the reference fuel properties for all fuels defined in Table 1 of 40 CFR 1036.530. For natural gas the reference fuel carbon-mass-specific net energy content was carried over from the Phase 1 rule and the reference fuel carbon mass fraction was determined based on a fuel composition consistent with Table 1 of 40 CFR 1065.715 and the carbon mass fraction of the pure compounds (methane, ethane, etc).

Consistent with AGA’s comment about weight for natural gas vehicles, we have removed all weight penalties from the weight reduction tables included in 40 CFR part 1037. The tables only recognize weight reductions. The final Phase 2 GEM does not contain any weight penalties.

Organization: NGVAmerica

Weight Penalty for Natural Gas Vehicles. The agencies have proposed specific weight penalties to be assigned to natural gas trucks. These default figures would be used as part of the GEM modeling of emissions and fuel economy. [EPA-HQ-OAR-2014-0827-1270-A1 p.3]

NGVAmerica believes that the weight penalties included in the proposal for vocational vehicles are too high and are not reflective of fuel systems in use today. We would welcome the opportunity to discuss this issue further with the agencies. We note that the comments submitted by Gladstein and Neandross on behalf of the American Gas Association, Clean Energy and Westport Innovations also address this issue and we support their remarks on this issue. [EPA-HQ-OAR-2014-0827-1270-A1 p.3]

Response:

We agree with NGVA’s comment about weight for natural gas vehicles and have revised the regulation to remove the proposed fixed weight penalties. The agencies are not finalizing a weight penalty for any components since this would require detailed information on conventional and light-weight vehicle components to establish a baseline and the weight reduction potential for each component. Although we are not requiring a weight penalty in GEM at the time of certification for any technology, the agencies...
have accounted for increased weight due to projected adoption of some technologies (i.e. for vocational vehicles we accounted for added weight in subcategories where hybrid systems are projected) as part of our inventory modeling with the MOVES model.

**Organization:** California Air Resources Board (CARB)

**Support Comment**

**Comment – Reflecting weight decreases for lightweight components, and weight increases for natural gas fuel tanks versus gasoline or diesel tanks**

CARB staff supports the Phase 2 proposal to give weight reduction credit for the use of lightweight components, and a weight increase (i.e., negative credit) for natural gas vehicles to reflect the increased weight of natural gas fuel tanks versus gasoline or diesel tanks. The weight reductions or increases translate into decreased or increased CO2 emissions in GEM. The weight increases would be 600 lbs for a compression ignition LNG tractor, 525 lbs for a spark-ignited CNG tractor, and 900 lbs for a compression ignition CNG tractor; those same weight increases would also apply to vocational vehicles. The weight reductions (credits) for lighter components range from 4 lbs to 588 lbs. [EPA-HQ-OAR-2014-0827-1265-A1 p.163-164]

**Response:**

We appreciate CARB’s support regarding reflecting weight of lightweight components in GEM. The agencies are not finalizing a weight penalty for any components since this would require detailed information on conventional and light-weight vehicle components to establish a baseline and the weight reduction potential for each component. Although we are not requiring a weight penalty in GEM at the time of certification for any technology, the agencies have accounted for increased weight due to projected adoption of some technologies (i.e. for vocational vehicles we accounted for added weight in subcategories where hybrid systems are projected) as part of our inventory modeling with the MOVES model.

**Organization:** California Air Resources Board (CARB)

**Oppose/Requested Change Comment**

**Comment – Phase 2 GEM improvements**

CARB staff has evaluated and run GEM P2v1.0 and has several suggestions and recommends for clarification: [EPA-HQ-OAR-2014-0827-1265-A1 p.122]

While GEM for Phase 1 included a graphical user interface (GUI), GEM P2v1.0 does not. CARB staff still prefers GUI for data input. We believe that GUI makes it easy for users to select or input data without the need to see behind the scenes information. We understand that GUIs are not simple to make or upgrade. However, we encourage U.S. EPA to develop a GUI for GEM P2 that can integrate the added Phase 2 technology information. [EPA-HQ-OAR-2014-0827-1265-A1 p.123]

In the GEM user manual, it is not clear on how to input or edit parameters. We recommend adding clarification regarding how to create new input files and how to use the ‘Sample Input Files’. [EPA-HQ-OAR-2014-0827-1265-A1 p.123]
The proposed GEM was generally designed for diesel engines. We recommend that natural gas engines be treated separately in GEM because their specifications are significantly different from the diesel engines. Please see page 148 for detailed comments on natural gas requirements. [EPA-HQ-OAR-2014-0827-1265-A1 p.123]

In the future, we encourage U.S. EPA to consider linking GEM to the VERIFY database to make analysis of GHG and criteria pollutant data more convenient. [EPA-HQ-OAR-2014-0827-1265-A1 p.123]

**Oppose/Requested Change Comment**

**Comment – Phase 2 GEM technologies included**

We appreciate U.S. EPA and NHTSA including additional technologies such as low friction axle lubricant in GEM P2’s pull-down menus that were not included in GEM for Phase 1. We recommend U.S. EPA and NHTSA also add to GEM P2 potential aerodynamic improvements and electrified accessories for vocational vehicles and solar control for heavy-duty pickups and vans in the pull-down menu as well. We believe that both technologies must be considered in the overall stringency to further improve emissions in the vocational sector. [EPA-HQ-OAR-2014-0827-1265-A1 p.123]

Please see detailed comments on vocational vehicles, vocational aerodynamics, and BEVs on pages 36, 44, and 84 respectively. [EPA-HQ-OAR-2014-0827-1265-A1 p.123]

**Response:**

CARB recommended a graphic user interface (GUI) for Phase 2 GEM. After consulting all the major vehicle manufacturers, however, it appears there is consensus against a GUI. In particular, GUI is viewed as an impediment for batch operations – the industry norm. Consequently, we decided not to develop any GUI.

CARB also commented that GEM should include all other engines instead of diesel engine alone. The response to this comment is that we have modified GEM to allow gasoline and natural gas engines as input to GEM.

The GEM user’s manual issued with the final Phase 2 rule includes sample input and output files.

Regarding the comments on aerodynamic improvements and electrified accessories for vocational vehicles, we have taken actions to implement these two things into GEM as inputs. See RTC Section 6.3 for a discussion of comments and responses related to applying aerodynamic improvements and electrified accessories on vocational vehicles. In general, heavy-duty pickups and vans are chassis-certified and do not use GEM, therefore, ARB’s suggestion is not applicable to GEM.

**Organization:** Clean Air Task Force et al.

Modifications made to the compliance model (GEM) help ensure that we are driving real-world performance improvements and capture even more of the fuel consumption reductions possible from future technology, especially to the powertrain. In addition, the new analysis put in the docket shows that vocational trucks idle much more than the agencies realized. Therefore the agencies should do more to incentivize idle reduction technologies, which result not only in lower fuel use but also improved
health outcomes for communities. The improved analysis of how vocational trucks operate also underscores the importance of moving towards more advanced technologies as we look beyond this rule towards continued reductions in fuel use and emissions from the freight sector. [EPA-HQ-OAR-2014-0827-1925-A1 p.2]

Response:

We have made significant improvements on idle reduction, which includes neutral idle, start/stop, and automatic engine shutdown, thus greatly incentivizing the idle related technologies. See RTC Section 6.1 for a discussion of comments and responses related to vocational vehicle duty cycles including the appropriate test cycle weighting of idle. See RTC Section 6.3 for a discussion of comments related to applying workday idle reduction technologies on vocational vehicles.

Organization: Daimler Trucks North America and Detroit Diesel Company

Although the agencies have made all of the changes to GEM that they said they would, we cannot repeat and verify the agencies’ stringency analysis. Despite the changes to GEM, there remain problems with the program. First, it incorporates a drive cycle (Drive Cycle D) that diverges significantly from real world driving, as we have discussed with the EPA. In particular, the driving appears very binary: full torque and zero torque are over represented, while medium torque is underrepresented, relative to actual on-road driving—either based on Daimler’s internal simulation or based on in-vehicle data collected by other manufacturers. We commend the EPA for recognizing the problem and seeking a solution. But we fear that the proposed solutions, allowing over- and under-shoot in vehicle speed as well as slight modifications of the Profile D, will not fully resolve the problem. It is very important for the drive cycle to line up with real-world driving, so that manufacturers can design for on-road fuel savings and do not erroneously design to a mismatched cycle. So we need to reach a good solution, perhaps even revising the drive cycle or scrapping Drive Cycle D altogether, to ensure GEM improvements translate to the real world.

- Adding road grade to the GEM Duty Cycles for Tractors and Vocational Vehicles - The agencies propose to add road grade to the 55 mph and 65 mph drive cycles. We strongly agree, as this is necessary to show the full powertrain operation and engine map (as opposed to showing the operation at one point in a map). [EPA-HQ-OAR-2014-0827-1164-A1 p.35]

- Basic Philosophy Behind the Choice of Road Grades - The agencies request comment on the proposed road grade profile, other ways in which the proposed 55 mph and 65 mph duty cycles could be enhanced, whether a more aggressive road grade profile would induce a more realistic and representative number of transmission gear shifts, and whether to apply a workday idle cycle to certain tractor types like day cabs that could experience more significant amounts of time stopped or parked as part of an urban deliver route. We have had discussions with the agencies about what constitutes a proper regulatory drive cycle, how we characterize drive cycles (including the speeds, hilliness factor, and coast factor), and how the agencies’ initially proposed drive cycles compare to several representative cycles. Our underlying philosophy is that the agencies should try to match the regulatory cycles as closely as possible to nationwide average driving, not to (for example) enhance the aggressiveness of the drive cycles beyond the average in order to test the impact of an increased number of gear shifts. Similarly, we believe the agencies should try to match the vehicle speed and torque that would be observed for the average vehicle, so that manufacturers designing for on-road fuel savings will also do well in
the regulatory arena (as opposed to making one arena differ from the other). [EPA-HQ-OAR-2014-0827-1164-A1 P.35]

- **Originally proposed road grades** – Following the philosophy stated above, we voiced concerns that the agencies’ originally proposed topography differed from real-world driving by having too high of torques. [EPA-HQ-OAR-2014-0827-1164-A1 P.36]

[The graphics, illustrating GEM drive cycle and nationwide average on-road drive cycles, can be found on p.36 of EPA-HQ-OAR-2014-0827-1164-A1]

Left is the GEM drive cycle, right is the nationwide average on-road drive cycles. The circles show the areas of highest frequency—clearly in different areas of torque and speed. As we have done more study of this road grade profile and the agencies’ newly proposed one (discussed below), we think that either profile is generally sufficient, although neither is perfect. The original one might be better than the new. In any case, we welcome the opportunity to discuss the drive cycles further with the agencies.

Newly proposed road grades - Near the end of the comment period, we learned that the agencies are working on revised drive cycles with NREL. The agencies request comment on the new road grades. We have begun to analyze the drive cycles but are not yet finished. As we look at the new road profile, again compared to a nationwide average, we find that the new profile has a lot of up and down-grades with a lot less flat ground driving than experienced on the road in the US, as shown in the charts below:

This is the nationwide average of seven major on-road drive cycles. The darkest red shows the areas of highest frequency. As can be seen, most of the activity takes place in the center of the torque band, representing flat roads or gentle grades. Note that we present more detail, showing individual routes, in the Appendix. [EPA-HQ-OAR-2014-0827-1164-A1 p.37]

These, by contrast, are the agencies’ newly proposed cycles, showing that the cycles still do not line up with the on-road driving. Unlike the cross country routes, for which most of the activity is at the center of the torque range, representing flat roads or gentle grades, the agencies’ proposal focuses on the highest and lowest torques with very little operation in the center of the operating map. In other words, the agencies’ route is predominantly hilly—either up or down with nothing in between—while we find that many routes contain flat ground not represented by the agencies’ route. Note that we used two assumed final drive ratios [redacted] for comparison purposes as these are ratios that we think might represent the 2027 fleet. [EPA-HQ-OAR-2014-0827-1164-A1 p.39-40]
Whichever drive cycles the agencies choose, the original ones, the new ones, or still some newer ones, we need to discuss the drive cycles further with the agencies to ensure that these properly characterize actual vehicle operation. [EPA-HQ-OAR-2014-0827-1164-A1 p.40]

Suggestion for choosing a final road grade profile - The best way to create drive cycles is to work with NREL and manufacturers to mine on-vehicle data collection during fleets’ driving, then to create an aggregate that matches this driving in vehicle speed and torque (in other words, making the histograms of speeds and torques from the regulatory cycle line up as closely as possible with those from the real-world driving). We strongly advocate for the agencies to use a route profile that is representative of the ton-mile freight national average. Considering that 1) for practical purposes the regulatory high speed cycles can only have a limited length yet 2) short cycles can overemphasize minor components of those cycles, it is vital that the profile that is ultimately chosen is a true representation of average real world driving conditions with no unrepresentative portions. Otherwise a significant disconnect between regulatory and real world driving could have the unintended consequence of OEMs having to focus too much on regulatory requirements instead of what the customers really need in order to do their job in the most fuel efficient manner. In the same vein, we think that the amount of idling for both vocational vehicles and day cab vehicles should align with the data collected from real-world vehicles, including the idle time data that can be downloaded from engine control modules. (For sleeper cab vehicles, the ECM idle time would be misleading as most customers these days opt for idle shutdown timers, such that their engine-off hoteling time—the time that the agencies want to reflect with the idle portions of the cycles—would not be accurately captured by the ECM data). 80 FR 40188. [EPA-HQ-OAR-2014-0827-1164-A1 p.40]

Response:

We appreciate DTNA’s comments on the road grade. Since we released the earlier proposal on road grade profile called Profile D, we received many constructive comments from stakeholders. Consistent with DTNA’s suggestion, the agencies obtained comprehensive data from NREL and based the final road grade simulation in GEM largely on those data (as well as reflecting comments the agencies received in response to the NODA setting out those data for comment). The agencies made many changes to the road grade as proposed. Examples include adding flat road and ±0.5 percent road grade at the beginning and end of cycle, and shrinking the peak grades. See Chapter 3.4.2.1 of the RIA for the detailed description of the process the agencies took in creating the road grade profile.

Organization: Daimler Trucks North America LLC

Other Structures Considered, Alternative aka Cycle Average Mapping Approach – The agencies discuss the complex cycle average approach of engine-only testing over the GEM duty cycles over a range of simulated vehicle configurations, which then gets used in GEM through interpolation based on cycle-average N/V and cycle work. And the agencies request comment on whether to replace the steady-state operation representation of the engine in GEM with the alternative cycle mapping approach. 80 FR 40176. DTNA strongly urges the agencies not to replace the proposed steady state map engine representation with the cycle average approach. Given the fact that there is not enough time in this rulemaking to adequately familiarize ourselves with this concept we believe this concept should stay outside of this rule altogether. While we do not dismiss the possible technical merits of this idea outright, there are just too many unknowns left at this point to support its immediate adoption in the GHG Phase 2 rule. Having said that, after finalizing this rule we are open to collaborate with the agencies in a future industry – agency cooperative effort to further investigate this approach in order to thoroughly weigh its pros and cons and if the approach is found to be viable and equitable, aid in development of procedures to ensure that regulatory stringency is not compromised. As it stands, the
lack of definition of the process and requirements are such that there is an unquantified risk that the cycle average mapping procedure will provide an “easy path” to certification and circumvent the stringency that the agency intends for Phase 2. [EPA-HQ-OAR-2014-0827-1164-A1 P.34-35]

- **Distance-based drive cycle**: DTNA welcomes the agencies’ proposed approach to ensure a distance neutral simulation for all vehicle configurations. In our opinion using a distance-based road profile definition in conjunction with a time-based speed profile that includes a distance correction is an important/integral improvement to GEM for Phase 2. 80 FR 40187. [EPA-HQ-OAR-2014-0827-1164-A1 P.35]

- **Adding GEM Inputs** – The agencies request comment on the inclusion of new proposed technologies into GEM in Phase 2. Although, as we stated above, DTNA fully supports the proposed additional inputs to GEM, we recommend adding still further inputs—for example OEM measured transmission efficiencies and a pulldown credit for neutral coast technology like eCoast. [EPA-HQ-OAR-2014-0827-1164-A1 p.42]

Detailed proprietary transmission shift logic omitted from GEM as too complicated: DTNA agrees that in a regulatory context it makes sense to use a generic shift strategy in GEM as oppose to using a manufacturer's actual shift strategy. Especially for long-haul applications DTNA simulations have shown that a generic shift algorithm can sufficiently reflect real world shift behavior (absent a neutral coast feature like our eCoast). In case of more transient operation the differences between simulated and actual shift behavior are admittedly larger, but avoiding the implications of implementing actual shift strategies in GEM (i.e., definition of a generic GEM interface, maintaining a level playing field between OEMs, IP concerns) by far outweighs the loss of simulation accuracy. [EPA-HQ-OAR-2014-0827-1164-A1 p.42]

[Table is redacted, showed results of an analysis presented earlier to EPA]

This table, above, shows the results of an analysis that we presented the EPA earlier, an analysis of several vehicle types simulated over several drive cycles with several shift strategies. The leftmost column is the drive cycle. The next column is the vehicle configuration. The columns labeled “Shift strategy” show the results of the analysis using DTNA’s proprietary strategy, simulated using Software In the Loop (SIL), and ACEA’s “polygon approach.” Although the agencies have advanced their shift logic in GEM since using a strategy like the polygon approach, the polygon approach is representative of what would result with any non-SIL strategy, including the agencies’ new one. (Note that these fuel consumption values in l/100 km are simulation values for specific vehicles under specific boundary conditions and do not indicate that a DTNA customer should see the same values). The columns labeled “Difference” show the difference in results with the different shift strategies. [EPA-HQ-OAR-2014-0827-1164-A1 p.42-43]

As can be seen from the columns labeled “Difference,” there is negligible difference in the results using the simpler and the more complex shift logic. The reason is that there is so little gear shifting occurring. So the agencies’ use of a generic shift strategy for tractors is valid. [EPA-HQ-OAR-2014-0827-1164-A1 p.43]

Idle Fuel Consumption Inputs - The agencies request comment on the inclusion of two idle points from the engine test for use in GEM for purposes of calculating emissions during vehicle idling over the vocational vehicle test cycles. We think that this is appropriate and will help to quantify idle fuel saving technologies like neutral at idle. We do, however, want to make sure that the agencies properly use
those idle fuel consumption rates: if a transmission has neutral idle or a clutch, it should get the lower fuel consumption rate during any GEM idle time step. [EPA-HQ-OAR-2014-0827-1164-A1 p.45]

Steady state to transient correction factor (1.05) – The agencies seek comment on whether the single value multiplier (1.05) is an appropriate way to correct between steady-state and transient engine fuel consumption and CO2 emissions, specifically over the ARB transient duty cycle. 80 FR 40184. The agencies propose that a multiplicative factor of 1.05 be applied to the steady state map for transient simulation. Firstly, DTNA believes that inputting the actual engine data in GEM is an important and necessary step to improve the fidelity of simulations in Phase 2. Use of a default or assigned fuel map in GEM restricts a manufacturer from showing in GEM any benefits from improvements to engine systems or their unique integration with the drivetrain and vehicle. It is critical in Phase 2 that manufacturers be enabled and encouraged to seek fuel efficiency improvements through innovative engine and drivetrain integration and optimization. Use of the actual engine data in GEM facilitates manufacturers to seek improvements in this manner. That said, there is a question as to the use of a map or a cycle-averaged approach. [redacted] [EPA-HQ-OAR-2014-0827-1164-A1 p.45]

This results from differences in engine combustion and controls and the performance of the aftertreatment system under generally lower operating temperatures. Applying the steady state fuel map in GEM without some level of adjustment to reflect this difference could be interpreted as overstating or misrepresenting the actual vehicle efficiency which would be detrimental to the integrity and objectives of the Phase 2 program. That said, use of the cycle averaged approach is problematic, because of (among other things) the differences between the shifting and emissions profile of the children relative to the parent—which the agencies claim not to be an issue but which has not yet been demonstrated. This is not a problem with a fuel map approach. So we recommend the map approach. [EPA-HQ-OAR-2014-0827-1164-A1 p.45]

DTNA’s investigation of the transient vs. steady-state efficiency difference leads us to believe the EPA’s suggested 1.05 multiplier is generally conservative in that it overestimates the actual difference between modes of operation, and clearly should mitigate concerns that the GEM simulation is overstating a transient cycle performance. EPA asks for comment regarding whether the multiplier should be higher considering that its investigation showed that the 1.05 factor represented the mean difference observed for the population of engines that it tested and that a higher factor could encourage manufacturers to pursue powertrain testing in order to establish a less punitive factor. DTNA shares EPAs concern that a higher multiplier, for example 1.07 would force some manufacturers to implement costly and burdensome powertrain testing to “provide credits for many current powertrain designs.” In DTNA’s view it does not make sense to set an artificially high factor that would result in extraordinary expenses for manufacturers to prove that their nominally average systems do not perform poorly. Rather, setting the level at 1.05 is sufficiently conservative to meet the needs of avoiding overestimation of transient performance and providing room for manufacturers to demonstrate better performance. [EPA-HQ-OAR-2014-0827-1164-A1 p.45]

DTNA believes that both powertrain testing and the “alternative” approach are, at the least, overly burdensome and complex methods for engine manufacturers to represent powertrain performance in GEM. We suggest a simpler approach: if EPA seeks to improve the fidelity of the adjustment factor, as opposed to using a “fits all” 1.05 factor, EPA should allow manufacturers to establish an engine family specific factor that more accurately reflects the effect of the manufacturer’s control strategies. The manufacturer would conduct testing a representative rating of their engine family by running the ARB Transient Cycle on the engine dyno (using an EPA defined generic representative vehicle configuration) and comparing the resulting CO2 emissions level against the result of a simple simulation of the same test cycle (speed – torque sequence) using the steady state map that is defined for GEM input. The
results of the test and simulation would be used to derive the unique multiplier for the engine family. This approach essentially reflects the methodology used by EPA to derive its recommended factor of 1.05. Additionally, such a manufacturer derived factor would be simple to audit or evaluate during confirmatory testing since only one additional test (the engine dyno test on the ARB Transient Cycle) and a simple simulation would be required. 80 FR 40184. [EPA-HQ-OAR-2014-0827-1164-A1 p.45-46]

Default engine maps - The EPA and NHTSA request comment on whether the agencies should provide default generic engine maps in GEM for certain vehicle sub-categories, albeit allowing manufacturers to optionally override these generic maps with actual maps measured in the normal manner (the agencies' proposed engine dynamometer steady-state test procedure). 80 FR 40184. We think that this is unnecessary. Engine manufacturers will have to generate fuel maps for engines, so the only time a vehicle manufacturer would choose not to use the optional, actual map is when that actual map is worse than the generic one--thus giving a credit for use of bad engines. Since manufacturers will have the actual maps, they should use those maps. [EPA-HQ-OAR-2014-0827-1164-A1 p.46]

Simulating Accessories for Vehicle Certification - The agencies request comment on several aspects of simulating accessories for vehicle certification: whether to allow some manufacturer input to reflect the installation of accessory load reduction in GEM, how to distinguish advanced accessories that would qualify for load-reduction credits, how to unambiguously distinguish these from other similar components that do not decrease accessory loads, and how much credit to give. 80 FR 40186. We recommend that the agencies follow an approach similar to that used by ACEA in Europe: taking different literature values (for example) for fans that are 1) crankshaft mounted, 2) belt driven with a transmission, 3) hydraulically driven, and 4) electrically driven, with each variant given a value representative of the actual energy consumed. This would give manufacturers incentive to use the most efficient accessories without putting a large burden on manufacturers to demonstrate the relatively small energy savings from each individual accessory. With such an approach, it will be easy to distinguish the advanced accessories, as it is easy to tell just by sight whether (again using the same example) a fan is mounted off the crankshaft, mounted by a belt with a transmission, and so on. With accessories that are more difficult to see, like water pumps or steering pumps, the manufacturer can declare the pump type in the end-of-year report; if the agencies wish to audit, then the agencies can see part numbers on any particular vehicle's pumps and compare these too broadly available descriptions of the part by part number. The process for certifying to the agencies that the accessories are fuel saving accessories would be simple: it would simply be a declaration that the accessory works as described, for example, is a hydraulic fan. And the amount of credit should be similar to that tabulated by ACEA for the same accessories. We would be happy to work further with the agencies on how this would work. Refer to Appendix C, Truck Auxiliaries for more details of the ACEA approach. [EPA-HQ-OAR-2014-0827-1164-A1 p.50]

Tire Revs Per Mile is the Correct GEM Input - GEM should use either dynamic tire radius (meaning, not the static loaded radius but the radius during motion) or better tire revs per mile, from the tire manufacturer. This information is routinely collected by tire manufacturers and should be supplied as part of the tire manufacturer information in 1037.520(c) and 1037.650. Using such data will improve GEM fidelity by aligning GEM engine speeds with real engine speeds. 80 FR 40187, the agencies ask for comment on whether the proposed test procedure should be modified to measure tires' revolutions per distance directly, as opposed to using the loaded radius to calculate the drive axle rotational speed from vehicle speed. We recommend tire manufacturers' stated tire rev per mile numbers. 1037.520(a)(2)(vii), 1037.520(c), and 1037.650. [EPA-HQ-OAR-2014-0827-1164-A1 p.53]
GEM needs a way for manufacturers to input different Crr’s for vehicles with different tires on each axle, 1037.520(a)(1)(iv) - The agencies have not clarified how we enter into GEM the Crr’s for vehicles with different tires on each axle or with lift, tag, or pusher axles having different Crr’s than the drives. There are many such vehicles. GEM should allow for such entry, or a manufacturer should be explicitly allowed to enter the numerical average of the axles’ Crr’s. [EPA-HQ-OAR-2014-0827-1164-A1 p.53]

Tire Test Procedures – The agencies request comment on whether the proposed test procedure should be modified to measure the tires’ revolutions per distance directly, as opposed to using the loaded radius to calculate the drive axle rotational speed from vehicle speed. 80 FR 40187. As we note elsewhere, the agencies should. The agencies should use tire manufacturers’ measurements of tire revolutions per mile, in order to get correct GEM results. [EPA-HQ-OAR-2014-0827-1164-A1 p.62]

Vehicle Manufacturers Receiving Tire Data from Tire Manufacturers – In Phase 1, the agencies established a procedure by which vehicle manufacturers could rely on tire data measured by tire manufacturers. The agencies propose to carry over this procedure for Phase 2. This is an invaluable procedure, and we strongly agree with the agencies’ proposal. We as vehicle manufacturers, not tire manufacturers, do not routinely test tire rolling resistance, static loaded radius, or tire revolutions per mile. Therefore we agree with the agencies’ proposal for vehicle manufacturers’ getting tire data from tire manufacturers. [EPA-HQ-OAR-2014-0827-1164-A1 p.62]

ePTO Test Procedures – We have several concerns with the ePTO procedures. The procedures are written to test the PTO by ensuring that the engine produces all of the energy with no net change in stored energy. But plug-in electrified PTOs are already on the market, so there should be a provision for vehicles which can charge up fully from the grid, perform the prescribed PTO duty cycle, and are then recharged from the grid. There are other sections in this procedure which seem to ignore this possibility as well. [EPA-HQ-OAR-2014-0827-1164-A1 p.64]

In § 1037.540(b), the agencies prescribe the duty cycle based on target pressures that a hybrid vehicle must hit, insinuating that the hybrid vehicle spins a PTO pump constantly just as an idling truck would. However, an electrified PTO doesn’t operate in this manner at all; the pump can stop completely if there is zero demand, which would be used in practical use to maximize engine-off time and overall efficiency. While a typical conventional vehicle does idle constantly during PTO use, creating a mean minimum pressure greater than zero, the hybrid vehicle would have zero pressure with zero demand. It would make much more sense if the PTO duty cycle prescribed PTO power. [EPA-HQ-OAR-2014-0827-1164-A1 p.64]

There are only two duty cycles listed in Appendix II, but there are many different target customers for which any given ePTO system might be designed. The OEM should have the ability to propose alternative duty cycles to the EPA for approval if other duty cycles are more appropriate in the future, but we do not see this as a possibility the way the regulation is currently worded. Subsection (e) also says that all cycles should be used (refuse and utility), even though the hydraulics required for these applications might be quite different. Again, this highlights that power (pressure*flow) required for the job should be used rather than only pressure, and only systems designed for refuse vehicles should use that duty cycle (likewise for utility vehicles using utility duty cycle). If a multi-cycle system is intended to be used as a catch-all to create a single, more simplified certification, power vs. time should be the expected measurement method rather than pressure vs. time. [EPA-HQ-OAR-2014-0827-1164-A1 p.64]

· Post-processing technology credit values not given for fuel saving accessories like variable speed water pump or clutched air compressor. The agencies propose to give credits for electrified accessories but not for equally fuel saving alternatives like [redacted]. 80 FR 40304. First, we think that
if the accessory is active in the engine cert test, then its benefit should not be included in post-processing drop down. For example the [redacted] water pump is actually active during the RMC. But, second, if it is not active in the test cycle, such as a [redacted] feature, then it should get post-processing credits whether it saves fuel through electrification or through some alternative. [EPA-HQ-OAR-2014-0827-1164-A1 p.80]

- **TPMS and Alternative Tire Pressure Systems Should Be Sufficient for Credits** - We disagree with the EPA’s approach of not crediting tire pressure monitoring systems (TPMSs) in GEM. Several studies have been performed on fleets of vehicles which demonstrate an FCR of 1-2% for TPMS without any special intervention to ensure the operators act on the notifications. One such study was FMCSA-RRT-13-021 published in February 2014 which showed an average 1.4% FCR attributed to TPMS. Similarly, there are systems that need not be carried around on vehicles, which measure tire pressure as a vehicle is driven over them. These can be placed in a fleet’s truck yard to catch vehicles with low tire pressure. There is no reason to credit vehicles with systems that prevent low tire pressure only if the systems must be carried on the vehicle; these systems add weight. Rather, there should be a method to get credit for these alternatives that add no vehicle weight. If the agencies’ concern is that the systems might not catch a low tire pressure immediately and might allow a vehicle to operate with low pressure for some time, then the agencies can give a slightly reduced FCR benefit. [EPA-HQ-OAR-2014-0827-1164-A1 p.80]

- [entire bullet redacted]

- **Electric Accessories Given GEM Credits But [redacted] Ones Not Given Credit:** The agencies propose to treat differently accessories that have similar FCR benefits. 1037.520(f)(6). Electric accessories get their power from the engine, albeit through the electrical system (with the inefficiency associated with energy conversion to and from electrical energy), while the [redacted] accessories do the same thing—reduce energy consumption and save fuel—but they do it without the energy conversion losses. DTNA testing indicates that [redacted]. Therefore, these accessories should get credit too. We can support this claim with data, in a confidential setting. [EPA-HQ-OAR-2014-0827-1164-A1 p.81]

**Response:**

We understand DTNA’s concerns regarding the cycle average approach. However, we initiated this approach in the fall of 2014. Since then, we have received strong support for most of the major industry manufacturers. More importantly, significant progress has been made in both the engine dynamometer tests and the test procedure development. Six different engine platforms, including Cummins ISX, ISB, ISL engines, Navistar N13 engines, Volvo D13 engines and Ford Gasoline engine, some of which were conducted at manufacturers site. Parent and child ratings were also extensively tested. All the results point to the same conclusion – cycle average approach is more accurate than the steady state map approach, specifically in transient cycle even with a transient correction factor. As a result of that, we believe that use of cycle average approach would be justifiable. With this change, we completely removed the transient correction factor proposed in NPRM. Many of these activities were conducted through the industrial group regular meetings that have been put into the memo docket (Docket EPA-HQ-OAR-2014-0827). See RIA Chapter 3.1.2.6 for further discussion on the cycle average test procedure.

We appreciate the DTNA’s support on our decision to use the agency’s auto-shifting for transmission model. We also modified idle fueling to update our idle fueling maps based on many constructive comments from manufacturers, including DTNA.
Regarding simulations on accessories for vehicle certifications, we decided not to model these features. Model validation would be very difficult given the range of potential accessories. Similarly, each manufacturer may have unique accessories, which are virtually impossible to capture in a simulation tool. Consequently, we decided to use the same principle as in Phase 1: to use constant accessory power in GEM. In addition, Phase 2 GEM does provide additional opportunity to recognize advanced accessories through the mechanism of technology improvement input from the main GEM input file.

We agreed with DTNA’s comments on tire input using tire revs per mile. We also allow the user the input different Crr for vehicle with different tires on each axle.

**ePTO Test Procedures**

Based on DTNA and others’ comments, the agencies have expanded 40 CFR 1037.540 for Phase 2, to test PHEV PTO systems in charge depleting mode in addition to charge sustaining mode. With this change and with the utility factor curve that we developed jointly with National Renewable Energy Laboratory, the procedure can now account for the full benefit of plug-in hybrid PTO systems. See Chapter 3.7.4 of the RIA.

The PTO cycle is deformalized by zero PTO demand and maximum PTO demand. If an ePTO system has zero pressure with zero demand then the ePTO system will not run during the 0% points, which is consistent with how the systems run in-use.

Just like the vehicle duty cycles that are used in this rule, the agencies have defined the PTO duty cycle but manufacturers have the opportunity to ask for approval for a different cycle under the off-cycle provisions.

The systems we test for the development of the PTO procedure in the first heavy-duty greenhouse rule, the flow was generally independent of the pressure, so the pressure determined the power output of the PTO system. Because of this the agencies defined the cycle in terms of normalized pressure. We appreciate the DTNA comments on TPMS. In the final rule, the agencies defined an effectiveness for both TPMS and ATIS and each is allowed for as a technology improvement input of the GEM input file. Those accessories that can be recognized through engine certification tests, such as variable water pump and oil pump, are not included as part of technology improvement inputs. Accessories that cannot be measured from engine tests can be either recognized in GEM as a technology improvement input or through off cycle credit.

**Organization:** Dana Holding Corporation

Simulating axles for vehicle certification

Dana offers various products related to the entire scope of the proposed rule (Class 2b – Class 8 trucks); however, we see the most significant impact of the proposed rule in relation to the class 7 and 8 line haul application. Within this heavy-duty class 7 and 8 market, Dana has made several significant technology advancements. In fact, our company continues to develop our latest technology offerings that are scheduled to be released in advance of the implementation of the new standards proposed by EPA and NHTSA in Alternative 3 of the proposed rule. [EPA-HQ-OAR-2014-0827-1138-A1 p.2]

Dana’s current portfolio of technology offerings that would support the proposed Phase 2 improvements in fuel efficiency include the Spicer® AdvanTEK® heavy-duty (40,000 lb. GAWR) tandem axle that is currently offered at a rear-axle ratio as low as 2.26:1. This latest axle development was designed to
operate with the increased torque loads experienced through engine down-speeding. The new fast ratios below 2.64:1 is one key enabling factor to support reducing the engine speed toward 1150 rpms at 60-65 mph cruise speeds. Given the generally accepted principle that every 100 rpm reduction in the engine (at cruise speeds) accounts for a 1% fuel-efficiency improvement, Dana is pleased that the EPA and NHTSA have recognized the need to include axle-ratio as an input in the proposed Phase 2 GEM simulation. [EPA-HQ-OAR-2014-0827-1138-A1 p.2]

In addition to enabling engine down-speeding, a reduction in the axle ratio at highway speeds provides further efficiency improvement within the axle. Dana’s efficiency testing clearly indicates that a reduction in axle ratio (i.e. a lower numerical ratio) improves the efficiency of the axle. Therefore, the ratio reduction will provide two forms of efficiency improvement: first, engine efficiency due to engine down-speeding and secondly, drive axle efficiency through the inherent efficiency gain with the reduction of the axle input speed. [EPA-HQ-OAR-2014-0827-1138-A1 p.2]

In fact, there are several other axle features in addition to axle-ratio that influence axle efficiency and can be visually verified during an in-use compliance audit. Such features include pinion gear offset (spiral beveled, hypoid, or amboid gearing), axle lube quantity, dual-range, and axle weight. Based on these easily verifiable features, Dana believes that the proposed 95.5% fixed axle efficiency rating (while lower than Dana’s reported efficiency in most axle families) is reasonable and additional credit should be provided for specific improved axle features. It is Dana’s opinion that the dynamometer testing proposed as an alternative in Section II.C.1.(c) (pg. 40185) of the proposed rule would result in excessive complexity and documentation for fractions of a percent improvement in efficiency, while easily identified features (such as the ones noted above) can serve as a less complicated checklist of credits with prescribed efficiency improvement values as used in the post-simulation approach. [EPA-HQ-OAR-2014-0827-1138-A1 p.2-3]

With regards to the emission reduction for fuel-efficient synthetic lubricants (40 CFR 1037.520(f)(2), pg. 40631 of the proposed rule), Dana fully supports the 0.5% efficiency credit offered towards the use of BASF FE 75 W90 lubricant. BASF FE 75 W90 qualifies as a Dana SHAES 256 Rev. C. approved lubricant. As a further advantage, Dana promotes the use of a BASF XFE 75 W90 as an extreme high-efficiency lubricant. Based on internal testing at Dana, we propose that the agencies offer a 0.7% minimum credit for the use of the XFE 75 W90 lubricant as a 6x4 tandem drive axle lubricant. [EPA-HQ-OAR-2014-0827-1138-A1 p.3]

Modeling CO2 emissions to show compliance with the proposed rule

As truck manufacturers take steps to comply with the proposed Phase 2 GHG and fuel-efficiency standards, Dana believes there will be a continued need to further down-speed the engine. To facilitate this “extreme” engine down-speeding need, Dana is currently developing technologies that will support our customers’ ability to reduce engine speeds to 1050 rpm or below (at cruise speeds). This new level of extreme down-speeding can provide an estimated 3% (with a 300 rpm engine-speed reduction from current state) of additional GHG and fuel-efficiency improvement. However, this aggressive down-speeding can result in a series of trade-offs, such as: compromised low-speed vehicle maneuverability and performance; increased noise, vibration and harshness; higher torque through the drivetrain of the vehicle. [EPA-HQ-OAR-2014-0827-1138-A1 p.3]

To overcome these issues, Dana has developed a dual-range, “disconnectable,” tandem axle. This new axle innovation will operate as a traditional axle in 6x4 configuration with a higher numerical rear axle ratio to support the low-speed vehicle performance and safety. While approaching cruise speeds the tandem axle will “disconnect” and no longer turn the inter-axle driveshaft, rear-rear pinion and ring-
gear, therefore, operating fully on the forward of the rear axle. During this disconnected configuration, the axle operates at the equivalent efficiency of a 6x2 arrangement offering an additional 2.5% of improved GHG and fuel-efficiency. [EPA-HQ-OAR-2014-0827-1138-A1 p.3]

It is our interpretation of the proposed rule that the Phase 2 GEM accounts for additional technologies and vehicle configurations that are applied after the simulation is completed. Within the post-GEM simulation the proposed rule and the GEM Phase 2 user manual (Table 6, pg. 16, of the user manual) list a series of technologies that reduce GHG emissions and fuel consumption in Class 7 and 8 tractors but are not easily captured in GEM. The proposed rule allows Class 7 and 8 tractor manufacturers to take a further post-simulation “reduction value” if their vehicles contain these technology improvements.

Given our latest disconnecting axle innovation noted above, Dana further interprets that the proposed post-GEM simulation includes provisions for 6x2 configurations (noted as “permanent 6x2 configuration”) and disconnecting axles (noted as “part-time 6x2 configuration”). [EPA-HQ-OAR-2014-0827-1138-A1 p.3]

If we are interpreting the proposed rule correctly, Dana supports both having these axle arrangements listed as a post-simulation technology and providing a 2.5% reduction value for permanent and part-time drive axles. Dana further suggests including an additional efficiency improvement value for dual-range axle configurations as it enables slower engine speeds and faster axle ratios at highway speeds, boosting the vehicle’s efficiency performance. [EPA-HQ-OAR-2014-0827-1138-A1 p.3]

Tires and tire inflation systems

In addition to driveline systems (steer axles, driveshafts and drive axles), Dana offers tire pressure management systems that can be used on the full range of vehicles associated with the proposed rule (class 2b – 8). The Spicer® Optimized Tire Pressure System is designed for use with steer and drive axles, ensuring that tires in all tractor positions are at their target inflation without dependence on human intervention. Dana’s automatic tire inflation (ATI) solution is one of a number of available systems in the commercial vehicle space that automatically keep tires at the appropriate inflation to reduce rolling resistance, and provide significant fuel economy benefits. [EPA-HQ-OAR-2014-0827-1138-A1 p.4]

Dana’s independent studies support the findings in Section II.C.1.(f) (pg. 40187) of the proposed Phase 2 rule, highlighting that tire pressure monitoring systems cannot sufficiently guarantee the proper inflation of tires. These studies are supported by substantial fleet testimonials suggesting that monitor-only systems are too dependent on driver intervention to be effective, and even when used in combination with telematics, fleet managers typically only direct a truck in for unscheduled service if tires are at dangerously low pressures and at risk of blowout. Until tires reach this point, the benefits of reduced rolling resistance are typically not realized. [EPA-HQ-OAR-2014-0827-1138-A1 p.4]

While Dana supports the agency’s findings as it relates to providing post-simulation adjustments for class 7 and 8 tractors, the fuel economy benefits of reduced rolling resistance can be realized for all vehicles spending time on highway. As a result, Dana proposes that credit for automatic tire inflation systems be granted for all vehicle classes (2b-8) included in the rule, including credit for vocational vehicles as these vehicles tend to be on-highway between 40-60% of their life. [EPA-HQ-OAR-2014-0827-1138-A1 p.4]

Finally, the proposed rule grants a 1% “reduction value” as a post-simulation adjustment for the use of ATI systems on drive axles in tractors (40 CFR 1037.520(f)(7), pg. 40631 of the proposed rule). Maintaining proper tire inflation of the front tires on the steer axles can also contribute to reduced
rolling resistance, and improved fuel economy. Dana proposes an additional 0.25% credit be granted for tractors with ATI systems equipped on both steer and drive axles, for a total credit of 1.25 percent. [EPA-HQ-OAR-2014-0827-1138-A1 p.4]

Response:

We made appropriate changes relating to axle efficiency. Unlike the NPRM, where a fixed efficiency with 95.5% was used, the final rule uses the default power loss to represent the axle. The default power losses are derived from CBI data from two major axle manufacturers. The manufacturer has an option to override the default losses using the specified test procedure in 40 CFR 1037.560. With full axle testing, the benefits resulting from lubricants can be recognized as well. We also provide a mechanism to account for Dana’s disconnectable axle defined 6x4D. However, only one axle ratio can be selected, requiring the OEM to select the axle ratio that is expected to be engaged for the greatest driving distance. The main reason for this decision is that we believe that disconnectable axle is primarily used in tractor applications, where cruise speeds are predominate. The cycle weighing on transient cycle is small compared to the weighting of the two cruise cycles. We also recognize either ATIS or TPMS through the technology improvement input of the GEM input file (see Preamble Section III.D.1.b.iv).

Organization: Eaton Vehicle Group

Drive cycles
We have seen the briefly analyzed proposed new drive cycles. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]

New high speed cycles in GEM have a significant grade.
- We understand that the steeper grades in the cycles mimic national statistics of road grade and we have seen that the steeper grades exercise more shift control and other features, such as neutral coasting. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- We believe the Agency may want to revise actual profiles to mimic realistic roads, eg. piece-wise constant grade, besides the national statistics. The unrealistic hill shapes not realistic will distort shifting algorithms, especially significant when exercising the powertrain test. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- With higher grades, the simulated truck will also lose road speed while climbing. Thus it is important that these cycles should be distance-based and throttle demand should be 100% during the entire speed loss [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- Neutral coasting is “witnessed” by this test. There is a potential “double counting” with pull-down option. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- Eco-Roll like techniques are also credited by the powertrain test version, however these may clash with constant speed requirement and there is potential double counting the benefit with pull-down option. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- The grade sensor must be active in powertrain test mode and grade data set from the simulation. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]

Transient drive cycles proposed by NREL
We fully support the transient drive cycles proposed by NREL. In our experience, these are more representative of how trucks are being driven and thus we use very similar cycles to calibrate our shift controls. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]

Value of transmissions in GEM-based certification: Advanced transmissions, deeply integrated powertrains and the powertrain test option deliver a significant part of the compliance burden without significant incremental product cost, complexity, weight or vehicle architecture changes. We have provided data to the EPA showing that 25-33% of the line haul tractor compliance gap between
MY2017 and MY2027 can be covered through such technologies, and 33-50% of that gap can be covered in the vocational segment. [EPA-HQ-OAR-2014-0827-1194-A1 p.3]

A consistent approach to manual drivers: Fleet data indicates that automation introduces a 2% or more fuel economy advantage through human factors that go beyond technology -- making vehicles shift at the correct conditions and drive more efficiently. We caution the EPA that this behavior is already coded in GEM -- manual transmissions are shifted at higher engine speeds, with longer shift times -- as well as a 2% “automation bump” given in post-processing. A consistent set of assumptions should be adopted, carrying over to both GEM simulations and powertrain tests. [EPA-HQ-OAR-2014-0827-1194-A1 p.4]

**Consistent approach to manual drivers**

The NPRM suggests that GEM accounts for the fuel economy benefits of automation realized in line haul and some vocational applications. We agree with the EPA assessment that based on fleet reports, the impact of automation is around 2% fuel reduction or better. These efficiencies are realized primarily through human factors that go beyond technology: making vehicles shift at the correct conditions and drive more gently. They also do not apply to any particular driver but rather hold in a statistical sense. Due to these considerations, the EPA opted for a 2% automation benefit to be given to automated powertrain technologies as a post-GEM simulation of the fuel consumption. [EPA-HQ-OAR-2014-0827-1194-A1 p.15]

We caution the EPA that some driver behavior is already coded in GEM (manual transmissions are shifted at higher engine speeds, with longer shift times in GEM simulations), as well as a “2% automation bump” given in post-processing of GEM simulations. Furthermore, the fleets tend over time to configure AMT trucks for more engine downspeeding by deploying faster axles. We have CBI data that shows the trend toward higher final drive ratios as AMTs penetrate fleets. Thus, part of the 2% fuel benefit is in fact an artifact of the engine downspeeding enabled by automation that is already captured in GEM. [EPA-HQ-OAR-2014-0827-1194-A1 p.15-16]

We prefer that GEM codes the manual driver as a higher shift point and longer shift because in that case, we are able to run manual transmissions on powertrain tests using their AMT versions. As the AMT also uses some power from fuel to perform shifts, the test will in fact slightly overstate the manual transmission fuel economy benefit, in the spirit of always being “slightly conservative.” [EPA-HQ-OAR-2014-0827-1194-A1 p.16]

**Recommendation:** The EPA should consistently adopt one of the following hypothesis: either A) the AMT shift strategy is already programed to emulate a normal driver (and hence the manual transmissions should be simulated identically to an AMT) in which case a uniform “automation bump” should be maintained, B) or B) the poor efficiency manual drivers shift late and at higher speeds (as in current GEM), but then the benefit of automation was already encoded in the manual shift schedule so that no “automation bump” is necessary. [EPA-HQ-OAR-2014-0827-1194-A1 p.16]

**Recommendation:** Should the EPA decide to treat manual transmissions identically to AMTs from a shifting perspective and provide a post-GEM simulation “2% automation bump,” then the GEM simulations using powertrain results should benefit from the same treatment when implemented in GEM (currently is seems that if powertrain data is used, there is no means to alert GEM to an automated transmission). [EPA-HQ-OAR-2014-0827-1194-A1 p.16]

**Higher grade drive cycles**
We support the existing grade profiles for the 65 mph and 55 mph cycles with up to +/-2% grades. We do understand those road grades correspond to actual highway conditions in a relatively flat part of the country. However, we are not opposed to steeper grades in the cycles shown recently by the EPA and developed by NREL to mimic the national grade distribution. In fact, we believe the steeper grades will exercise more shift control features and other features, such as neutral coasting. [EPA-HQ-OAR-2014-0827-1194-A1 p.16]

We do caution that the actual road profiles recently discussed, also called “half-hills,” need some re-thinking. Although we have not yet run either GEM simulations or powertrain tests by the end of the comments period, we are concerned with the rapidly changing slope that is unrealistic and may confuse the grade sensor. Should the actual profiles be revised to mimic realistic roads (with the potential consequence of a longer drive cycle), then we would have no objection to steeper grades. [EPA-HQ-OAR-2014-0827-1194-A1 p.16]

However, it is important to realize that the steeper grades can exceed the grade-ability of some configurations. Thus, not only will the shift controls be exercised significantly more, but the simulated truck will also lose road speed while climbing. For GEM simulations, this is not a significant issue, but for powertrain testing it may be. It is imperative that a constant speed cycle is not only distance-based (which is the current GEM setting) but that it also demands that the throttle be open 100% during the entire speed loss. Otherwise, the slower truck will look more fuel efficient but in reality it would be an artifact of reduced aerodynamic loads at lower speed, even if the route is completed in a longer time. [EPA-HQ-OAR-2014-0827-1194-A1 p.16]

The EPA asked if it should consider speeds other than 65 mph and 55 mph vs other speeds. We see no significant benefit to other highway speeds, although we have had a situation where the 55 mpg at zero grade happened to be a worst and relatively unique operating point on the engine. However, as soon as variable grades were introduced, that problem ceased to exist because the engine is still exercised at multiple points due to the changing grade. [EPA-HQ-OAR-2014-0827-1194-A1 p.19-20]

**Eaton comments on the EPA MD/HD Greenhouse Gas Phase II NODA**

**Background**

The Agency has provided the industry with several opportunities to monitor and provide input into the development of the Phase II regulations. Recently it has requested comments around several issues. Eaton will comment and share experiences around the technical implementation and updates of GEM, which we view as core to the rule and its success. [EPA-HQ-OAR-2014-0827-1875-A1 p.1]

GEM has improved significantly since its early Phase II version was released in 2015. We believe that the powertrain technology is now well represented in GEM. We believe that the following are characteristics are critical to the success of GEM as a tool and to realizing the improvements envisioned by the rule in an efficient way for the industry: [EPA-HQ-OAR-2014-0827-1875-A1 p.1]

- GEM predictions need to be “slightly conservative” versus real-life applications, so that GEM does not either create a bias or drive “paper-only” improvements. [EPA-HQ-OAR-2014-0827-1875-A1 p.1]

Eaton has noted significant improvement in GEM along the directions outlined above and we have a high degree of confidence that GEM will be ready and effective by the time of rule finalization. [EPA-HQ-OAR-2014-0827-1875-A1 p.1]

**Conclusions**

The improvements to GEM have improved significantly the quality of the predictions, making us believe that the Agency is on track to have a good and robust regulatory tool. We appreciate the open manner which the Agency solicited feedback from stakeholders and provided status updates and we believe it was a key factor in improving GEM. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
Based on hardware data and powertrain tests, we feel the Agency has achieved the following: [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- GEM results capture correctly the fuel consumption differences based on transmission architecture and fuel reduction technologies. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- The GEM predictions are “slightly conservative” when compared to non-optimized, commercially available transmissions. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- GEM has robust and accurate means to overwrite default loss models and default control logic, and thus account for advanced technologies and transmissions optimized for fuel efficiencies. [EPA-HQ-OAR-2014-0827-1875-A1 p.3]
- GEM predictions using the powertrain-based model reflect the real-life fuel efficiencies tested for optimized transmissions, and thus is reasonably future-proofed for new technology. [EPA-HQ-OAR-2014-0827-1875-A1 p.4]
- The high-speed test cycles exercise fully the powertrain and are statistically representative of national roads. However, the hill shape could be improved to mimic more realistic road grades and thus more realistic shifting. [EPA-HQ-OAR-2014-0827-1875-A1 p.4]
- The transient cycle proposed by NREL is better matched to what the industry uses to optimize fuel efficiency regardless of regulations. Its adoption will only increase the consistency between real-life design practices for fuel consumption reduction and the regulatory drive to reduce CO2. [EPA-HQ-OAR-2014-0827-1875-A1 p.4]

GEM offers manufacturers the ability to quantify significant CO2 reductions in both line haul and vocational segments, especially with the options to overwrite defaults with transmission loss data and/or powertrain test-based models. This enables manufacturers significant flexibility in achieving stringent standards with technologies that do not significantly add weight, complexity or cost. [EPA-HQ-OAR-2014-0827-1875-A1 p.4]

Response:

We appreciate Eaton’s various constructive and positive comments, specifically on the NODA version of GEM. We provide 2% benefits for automated manual transmission (AMT) as opposed to manual transmissions (MT). See RIA Chapter 2.8.2.5.

We seriously considered many constructive comments on the road grades. Consequently, we made quite a few changes to the road grade. Examples include adding flat road and ±0.5 percent road grade road at the beginning and end of cycle, and shrinking the peak grades of the shortest hills by capping the change in grade per change in distance to rates see from in-use CBI data provided by manufacturers. See Chapter 3.4.2.1 of the RIA for the detailed description of the process the agencies took to create the road grade profile.

In addition to modifying the road grade profile the agencies have also conducted many powertrain tests with the profile to see how actual powertrains responded to the cycle. From this testing the agencies not only believe that the road grade profile is representative but it also fully exercises the powertrain. With regard to the road grade of the cycle exceeding the grade-ability of the vehicle, GEM already handles this, because the drive model in GEM will go to 100% pedal position if the vehicle falls off the trace significantly. As for powertrain testing this is handled by the requirements of 40 CFR 1037.550 (g) that require the pedal to be at 100% if the vehicle speed is lower than the lower speed tolerance. The agencies understand the comment that the shape of the half-hills are synthetic and do not look like typical hills, but with regard to the shift strategy the agencies have not found that the synthetic hills
cause the transmissions that were powertrain tested at Oakridge National Laboratory\textsuperscript{29} or Southwest Research Institute\textsuperscript{30} to shift in an unrepresentative way. We agree with Eaton that the cycles should be distanced based and that the throttle demand should be 100% when the vehicle is not able to meet the demand of the cycle.

The agencies do not agree that there is double counting of neutral coasting and eco-roll technologies in the pulldown input and in the actual simulation of the vehicle on the cruise cycles. This is because the allowance for the vehicle speed to overshoot the cycle speed by 3 mph when going downhill is to simulate how conventional cruise-control algorithms run. The “Intelligent controls” pulldown is designed to give credit for technologies that use predictive control to adjust current operator demand based on future vehicles demands for example reducing operator demand even when going uphill, knowing that the vehicle will be going downhill in a short distance.

The agencies agree that grade or other sensors that allow the powertrain to operate in a way that is more representative of in-use operation should be used or should be simulated in another way. That is why we added change to 40 CFR 1037.550 (i) to allow this.

The agencies thank you for your comments regarding the transient drive cycles proposed by NREL, but since the agencies did not have enough time to fully evaluate the cycles the agencies finalized the cycle we proposed for the transient phase of the duty cycle.

\textbf{Organization:} Electric Drive Transportation Association (EDTA)

\textbf{Models and Testing}

To capture the full benefits of electric drive, compliance pathways should also recognize its diverse contributions to efficiency, particularly in the duty cycle of vocational vehicles. The EPA’s Greenhouse Gas Emissions Model (GEM) model should better model fuel efficiency improvements for hybrid and plug-in hybrid systems. Vocational vehicles, as defined by the EPA, represent about one fifth of the total medium- and heavy-duty fuel consumption and include numerous vehicles types: “delivery trucks, refuse haulers, public utility trucks, transit, shuttle, and school buses. This segment also includes very specialized vehicles such as emergency vehicles, and cement and dump trucks.”\textsuperscript{6} [EPA-HQ-OAR-2014-0827-1217-A1 p.3]

The varied nature of the vocational vehicle fleet calls for a more comprehensive accounting of efficiency and emissions reductions in the full duty cycle. Specifically, the rule should establish compliance pathways that recognize the efficiency and emissions contributions of electrification including Power Take Off systems, which are increasingly being integrated into fleets’ vocational vehicles. [EPA-HQ-OAR-2014-0827-1217-A1 p.3]

These systems could be recognized in the testing procedures for vocational vehicles or in off-duty cycle credits. In the former scenario, lessons can be learned from CARB’s modeling of the full day vocational duty cycle. In the latter, establishing off-duty credits based on clear criteria and eligibility will increase certainty and uptake in this area. [EPA-HQ-OAR-2014-0827-1217-A1 p.3]

\textsuperscript{29} Oakridge National Laboratory July 2016, “Powertrain Test Procedure Development for EPA GHG Certification of Medium- and Heavy-Duty Engines and Vehicles.”

\textsuperscript{30} Southwest Research Institute July 2016, “Validation Testing for Phase 2 Greenhouse Gas Test Procedures and the Greenhouse Gas Emissions Model (GEM) for Medium- and Heavy-Duty Engines and Powertrains.”

Response:

The agencies agree with EDTA that hybrid and plug-in hybrid systems should have a pathway to recognize the benefits of the technology in GEM and because of this have modified 40 CFR 1036.540, 40 CFR 1037.540 and 40 CFR 1037.550 to allow for testing of these systems. 40 CFR 1036.540 and 40 CFR 1037.550 can be used to test hybrids and PHEV that use the stored energy to propel the vehicle. For electrified and PHEV PTO systems 40 CFR 1037.540 can be used to recognize the benefits of these systems. Even though GEM does not model hybrid or plug-in hybrid systems, GEM has been designed to use the output of these tests to account for the benefits of the systems.

Organization: Hino Motors, Ltd.

2. Balancing of Battery SOC (State of Charge) for HEV Configurations
Vehicle fuel efficiency is measured as the efficiency of the energy supplied from external sources to the vehicle (i.e., diesel fuel for diesel vehicles). In this sense, HEV electric batteries energy for vehicle drive should not be included in the fuel efficiency measurement. If this energy is included in the calculation, the fuel efficiency value calculated will not represent the real-world fuel efficiency of the vehicle. For this reason, the energy from vehicle drive batteries must have an energy balance of ‘zero’ between start and end of the test. [EPA-HQ-OAR-2014-0827-1877-A1 p.2]

Yet, it is quite rare that the energy balance settled down at zero during actual tests without paying any attention to having the balance. Therefore, generally we conduct 3 or 4 tests with different SOC level to determine the balanced SOC level by interpolation from test result. [EPA-HQ-OAR-2014-0827-1877-A1 p.2]

Consequently, HEV fuel efficiency test by cycle average map will necessitate engine manufacturers to conduct three to four times more tests. This is extremely heavy burden for manufacturers to conduct GHG certification test for HEV. [EPA-HQ-OAR-2014-0827-1877-A1 p.2]

Request:
Hino would like to keep the discussion with EPA on the most practicable way of testing of hybrid system to reduce a number of test on SOC balance. [EPA-HQ-OAR-2014-0827-1877-A1 p.2]

3. Torque at Regeneration
Fundamentally, HEV fuel efficiency improvement is generated from the regeneration of vehicle energy. Therefore, it is necessary to use the correct regeneration energy in the HEV fuel efficiency calculation. [EPA-HQ-OAR-2014-0827-1877-A1 p.3]

In the proposed GHG Phase 2 regulation, the GEM program is used to convert the vehicle speed and traction force on propeller shaft, based on vehicle specifications and road grade data. The traction force to drive the vehicle is output from GEM, but it seems that negative traction force generated during vehicle deceleration (regeneration) did not output in GEM. [EPA-HQ-OAR-2014-0827-1877-A1 p.3]

Request:
Please confirm if GEM program takes into consideration regeneration force conversion. [EPA-HQ-OAR-2014-0827-1877-A1 p.3]

4. GEM Negative Torque Calculation during HEV Regeneration
Also we would like to know if the GEM correctly calculates the engine torque based on the grade data on a downward slope because a torque map (see the map below) in the EPA document does not show the negative value less than 0. [EPA-HQ-OAR-2014-0827-1877-A1 p.3]

Request:
Please confirm if GEM correctly calculates the negative engine torque based on the grade data on a downward slope. [EPA-HQ-OAR-2014-0827-1877-A1 p.3]
[Figure can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1877-A1]

5. Equivalent Opportunities for Various Hybrid Systems

There are several types of hybrid system, such as parallel hybrid system, series hybrid system, split hybrid system, etc. As represented by series hybrid system, there are some types of system which have several power sources. In such a system, motor to drive vehicle and engine to generate electric energy are not connected mechanically. Therefore two test dynamometer is required for such system. [EPA-HQ-OAR-2014-0827-1877-A1 p.4]

Generally speaking, this way of test equipment setup is practically difficult on the ordinary test bench. Because of this difficulty, equal opportunities for the hybrid system are disadvantaged compared with the conventional diesel engine from a certification standpoint. [EPA-HQ-OAR-2014-0827-1877-A1 p.4]

Request:
Provide a standard GEM improvement for hybrid systems and do not make powertrain testing a requirement for hybrid systems to accommodate various type of hybrid system. [EPA-HQ-OAR-2014-0827-1877-A1 p.4]

Response:
We share the same concern with Hino on the test burden for HEV systems. To help address this the agencies have extended the cycle average mapping procedure to HEV and PHEV systems. To do this we updated the definition of the motoring torque curve to include the braking torque of the hybrid. With this change GEM will calculate the braking torque that is required by the hybrid during the test. With regard to your comment on SOC balancing, the agencies would also be interested in continuing discussion on further ways to reduce the test burden on hybrid vehicles.

Organization: International Council on Clean Transportation (ICCT)

Testing and compliance protocols

Test procedures, cycles, and simulation modeling

We support the agencies decision to maintain the Phase 1 regulatory structure of including a separate engine standard for the reasons outlined in Sharpe, Delgado, Muncrief (2014). In summary, it was found that the benefits of a certification protocol that include a separate engine standard while simultaneously enhancing the GEM certification with improved inputs outweigh any potential disadvantages. Key advantages include acknowledging the market structure, promoting improvement in all technology areas, and linking to criteria pollutant emissions. We also raise several issues that could help strengthen the agencies’ regulatory design and testing procedures. [EPA-HQ-OAR-2014-0827-1180-A4 p.12]

There is a predefined list of off-cycle technologies that are not captured by GEM simulation but are recognized via post-simulation adjustment factors. The agencies set fixed default effectiveness values for such technologies. For example, automatic tire inflation systems effectiveness was set at 1.0%, and 6x2 axles was set at 2.5% (Table III-7 of NPRM). The following issues were identified with such technologies and adjustment factors. [EPA-HQ-OAR-2014-0827-1180-A4 p.13]

Drivetrain. An adjustment factor of 1.8% from downspeeding was set (Table III-7 of NPRM). There is no need for such an adjustment factor since the downspeeding of the engine through transmission gear ratio, drive axle ratio, and tire diameter is already captured by GEM. Also, a reduction in friction due to low viscosity axle lubricants is set to 0.5%. It is not clear how the agencies would verify the use of such
lubricants and there is the risk of giving 0.5% without any real-world fuel savings. [EPA-HQ-OAR-2014-0827-1180-A4 p.13]

**Transmission.** The benefits for automated transmissions (automated manual, automatic, and dual clutch transmissions) are set at 2.0%. This number seems high, taking into account that part of the benefit of such transmissions come from downspeeding and those benefits are already captured by GEM. Such high number may discourage the use of powertrain testing. We recommend setting the adjustment value to 1%. [EPA-HQ-OAR-2014-0827-1180-A4 p.13]

**Accessory improvements.** An adjustment factor of 0.5% is set for improved air conditioning systems. It is not clear in the rule how one would determine if an air conditioning has improved, but based on Reinhart (2015a), an improved air conditioning system would reduce power demand by 600 W. A 600 W reduction in power demand only represents 0.33% fuel consumption reduction in GEM simulation. Also, the air conditioner system is not used all the time so the real-world benefits will be even lower. We recommend setting the adjustment value to 0.3%. Also, an adjustment factor of 1% is set for electric accessories. It is not clear if these refer to all of any of the accessories that have potential to be electrified (e.g. water pump, oil pump, power steering pump). Note that the effect of some of these accessories (e.g. water pump, oil pump) is already captured in the engine mapping process and therefore would be captured by GEM simulation and there is no need for adjustment factor. [EPA-HQ-OAR-2014-0827-1180-A4 p.13]

The off-cycle technologies’ adjustment factors are additive, implying that there is not negative or positive interactions among technologies. We recommend that multiplicative aggregation of technologies’ effectiveness—similar to the one conducted for engine technologies—be applied in order to better quantify these effects. Also, these adjustment factors inherently assume that all the technology variants within a technology category provide the same fuel consumption benefits. Not all the models and brands of a certain technology feature would provide the same fuel consumption benefits. There is the risk of giving artificial credits to products that perform at a lower level than the value that is selected from the drop-down menu, thus rewarding poor performers. The default values ideally would be set to the minimum values of the ranges. The users have the option to use off-cycle credit proposed by the rule (similar to innovative credits in Phase 1) to quantify the additional benefits of individual technologies. [EPA-HQ-OAR-2014-0827-1180-A4 p.13]

**GEM Simulation.** The fact that the user can input specific powertrain parameters but does not have the option to input or modify the simulated payload could create the situation in which some simulated vehicles, the ones with low power-to-weight ratios, will show high deviations from the target speed-distance trace. This affects the simulation results since these underpowered vehicles will take more time to complete the assigned route and will show a lower average speed. This could lead to underpowered vehicles being improperly credited. We recommend that a performance criterion that captures the trace-following capabilities of the simulated truck (e.g. percent difference between target speed and simulated speed) is used and be a part of the output of the tool. Ideally, the allowed deviations from the target trace should be minimized for the simulations to be considered valid and allow comparisons between them. [EPA-HQ-OAR-2014-0827-1180-A4 p.13-14]

There are opportunities for fuel savings from mechanical accessories and electric accessories but the agencies decided to keep with the Phase 1 approach of having pre-defined and not customizable power from accessories. If these parameters are assigned default values, there are no incentives to implement new technologies that could have greater impact. Allowing accessories’ power consumption to be user-defined inputs in GEM can be used to promote developments in technologies that currently are not
Powertrain test

The ICCT supports the use of a powertrain test to ensure that transmission and integrated engine-transmission efficiency technologies are acknowledged and promoted within the regulation. To make sure the powertrain provisions serve that objective, the default credits (e.g., for automated manual transmissions) would ideally be established at the lowest potential improvement level that any company might reasonably achieve, such that any additional benefits would require data from the powertrain test submitted to the agencies. It would appear that the 2-3% automated manual transmission (AMT) benefit (for tractors and vocational) may be too high, considering that many AMTs based on company and fleet input may offer limited benefits compared to manual transmissions (Lutsey et al, 2014). We would recommend considering an AMT default at 1% to better reflect the range of transmissions in the marketplace and their various potential final drive ratios. Also, a 1% AMT default would encourage manufacturers to utilize the powertrain test. Greater potential exists to promote more powertrain technology, and the agencies could consider significantly more technology penetration and greater CO2-reduction effectiveness from integrated powertrain approaches that include shifting strategies and integrated controls directly in the stringency determination (Stoltz and Dorobantu, 2014; Jackson and Palazzo, 2015; ongoing Bosch track test results). In order to ensure that the GEM result reflects a slightly conservative value that does not unduly credit powertrain technology and that promotes the appropriate utilization of the powertrain test option, we suggest that the agencies conduct powertrain versus GEM testing on the most common integrated powertrains and adjust the GEM model appropriately. [EPA-HQ-OAR-2014-0827-1180-A4 p.14-15]

Response:

We thank ICCT for many constructive comments.

ICCT is correct in their assessment that the effectiveness of downspeeding is accounted for through the transmission gear ratio, drive axle ratio, and tire size. The downspeeding value listed in Table III-7 of the NPRM highlighted the approximate effectiveness of the change in axle ratios modeled for setting the proposed stringency levels. The agencies did not apply a separate adjustment factor for downspeeding in the NPRM. For the final rule, the agencies removed this row of the table and added a better description of how downspeeding is modeled through the use of axle ratios in GEM and used in setting the tractor standards.

The agencies determined the effectiveness of automated transmissions based on literature values, comments, and CBI of transmission suppliers. We believe that automated manual transmissions lead to a two percent reduction in CO2 emissions and fuel consumption compared to manual transmissions in real-world driving conditions. See Preamble Section III.D.1.b.vi.

The agencies have refined the definitions and the effectiveness of accessories in the final rule. See 40 CFR 1037.520. The agencies are only allowing the predefined accessories to be included in GEM. We are not allowing customizable power inputs for accessories because we do not have test procedures developed to quantify what the power requirement is for each subcategory of HD vehicle over each test cycle.

The agencies defined the curb weight of the HD vehicles and the associated payloads for each subcategory. This is necessary because allowing a variable payload would result in different numerical
standards. If a vehicle configuration, such as under-power engine vehicle, is not able to keep up with the drive cycle trace during the simulation, the vehicle will go to 100 percent pedal position when the vehicle speed is significantly below the cycle speed and the simulation will continue until the vehicle completes the entire cycle.

On powertrain testing, again we believe that an AMT is two percent more effective than manual transmissions in the real world driving and it is appropriate based on the information we received. We do believe that powertrain testing will still be the appropriate mechanism to evaluate shift schedules and other integrated controls, as noted by the commenter.

Organization:  Meritor, Inc

Expand GEM to Foster More Innovation

Meritor is supportive of the proposal “to significantly expand GEM” from Phase 1 “to account for a wider range of technological improvements that would otherwise need to be recognized through some off-cycle crediting approach.” Furthermore, Meritor believes that the inclusion of distinct GEM inputs “to represent the engine, transmission, drive axle(s) and loaded tire radius,” as opposed to the default value approach in Phase 1, incentivizes the development of fuel efficient individual and collaborative power/drivetrain technologies. In short, it supports competition and collaboration; both of which are needed to meet the proposed Phase 2 rule on greenhouse gas emissions and fuel efficiency. [EPA-HQ-OAR-2014-0827-1254-A1 p.3]

Response:

We very much appreciate the positive comments on GEM from Meritor.

Organization:  Navistar, Inc.

We note that GEM inputs add static loaded radius to inputs in GEM. Navistar does not oppose the addition of static loaded radius. However, we believe that the tire manufacturers are in the best position to make this measurement in a consistent manner. Static loaded radius should come from a tire manufacturer using their methodology and tire manufacturers should provide this information along with rolling resistance data. We agree with the EMA comments in this regard. [EPA-HQ-OAR-2014-0827-1199-A1 p.41-42]

IV. Revisions to GEM

a. Grade

The agencies released a new version of the Greenhouse Gas Emission Model (“GEM”) and sought comment in the NODA. A major change to the assumptions surrounding grade distribution and transitions is incorporated in the new version of GEM. The modeling framework that the NPRM is built around has had much time, effort and discussion around the specific inputs and the processes of generating these inputs. The grade profile is a topic that did not receive much attention from the vehicle manufacturers during the original NPRM phase due to the understanding that the grade profile would be revisited and a new one would be put forth for consideration. There were some concerns expressed by the industry during the initial release of the NPRM focused on the original grade profile which resulted in the engine being driven in an uncharacteristic manner. The root cause of this was not fully known at the time, but it was thought to be due to an unrealistic grade distribution. The expectation was that the
new grade profile the EPA was working on would be an improvement. [EPA-HQ-OAR-2014-0827-1919-A2 p.5]

The EPA proposed Grade D profile has been shown to match the grade histogram generated by the EPA-commissioned study, as well as lining up with manufacturer’s customer data, and the associated development cycles. With a brief look one would think the problem would be alleviated. However, upon more detailed analysis of the output of the recently released NODA GEM version it was quickly recognized that the original concerns are still not fully addressed. Even with the inclusion of the new grade profile the engine operation is still being incorrectly represented within the regulatory framework. [EPA-HQ-OAR-2014-0827-1919-A2 p.5-6]

[Figure, 'Grade Profile D: Nav Cruise', can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1919-A2]

To rehash, the main problem that Navistar has with the grade profile in the revised GEM is that it results in engine operation that is uncharacteristic, and misrepresentative of what actually occurs in the real world. It is unrealistic to the point that the simulation of vehicles on the Grade D Profile could (and already does) poses a risk for adverse consequences in the future. Information shared with the EPA provided evidence that customer data shows that there is significantly less time spent at WOT in the real world than the 40% shown above when using the Grade D profile. One way to alleviate this issue is to make changes to the driver model within the GEM simulation. The driver model improvements that are recommended are that the logic be updated such that for the highway cycles trucks be allowed to over speed the speed set point by an allowable amount when the vehicle is traveling downhill. This is a common driving behavior utilized by drivers and cruise controllers alike to increase fuel economy and productivity. Given the way in which the Grade D cycle is built, in that the road has repeated and discontinuous transitions from downhill to uphill segments, the improved driver model will allow the vehicle to carry more speed into the uphill section and thereby reduce need for WOT operation. The total effect of this is on the order of about 10% reduction in fuel used at WOT. [EPA-HQ-OAR-2014-0827-1919-A2 p.6]

The main reason for the unrealistic engine behavior is that although the grade profile distribution, aligns well in 1-D domain, it does not align well with the real world in how it transitions the grade profiles. This, as demonstrated in the two figures below, is found to be an artifact of trying to represent the national grade profile in a condensed length of road. These charts are the differences in the transition probability of the grade profiles and they show that, when compared to data collected from the real world, the Grade D profile is not very representative. [EPA-HQ-OAR-2014-0827-1919-A2 p.6-7]

[Figure, 'Transition Probability Matrix Differences', can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1919-A2]

The chart on the left represents grade profile that does not exist in the real world, and the one on the right shows places where there is a lack of grade information in the Grade D profile. [EPA-HQ-OAR-2014-0827-1919-A2 p.7]

The impact of this will be felt by both OEMs and customers alike and could negate the penetration rates and costs predicted by the agencies for the implementation of the rule. Certain technologies such as down speeding will be under represented in their impact which will result in other technologies being incentivized to meet the regulation versus this lower cost and potentially more suitable option. There is also the impact to technologies such as predictive cruise (should an OEM desire to do additional testing for a higher effectiveness number), and mild hybrids to name a few. There is also always the potential
risk due to the misalignment of regulatory and real world operation that other technological and/or certification issues present themselves in an adverse manner that is detrimental to either customers, OEMs, or regulatory agencies. The new grade in GEM could, thus, lead to the kind of distortions that the agencies should seek to avoid. [EPA-HQ-OAR-2014-0827-1919-A2 p.7]

b. Other Issues in GEM

Navistar has been attempting to evaluate GEM beyond the issues identified above with grade so that it may adequately comment on this latest version. However, given the very tight timeframe for comment we have been unable to fully assess whether GEM contains changes other than those specifically addressed. Navistar’s NPRM Comments addressed extensively what we felt was the lack of adequate opportunity to comment on GEM.9 Those issues with respect to adequate notice and comment still exist, and are not fully addressed by the short period with which impacted parties have to analyze the GEM. [EPA-HQ-OAR-2014-0827-1919-A2 p.7]

Moreover, the GEM version provided with the NODA did not contain any information as to the baseline values, which Navistar discussed at length in the NPRM Comments.10 Without that information, there is virtually no way to adequately determine, with reference to the agencies’ data, whether GEM is performing correctly or not. [EPA-HQ-OAR-2014-0827-1919-A2 p.7-8]

To create the hypothetical engine that forms the baseline for the vocational engine in GEM, the agencies constructed a hypothetical engine map. This was not derived from an actual in-use engine. Our current analysis of this hypothetical map shows a shift in the baseline from actual, real-world engines. That is, the theoretical starting point, the MY17 standards, changed. The baseline engine maps within GEM for the vocational vehicle are not aligned with current 2017MY compliant engines and hence, set up an unrealistic baseline for the vocational vehicle standard. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

Navistar took one of its MY2017 CO2 compliant engine families and created an engine map for use in the Phase 2 version of GEM. Comparing the tested engine map to the 2018MY baseline maps the tested engines showed differences ranging between 1 to 5% in the cruise part of the map and around 10% in the “acceleration” part of the map for the 345hp engine map to 10% to 15% differences for the 350hp engine map. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

The problematic areas of the hypothetical vocational baseline engine include the following: [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

- The EPA 345 hp HD generic engine map has an uncharacteristic shape where the minimum BSFC points is at 9% of maximum power. Other hypothetical engines show 80% of maximum power. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]
- The 270 hp MD hypothetical engine is flawed as well. Comparison with actual compliant MY2017 engines show that the hypothetical engines were 10% higher in fuel consumption than the real-world engines. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

Ultimately, this discrepancy must be corrected. Navistar will separately provide proprietary information to EPA showing this concern in greater detail. All manufacturers should begin from the same starting line, the actual MY2017 emission performance of the engines. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]
Response:

With respect to Navistar’s comment on adequate notice, please see the agencies’ response in RTC Section 15.5.

The agencies have changed the tire input to GEM from loaded radius to revolutions per mile because this is the value more often used by tire manufacturers. We have considered many constructive comments on the road grades. Consequently, we made quite a few changes to the road grade. The examples include adding flat road and ±0.5 percent road grade road at the beginning and end of cycle, and shrinking the peak grades. The changes to the road profile were made to better align the engine operation in GEM with the engine operation of in-use vehicles. See Chapter 3.4.2.1 of the RIA for the detailed description of the process the agencies took to create the road grade profile.

All the agencies’ baseline engines are developed based on real life in-use engines. In the final rule, we have combined a 345hp engine with a 350hp engine as one engine, which will be applied to both tractor and vocational vehicles. We also made changes to the 270hp baseline engine fuel map. However, it should be pointed out that the engine for the baseline 270hp rating engine was 7 liter based, and is much smaller than Navistar 9 liter engine. As a result, the engine sweet spot and the rated speed are also appreciably different. On the other hand, the 350hp engine used by the agencies is 11 liter based, and is bigger than Navistar’s N10 engine. Depending on the vehicle configurations, such as transmission, and axle ratio, the engine operating points in terms of engine speed and load can be so different between two different engines, resulting in different values of CO$_2$ g/hp-hr. Although we did not provide the baseline values, we made the best efforts to supply those vocational vehicle baseline values in the later power user release version.

Organization: Odyne Systems LLC

Odyne works closely with Allison and would like to echo their concerns on the need for better modeling since our system is integrated via the PTO interface on their transmissions. Not all hybrid systems are physically located in existing powertrain components; some systems can include external components added and integrated with powertrain components, which is the case with our system. So any issues that would impact the transmission could also impact our hybrid system. [EPA-HQ-OAR-2014-0827-1239-A1 p.19]

Allison Comments from public hearing in Chicago on August 10th

“Allison fully supports EPA’s ongoing efforts to make GEM more accurate and more representative of real world vehicles. We also support the use of GEM as the primary certification methodology -- but we have some significant concerns with the quality of GEM software and EPA technical and policy choices regarding GEM. [EPA-HQ-OAR-2014-0827-1239-A1 p.20]

First, GEM does not run well. When GEM was delivered, there were missing files and then when we got it to run, there were a number of coding errors identified. Secondly, the model produces unrealistic operation over the duty cycles. The lockup shift strategy and the neutral loading and automatic neutral
functionality are inappropriate. And, finally, there are major deficiencies in the base control algorithms. Some production vehicle configurations would not shift out of first range. Others do not downshift at highway speeds when a load is encountered. We have also seen the GEM controller release lockup at highway speeds which would never happen. [EPA-HQ-OAR-2014-0827-1239-A1 p.20]

These examples do not reflect how fully automatic transmissions operate. And flaws in GEM will directly translate into flaws in the final rule. In short, GEM is not ready for "prime time" as the certification tool. Given this situation, we believe that EPA and NHTSA must be mindful of the procedural requirements of the Clean Air Act and the Administrative Procedure Act. Adequate opportunity for comment must be provided, especially with regard to a central element of the rulemaking, such as GEM. [EPA-HQ-OAR-2014-0827-1239-A1 p.20]

With regard to GEM, the devil really is in the details. It is impossible to understand and reasonably project the effect of any final rule without understanding precisely how GEM will operate, what it will measure and how it will assess different systems. This is especially true in the vocational vehicle market where there are hundreds of different vehicle types and is amplified where, as here, EPA and NHTSA intend to decrease greenhouse gases and improve fuel efficiency through the deployment of new technology. [EPA-HQ-OAR-2014-0827-1239-A1 p.21]

When GEM executable files will not run; when other errors are found in GEM, when delays occur in making changes to the model -- the very process of the public comment period is called into question. Without refinement, GEM results could be considered arbitrary." [EPA-HQ-OAR-2014-0827-1239-A1 p.21]

Response:

We understand the commenter’s concerns on the early version of GEM. Since then, significant improvements have been made, such as the following:

- Modified road grade profile for 55- and 65-mph cruise cycles
- Revised idle cycles into overall vocational vehicles with new vocational cycle weightings
- Made significant changes on the input file structures. Examples includes additions of columns for axle configuration ("6x2", "6x4","6x4D", "4x2"), and additions of a few more technology improvement inputs, such as “Neutral Idle and Start/Stop.”
- Made significant changes on output file structures. Examples includes an option to allow the user to output detailed results on average speed, average work before and after transmissions, and the numbers of shift for each phase (55 and 65mph cycles and ARB cycle).
- Added input file for axle power losses (function of axle output speed and torque) and replaced single axle efficiency in model with lookup table of torque loss
- Added simulation of engine torque response with fast response region defined by engine displacement, and slower torque increase in boosted region with fast falloff on available torque
- Added regression models for all certification cycles to allow the user to simulate vehicle with cycle average approach
- Added different fuel properties according to 1036.530.
- Significantly improved shift strategy based on testing data
- Adjusted transmission loss & inertia scale factors per regulatory subcategory
- Added optional input table for transmission power loss data
- Added minimum torque converter lock-up gear input for AT
- Retuned the default transmission mechanical efficiency based on the testing data
- Added neutral idle and start/stop features during simulation
- Adjusted shift and torque converter lockup strategy

It should be mentioned that all hybrid systems and technical features are not modeled by GEM. The benefits of a hybrid can be addressed through the powertrain test in 40 CFR 1037.550. The provisions will work for hybrids that are integrated into the transmission or that interface with the PTO shaft. Using the powertrain test eliminates any issues with GEMs ability to model the transmission because the powertrain test results effectively replace the engine and transmission in GEM. In addition to 40 CFR 1037.550, the agencies have also finalized changes to 40 CFR 1037.540 to quantify the benefits of hybrid PTO systems including plug-in hybrids.

**Organization:** Owner-Operator Independent Drivers Association (OOIDA)

OOIDA appreciates the fact that the agencies decided to add road grade to Phase II’s Greenhouse Gas Emission Model (GEM) simulation tool in order to better reflect real-world operation. However, while the addition of road grade is laudable, it is disconcerting that the agencies could propose Phase I standards without considering terrain, as the Oak Ridge National Lab found that the impact of a mild upslope of one to four percent led to a decrease in average fuel economy from 7.33 mpg to 4.35 mpg.9 It is equally disturbing that while road grades were included for the urban and rural interstate driving cycles as part of the Phase II NPRM and Regulatory Impact Analysis (RIA), it was not included for the stop-and-go city driving. This fact coupled with the absence of considering LSFC, demonstrates the agencies’ lack of understanding of the trucking industry and ultimately the customers who purchase the vehicle. In addition, these facts have caused OOIDA to question the legitimacy of the agencies’ assertions. [EPA-HQ-OAR-2014-0827-1244-A1 p.9]

**Response:**

Although the Phase 1 standards did not seek to model road grade, the technologies on which the rule was predicated (chiefly tire and aerodynamic improvements) are not as sensitive to road grade as the driveline, transmission, and engine-based technologies that are included in the Phase 2 rule. Because the Phase 2 version of GEM uses data from the actual powertrain and driveline of the vehicle, the agencies added road grade to the cruise cycles. As described in Chapter 3.4.2.1 of the RIA, the agencies partnered with the National Renewable Energy Laboratory (NREL) to develop a nationally representative road grade profile. This was achieved by taking the half-hill road grade distribution of the limited access highways in each county in the United States and weighting it by the vehicle miles traveled in that county. The profile was further refined by limiting the change in grade per change in distance to the levels found on road and adding additional distance at zero percent and ±0.5 percent grade, to better align engine operation in GEM with engine operation of in-use vehicles.

**Organization:** PACCAR, Inc.

**Automatic Engine Shutdown (AES) System**

GEM currently does not account for the provisions in §1037.660 that allow the 5 percent reduction to be prorated as an input to GEM using the miles of expiration flexibility in the rule. This functionality was present in the Phase 1 GEM tool, but not carried over in the proposed Phase 2 GEM. The proposed GEM
only includes a “Y” or “N” input for this feature, which would indicate the technology must be set to be tamper-resistant for the full 1,259,000 miles. GEM needs to be corrected so that the proper calculated inputs can be utilized. Additionally, the examples for calculating the input to GEM for the expiration mileage option should all be updated to reflect the 5 percent reduction in addition to the 5 g/ton-mile reduction. [EPA-HQ-OAR-2014-0827-1204-A1 p.17]

Vehicle Speed Limiters (VSL)

Similar to AES, speed limiters can be programmed to be tamper-resistant for a reduced expiration time frame and the vehicle score will receive partial credit. §1037.640(c)(2) states that the input to GEM must be calculated and rounded to the nearest 0.1 MPH. PACCAR’s use of the Phase 3 GEM shows that GEM is not recognizing the decimal places on the GEM input and is effectively rounding the input to the nearest whole number. Therefore, the results from GEM is the same for every tenth of a decimal depending on how the inputs round (up or down). Without correction to this, the benefit of incremental changes to speed, expiration, or soft top limits would not be accurately recognized in the vehicle scoring model. [EPA-HQ-OAR-2014-0827-1204-A1 p.17-18]

GEM Runtime Errors/Crashes

Using the stand alone executable version of GEM, there are instances where GEM will not process the inputs and will crash, providing the user an error message. An example of an error message repeatedly received is:

Attempted to access result.phase_NV_ratio(2); index out of bounds because numel(result.phase_NV_ratio)=1. Error in => GEM_main.m at line 251

PACCAR provided the agencies examples of the configurations that failed to run and will work with them on testing and mitigation of the issues. [EPA-HQ-OAR-2014-0827-1204-A1 p.18]

NHTSA Phase 1 Stringency and Credits

In addition to the GEM-specific features above, PACCAR brought to the agencies’ attention the issue that the NHTSA stringency values were not determined the same way that the NHTSA vehicle assessment values were from GEM. The stringency was the rounded output of GEM 2.0 and all vehicles are being reported with the rounded output of GEM 2.0.1. The difference in GEM output for NHTSA showed some vehicles to be above the NHTSA standard when the same vehicle was at or below the EPA standard, and vice versa. This caused credits and debits to be inconsistent between the two agencies. The agencies corrected the discrepancy through the modification of the NHTSA stringency calculation and by changing the precision of decimal places to be used for the NHTSA FEL scores. Previous to the amendment, the level of precision of the NHTSA standards was to one decimal place, and the amendment revised this precision to 4 decimal places. While this addresses the misalignment issue, it does not address retroactively correcting any credit balances accumulated since model year 2013. In order to do this, the agencies will need to issue a modified version of GEM 2.0.1 to account for this level of precision. Additionally, PACCAR strongly recommends that EPA and NHTSA clarify in the Final Rule documents that credit balances for all model years will be adjusted by the agencies in accordance with the proposal and the adjusted totals will be communicated to the regulated entities (vehicle OEMs). [EPA-HQ-OAR-2014-0827-1204-A1 p.18]

Tire Size Input
PACCAR recommends that the agencies change GEM to utilize the tire manufacturers’ stated tire revolutions per mile data as the tire size input to GEM. This is the data that is used to spec vehicles for customers and therefore it should be used to assess vehicles for GHG performance. Tire static loaded radius, which is currently used in GEM Phase 2, is only used for determining vehicle height, not powertrain performance. [EPA-HQ-OAR-2014-0827-1204-A1 p.19]

**Road Grade Profile**

PACCAR has reviewed the updated road grade profile proposal that comes from the EPA commissioned NREL study. In general, the profiles appear to be an improvement over the road grades that were initially proposed in the NPRM. Additional time is needed to finish the assessment of the new profiles. PACCAR recommends that the agencies work with industry to make any needed modifications to the newly proposed road grades based on the assessments that all OEMs are now working on. PACCAR also requests that the agencies reissue GEM Phase 2 with the new road grades incorporated so that the assessment of the proposed regulation will include the correct performance of the technologies that the agencies are including in the stringency determination and that OEMs must use for compliance. [EPA-HQ-OAR-2014-0827-1204-A1 p.19]

For powertrain testing in a dyno cell, allowance should be made for any fuel-saving strategies that may result in a deviation from the desired vehicle speed during the 55 MPH and 65 MPH cycles. Strategies such as fuel cutoff while coasting, or even coasting in neutral, during slight down-grades show considerable potential for fuel savings especially if vehicle speed is allowed to deviate slightly below the set point (target speed of either 55 or 65 MPH). Additionally, if vehicle speed is allowed to be offset lower than target on uphills, and slightly above target on downhills, this could result in matching the considerable real world fuel savings during powertrain dyno testing. Furthermore, the inclusion of grade in the 55 and 65 MPH cycles will result in transmission gear shifts that may not be capable of allowing a ± 1 MPH tolerance band. [EPA-HQ-OAR-2014-0827-1204-A1 p.19]

It is recommended that the point-by-point tolerance be ±4 MPH, with the requirement that average vehicle speed for the entire cycle (for 55 and 65 MPH cycles) be held to ±2 MPH. [EPA-HQ-OAR-2014-0827-1204-A1 p.19]

**Natural Gas Engine**

PACCAR investigated the GHG / fuel consumption impact of compressed and liquid natural gas (CNG and LNG, respectively) engines in GEM. The weight penalties for the CNG and LNG fuel tanks were properly reflected in the GEM output, giving a GHG emission increase versus a diesel engine fuel tank. However, GEM did not properly calculate the carbon content differences between CNG or LNG and diesel. Specifically, when the same fuel flow map was used in GEM with for all three fuel types, GEM calculated the exact same grams per ton-mile result for the vehicle. The GEM output should have been notably different for all three fuels under these test conditions. [EPA-HQ-OAR-2014-0827-1204-A1 p.19-20]

PACCAR has notified the agencies of this issue and requests that the agencies investigate the GEM assessment of CNG and LNG engines and corrects GEM to properly determine the CNG and LNG engine performance. [EPA-HQ-OAR-2014-0827-1204-A1 p.20]

**GEM Integration**
Lastly, with the increased complexity in the GEM Phase 2 model, coupled with the increase in stringency of the proposed Phase 2 standards, the agencies should release a `.dll` executable version of GEM that can be integrated into manufacturer’s business systems. This would allow for real-time processing of changes and impact to compliance. This solution would need to be fully capable for performing certification and compliance purposes, as well as being backwards compatible to Phase 1 GEM. The `.dll` version of GEM should be a certified version from the agencies that can be used for the certification process and end of year compliance reporting to the agencies. PACCAR, along with EMA, is willing to work with the Agency to define the necessary inputs and outputs for this solution. [EPA-HQ-OAR-2014-0827-1204-A1 p.20]

**Off-Cycle Technologies**

PACCAR supports the concept of credits for reductions associated with off-cycle operation. At the present time, neither EPA nor NHTSA has outlined what technologies they believe should be eligible for such credits nor the amounts of any such credits. Some ideas for items that could be included are: solar reflective paints and glazing, workday idle reductions for day cab tractors, and any possible improvements in aerodynamics for vocational vehicles. Each of these involves significant research and may or may not have benefits. PACCAR also supports EPA considering the proposal advanced by the manufacturers of re-refined engine oil that credit should be provided for the use of such oil as original fill and service fill in vehicles used or sold by OEMs. The manufacturers of re-refined oil have peer reviewed studies showing that there are significant and quantifiable energy and GHG benefits to the use of such lubricants. [EPA-HQ-OAR-2014-0827-1204-A1 p.25]

PACCAR will work with the agencies to determine the process for evaluating such technologies and the proper credit amount. In no circumstances should early concepts such as those identified as examples be used as part of a stringency determination for Phase 2 standards. [EPA-HQ-OAR-2014-0827-1204-A1 p.25]

**Transmission Efficiency**

Phase 2 GEM uses default transmission efficiencies that were determined by the agencies. These efficiencies for gear and pumping losses can be reduced by approximately 1% to 2% through design-specific actions to transmissions. Having an optional test to capture the product-specific performance and transmission efficiency inputs for GEM would allow OEMs to determine and utilize the engineered GHG / fuel consumption benefits in Phase 2. The EU and European manufacturers are working on a transmission efficiency test procedure for their GHG Declaration regulation that should be the starting point for the agencies in developing the Phase 2 option. EMA recommends that the same test procedure and data input formats as Europe be finalized for Phase 2. PACCAR joins in that recommendation. [EPA-HQ-OAR-2014-0827-1204-A1 p.25-26]

**Response:**

We appreciate the many constructive comments from Paccar. Consequently, we have made many changes in the final GEM.

With regard to automatic engine shutdown, the agencies have modified Phase 2 GEM for the final rule to accommodate a percent input value to represent the emissions reduction due to various idle reduction technologies, as specified in 40 CFR 1037.520. The agencies are recognizing both tamper-proof and adjustable AESS in Phase 2, therefore, we are not applying the Phase 1 expiring mileage option to Phase 2. The Phase 2 AESS will either be tamper-proof for 1,259,000 miles or else it is deemed adjustable.
We also made the change to VSL, so that GEM accurately accounts for input values rounded to the nearest 0.1 MPH.

We recognized a few issues related to GEM runtime errors and crashes for the early released version of GEM, and all of these issues have been resolved by first identifying the bugs, and then correcting them, and finally testing them to make sure that GEM can produce the correct results.

Consistent with the recommendation of PACCAR and other manufacturers, the agencies have changed the tire size input to revolutions per mile.

In order to correct the misalignment noted by the commenter, NHTSA proposed to amend the existing fuel consumption standards and the method for calculating performance values for all compliance categories by increasing the significant digits in these conversion values. Increasing the significant digits in these values will result in more precise alignment between final compliance credit balances.

NHTSA proposed that the increased resolution would apply retroactively starting for the model year 2013 standard. However, because the Phase 1 fuel consumption standards created a difference in compliance margins which could potentially have an adversely impact for certain manufacturers who have already developed engineering plans considering previous credit balance, NHTSA sought comments on whether optional to allow manufacturer to continue using the Phase 1 standards.

NHTSA is finalizing its standards and method for calculating performance values for the Phase 1 and 2 programs with increased significant digits as the only option for compliance. Retaining the previous method would result in ongoing differences in credit plans and balances, and continue the associated burden on manufacturers. Since manufacturers already have and will continue to develop compliance strategies for the EPA GHG program, the change will enable those strategies to also directly comply with the NHTSA fuel efficiency program, creating a more aligned National Program. Compliance with the EPA GHG program is unaffected by the change. EPA will make the update to its system so that the NHTSA values with increased resolution can be applied retroactively.

With regard to the road grade profile of the cruise cycles the agencies shared the road grade profile in the NODA and continued to work with manufactures after the NODA to finalize a road grade profile that is nationally representative but also allows engine operation in GEM to match engine operation of in-use vehicles. See Chapter 3.4.2.1 of the RIA for the detailed description of the process the agencies took to create the final road grade profile.

Regarding the recognition of technologies that allow the powertrain to not maintain the commanded 55mph and 65mph of the cruise cycles the agencies have updated the powertrain procedure so that the speed of the powertrain can overshoot the cycle speed by up to 3 mph when going downhill. This change has been added to the powertrain procedure as well as in GEM to better align with how vehicles are driven. The agencies did not change the lower speed tolerance for two reasons. The first is that GEM already has an input for vehicle speed limiters. Second, because changes in vehicle speed have a significant effect on the work the vehicle does per mile. If the powertrain procedure allowed for significant deviations from the cycle the results would not be representative. However, the procedure does allow for greater than 1 mph deviation from the cycle during shifts. In addition, the agencies have added neutral coast as an intelligent control technology that is recognized in GEM (see 40 CFR 1037.520).
On natural gas engine fuel properties, as noted in previous responses, we did make changes to GEM to include all the reference fuel properties defined in Table 1 of 40 CFR 1036.530. This change will allow GEM to accurately calculate the CO2 emissions from all fuel covered by 40 CFR 1036.530.

We appreciate Paccar’s comments on a “.dll” executable version of GEM. We are considering the implement this feature into the GEM after the final rule is signed. Since this “.dll” only acts like an interface between GEM output and OEM’s information system, it would not change the GEM results, and therefore, this can be done after the final rule is signed.

We have made changes to the off-cycle technologies as evidenced by the technology improvement inputs from the input files of both tractor and vocational vehicles.

Significant changes on transmission modeling has been made since the NPRM GEM. We now allow the OEMs to input their own power loss for each gear to replace the default power loss tables based on a transmission efficiency test.

**Organization:**  Plastics Industry Trade Association (SPI)

Specifically, we support the inclusion of thermoplastic parts in the Green House Gas Emissions Model (GEM) lightweighting credit menu, and the agencies’ efforts to better recognize parts and materials with superior aerodynamic performance. [EPA-HQ-OAR-2014-0827-1225-A1 p.1]

**Thermoplastic Lightweighting**

SPI strongly supports the inclusion of lightweight thermoplastic materials in the GEM lightweighting credit menu. Thermoplastics are a reliable way of reducing greenhouse gas emissions by improving fuel consumption rates. The credit menu includes thermoplastic hoods and front fender, day and sleeper cab roof fairings and the aerodynamic side extender. This grants OEMs another path to lightweight vehicles and comply with more stringent regulations. [EPA-HQ-OAR-2014-0827-1225-A1 p.2]

SPI also encourages EPA and NHTSA to include thermoplastics that are in development in the GEM credit menu. SPI members are currently developing plastics, and are working to transfer technologies that have been successful for lightweighting light duty vehicles to heavy duty vehicles. These technologies should be included in the menu because it will encourage further breakthroughs in lightweighting vehicles. [EPA-HQ-OAR-2014-0827-1225-A1 p.2]

**Response:**

We appreciate SPI’s comments on lightweighting. The thermoplastic lightweighting is part of the weight reduction of the GEM input.

**Organization:**  Rubber Manufacturers Association (RMA)

**The Agencies Should Clarify Terms When Referring to Loaded Radius** to avoid confusion and provide clarity for compliance. [EPA-HQ-OAR-2014-0827-1304-A1 p.2]

Other GEM Input Issues. Tire Loaded Radius and Tire Revolutions per Mile

i. The Agencies Should Clarify Terms When Referring to Loaded Radius – Static vs. Dynamic

As an input into the GEM, clarification is needed as to what is intended, i.e. static or dynamic, for the GEM conversion of simulated vehicle speed into axle speed, transmission speed, and ultimately engine speed. Throughout the NPRM, the agencies refer to the static loaded radius measurement from the ISO 28580 tire rolling resistance test method, i.e. “rL,” and in the NPRM, the terms “static loaded radius” and “loaded radius” are both used. After reviewing where the terms are used, it seems that the agencies refer to these terms for three purposes: when referring to the ISO 28580 test method for measuring tire rolling resistance, for use in measuring roof height and as an input into the GEM. The agencies may be intending to refer to terms with the same meaning for all three purposes, or not. The agencies should clarify the term intended for each of these purposes and provide unambiguous definitions for each terms used. [EPA-HQ-OAR-2014-0827-1304-A1 p.31]

When referring to the ISO 28580 test method for measuring tire rolling resistance, the proper term is dynamic loaded radius. In Section 7.5, subsection (e) of ISO 28580 (2009), rL is defined as “the distance from the tire axis to the drum outer surface under steady-state conditions” and is expressed in meters. The term “steady-state conditions” indicates that this is a dynamic, rather than a static measurement of the tire’s radius. It is also important to note that this measurement is conducted on a curved wheel. Depending on the agencies’ needs, this may or may not be an appropriate measurement for use in calculating roof height or as a GEM input, without first adjusting from a curved surface to a flat surface. [EPA-HQ-OAR-2014-0827-1304-A1 p.31-32]

Table 1 below shows the various times similar terms are used in the NPRM. Interestingly, in the Department of Transportation proposed regulatory text, of all of the terms listed above, the only term defined in the definitions section is “static loaded radius arc.” [EPA-HQ-OAR-2014-0827-1304-A1 p.32]

Table 1, 'List of References in the NPRM to Tire Loaded Radius or Similar Terms', p.32 of docket number EPA-HQ-OAR-2014-0827-1304-A1

ii. The Agencies Could Use Tire Revolutions per Distance or Use Dynamic Loaded Radius per ISO 28580 to Calculate the Drive Axle Rotational Speed from Vehicle Speed

In the NPRM, the agencies propose for the vehicle manufacturers to “enter into GEM the tire manufacturer’s specified tire loaded radius for the vehicle’s drive tires,” but the agencies also ask for comments on “whether the proposed test procedure should be modified to measure the tire’s revolutions per distance directly, as opposed to using the loaded radius to calculate the drive axle rotational speed from vehicle speed.” RMA views both tire revolutions per distance, recognizing that this may require a separate test, and dynamic tire loaded radius, per ISO 28580, as candidates for this purpose. [EPA-HQ-OAR-2014-0827-1304-A1 p.33]

Truck tire revolutions per mile (RPM) can be measured separately on a flat road surface using for example SAE 1025-2012 “Test Procedures for Measuring Truck Tire Revolutions per Kilometer/Mile. It is important to note that the test methods may cause variations on both “loaded radius” and “RPM” among similar tires. Even if the similar tires have the same overall diameter, it does not mean that they will have the same tire RPM. Some factors that cause variations include load and pressure, tread wear, tread geometry, driving and braking torque, and type and condition (wet, dry) of the pavement. [EPA-HQ-OAR-2014-0827-1304-A1 p.33]
Trailer yaw at 0° vs the average yaw at 0° – 6° as a GEM P2 v1.0 input

The NPRM states that tractor aerodynamic drag is determined by testing conducted over a range of 0° – 6° yaw and averaged for the GEM P2 v1.0 input. The NPRM requires only a trailer aerodynamic drag delta CDA for trailer aerodynamics using the zero-yaw, e.g. 0° (or head-on wind) values. For a realistic and complete assessment of the overall trailer aerodynamic performance, a range of yaw angles, e.g. 0° – 6°, needs to be included for an averaged aerodynamic drag delta CDA GEM input, i.e. effects of real world cross winds on such tractor-trailer combinations. [EPA-HQ-OAR-2014-0827-1304-A1 p.33]

b. The Agencies Should Consider Subcategorizing Vocational Vehicles to Address the Wide Diversity of Configurations and Applications

Referencing the proposed updates to the GHG Phase 2 GEM, outlined in EPA-HQ-OAR-20140827-DRAFT-1768, the agency is recognizing that varied and complex axle configurations exist in the NAFTA Market. It has been proposed that these complex axle configurations be grouped into the model designation for a standard 6X4 Tractor. [EPA-HQ-OAR-2014-0827-1933-A1 p.3]

While this grouping to the classification would help OEMs utilize the GEM, it underscores the RMA position that the vocational classification is widely varied in scope, and should be defined to match the actual market diversity. The driving need to manufacture axle configurations such as an 8X4, or 10X4 single unit truck, is governed by the specific needs of loading and road type. It is clear that these configurations would be considered non-standard, but still subject to the GHG regulation. To group configurations with non-standard needs into the 6X4 classification could place OEM at disadvantage for loading specific, or environmental specific designs. [EPA-HQ-OAR-2014-0827-1933-A1 p.3]

In contrast, the long distance fuel-efficient market segment can be characterized by a homogenous application with fairly consistent axle configurations. The only reasonable method to address the vocational applications is to define subsets that take into account the varied needs of the vocational marketplace. [EPA-HQ-OAR-2014-0827-1933-A1 p.3]

III. Other GEM Input Issues

In its October 1, 2015 comments, RMA highlighted several issues associated with the GEM. RMA continues to believe that these issues should be addressed in the final GEM. It is unclear whether the updated version has been adjusted to address these concerns. RMA encourages the agencies to assure that these issues are addressed when the rules are promulgated. [EPA-HQ-OAR-2014-0827-1933-A1 p.4]

First, RMA commented that the agencies should clarify what is intended when the term “loaded radius” is used. It is unclear whether the agencies are intending static loaded radius or dynamic loaded radius. When referring to the ISO 28580 test method for measuring tire rolling resistance, the proper term is dynamic loaded radius. However, throughout the NPRM, the agencies refer to the static loaded radius measurement from the ISO 28580 tire rolling resistance test method, i.e. “rL” and in the NPRM, the terms “static loaded radius” and “loaded radius” are both used. After reviewing where the terms are used, it seems that the agencies refer to these terms for three purposes: when referring to the ISO 28580 test method for measuring tire rolling resistance, for use in measuring roof height and as an input into the GEM. The agencies may be intending to refer to terms with the same meaning for all three purposes, or not. The agencies should clarify the term intended for each of these purposes and provide unambiguous definitions for each terms used. [EPA-HQ-OAR-2014-0827-1933-A1 p.4]
Second, the agencies should use tire revolutions per distance or dynamic tire loaded radius to calculate the drive axle rotational speed from vehicle speed. In the NPRM, the agencies propose for the vehicle manufacturers to “enter into GEM the tire manufacturer’s specified tire loaded radius for the vehicle’s drive tires,” but the agencies also ask for comments on “whether the proposed test procedure should be modified to measure the tire’s revolutions per distance directly, as opposed to using the loaded radius to calculate the drive axle rotational speed from vehicle speed.” RMA views both tire revolutions per distance, recognizing that this may require a separate test, and dynamic tire loaded radius, per ISO 28580, as candidates for this purpose. [EPA-HQ-OAR-2014-0827-1933-A1 p.4-5]

Third, the agencies should include a range of yaw angles, e.g. 0° – 6°, for an averaged aerodynamic drag delta CDA GEM input, for a realistic and complete assessment of the overall trailer aerodynamic performance. The NPRM states that tractor aerodynamic drag is determined by testing conducted over a range of 0° – 6° yaw and averaged for the GEM P2 v1.0 input. The NPRM requires only a trailer aerodynamic drag delta CDA for trailer aerodynamics using the zero-yaw, e.g. 0° (or head-on wind) values. For a realistic and complete assessment of the overall trailer aerodynamic performance, a range of yaw angles, e.g. 0° – 6°, needs to be included for an averaged aerodynamic drag delta CDA GEM input, i.e. effects of real world cross winds on such tractor-trailer combinations. [EPA-HQ-OAR-2014-0827-1933-A1 p.5]

Response:

With regard to loaded radius, GEM now uses tire revolutions per mile instead of loaded radius. See 40 CFR 1037.520 (g), which refers to SAE J1025 for the prescribed test procedure for determining tire revolutions per mile. If a vehicle is certified to the custom-chassis standards of 40 CFR 1037.105 (h) tire revs per mile is not an input for GEM.

The agencies agree with the comments from Rubber Manufacture Association regarding TPMS and have added the ability to recognize the effectiveness of TPMS in GEM.

The agencies evaluated the aerodynamic test data for our trailer program and concluded (consistent with this comment) that wind-averaging is able to better capture aerodynamic improvements from many devices, including several small-scale devices. We are adopting a wind-averaged approach for aerodynamic testing in the trailer program. Consistent with the tractor program, the trailer program is basing its wind-averaged values on the average of results from +4.5 and -4.5 degrees yaw.

On Diversity of Configurations and Applications

The agencies disagree that grouping configurations with non-standard axles into the 6X4 classification could place OEMs at a disadvantage for loading specific, or environmental specific designs. Because GEM uses a default vehicle tare weight and payload, we do not believe that certifying vehicles that are designed to haul heavier loads in GEM using the default settings will create a meaningful disadvantage for such vehicles. One clear disadvantage of simulating the additional axles of say a 10x6 as a 10x6 instead of a 6x4, is that these vehicles would have higher CO₂ compared to a vehicle with a 6x4 axle.
which would put these vehicles at a disadvantage. Doing so could take away these options or at a minimum make them cost more from a certification perspective. Potentially one disadvantage could be if the configuration uses an overpowered engine for the default vehicle weight and payload, but adding additional vehicle categories comes with many other complexities. We conclude the advantages of regulatory simplicity outweigh the potential disadvantages to a small sales volume of specialty configurations. For further discussion of comments related to heavy-haul vocational vehicles, see the Preamble Section V.

Organization: SABIC Innovative Plastics US LLC

Credits for Lightweight Components Acknowledge their Contribution

SABIC strongly supports the agencies' inclusion of lightweight thermoplastic materials in the GEM model lightweighting credit menu, summarized below in Table 1. The competitive fuel conservation and emission reduction benefits offered by thermoplastics can and should be on equal footing with those achievable by aluminum and high-strength steel. The credit menu for the proposed Phase 2 rule includes thermoplastic hoods and front fenders, Day and Sleeper Cab roof fairings and aerodynamic side extenders, as shown in Table 1 below. These components have been commercialized or validated by customers, or in the case of the Sleeper Cab fairing, are in the process being validated. This supports their marketplace potential, while also allowing the agencies to gauge their lightweighting benefits. These components typify the 'emerging technologies not yet in widespread use' whose adoption is promoted by the credit menu. [EPA-HQ-OAR-2014-0827-1207-A1 p.2]

[Table 1, NPRM Proposed Weight Reduction Credits, can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-1207-A1]

Lightweighting and aerodynamic improvements will provide cost-effective pathways to greater fuel efficiency and reduced emissions, while preserving vehicle performance and utility. SABIC appreciates the opportunity to comment and looks forward to working with the agencies and the industry to achieve that goal. [EPA-HQ-OAR-2014-0827-1207-A1 p.6]

In summary: SABIC supports the addition of thermoplastic parts to the lightweighting credit menu, including Day cab roof fairings, Sleeper Cab roof fairings, hood and front fenders and aerodynamic side extenders. [EPA-HQ-OAR-2014-0827-1207-A1 p.6]

Response:

We appreciate SABIC’s support on the thermoplastic lightweighting components included in the regulations (see 40 CFR 1037.520).

Organization: Securing America's Future Energy

Greenhouse Gas Emissions Model (GEM)

We agree with the agencies' efforts to modify the GEM in the Phase 2 Proposal. However, we recommend addressing two important issues: [EPA-HQ-OAR-2014-0827-1462-A1 p.10]

- The Proposal does not include weight penalties for other weight-increasing technologies in the GEM. [EPA-HQ-OAR-2014-0827-1462-A1 p.10]
The proposed weight increases that are assigned to natural gas vehicles do not take into account the weight differences among the wide variety of natural gas fuel systems. [EPA-HQ-OAR-2014-0827-1462-A1 p.10]

For parity, we suggest the agencies assign weight increases to hybrid and Rankine cycle engines and non-engine technologies that add weight. There are numerous technologies used by both conventional and alternative fuel vehicles that increase the weight of the vehicle but do not receive weight penalties in the GEM. (We acknowledge that all-electric and fuel cell vehicles generate zero GHG tailpipe emissions and therefore do not include these technologies in our request). [EPA-HQ-OAR-2014-0827-1462-A1 p.10]

Additionally, we recommend the agencies consider reducing the proposed weight increases that apply to natural gas-fueled vocational vehicles. The proposed use of a fixed weight increase for both tractors and vocational vehicles fueled by natural gas does not appear to take into consideration the weight differences between the fuel tanks in these vehicles, and therefore may unfairly penalize vocational vehicles. The amount of fuel storage required varies considerably with the class and type of the vehicle. As a result, natural gas fuel storage systems installed on vocational vehicles typically are smaller and weigh less than those installed on Class 7 and 8 tractors. [EPA-HQ-OAR-2014-0827-1462-A1 p.10]

Response:

The final rule will only provide opportunities for weight reduction and the agencies have removed all weight penalty items.

Organization: Truck & Engine Manufacturers Association (EMA)

Automatic Engine Shutdown (AES) Systems

GEM currently does not account for the provisions in proposed section 1037.660 that allow for the 5 percent credit to be prorated as an input to GEM based on the number of miles that tamper-resistant AES features will be in place. This feature, albeit a 5.0 g/ton-mile reduction, was included in the Phase 1 GEM tool, but not carried-over in the proposed Phase 2 GEM. The proposed Phase 2 GEM only includes a “Y” or “N” input for this feature, which would indicate that the prorated distance is no longer applicable and that credit-generating AES technology must be tamper-resistant for the full 1,259,000 miles. GEM should be corrected so that properly calculated, prorated inputs can be utilized. Additionally, the examples for calculating the input to GEM for the expiration mileage option should be updated to reflect the 5 percent reduction in addition to the 5.0 g/ton-mile reduction. [EPA-HQ-OAR-2014-0827-1269-A1 p.57]

Vehicle Speed Limiters Similar to AES, speed limiters can be programmed to be tamper-resistant for a reduced expiration time frame (or mileage) and the vehicle should receive corresponding partial credit. In that regard, proposed section 1037.640(c)(2) states that the input to GEM must be calculated and rounded to the nearest 0.1 mph. However, GEM does not recognize decimal places on the GEM input and is effectively rounding the input to the nearest whole number. Consequently, the results from GEM are the same for every tenth of a decimal depending on how the inputs round (up or down). Without correcting this error, the benefit of incremental changes to speed, expiration times, or “soft top” limits will not be accurately recognized in the vehicle scoring model. [EPA-HQ-OAR-2014-0827-1269-A1 p.57]
GEM Runtime Errors and Crashes Using the stand-alone executable version of GEM, there are instances where GEM will not process the inputs and will crash, providing the user with nothing other than an error message. An example of an error message repeatedly received is: [EPA-HQ-OAR-2014-0827-1269-A1 p.57-58]

Attempted to access result.phase_NV_ratio(2); index out of bounds because numel (result.phase_NV_ratio)=1. Error in => GEM_main.m at line 251 [EPA-HQ-OAR-2014-0827-1269-A1 p.58]

The agencies will need to work on resolving these significant functionality issues. [EPA-HQ-OAR-2014-0827-1269-A1 p.58]

Torque Response

GEM has no torque lag and so assumes instant torque response to the throttle command. In reality, however, every engine requires some time to build up torque, particularly highly turbocharged heavy-duty diesel engines. This issue is not significant for vehicle simulation, but becomes significant when GEM output is used to create engine test cycles as proposed by the alternative engine certification (“cycle-average”) method. Although each engine has a unique torque response, inclusion of an average response characteristic would be much better than the current simulation. [EPA-HQ-OAR-2014-0827-1269-A1 p.58]

Gear Shifting

GEM shifting does not match either a typical driver using a manual transmission or an automated manual transmission. This results in engine operation that does not match the real world. For example, GEM does not skip-shift either on acceleration or deceleration. Drivers and automated transmission will skip-shift when accelerating whenever conditions permit and will certainly skip-shift under deceleration. Again, this may not create a significant problem when GEM is used to simulate vehicle fuel consumption as originally intended, but can create significant anomalies when GEM is used to create engine test cycles. [EPA-HQ-OAR-2014-0827-1269-A1 p.58]

N/V Output

GEM has an N/V output function that was set up for powertrain testing – i.e., the N/V is the transmission output speed over the vehicle speed. If the agencies intend to continue development of the alternative engine certification method, GEM must be set up to output engine speed over vehicle speed as well. [EPA-HQ-OAR-2014-0827-1269-A1 p.58]

Additional GEM Features Needed

Transmission gear efficiency should be an input to GEM based on a defined test protocol. As noted, since the European Union is undertaking considerable work in defining a transmission test, and since similar transmissions are used in the US and EU, a common test protocol based on the EU test method should be considered. Currently, the only provision in the NPRM to account for gear efficiencies requires running the powertrain test. However, as also noted earlier, there are significant costs and facility constraints to running a powertrain test. Adding a transmission test and input to GEM would capture the benefits of more efficient gear meshes without the need to run the powertrain test. [EPA-HQ-OAR-2014-0827-1269-A1 p.58]
Tire Rolling Resistance

When using the tables in the NRPM, the calculation of the model year 2024 tire Crr GEM input that is determined (by multiplying the penetration rate times the Crr value for each of the levels and then summing them together) does not match the GEM input value that EPA has shown for model year 2024 stringency determination. For example, for tractors, the baseline Crr of 7.8 multiplied by the 5% penetration rate, plus Level 1 Crr of 6.6 multiplied by the 50% penetration rate, plus Level 2 Crr of 5.7 multiplied by the 30% penetration rate, plus the Level 3 Crr of 4.3 multiplied by the 15% penetration rate, equals a Crr value of 6.045. However, EPA is using a Crr of 5.9 for the GEM-based stringency determination, which yields a more stringent standard than the technology performance and rates would dictate. [EPA-HQ-OAR-2014-0827-1269-A1 p.58-59]

Provisions also should be added to GEM to allow for the specification of different tire rolling resistance for vehicles equipped with tandem axles. That input is particularly important for 6x2 axle configurations where only one axle is driving and the tires are transmitting higher torque values than in a 6x4 configuration, which requires higher traction and more durable construction. At the same time, the tag axle has no torque transfer requirement, and so may be fitted with a low Crr tire that is typically used in trailers. In such cases, the tractor should not be penalized with the incorrect assumption that both axles use higher Crr tires. [EPA-HQ-OAR-2014-0827-1269-A1 p.59]

In addition to implementing the foregoing updates to GEM (as it continues to evolve), and to facilitate the implementation of Phase 2, especially in light of the increased complexity and stringency of the Proposed Phase 2 Standards, EPA should make available to engine and vehicle manufacturers a .”dll” executable version of GEM (along with a source code that matches the executable code) that can be integrated into manufacturers’ production systems to allow for real-time processing and scoring of vehicles. That “final” version of GEM should be fully capable of being used for certification and compliance purposes. EMA’s members are willing to work with EPA to define the input and output files for a .”dll” version and a suitable source code version of GEM. [EPA-HQ-OAR-2014-0827-1269-A1 p.59]

Response:

We appreciate EMA’s constructive comments. Consequently, we have made many changes to address to GEM.

With regard to automatic engine shutdown, the agencies have modified Phase 2 GEM for the final rule to accommodate a percent input value to represent the emissions reduction due to various idle reduction technologies, as specified in 40 CFR 1037.520. The agencies are recognizing both tamper-proof and adjustable AESS in Phase 2, therefore, we are not applying the Phase 1 expiring mileage option to Phase 2. The Phase 2 AESS will either be tamper-proof for 1,259,000 miles or else it is deemed adjustable.

We also made the change on VSL, allowing the user to input a value rounded to the nearest 0.1 MPH.

We recognized a few issues related to GEM runtime errors and crashes for the early released version of GEM, and all of these issues have been resolved.

The agencies agree with the comment regarding engine torque lag and have updated GEM to have a realistic torque response. The torque response in GEM was validated using data from a 2012 Cummins ISX.
With regards to comments on transmission shifting GEM does skip shift has the algorithm has been validated with powertrain, chassis and on-road vehicle data.\textsuperscript{31,32} We also have made significant improvement on gear shifting based on many testing data, which should address the gearing issues mentioned by EMA.

The agencies agree with the comment regarding GEM outputting engine N/V for the cycle average procedure and have added average vehicle speed to the GEM output file containing the engine cycle. The average engine speed comes for the engine test to get N/V.

Significant changes to transmission efficiency modeling in GEM have been made since the NPRM. We now allow the OEM to input the power loss for each transmission gear to replace the default power loss tables as indicated in Chapter 4.2.2.3.3 of the RIA. The test procedure that defines how to measure the transmission power losses is in 40 CFR 1036.565.

The agencies have modified the Crr levels and adoption rates for tractors in the final rule (see Preamble Section III.D.1.b). During that process, we have addressed the error highlighted by the commenter.

We also made changes to GEM that allow the manufacturer to input a different Crr value for each axle of the tandem to address the mismatched issue raised by the commenter. Since we implement a mechanism to account for the power loss of different axles, such as 6x4 and 6x2, the power loss for each type of axle can be input from the user. The user can also select default axle power loss specified by the agencies.

We will implement a “.dll” solution in the future. Since this “.dll” only acts like an interface between GEM output and OEM’s information system, it would not change the GEM results, and therefore, this can be done after the final rule is signed.

**Organization:** Truck & Engine Manufacturers Association (EMA)

### 2. Updated Version of GEM

While the updated version of GEM that the NODA describes and makes available is improved, it still contains a number of significant problems. Those problems include: [EPA-HQ-OAR-2014-0827-1891-A1 p.3]

- GEM incorporates a new road grade model (Road Grade Profile “D”) that is unrealistic and overly aggressive, including grades that are too steep over the modeled road cycle (which is only 12 miles). That results in forcing unrepresentative transmission behavior and engine performance. EMA is working on an alternative revised road grade profile, and encourages the agencies to adopt the necessary revisions to the road grade profile. [EPA-HQ-OAR-2014-0827-1891-A1 p.3]

**Response:**

\textsuperscript{31} SwRI July 2016, “Validation Testing for Phase 2 Greenhouse Gas Test Procedure and Greenhouse Gas Emissions Model (GEM) for Medium- and Heavy-Duty Engines and Powetrains.”

\textsuperscript{32} Oakridge National Laboratory July 2016, “Powertrain Test Procedure Development for EPA GHG Certification of Medium- and Heavy-Duty Engines and Vehicles.”
Since releasing Road Grade Profile D, we have received many constructive comments from various stakeholders. We discussed many potential solutions through many EMA meeting held at the EPA site as well as many industry group conference calls. Some of the stakeholders also shared their CBI data with us, helping the agencies to develop a more reasonable grade profile. Consequently, we have made many changes to continue improve the road grade profile to better represent the real-life driving conditions. Those changes include addition flat road and ±0.5% road grade at the beginning and end of cycle, and reducing the peak road grades.

Organization: Volvo Group

Because some vocational vehicles are gear-bound at speeds below 65 MPH, the engines in these vehicles will necessarily run on the high speed governor when the GEM duty cycle drives the engine above the rated speed. To properly account for how these vehicles run at high road speed, the GEM torque curve input should be extended to the high idle speed. Fuel rate should be interpolated from the highest speed point measured in the proposed fuel map down to zero at the high idle point. [EPA-HQ-OAR-2014-0827-1290-A1 p.37-38]

It must also be noted that since the entire range of the engine fuel map is to be regulated and subject to compliance testing, the OEM will be subject to review and approval of even minor and inconsequential changes to the engine calibration. Furthermore the EPA will be obliged to provide such a review and approval. Such requirements will greatly increase the workload of both the OEM and the EPA with little benefit. [EPA-HQ-OAR-2014-0827-1290-A1 p.38]

Since the Agencies have chosen to regulate both the engine and the vehicle (including the engine), Volvo Group believes that the composite emissions from the regulated engine cycles (FTP, RMC) should be sufficient to ensure engine efficiency and fuel map compliance as has traditionally been the case. This also has the benefit of eliminating the non-value added work created by reporting and approving inconsequential changes to engine calibrations. [EPA-HQ-OAR-2014-0827-1290-A1 p.38]

Lastly, it should be noted that the advent of technologies being deployed to learn and adapt calibrations to customer duty cycles could be stifled by such restrictive requirements. [EPA-HQ-OAR-2014-0827-1290-A1 p.38]

Currently no credit is provided for vehicle speed limiters set at 65 MPH or above, despite the fact that a significant number of vehicles and miles are run above this speed. Duty cycles should account for the actual speeds run by heavy duty vehicles and speed limiter credit should be determined in GEM based on the actual speed reduction. This should apply to vocational vehicles and tractors. [EPA-HQ-OAR-2014-0827-1290-A1 p.50]

Transmission gear efficiency should be an input to GEM based on a defined test protocol. Since the European Union has done considerable work to define a transmission test and since similar transmissions are used in both the US and EU, a common test protocol based on the EU test should be established. Currently, the only provision in the NPRM to account for gear efficiencies requires running the powertrain test. As noted earlier, there are significant costs and facility barriers to running a powertrain test. Adding a transmission test and input to GEM would capture the benefits of more efficient gear meshes without the need to run the powertrain test. [EPA-HQ-OAR-2014-0827-1290-A1 p.50-51]
The NPRM does provide an axle efficiency test protocol but GEM currently has no means to input axle efficiency. We strongly support use of the axle test and request that GEM be upgraded to incorporate the results. [EPA-HQ-OAR-2014-0827-1290-A1 p.51]

GEM Executable Format

The EMA has requested that a ."dll" or other source code version of GEM be compiled to allow for easier system integration. As did other manufacturers, Volvo Group invested significant time, effort, and money in development of IT infrastructure and programming to allow for automated batch processing of production data to meet the Phase 1 reporting and storage requirements. Due to the Linux based production systems that Volvo Group utilizes and the Windows based Phase 1 GEM executable, the architecture that Volvo Group developed required complex system integration across multiple platforms. This integration would still be necessary with a ."dll" compiled Phase 2 version of GEM 2.0, as the .dll format is a Microsoft format used for storing code and procedures for Windows based programs. As such, Volvo Group also requests that the agencies provide a GEM 2.0 version that is compiled and validated in Linux based architecture. Another solution would be to provide the GEM 2.0 source code to the regulated entities and allow them to compile the code into any platform necessary and then validate the results against the agencies’ GEM 2.0 file. In this way each manufacturer could simplify the integration of the GEM model as necessary for their specific platforms. [EPA-HQ-OAR-2014-0827-1290-A1 p.51]

Torque Response

GEM assumes zero torque lag, and therefore assumes instant torque response to the throttle command. In reality, every engine requires some time to build up torque, particularly highly turbocharged heavy-duty diesels. This issue is not significant for vehicle simulation but becomes significant when GEM output is used to create engine test cycles as proposed by the alternative engine certification (cycle average) method. Although each engine has a unique torque response, inclusion of an average response characteristic would be much better than the current simulation, allowing actual engines to more closely follow the GEM engine cycles. [EPA-HQ-OAR-2014-0827-1290-A1 p.51]

Gear Shifting

GEM shifting does not match either a typical driver using a manual transmission or an automated manual transmission. This results in engine operation that does not match real world. For example, GEM does not skip shift either on acceleration or deceleration. Drivers and automated transmission will skip shift when accelerating whenever conditions permit and will certainly skip shift under deceleration. Again, this may not create a significant problem when GEM is used to simulate vehicle fuel consumption as originally intended, but can create significant anomalies when GEM is used to create engine test cycles. [EPA-HQ-OAR-2014-0827-1290-A1 p.51]

N/V Output

GEM has an N/V output function that was set up for powertrain testing, i.e. the N/V is the transmission output speed over the vehicle speed. If the agencies intend to continue development of the alternative engine certification method, GEM must be set up to output engine speed over vehicle speed as well. [EPA-HQ-OAR-2014-0827-1290-A1 p.52]

Tire Rev/Mile
For accuracy in GEM calculations and in the proposed Vocational Duty Cycle segmentation calculations, the agencies should utilize tire revolutions per mile (rev/mile) as the GEM input and in the segmentation calculation as opposed to tire static loaded radius (SLR). Tire manufacturers should be given a standard procedure, such as SAE Recommended Practice J1025, to provide calculated tire rev/mile data, correlated to the standard procedure. [EPA-HQ-OAR-2014-0827-1290-A1 p.55]

The agencies have proposed utilizing tire static loaded radius in both GEM and Vocational segmentation. Based on discussions with tire manufacturers, SLR, when used alone, is not an accurate determinant of a tire’s rotational speed at a given vehicle ground speed due to the tire’s deflection under load. As a result unnecessary error is introduced and a higher GEM output is produced since GEM calculates axle RPM and, subsequently, engine speed based on the tire static loaded radius. [EPA-HQ-OAR-2014-0827-1290-A1 p.55]

As seen in the Michelin Truck Tire Service Manual pg. 131 inserted below, Michelin uses SAE Recommended Practice J1025 to measure tire rev/mile and has developed a correlated calculation to determine rev/mile based on the tire’s outside diameter, SLR, and deflection under load that matches the measured value in the inserted example within 0.1% for a new tire. In contrast to the described method, using only SLR to calculate tire rev/mile provides a value of 536.4 rev/mile, which differs from the measured value of 513 rev/mile by 23.4 rev/mile, or 4.6%. [EPA-HQ-OAR-2014-0827-1290-A1 p.55]

GEM currently uses the vehicle speed, SLR, and total drivetrain gear ratio to determine engine speed, resulting in an engine speed over 50 RPM higher in GEM for a typical vehicle with a targeted cruise speed of 1,250 RPM. For this reason Volvo Group believes Tire Revolutions per Mile, provided by tire manufacturers, should be used instead of Static Loaded Radius. [EPA-HQ-OAR-2014-0827-1290-A1 p.55]

Volvo has been evaluating the latest GEM release (P2V2.1) and providing feedback on issues affecting GEM performance as they arise. We will continue to work with the Agency to bring these issues to light. In addition we have noted some assumption and calculation issues that impact GEM’s ability to accurately reflect vehicle operation and improvements. [EPA-HQ-OAR-2014-0827-1928-A1 p.18]

**NREL Road Grade Profile**

Volvo cannot support a duty cycle which results in engine operational characteristics that are not supported by real world data and could cause vehicle specifications driven by regulatory compliance, but that do not meet the end-user’s application requirements and need for real-world fuel economy improvements. [EPA-HQ-OAR-2014-0827-1928-A1 p.11]

Volvo analysis of ~8,000 tractors equipped with Volvo’s proprietary XE powertrain package (which was previously submitted to the agencies as CBI) shows the proposed NREL Road Grade Profile D results in engine operation on the 55 MPH and 65 MPH cruise cycles that is not representative of real-world engine operation in that the engine experiences significantly more time at 100% torque when simulated on the proposed profile. A result of this increased torque demand is a higher average power demand, along with an increased shift schedule. Volvo has worked with the EPA to understand significant contributing factors that may bias the analysis of Volvo’s data, such as average vehicle mass compared to the default GEM value; however, the cumulative bias is insignificant when compared to the overall differences in results. [EPA-HQ-OAR-2014-0827-1928-A1 p.11]

As a result of this intense analysis, Volvo believes that NREL’s method of looking only at road grade distribution is incorrect, as it does not provide for GEM simulations that appropriately reflect the actual
operation of vehicle systems in real-world operating modes. Volvo does agree that grade distribution should be considered, but not as the only variable to be matched. Though Volvo’s data shows road grade distributions that match fairly well with the NREL analysis, at least on a macro scale, we find the way the distribution was stitched together inappropriately biases simulation results. Because of this we believe that NREL should consider additional parameters in their development of a realistic road grade profile, to include speed, torque, and power distributions, percent time in transmission top gear, number of shifts, and percent time coasting. Without considering these additional parameters to validate the road grade profile there is significant chance the regulation will drive vehicles configured for the demands of the regulatory model and not provide the in-use benefits projected in terms of reduced fuel consumption and greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1928-A1 p.11]

The Agency has proposed a modified Profile D and analysis is ongoing, but the mandated timeline is driving decision timing, rather than decision timing being driven by a validated solution; thus, Volvo recommends the agencies take the appropriate time to develop a new road grade profile with the above considerations included in the analysis. [EPA-HQ-OAR-2014-0827-1928-A1 p.11-12]

Response:

With regard to the engine torque curve and fuel map covering the entire operating range of the engine, the fuel mapping procedure in 40 CFR 1036.535 has been modified to map the engine from idle speed to $n_{hi}$. $n_{hi}$ is defined in 40 CFR part 1065 as the highest speed where engine power equal to 70 percent of maximum engine power. Since 40 CFR part 1065 already requires the engine torque curve to be measured up to $n_{hi}$, both procedures now cover the full engine operating range.

The agencies do not agree that the FTP and SET are sufficient for determining compliance of the procedures defined in 40 CFR 1036.535, because the FTP and SET are different duty cycles from the cruise cycles where the fuel map is used to determine the vehicle CO$_2$ emissions.

The 65 mph cycle was created to be representative of the heavy-duty vehicle VMT-weighted speed limits, as detailed in RIA Chapter 3.4.2. The agencies did not receive any new data to support increasing the speed of this cycle. In addition, DOT is considering heavy-duty vehicle speed limiters in a separate rulemaking.

Significant changes on transmission modeling has been made since the NPRM GEM. We now allow the OEM to input the power loss for each gear to replace the default power loss tables by following the test procedure 40 CFR 1036.565. We have made many improvements on transmission gear shifting. The shifting logic in GEM now includes gear skip and we continued to improve the shifting in GEM based on new data including both CBI from our stakeholders and the agencies-sponsored programs at both SwRI and ORNL. The final GEM allows the user to input their own axle power loss by following the test procedure 40 CFR 1036.560.

We will implement a ."dll" solution. Since this ."dll" only acts like an interface between GEM output and OEM’s information system, it would not change the GEM results, and therefore, this can be done after the final rule is signed.

We also modified GEM to better model torque response during transient operation in response to the comments by Volvo as well as others. We also made N/V changes, allowing it to work with the cycle average approach.
With regard to loaded radius, GEM now uses tire revolutions per mile instead of loaded radius. See 40 CFR 1037.520 (g), which refers to SAE J1025 for the prescribed test procedure for determining tire revolutions per mile. If a vehicle is certified to the custom-chassis standards of 40 CFR 1037.105 (h) tire revs per mile is not an input for GEM.

We appreciate the comments made on “NREL Road Grade Profile.” In the final rule, we did not fully adopt the proposal made by Volvo, the proposal by NREL, but we did combine the NREL analysis with the other in-use data received from Volvo and other manufacturers. One of the reason why we did not fully adopt Volvo’s suggestions is that we recognize that their data only represented one engine power rating and a lower average vehicle mass than the average vehicle mass of our defined regulatory categories, so it does not represent the higher power ratings and higher vehicle weights. After taking all comments obtained from all stakeholders into consideration, we have made many changes on the road grade called Profile D after we released the NODA version of GEM to maintain the national representativeness of the profile and to better match engine operation of on road tractors. Some of the ways we did this was by adding additional miles at zero grade and ±0.5 percent road grade road at the beginning and end of cycle, and reducing the peak grades, and to match the rate of change in grade of actual roads. See Chapter 3.4.2.1 of the RIA for the detailed description of the process the agencies took to create the final road grade profile.

Organization: Walsh, Michael and Charlton, Stephen

3.2.2 Vehicle Drive Cycles

Many vehicle drive cycles have been created, all with the objective of representing a given duty-cycle for a given vehicle class for the purpose of measuring emissions, fuel economy or performance under controlled and standardized conditions. Here the focus is on HD tractor engine drive cycles and especially their equivalence with engine test cycles. In a later section, engine BTE and fuel consumption data will be compared across several different sources, using a range of metrics. Therefore, the goal of this analysis is to compare and contrast the various cycles and to understand how they align one with another. [NHTSA-2014-0132-0102-A1 p.12]

Considering the key references reviewed in the report, the most important drive cycles to consider are:

1. NESCAUM / NESCCAF long haul cycle with gradient
2. GEM 55mph cruise with gradient
3. GEM 65mph cruise with gradient
4. World Harmonized Vehicle Cycle (WHVC)

The NESCAUM/NESCCAF long haul cycle [47] is a 117 minute road test simulation with approximately 27 minutes of urban driving and 90 minutes of interstate driving. The interstate portion is at vehicle speeds between 65mph and 70 mph. The cycle includes gradient changes which will require operation on the engine torque curve and gear shifts to access higher engine speeds. Figure 5 shows the region of the engine speed / load map where the NESCAUM long haul cycle will operate the majority of the time, assuming the truck is geared for 65mph between the A and B speeds. The region indicated is where the engine will spend most time on the cycle, it also the region of highest fuel burn – which largely determines CO2 emissions on the cycle. The WHVC and NESCAUM/NESCCAF cycles are shown in Appendix C [see p.38 of docket number NHTSA-2014-0132-0102-A1], Figure 18 for reference. [NHTSA-2014-0132-0102-A1 p.13]
The GEM 65mph cycle with gradient [51] is very similar to the NESCAUM cycle, spending significant time at the cruise speed with gradient changes requiring access to the torque curve and gear shifts to access higher engine speeds. The GEM 65mph region is narrower than the NESCAUM/NESCCAF region since the NESCAUM/NESCCAF cycle is essentially 65mph to 70mph cruise, see Figure 5. [NHTSA-2014-0132-0102-A1 p.13]

The WHVC cycle [49] consists of urban, rural and motorway segments. For simulation of HD tractor-trailers the recommended weighting factors are 90% motorway, 10% urban. The average vehicle speed on the motorway segment is only 55mph (88kph). Therefore this cycle is very close in character to the GEM 55mph cruise with gradient drive cycle [51]. There is a danger at 55mph that a tractor-trailer engine could be operated at the edge or outside of the NTE zone, if the engine were integrated with a DCT or AMT transmission, allowing operation in top gear at low engine speeds. [NHTSA-2014-0132-0102-A1 p.13]

While there are a variety of engine test cycles and vehicle drive cycles, this analysis shows that the 55mph drive cycles (GEM 55mph and WHVC) are outliers and unlikely to be comparable with the other cycles from a CO2 perspective. These cycles are valuable in illustrating the risk that engines could be operated outside of the NTE zone, with resulting risk to NOx and PM emissions. [NHTSA-2014-0132-0102-A1 p.13]

The remaining test cell and vehicle drive cycles overlap considerably as would be expected since they are all attempting to achieve the same goal. Data from various sources with the exception of GEM 55mph and WHVC will be directly comparable within a small margin of error, estimated at 1-2% of CO2 or fuel consumption. Figure 6 from SWRI [42] confirms this finding where results are compared for the GEM 65mph cycle, modeled by SWRI as a single engine operating point, and NESCAUM long haul cycle, and show little to no difference in fuel savings with different technologies. [NHTSA-2014-0132-0102-A1 p.13]

This is important because it allows direct comparison of data from the various sources referenced in this study, even though they were gathered in slightly different ways. [NHTSA-2014-0132-0102-A1 p.13]

5.3 SWRI Report #1 Commissioned by NHTSA, June 2015 [42]

The SWRI research project, contained in two reports by Reinhart [42, 43], was designed to inform NHTSA and EPA’s development of Phase 2 Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles (Class 2b – 8). [NHTSA-2014-0132-0102-A1 p.16]

The study included a literature review to identify potential fuel saving technologies and to assess the state of the art. A large number of engine and vehicle technologies were selected for analysis, and their fuel saving performance was simulated to assess the fuel savings potential of each technology over a wide range of duty cycles. The study used a combination of computer simulation and experimental data to assess the potential for improvements in engine and vehicle fuel efficiency. [NHTSA-2014-0132-0102-A1 p.17]

The engine study assessed a range of incremental improvements and new technologies in two stages. Report #1 [42] assessed the fuel efficiency impact of technologies individually. Report #2 [43] assessed the fuel efficiency impact of technologies in combination. The assessments were made over a range of drive cycles, including: [NHTSA-2014-0132-0102-A1 p.17]
- GEM 55mph cruise and GEM 65mph cruise - without gradient changes [51], single operating point
- WHVC [49]
- NESCAUM/NESCCAF Long Haul Cycle with gradient changes [47]

Each of the above cycles was studied at 0%, 50% and 100% payload. The engine used in the study was the MY 2011 14.8L DD15 produced by Daimler for application in Freightliner and Western Star trucks in the U.S. The vehicle road load was represented by a Kenworth T700 tractor unit with empty weight of 33,960 lb., payload capacity of 46,040 lb., and a GVWR of 80,000 lb. [NHTSA-2014-0132-0102-A1 p.17]

The analysis consisted of running GT-Power simulations at multiple steady-state engine operating points to allow estimates of drive-cycle fuel economy to be made. Appendix E [see p.40], Figure 21 describes the analysis plan for the assessment of engine technologies and Appendix F [see p.41] describes the analysis plan for the assessment of vehicle technologies. [NHTSA-2014-0132-0102-A1 p.17]

It should be noted that the SWRI analysis was carried out at a single operating point for the GEM 55mph and 65 mph drive cycles, which is also the approach taken by the SuperTruck projects in demonstrating engine BTE performance. Unlike the SuperTruck over-the-road drive cycle demonstrations, the SWRI analysis did not include transient performance. [NHTSA-2014-0132-0102-A1 p.17]

The literature review covered air handling, combustion, aftertreatment, friction and parasitic losses, and waste heat recovery. However, with few exceptions, only a modest attempt was made to quantify the potential fuel consumption gains of these areas of advanced technology – either for the near term or for the time frame of the proposed Phase 2 rule. Where estimates of fuel savings are made, there is little evidence those estimates were used in the analysis, preferring instead to perform ‘parametric sweeps’ over a range of values which seem to have been chosen semi-arbitrarily. [NHTSA-2014-0132-0102-A1 p.17]

This is a weakness of SWRI report #1 [42], which is carried over into SWRI report #2 [43], where combinations of advanced technologies are assessed to ensure interactions are accounted for. The GT-Power simulation study which forms the basis of SWRI report #1, is a parametric study which in significant areas is a simple sensitivity study with ranges applied to key parameters, for example: [NHTSA-2014-0132-0102-A1 p.17]

- 10% reduction in engine friction (FMEP) at high loads, 35% at lower loads
- 10% reduction in turbocharger efficiency
- 25% reduction in tractor aerodynamic drag (Cd)
- 30% reduction in tire rolling resistance [NHTSA-2014-0132-0102-A1 p.17]

Results from this parametric ‘sweep’ study are shown in Figure 6 for engine, and Figure 7 for vehicle technologies. Below is an example of a ‘technology package’ with semi-arbitrary values given to key parameters taken from the second study where technologies are studied in combination [43]. [NHTSA-2014-0132-0102-A1 p.17]

[Figure 6 and 7 can be found on p.18 of docket number NHTSA-2014-0132-0102-A1]
“T700 Package 2 has a 25% Cd reduction, a 30% Crr reduction, and a 6.5% empty weight reduction, with the 2019 baseline DD15 engine. This package provides 19 to 24% fuel savings on the three high speed cycles, with the smaller values coming on the more realistic NESCCAF cycle, which includes grades and a small stop and go segment. Fuel savings are over 7% even on the low speed CARB cycle [43][NHTSA-2014-0132-0102-A1 p.17].”

When viewing these results it important to bear in mind the nature of the study. The study is simply exploring the parametric design space, and makes little attempt to assess or extrapolate the state of the art between 2015 and 2027. [NHTSA-2014-0132-0102-A1 p.17]

Downspeeding results are shown in Figure 6, which presents results from a GT-Power cycle simulation of a HD tractor engine – in this case a Daimler DD15 engine rated at 455 HP. Through gearing and drive axle selection the highway cruise speed of the engine was reduced from 1368 rpm to 1209 rpm at 65 mph (Downspeed A) and reduced further to 1051 rpm (Downspeed B). Figure 6 shows that downspeeding can reduce fuel consumption by between 2% and 4% with engine speeds as low as 1051 r/min at 65 mph. [NHTSA-2014-0132-0102-A1 p.18]

Turbocompound results are also shown in Figure 6 in two different formats – with electric drive, and downsized power turbine (‘optimized turbocompound’). The results show fuel savings of less than 1% on all drive cycles, compared with WHR, which shows 2.5%-5.0% fuel savings with these assumptions. [NHTSA-2014-0132-0102-A1 p.18]

Response:

We appreciate the commenter’s comments on vehicle drive cycles, and some of points on NTE for WHVC and 55mph cycles are very well taken. We are aware that there is a possibility that under some vehicle configurations, such as very low axle ratio, the vehicle operating points could be in or even slightly out of the boundary of NTE zone. We also notice that for those potential vehicle configurations with very low axle ratio may run into the issue with higher frequent gearing shifting due to lack of torque margin at such low engine speeds, which could result in poorer fuel economy. Therefore, it would not be vehicle manufacturers’ interests to design a vehicle to continue running the engine into this operational region. Even though this could happen, 55mph cycle is still a small portion of the tractor CO₂ emissions and fuel consumption. Regarding the SwRI report, we believe that SwRI has done a
good job in analyzing the potential impact of future technologies. These were done by varying a range of vehicle and engine key parameters to address the impact of the future technologies on fuel economy. While it seems that the range of variations sounds to simply explore the sensitivity studies, more careful review on the range of parameter variation shows that the range is consistent with our finding based on different sources. For example, 25% of Cd reduction translates the CdA drops from 6.481 to 4.86, which is just in the range of Bin V of our evaluation for 2027 vehicle (Table III-10 of Section III.D of the Preamble), while our data collection is completely independent of SwRI report. Furthermore, with the limited data source, we are not sure how they could do better to define the range of the parameters to predict the long-term technology impacts.

Organization: ZF TRW Commercial Steering

Introduction

ZF TRW has been a supplier to the automotive and commercial vehicle market for over 100 years. ZF TRW Commercial Steering Division is based in Lafayette, Indiana, and specializes in Steering Systems for the Class 5 -8 market with a very strong presence in North America. Part of the steering system is the power steering pump, which is traditionally driven by the engine. This is a parasitic loss in a similar manner as the alternator, air compressor, and water pump. Any efficiency improvements to these subsystems also improve the overall efficiency of the vehicle. [EPA-HQ-OAR-2014-0827-1882-A1 p.1]

On March 2, a revised version of GEM was included as part of the Phase 2 Notice of Data Availability. As explained in our comments to follow, ZF TRW requests that a power steering pump using secondary chamber deactivation be credited and accounted for in the Phase 2 Standards’ Greenhouse Gas Emissions Model (GEM). [EPA-HQ-OAR-2014-0827-1882-A1 p.1]

Power Steering Background and Power Consumption

The power steering system is sized to match the vehicle needs and the driver’s expectations. This includes the ability to have full power assist during a docking or parking maneuver when the engine is at idle speed, and the vehicle is not moving. The driver expects to be able to turn the steering wheel approximately 1.5 turns per second. This performance expectation is part of what determines the size of the power steering pump. As the vehicle is driven at speed and the engine rpm increases, the extra flow generated by the pump must be controlled and re-circulated. This extra flow is wasted energy and is a parasitic loss to the engine above what is necessary for proper function of the steering. Per SAE J1343, a typical line haul truck requires an average of 0.4 – 1.1 kW for hydraulic steering. [EPA-HQ-OAR-2014-0827-1882-A1 p.1]

Current Technology Considerations

**EPS (Electric Power Steering)** - This technology holds great promise, but is power limited and the adoption rate and business case limit the potential environmental impact in the near future. The ability to steer Class 7- 8 vehicles will require electrical upgrades and is likely 10 years away. [EPA-HQ-OAR-2014-0827-1882-A1 p.2]

**EHPS (ElectroHydraulic Power Steering)** – This technology (or the above) allows for engine off power steering, but the efficiency of an EHP S system is highly dependent upon the duty cycle of the vehicle. Line haul vehicles benefit more from a direct drive power steering pump, without the electric conversion efficiency losses. Again, adoption rates and return on investment will limit the impact to the environment on a large scale. [EPA-HQ-OAR-2014-0827-1882-A1 p.2]
ZF TRW Consideration

ZF TRW has been working on fuel efficient options for several years. Based on vehicle duty studies, line haul commercial vehicles spend most of their time either at engine idle, or at cruising speed. While efforts to reduce idle time are being addressed by OEMs, ZF TRW has developed a new power steering pump that addresses the wasted energy of excess flow at cruising speed. This pump is called ActivMode (trademark pending), and it effectively behaves as two pumps in one. At engine idle, both sides of the pump combine to provide the required flow and pressure for the system needs. At highway speeds, the pump flow control system shifts to generate flow only from one side, thereby deactivating the secondary chamber. The effect of this deactivation is to reduce the pump drive torque by approximately 30-40%. In addition, since it is not generating extra flow, it also reduces the system temperature of the power steering fluid. As such, power steering coolers can be avoided or eliminated for further cost and weight savings. This technology is undergoing vehicle fleet testing and will be available for full production in 2017. [EPA-HQ-OAR-2014-0827-1882-A1 p.2]

This pump is a direct bolt on replacement, requiring only minor changes (if any) to the hose connections, but without any performance sacrifice for the driver. The cost impact is a minimal up charge from current production, approximately $25-50 more than a standard hydraulic pump. The anticipated payback on fuel savings alone is less than 6 months for a normal line haul application. [EPA-HQ-OAR-2014-0827-1882-A1 p.2]

As such, this type of product has the potential for a rapid, high adoption rate at the OEMs, with additional benefits of improved fuel economy and reduced power steering temperatures for the end user. The cumulative effect for the environment can be very positive. [EPA-HQ-OAR-2014-0827-1882-A1 p.2]

We request that this technology is accounted for and added to the Phase 2 regulations for greenhouse gas credit. [EPA-HQ-OAR-2014-0827-1882-A1 p.2]

Response:

We introduced a mechanism to recognize some accessories, including electric power steering pumps. More information can be seen in 40 CFR 1037.520 (j). Manufacturers have the option to apply for off-cycle credits for the other types and designs of high efficiency accessories, such as dual displacement power steering pumps.

2.3 Validation of GEM

Organization: Daimler Trucks North America LLC

Flaws of EPA's GEM validation testing - The EPA purports to have validated GEM but, in doing so, some of the validation used different powertrain inputs than are available in GEM. Specifically, in testing 28 vehicles with SwRI and putting their corresponding inputs into GEM, the EPA did not use GEM as the agency would require manufacturers to do; the EPA used the vehicles' actual transmission characteristics in simulating the vehicles. By contrast, the regulatory GEM uses default transmission information like gear efficiencies. The agencies should recognize that manufacturers will need accurate GEM results, like the agencies did, and therefore should be similarly willing to let vehicle manufacturers input actual transmission information into GEM. Manufacturers should get the same benefits as the agency. 80 FR 40522. [EPA-HQ-OAR-2014-0827-1164-A1 p.54]
Response:

Please see the agencies’ general response to GEM validation in RTC Section 2.1 above. In the final GEM, the transmission efficiency and power loss are part of the user input.

Organization:  Truck & Engine Manufacturers Association (EMA)

Open Issues With the Revised GEM

The agencies purport to have validated GEM. While the agencies have undertaken validation testing – for example, testing 28 vehicles at SwRI and incorporating the corresponding inputs into GEM – that testing did not demonstrate GEM's validity as EPA claims. In particular, EPA used different powertrain inputs in GEM than are available in the regulatory program. EPA also used the vehicles' actual transmission characteristics in simulating the vehicles. By contrast, the regulatory GEM process uses a default shift schedule and gear efficiencies. Therefore, it is not correct to assert that the alignment of test and simulation results validates GEM. EPA did not actually simulate GEM results as manufacturers must. [EPA-HQ-OAR-2014-0827-1269-A1 p.56]

Moreover, as noted above, there are still many issues that need to be finalized and accounted for in the revised GEM. For example, there currently is no means to account for rear axle efficiency in GEM. That needs to be corrected. Similarly, there are inadequate means to account for auto-shut down features and, more importantly, programmable idle-shutdown, which is widely deployed in the heavy-duty and medium-duty vehicle fleet, in part due to state and local regulations that mandate idle-shutdown after a prescribed number of minutes. GEM needs to give clearly defined credit for those factors, and others impacting vehicle fuel efficiency, including, but not limited to, “Eco-Roll” and “E-Coast” technologies, programmable automatic engine-shutdown systems, and tire-pressure monitoring systems. Further, transmission modeling is inadequate in GEM, forcing the engine to run at unrealistic speeds and loads in some cases. That could be especially problematic if GEM were used to create test profiles, as proposed under the alternative certification (“cycle-average”) method. [EPA-HQ-OAR-2014-0827-1269-A1 p.57]

Among the many specific revisions and updates that still need to be incorporated into GEM are the following: [EPA-HQ-OAR-2014-0827-1269-A1 p.57]

Response:

Please see the agencies’ general response to GEM validation in RTC Section 2.1 above. Validation against the transmission shifting tables provided by manufacturers are the first, and most important step to demonstrate the model fidelity, ensuring all components to work properly. We made improvements on transmission gear shifting prior to the final rule to more realistically represent the real world driving condition. Since NPRM, significant model validations have been conducted against powertrain tests with the agencies’ default shifting strategy. In addition, GEM validation with default transmission shifting logic was also conducted against a real-world driving routes with two very well defined trucks. The detailed comparisons and discussions can be seen in Chapter 4 of the RIA. More detailed explanation and derivation on the gasoline engine map can be seen by SwRI final report entitled “Validation Testing for Phase 2 Greenhouse Gas Test Procedures and The Greenhouse Gas Emissions Model (GEM) for Medium- and Heavy Duty Engines and Powertrains” [EPA-HQ-OAR-2014-0827]. In the final GEM, the transmission efficiency and power loss are part of the user input. The axle efficiency is also part of the user input by allowing the user to input their own power lass table. We have made many improvements and changes in those technology inputs to GEM related to idle, tire pressure.
monitoring systems, intelligent control such as predictive cruise and neutral coast to address these concerns, which are specified in CFR 40 1037.520 (j).

2.4 Supplements to GEM Simulation

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Powertrain testing

ACEEE strongly supports the inclusion of an option to test tractors and vocational vehicles using a powertrain test (p.40179). Given the very substantial benefits to be gained from the integration of engine and transmission, it is important that the efficiency benefits of such integration be not only recognized but factored into the stringency of the standards, especially for vocational vehicles. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]

Needless to say, this option will not help to incentivize engine-transmission integration unless powertrain testing can demonstrate the efficiency benefit of the integration. If the integrated powertrain does not achieve better results on the powertrain test than it – or a less efficient powertrain – achieves in GEM testing, the powertrain option will serve no purpose. Transmission loss in present GEM is conservative and efficiency gain from transmission is generous than powertrain testing. It is important that the agencies keep this issue in mind as they determine how the GEM executable handles the various transmissions types. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]

-Calibrate GEM treatment of transmission efficiency to yield result that can be compared to results of powertrain testing. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]

Response:

We appreciate the ACEEE’s support on powertrain testing.

Organization: Daimler Trucks North America LLC

Advantages of Complete Vehicle Simulation – In the NPRM the agencies discuss how they intended to provide regulatory incentives to use more fuel efficient technologies and expanded GEM to recognize engine and other powertrain component improvements. But the agencies state one disadvantage of the increased complexity of including engine details in GEM: vehicle manufacturers would be required to conduct additional engine tests, and track additional GEM inputs for compliance purposes. 80 FR 40181. The agencies seek comment on the changes. DTNA strongly agrees that expanding GEM to recognize more engine and other powertrain components provides flexibility and reduces the risk of a divergence between test-cycle and real-world fuel efficiency improvements. We think that the benefits of a more accurate GEM outweigh the drawback that we will need to do more testing. Rather, we think the solution to the problem of additional testing is that the EPA and NHTSA try to align their test procedures as much as possible with those being used in Europe, so that there is commonality of testing. For example, there is no reason to test rear axles differently in the US than in Europe. [EPA-HQ-OAR-2014-0827-1164-A1 p.13]
Moreover, the agencies request comment on the advantages and disadvantages of the proposed structure that would require vehicle manufacturers to provide additional inputs into GEM to represent the engine. 80 FR 40250. DTNA thinks it is unlikely that recognizing engine improvements in GEM could force a vehicle manufacturer to do engine testing as the engine manufacturer must provide certified engine data to the OEM for use in GEM. A vehicle OEM would not rely on its own engine test data in order to certify a vehicle in GEM, nor (as we understand) would the regulations require a vehicle manufacturer to do so. Rather, a vehicle OEM would rely on engine manufacturer data in Phase 2 just the same as it relies on tire manufacturer data in Phase 1. In summary, we strongly support adding inputs to GEM, as this makes for a more accurate simulation process that can better regulate what is important—the fuel consumption of the full vehicle. [EPA-HQ-OAR-2014-0827-1164-A1 p.13]

DTNA Agrees that GEM Should Be Updated and Expanded - The agencies request comments on the proposed GEM structure that would require vehicle manufacturers to provide additional inputs into GEM to represent the engine, transmission, drive axle(s), loaded tire radius, etc. We strongly agree with the agencies’ approach of regulating through an updated version of GEM that incorporates many more vehicle and engine parameters and with realistic drive cycles. This better represents the actual vehicle in real-world operation than does the Phase 1 GEM. 80 FR 40181. [EPA-HQ-OAR-2014-0827-1164-A1 p.42]

Transmission Mapping Improvement to GEM - The agencies requested comment on aspects of the GEM tool relating to how it models transmissions and shifting strategies. 80 FR 40297. Separately the agencies proposed a powertrain test in order to incorporate to the GHG Phase 2 program the ‘deep integration’ of the transmission with the engine. As we discuss in our comments, below, we believe that what the agencies mischaracterize as deep integration is in significant part just the benefit of using actual transmission gear efficiencies in GEM calculations. That is, if the agencies would allow vehicle manufacturers to input into GEM the measured transmission efficiency map, as is proposed for rear axles, then GEM would properly capture integration effects. For example, in tractor applications, there is little gear shifting in GEM for tractor applications so that, no matter the gear shifting strategy, there is so little shifting that there is no room for improvement (as we have shown the EPA and would be willing to show again in a confidential setting). Similarly, for vocational vehicles, although there is more gear shifting, much of the deep integration benefit comes from efficient gearing and only a part from optimized shifting, such that the agencies penalize manufacturers by using the default gears or forcing manufacturers into expensive and resource intensive powertrain testing. In short, we recommend allowing transmission efficiency maps as inputs to GEM, and we propose that the agencies adopt the European transmission mapping procedure to do so. [EPA-HQ-OAR-2014-0827-1164-A1 p.54-55]

Hybrid Test Procedures – The agencies propose to keep hybrid features out of GEM and to only credit hybridization if a manufacturer does actual powertrain or vehicle testing. We agree with this approach. GEM would become too complicated if it had to account for all types of hybrids. In their comments and the new regulatory text about the hybrid powertrain testing, the agencies seem to propose that manufacturers would perform powertrain testing using only powertrain and hybrid components, omitting all “non-powertrain features” like variations in aerodynamics or tires. 80 FR 40298 and § 1037.550. We agree that this is the correct approach to minimize test burden yet get sufficiently accurate results.[EPA-HQ-OAR-2014-0827-1164-A1 p.64]

Response:

We appreciate DTNA’s support adding more inputs to GEM and the support to keep hybrid out of GEM. We also made significant changes and improvement on GEM, which can be summarized as follows, which address the comments related to GEM.
- Added optional input table for transmission power loss data
- Modified road grade profile for 55- and 65-mph cruise cycles
- Revised idle cycles into overall vocational vehicles with new vocational cycle weightings
- Made significant changes on the input file structures. Examples include additions of columns for axle configuration (“6x2”, “6x4”, “6x4D”, “4x2”), and additions of a few more technology improvement inputs, such as “Neutral Idle and Start/Stop.”
- Made significant changes on output file structures. Examples includes an option to allow the user to output detailed results on average speed, average work before and after transmissions, and the numbers of shift for each phase (55 and 65mph cycles and ARB cycle).
- Added input file for axle power losses (function of axle output speed and torque) and replaced single axle efficiency in model with lookup table of torque loss
- Added simulation of engine torque response with fast response region defined by engine displacement, and slower torque increase in boosted region with fast falloff on available torque
- Added regression models for all certification cycles to allow the user to simulate vehicle with cycle average approach
- Added different fuel properties according to 1036.530.
- Significantly improved shift strategy based on testing data
- Adjusted transmission loss & inertia scale factors per regulatory subcategory
- Added minimum torque converter lock-up gear input for AT
- Retuned the default transmission mechanical efficiency based on the testing data
- Added neutral idle and start/stop features during simulation
- Adjusted shift and torque converter lockup strategy

**Organization:** Natural Resources Defense Council (NRDC)

In our comments to the Phase 1 rule, NRDC urged the agencies to ensure that the medium- and heavy-duty standards and compliance mechanisms recognize the potential for fuel efficiency technologies applied across the vehicle. Therefore, NRDC greatly appreciates the agencies’ proposed expanded full vehicle simulation Greenhouse Gas Emissions Model (GEM). By expanding GEM to include the engine, transmission, axle and tires in actual vehicle configurations (instead of the constant default values), manufacturers have an enhanced incentive to integrate the various components to improve efficiency. NRDC agrees with the agencies’ assessment that the GEM improvements also enhance manufacturer flexibility to mix and match technologies as they wish to meet the performance-based targets of the standards. [EPA-HQ-OAR-2014-0827-1220-A1 p.6]

**Response:**

We appreciate NRDC’s comments on GEM.

### 2.4.1 Technology Test Procedures

**Organization:** Afton Chemical

As a leading producer of fuel and lubricant additives, Afton Chemical Corporation has long been recognized as an expert in developing and testing products that lead to an increase in fuel efficiency while reducing emissions. It is with this expertise in mind that we would like to comment on EPA and
NHTSA's proposed rule on Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles; Phase 2. [EPA-HQ-OAR-2014-0827-1129-A2 p.1]

Our comments will be focused on the Heavy Duty Axle Efficiency procedure and how lubricant oils will be tested in this process. We agree with EPA that fuel efficient gear lubricants can make a worthwhile and measurable contribution to fuel efficiency. Thus Afton's comments are directed at comparing fuel efficient commercial gear lubricants in a way that can precisely detect efficiency differences in these lubricants. Afton has significant experience in running gear fuel efficient tests. We believe the procedure as proposed by EPA has areas that will lead to high variability of results. As proposed, there is the potential for poor performing oils to be determined good and good oils to be rejected. We do not believe that it is EPA's intent to develop a procedure that will inaccurately demonstrate the effectiveness or lack thereof of lubricant oils. Such a result will not help EPA or the country reach the stated goals of the proposed rule. [EPA-HQ-OAR-2014-0827-1129-A2 p.1]

We have separately attached our comments that look at modifying the procedure and how the lubricant is evaluated. We would be pleased to work and discuss with EPA how these changes and refinements can improve the procedure. We believe these refinements to the procedure can be run by a number of laboratories, provide precise results at meaningful speed and torque combinations, produce an incentive for lubricant suppliers to innovate for better lubricant efficiency and be accomplished in a cost effective fashion. In this way, we believe this will help carry out EPA's mandate. [EPA-HQ-OAR-2014-0827-1129-A2 p.1]

Areas of comments related to the EPA test procedure given in 40 CFR 1037.560 of the Phase 2 [EPA-HQ-OAR-2014-0827-1129-A2 p.2]

- The Emgard® FE 75W-90 lubricant has been assigned a 0.5% efficacy advantage over normal lubricants in axle efficiency. We agree that this is realistic and propose the Emgard® FE 75W-90 lubricant be considered a reference oil by which other lubricants can be measured in an axle efficiency test. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
- We know lubricants can exceed the FE improvement offered by the Emgard® FE 75W-90 lubricant. The EPA proposal does not indicate additional credit can be gained by these lubricants. This could stifle innovation. We believe if an oil run in the FE test shows statistically significant better FE than Emgard® FE 75W-90 it should be awarded additional efficiency credit beyond the 0.5% afforded by Emgard® FE 75W-90 if employed as initial fill by the truck manufacturer. If it shows statistically equivalent to Emgard® FE 75W-90 it should be awarded the same 0.5% improvement. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
- All tested lubricants must hold SAE J2360 performance credentials to demonstrate fluid performance for major commercial vehicle axles. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
- As acknowledged by your comments in the proposal, axle efficiency varies by speed and torque with highest efficiency being given at high torque, high speeds. Hence at high efficiency conditions, there is little room for improvement. However, most commercial vehicles run only a small portion of time at these high torque values and in general run at a fraction of rated speed and torque. It is at these lower speeds and loads that one can see significant differences in lubricant efficiency. Thus, we propose that lubricants be evaluated at a maximum of 4 speeds and loads with greater weight being given to those areas of speed and load that correspond to actual vehicle service. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
- Different axles can give different efficiencies; however, a FE lube will generally be efficient regardless of the axle. To verify the efficiency, we believe a matrix of no more than 2 axles, one each from the two major axle manufacturers supplying the U.S. commercial vehicle market. These axles could be specified by these same manufacturers. If a lube shows an average
efficiency statistically the same or better than Emgard, it should be awarded FE credit. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]

- The test was originally defined to measure axle hardware capabilities. It was not defined for lubricant efficiency measurements. However, areas within the test procedure that could be improved: [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
  - Break-in time of 3 increments of 77 minutes may not be enough. In our experience, the axle requires at least a full day of break-in and often more before stable results are obtained. We believe the break-in should be run until a measure of adequate repeatability is obtained to show stable results. This could be something akin to repeat runs of efficiency which show an effective repeatability of no more than 0.2%. If as noted above no more than 2 'mainline' axle assemblies are used to measure lubricant efficiency, then these 2 axles once broken in can be repeatedly used for different lubricants. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
  - Order of running for FE measurement should be Emgard® FE 75W-90 at different speeds and loads run multiple times with repeatability of the runs falling within an appropriate band followed by the lube to be measured at same conditions and repeatability followed by Emgard to verify there has been no change in the repeatability measurements or the test stand or axle. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
  - Test rig capability needs to be defined, but ultimately it needs to achieve the precision necessary for measuring the FE differences in lubes. Thus, a precision statement or rig precision requirements will be very important. [EPA-HQ-OAR-2014-0827-1129-A2 p.2]
  - In our experience, a test point of 0 Nm can create control problems for the dynos. This could lead to dangerous instability and thus we never run or try to control a large dyno rig at that point. 0 Nm is more suited to what is measured by a 'spin loss' rig. [EPA-HQ-OAR-2014-0827-1129-A2 p.3]
  - Testing order, sets of test, calculation of efficiency data, data quality and acceptance limits, and statistical methods to be used all need to be defined to assure adequate precision and quality testing. [EPA-HQ-OAR-2014-0827-1129-A2 p.3]

- The time for release of the proposal is first part of 2016. This does not leave much time to develop a comprehensive and well thought out procedure. However, Afton stands ready to work with EPA and other parties to help develop and refine a procedure. [EPA-HQ-OAR-2014-0827-1129-A2 p.3]

Response:

We appreciate many constructive comments by Afton Chemical. We recognize the importance of lubricant additives used in axle. As a matter of fact, we modified the final GEM to allow the user to input their own axle power loss, where the measurement on the power loss will include any benefits due to lubricant and its additives. See 40 CFR 1037.560.

Organization: Allison Transmission, Inc.

The Version of GEM Available For Public Comment Contains Several Deficiencies and Inaccuracies; EPA and NHTSA Must Revise GEM and Allow for Further Review and Comment

On the whole, Allison believes that EPA and NHTSA have made substantial progress in revising GEM for the Phase 2 rule to make this model a more accurate predictor of real world GHG emissions and FE. In the Phase 2 GEM, the engine is better defined and the agencies have incorporated or improved
several vehicle elements that can have significant impact on the emissions profile and fuel use of MD/HD vehicles. GEM inputs concerning transmission ratios, axle ratios and tire size all represent improvements compared with the inputs utilized in the Phase 1 GEM. And, as we stated at the beginning of these comments, Allison supports the use of GEM as the primary certification tool. [EPA-HQ-OAR-2014-0827-1284-A1 p.18]

Despite improvements to GEM, however, the agencies must recognize that this model is still somewhat a work in progress. Allison addressed this issue in its comments at the public hearing held in Chicago, Illinois on August 6th along with specific recommendations as to how the agencies should proceed with further GEM development after the close of this comment period, including with regard to seeking additional public review and comment of significant alterations to GEM. In the comments, below we submit additional technical issues with GEM P2v1.0 along with proposed solutions.

EPA and NHTSA Must Make Several Changes In Order to Properly Credit Neutral-Idle Technology Within GEM

In the Proposed Rule, EPA and NHTSA explicitly state that GEM is intended to address Neutral-Idle technology that is utilized during the transient cycle. We agree with the agencies that many vocational vehicle applications operate on patterns implicating workday idle cycles and that GEM should account for these cycles and the control of emissions which results through the use of Neutral-Idle technology. Including such technology within GEM would both increase the accuracy of projected emissions/fuel consumption of the vehicles being modeled as well as more accurately represent what is already occurring within the marketplace. [EPA-HQ-OAR-2014-0827-1284-A1 p.19]

Given the overall purpose and intent to account for such systems in GEM, however, it is inconsistent for EPA and NHTSA to not simulate Neutral-Idle within GEM during the ARB transient cycle – or to not credit this technology within the ARB transient cycle through post processing for an AT. Specifically, it can be seen that since 16% of the ARB transient cycle consists of idle, the impact of ARB transient idle time can be nearly as much in the weighted CO2 emissions calculation (i.e., 74%) as the idle cycle itself (depending on vocational chassis subcategory). EPA and NHTSA cannot ignore such significant periods of vehicle operation and must accordingly make changes to GEM to account for Neutral-Idle in the ARB transient cycle. The GEM simulation does credit the AMT and the MT with Neutral–Idle fuel rate during the ARB transient cycle simulation and does not use Neutral-Idle fuel rate for the AT even when Neutral-Idle is selected as an option. The agencies must correct this disparity. [EPA-HQ-OAR-2014-0827-1284-A1 p.19]

This disparity is even more important to address when one considers that GEM correctly rewards Neutral-Idle technology in the idle cycle. Recognizing Neutral-Idle technology in the idle cycle, but not within the transient cycle, would lead to inconsistent results in projecting real world emissions and would be arbitrary and capricious. Retaining this differential treatment in the final rule would effectively give partial credit for this important and effective emission reduction technology and unduly and incorrectly penalize ATs that incorporate the technology. [EPA-HQ-OAR-2014-0827-1284-A1 p.19]

The agencies should also be aware that Eaton has announced AMT product changes affecting low speed operations. Allison does not know precisely how this functionality is achieved; its existence, however, it raises serious questions as to whether the AMT will always operate at a true Neutral-Idle state as modeled in GEM. Therefore, given the possibility that AMTs operation may change in the direction of higher fuel consumption during the lifespan of the Phase 2 rule, Allison recommends that GEM drop-downs for Neutral-idle also be used for AMTs. Since new features may consume more fuel at idle, the
likelihood of higher fuel rates being reflected via an optional powertrain test is unlikely and further reinforces the need to account for this fuel usage in GEM. [EPA-HQ-OAR-2014-0827-1284-A1 p.19]

In addition, EPA and NHTSA must also address engine Start-Stop technology within the ARB transient cycle. GEM already provides such credit in the idle cycle, creating the same issues as described above with respect to Neutral-Idle technology. Again, EPA and NHTSA must correct this differential treatment in the final rule. The Proposed Rule does not allow Neutral-Idle technology and engine Start-Stop to both be utilized in the same simulation even though both features are offered together with an AT transmission. If engine Start-Stop credit remains in the idle cycle only, then Neutral-Idle technology option should be available to be utilized in the GEM simulation of the ARB transient cycle for the AT transmission. AMT and MT simulation will assume Neutral-Idle fuel rates during the ARB transient cycle and the AT should be treated similarly as well if the Neutral-Idle option is selected. [EPA-HQ-OAR-2014-0827-1284-A1 p.20]

Finally, EPA and NHTSA must recognize Neutral-Idle technologies within the ARB transient cycle not only with respect to vocational vehicles, but also with regard to tractors. Even if an idle cycle is not added to the tractor weighted emission calculations, there is still no rational reason to exclude Neutral-Idle technology in tractors during ARB transient idle time. The chart below summarizes our recommendations as to the periods of time when both Neutral-Idle and Stop-Start technologies should be credited within the ARB transient cycle for all vehicles subject to such testing/simulation: [EPA-HQ-OAR-2014-0827-1284-A1 p.20]

EPA and NHTSA Should Not Include Dual-Clutch Transmissions Within GEM

In the Proposed Rule, manufacturers can select from one of three types of transmissions in GEM: MTs, AMTs and ATs. With regard to heavy-duty DCTs, the agencies explain that “because production of heavy-duty dual clutch transmissions has only begun in the past few months, we do not yet have any experimental data to validate our GEM simulation of this transmission type.” Despite lacking data with regard to DCTs, however, EPA and NHTSA have indicated that they “may finalize GEM for Phase 2 with a fourth transmission type for dual clutch transmissions.” The agencies also indicate that they may address DCTs through post-simulation adjustment. Table 4-12 of the RIA lists a 2% adjustment for DCTs for certain Class 7 and 8 vehicles, the same adjustment as provided for ATs and AMTs. Table 4-13 of the RIA provides a 2.3% adjustment for Vocational Vehicle HHD AMTs or DCTs, but no similar adjustment for ATs. [EPA-HQ-OAR-2014-0827-1284-A1 p.20-21]

EPA and NHTSA do not have a sufficient basis in the record to either include DCTs within GEM or to allow for a post-simulation adjustment such as that indicated in the RIA. First, as EPA and NHTSA admit, there is no data to validate GEM simulation of DCTs. Without such data, any value that would be included within GEM for DCTs would be without foundation and, by definition, arbitrary and capricious. Second, even if there were some data available, the agencies need to account for the fact that there are a number of DCT variants and a number of control strategies that could potentially affect related emissions and fuel efficiency. Due to all of this variation, it would not be possible to render a singular GEM value for this technology. Finally, EPA and NHTSA must take into account the fact that DCTs are often larger and heavier than current MTs, AMTs and ATs. This additional weight would negatively affect the emissions and fuel efficiency associated with DCTs. Yet Allison has not uncovered anything in the rulemaking record to indicate that the agencies are aware of this negative effect and have
taken it into account in calculation of technology improvement values. [EPA-HQ-OAR-2014-0827-1284-A1 p.21]

In general, DCTs share some characteristics of AMTs and some characteristics of powershifting ATs. For many of the same reasons that DCTs cannot be included in GEM, however, a post simulation adjustment also cannot accurately characterize DCT performance when compared to a MT, AMT or AT. Specifically, the agencies lack any basis in this rulemaking to assign the same value of 2% for DCTs in certain Class 7 and 8 applications as AMTs and ATs and there is no record support for a 2.3% value for DCTs and AMTs in the Vocational Vehicle category when denying such an adjustment for ATs. Again, since EPA and NHTSA cannot reasonably predict the effect of utilizing DCTs in vocational vehicles or tractor applications, the percentage values for DCTs are inherently unsupported in the record. As a data point, Allison recently completed competitive assessment testing of the Eaton Procision DCT. During that assessment, the Procision DCT fuel usage at idle in drive was significantly higher than the fuel usage for the Allison 2000 SeriesTM used in the assessment. This seems to be a result of the Eaton hardware/software implementation that some clutches stay applied during stop in drive scenarios (see table below). [EPA-HQ-OAR-2014-0827-1284-A1 p.21]

Instead, EPA and NHTSA must only include DCTs in GEM when there is a verified model available. Since that currently does not exist, the agencies must develop or obtain such data and make it available for public review prior to assigning a regulatory value to utilization of DCTs. Such data must be done with a 2010 engine in order to have the same baseline as other transmission technologies; utilizing a newer engine would create unacceptable bias in the results. Altogether, without a factual basis in the Proposed Rule, including DCTs in GEM or allowing for post-simulation adjustment cannot be considered a logical outgrowth of the general discussion of this technology provided in the Preamble and supporting documents. 38 [EPA-HQ-OAR-2014-0827-1284-A1 p.21-22]

Moreover, if additional information is provided regarding DCTs, EPA and NHTSA must conduct additional notice and comment rulemaking before including DCTs in GEM or otherwise allowing for crediting of this technology. This is especially true since testing conducted by Allison has indicated that DCTs have more GHG emissions and less fuel economy in transient operation when compared to vehicles incorporating ATs. [EPA-HQ-OAR-2014-0827-1284-A1 p.22]

In recent testing, two trucks were setup to be identical except for the transmission for each vehicle. Full throttle shift speeds were changed on the Allison 2000 SeriesTM to match the Eaton Procision DCT and Neutral at Stop was enabled for the AT. Subsequently, ARB Transient, 55 mph, 65 mph and idle tests were conducted following SAE1526 testing guidelines. The 55 mph and 65 mph tests were conducted on a circle track with a maximum positive grade of 0.78% and maximum negative grade of -0.78%.39 The results of this testing are contained on the chart below: [EPA-HQ-OAR-2014-0827-1284-A1 p.22]

[EPA and NHTSA Must Revise Assumptions on Full Pressure Pump Loss]

For Idle Stop simulation of ATs, GEM assumes full pressure pump loss. In current production, AT transmissions reduce pressure when not needed for clutch capacity or other purposes. By 2021, this on-demand pressure reduction will operate at even lower pressures at idle in all AT transmissions. This pressure reduction directly reduces the pump loss and thus emissions. GEM must therefore be adjusted to take this capability into account. [EPA-HQ-OAR-2014-0827-1284-A1 p.26]
The example below is a combination of test results and analytical post-processing (to convert measured pressures to torque). The figure demonstrates a real world reduction in pump loss during an Idle Stop, versus a Drive Stop. The pump loss reduction is approximately 66%, with very little influence from idle speed. [EPA-HQ-OAR-2014-0827-1284-A1 p.26]

[Chart, 'Pump Loss Reduction at Idle Stop', can be found on p.26 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

**EPA and NHTSA Should Reweight Drive Cycles Used in GEM**

The agencies have requested comment on whether there is a need to “include segments of lower or variable speed operation in the nominally 55 mph and 65 mph drive cycles used in GEM and how this may or may not impact strategies manufacturers would develop.” Data that Allison has developed indicate that average cruising speeds and stops are much greater than reflected in the proposed duty cycle weightings. [EPA-HQ-OAR-2014-0827-1284-A1 p.27]

Allison has assembled data from 16 different tractor fleets using the TC10 transmission. TC10 customer evaluation fleets average 1.5 stops/mile, with a range of 0.2 to 8.9 stops/mile. Duty cycle information for the TC10 therefore indicates that more stops/mile and idle time should be incorporated into the day cab cycle. In general, Allison supports weighting the ARB transient cycle more heavily, reducing the 65 mph cycle percentage and adding 5% idle cycle to the tractor day cabs. Our specific recommended values as weighting and average speeds are contained below: [EPA-HQ-OAR-2014-0827-1284-A1 p.27]

[Tables, 'recommended values for weighing and average speeds', can be found on p.27 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

**Allison Agrees With EPA and NHTSA General Approach on Shift Strategies, But Improvements Are Necessary To Generic Shift Algorithm To Address Lockup**

EPA and NHTSA have recognized that there are a number of technical and policy barriers to incorporating proprietary shift strategies within GEM, including the disclosure of proprietary information and the total number of such strategies and the use of dynamic switching as between strategies. Including such strategies within GEM could also be counterproductive and lead to sub-optimal vehicle configurations. Allison concurs with the agencies in this assessment. It would be exceedingly complex to simulate all the various shift strategies which exist in a single Transmission Control Module (TCM). Utilization of a generic shift algorithm presents a reasonable approach and strikes a reasonable balance between the testing burden imposed and the need for accuracy in testing and certification. [EPA-HQ-OAR-2014-0827-1284-A1 p.29]

Allison does have several concerns regarding the general shift algorithms; however, Allison is concerned about the timing of torque converter lockup (LU) engagement. Allison’s TC10, 2000 xFETM and 3000 xFETM transmission models operate with LU in 1st range. Early LU operation increases efficiency significantly and improves fuel economy by up to 3%. Due to the larger ratio step required for some transmissions, Allison does not believe that all transmissions will have LU in 1st. Allison recommends that GEM be modified to require input of the range in which LU is applied in order to better represent the real world fuel efficiency. [EPA-HQ-OAR-2014-0827-1284-A1 p.29]

In addition, within GEM, the MLHD AT and HHD AT lock/unlock schedules appear to match Allison maximum performance shift schedules. These samples are outliers and do not accurately represent
typical shift schedules in today's fuel economy-driven industry. Further, these lock/unlock schedules must not be used for slower engines because lockup may be unattainable and GEM emissions results would be unrealistically high. [EPA-HQ-OAR-2014-0827-1284-A1 p.29]

Therefore, Allison requests to replace the current MLHD AT lock/unlock schedule (similar to Allison 2600 performance schedule) with the Allison 1800 performance schedule. The Allison 1800 performance schedule still has a performance-oriented shift strategy, but the lower speeds would make it universally compatible with engines in this category. Likewise, we request to replace the current HHD AT lock/unlock schedule (similar to Allison 2100 performance schedule) with the Allison 1600 performance schedule. The Allison 1600 performance schedule still has a performance-oriented shift strategy, but the lower speeds would make it universally compatible with engines in this category. [EPA-HQ-OAR-2014-0827-1284-A1 p.29-30]

Lastly, Allison requests to utilize the 1st Range lock and unlock schedules from these respective shift schedules in those cases where 1st lockup is selected by the user and enabled by GEM. [EPA-HQ-OAR-2014-0827-1284-A1 p.30]

[EPA and NHTSA Must Give Equal Credit to ATs for 1:1 Gear Ratio]

GEM assumes certain transmission gear efficiencies for all ranges. Furthermore, GEM credits a 2% gear efficiency improvement for any range with a 1:1 gear ratio. Allison agrees this is a reasonable assumption, since 1:1 ranges do not exercise any dynamic gear meshes, thus gear meshing losses are reduced. However, this 2% gear efficiency credit for 1:1 ranges is applied to AMT and MT only. Allison requests the same credit for AT, since the same physical phenomenon is observed in AT planetary and countershaft systems alike. Since EPA and NHTSA lack a reasoned basis to distinguish between ATs, AMTs and MTs with regard to 1:1 gear ratios, it would be arbitrary and capricious to selectively grant credits to some, but not all, transmission architectures where this gear ratio is included in the certified vehicle. [EPA-HQ-OAR-2014-0827-1284-A1 p.30]

[EPA and NHTSA Must Fix GEM “Bugs”]

In GEM simulations with automatic transmissions, Allison has commonly observed the lockup clutch cycling during vehicle launches. When this cycling occurs, it is generally followed by 3rd Range torque converter operation. This behavior is unrealistic and does not reflect the lockup schedules embedded within GEM. If followed correctly, those GEM TCC schedules would result in vehicle launches which lockup in 2nd Range and stay locked until vehicle slows to the 2nd Range unlock shift point. [EPA-HQ-OAR-2014-0827-1284-A1 p.30]

The GEM transmission controller also consults the lockup schedules using the current range, rather than the selected range. Thus, during a 2-3 upshift, turbine speed is commonly pulled below the 2nd Range unlock threshold, thereby triggering GEM to unlock incorrectly. EPA and NHTSA should allow the GEM transmission controller to consult the lockup schedules using the selected range. This would result in the 3rd Range unlock threshold being much lower and correct the unintended unlock and lockup cycling defect. Other solutions do exist, but for any solution, Allison requests that the GEM lockup controller be corrected to reflect real world behavior of the torque converter lockup operation. In 2nd Range lockup transmissions, this means that the torque converter locks in 2nd Range and stays locked.
Likewise, in 1st Range lockup enabled transmissions, the torque converter should lock in 1st Range and stay locked. [EPA-HQ-OAR-2014-0827-1284-A1 p.30-31]

**GEM Should Include Starting Range Input for ATs**

Allison manufactures a 7 speed transmission. The 7 speed transmission is a 6 speed gear box with an adaptor housing for a low range or “granny” gear. This low range is only accessible via a manual range selection made by the operator and is only used in off-road conditions. Normal on-highway driving utilizes 2nd thru 7th ranges. The current GEM model operates the ARB Transient cycle using 1st through 7th ranges which does not reflect real world operation. Therefore Allison recommends GEM add a starting range input and the criteria for selecting the starting range would be the starting range used most often (similar to the two speed axle requirement). [EPA-HQ-OAR-2014-0827-1284-A1 p.31]

32 Attachment 3.

34 See Attachment 4.

37 RIA at 4-36.

39 It should be noted here that the grades to do not match the GEM simulation grades.

48 “MLHD” is the term utilized in GEM for the combination of LHD and MHD vehicle classes.

**I. EPA and NHTSA Must Correct Stop Start Delay Time**

From Allison’s review of the NODA and associated documents, it appears that when using engine stop/start in GEM, the simulation puts the transmission into neutral at stops, waits for 5 seconds, and then stops the engine. Specifically, during analyses that we performed using GEM 2v2.1, the following transmission/engine behavior was observed for the simulated engine stop/start feature during the transient cycle: (1) vehicle decelerates to a stop; (2) transmission shifts to neutral (if automatic transmission neutral idle is enabled); (3) a 5 second period ensues; and (4) after this 5 second period, the engine shuts down. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

This element of GEM, however, is inaccurate when compared to the operation of an engine stop-start system that is under development. Based on the current Allison stop-start development level with the 1000/2000 SeriesTM, the transmission generated delay time is less than 1.5 seconds. Overall, the time from vehicle stop, to engine stop, is typically less than 2 seconds. EPA should therefore correct the model’s time variable to substantially revise downward the current level of 5 seconds, to something approximating Allison’s experienced delay of between 1.5 and 2.0 seconds. [EPA-HQ-OAR-2014-0827-1892-A1 p.2]

Although less of a concern for non-transient duty cycles that are largely composed of 55 miles per hour (“MPH”) and 65 MPH operation, the excessive time that the model places a vehicle in neutral disadvantages an automatic transmission (“AT”) more severely than an automated manual (“AMT”) or manual transmission (“MT”) since ATs are more efficient in transient drive cycles than AMTs. A longer period of time before engine-shut down occurs directionally hurts the more efficient operation of ATs in
transient cycles and creates an unjustified disparity in measuring the emissions performance of AT versus AMT or MT transmissions. [EPA-HQ-OAR-2014-0827-1892-A1 p.2-3]

IV. GEM’s Estimation of Transmission Losses is Flawed and Results in Unjustified Benefits to AMTs

After reviewing the most recent updates to GEM, it is clear that EPA has adopted a conservative approach towards modeling losses in a transmission. That is, GEM results in an overestimation of transmission losses in order to provide an incentive for a transmission manufacturer to either provide actual loss data or conduct powertrain testing. This result first conflicts with what should be the goal of GEM modeling: to provide the best estimation of real world performance. But additionally, this result unduly and unjustifiably favors AMTs over ATs. [EPA-HQ-OAR-2014-0827-1892-A1 p.8]

For an AMT, there are two areas of losses: gear efficiency and spin loss. For an AT, there are four areas of losses: gear efficiency, spin loss, pump loss and torque converter loss. Therefore, in GEM, an AT may have a larger total number of losses than an AMT/MT transmission. But it appears that EPA may have applied a “conservative factor” to each such loss in the form of a percentage. This has the effect of multiplying losses for transmissions with higher number of losses. In other words, if the conservative factor is 1.2 (20% higher losses) when applied to a transmission with a 20 Nm loss – this results in 4 Nm of extra loss. But if a transmission has higher losses, for example 100 Nm, then applying the same 1.2 factor results in 20 Nm of additional loss which is highly overstated on an absolute basis. Allison does not believe that application of such a factor – presuming we are right in how the calculation was made -- is either technically supported or justified. [EPA-HQ-OAR-2014-0827-1892-A1 p.8]

As an example of this effect, the GEM model was executed on two 10-speeds, an Eaton MT and an Allison TC10® AT on both tractor day cab and sleeper cab weighted cycles. Then, actual loss numbers were substituted into GEM. The results are contained in the chart below: [EPA-HQ-OAR-2014-0827-1892-A1 p.8]

[Chart, 'CO2 Impact of Power Loss', can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1892-A1]

The above chart shows when going from GEM default losses to actual losses for the MT, CO2 was reduced 1.5% and 1.4%. But when GEM default losses to actual losses are compared for the AT, actual loss data resulted in CO2 reductions of 3.2% and 2.6%. This means that the GEM modeling of ATs would be severely disadvantaged relative to AMTs no matter what specific method was used to calculate the differentials. The important, real world effect of this calculation, however, is to create significant incentives to not use GEM defaults for ATs; an undue test burden is placed on manufacturers who produce AT-equipped vehicles and/or ATs creating an associated market disadvantage. [EPA-HQ-OAR-2014-0827-1892-A1 p.9]

Instead, Allison recommends that EPA apply a fixed amount of extra loss (i.e., a single Nm amount) to all transmission types. Such an approach would level the playing field as between all transmission types and not unduly favor a transmission with lower actual losses in GEM. A manufacturer would always be free to provide actual loss data or conduct powertrain testing in order to replace the default values, but would not be “forced” to do so based on transmission type. [EPA-HQ-OAR-2014-0827-1892-A1 p.9]

Response:

We have made significant changes and improvements based on Allison comments as well as address the issues Allison raised regarding GEM.

- Modified road grade profile for 55- and 65-mph cruise cycles
- Revised idle cycles into overall vocational vehicles with new vocational cycle weightings
- Made significant changes on the input file structures. Examples includes additions of columns for axle configuration (“6x2”, “6x4”, “6x4D”, “4x2”), and additions of a few more technology improvement inputs, such as “Neutral Idle and Start/Stop.”
• Made significant changes on output file structures. Examples includes an option to allow the user to output detailed results on average speed, average work before and after transmissions, and the numbers of shift for each phase (55 and 65mph cycles and ARB cycle).
• Added input file for axle power losses (function of axle output speed and torque) and replaced single axle efficiency in model with lookup table of torque loss
• Added simulation of engine torque response with fast response region defined by engine displacement, and slower torque increase in boosted region with fast fall off on available torque
• Added regression models for all certification cycles to allow the user to simulate vehicle with cycle average approach
• Added different fuel properties according to 1036.530.
• Significantly improved shift strategy based on testing data
• Adjusted transmission loss & inertia scale factors per regulatory subcategory
• Added optional input table for transmission power loss data
• Added minimum torque converter lock-up gear input for AT
• Retuned the default transmission mechanical efficiency based on the testing data
• Added neutral idle and start/stop features during simulation
• Adjusted shift and torque converter lockup strategy

The agencies made changes to GEM with respect to neutral idle as well as start-stop. More can be seen in Chapter 4.4.1.7 of the RIA.

We agree that DCT should not be included in the final GEM. As a matter of fact, DCT is modeled as AMT. More can be seen in Chapter 4.4.1.1 of the RIA.

We also made a number of improvements on pressure pump loss of the transmission as the default input tables. We also allow the OEM to input their own power loss tables if they believe our default power loss is too conservative. In addition, we also provide OEM an option to conduct powertrain test if its own power loss table would not be able to address the benefits related the integration of engine and transmission.

The agencies considered these comments along with the information that was used to derive the drive cycle weightings in Phase 1. The agencies are adopting provisions in Phase 2, and have existing provisions in Phase 1 (EPA’s 40 CFR 1037.630 and NHTSA’s regulation at 49 CFR 523.2), that allow low-roof tractors intended for intracity pickup and delivery, such as those that deliver bottled beverages to retail stores, to be treated as vocational vehicles. The vocational vehicle standards are predicated on drive cycles with distance-based weighting factors of 20, 54, or 90 percent transient cycle depending on the type of vocational operation (see 40 CFR 1037.510). The agencies cannot determine based on the information provided whether some of these tractors may actually be treated as vocational vehicles in the regulations, but it is possible. The agencies believe this new data from a small subset of the tractor fleets falls within the range of drive cycle weightings for day cabs and the final vocational drive cycle weightings. Therefore, we are adopting the drive cycle weightings for tractors that we adopted for Phase 1 and proposed for Phase 2.

We did change the 1:1 gear ratio efficiency based on the data we obtained for both AT and AMT.

We did not make the stop-start delay time shorter as Allison recommended. We have to consider all related technologies on the market, making sure that we would not reward those technologies that cannot shut down in 5 seconds.
We have made many changes on AT transmission loss.

We did add features into GEM, allowing idle stop, neutral stop, and Start/Stop technologies to be accounted for.

The agencies evaluated an AT and AMT during powertrain testing. Please see RIA Chapter 2.8.2.6. The AT we tested included some features that are unique to AT, such as TC 1st gear lockup, and neutral idle, and start/stop features. Once AT can utilize those features, difference between AT and AMT would be small. As a matter of fact, AT can perform better than AMT for certain conditions. However, we have a concern using the Allison TC10 as the default automatic transmission. This is because this TC10 is unique and it appears more efficient than many other transmissions, and using it as the baseline would award those transmissions that do not have the same performance as the TC10.

With regard to the default transmission losses, the agencies used data provided by manufacturers to set the losses for each transmission type and weight class so that GEM represented a conservative 2018 MY baseline. This was done to fairly represent each transmission architecture without overly benefiting transmissions that have lower efficiency than the high volume transmissions. With regard to increasing the losses of all transmission, we did not do this because we did not want manufactures to get credit for just performing the test without improving the efficiency of the transmission.

With regard to manually engaged granny gears, 40 CFR 1037.520 (g) states to input into GEM all the “available” gears. This language was written to address transmissions that have gears that are not available to the operator, but could be expanded to automatic transmission that have manually engaged granny gears. The agencies welcome input on how this language could be modified to more clearly apply to these transmissions.

**Organization:** Aluminum Association

**Freight Efficiency Benefits**

As regards item 2 above, the Association is concerned that the existing EPA GEM methodologies do not adequately account for the benefit inherent in the lightweighting of medium and heavy duty vehicles. The GEM calculates the benefit of lightweighting a heavy duty tractor and/or trailer by assigning 33% of the decrease from lightweighting to a payload increase and 67% of the decrease from lightweighting to a vehicle mass decrease. For vocational trucks, the GEM assigns 50% of the decrease from lightweighting each to a payload increase and to a vehicle mass decrease. This makes sense when applied to the fuel efficiency calculation for an individual heavy duty tractor, trailer, or vocational truck and EPA’s GEM ratios in this area account for the fact that the trucking industry values lightweighting benefits differently according to whether or not the truck/trailer is ‘weighted out’ or ‘cubed out’. [EPA-HQ-OAR-2014-0827-1260-A1 p.4]

What they significantly fail to capture, however, is the benefit that lightweighting provides to dramatically increase overall freight efficiency in addition to individual truck fuel efficiency. This is a key distinction and the difference between the two is best captured by the Lightweighting Confidence Study report issued on August 25, 2015 by the National Council on Freight Efficiency (NACFE) which notes – [EPA-HQ-OAR-2014-0827-1260-A1 p.4]

“Freight efficiency is the measure of the quantity of goods moved per unit of energy needed (measured in ton-miles per gallon of fuel if the load is heavy and cube-miles per gallon for lighter weight loads), while fuel efficiency is simply the miles per gallon achieved by the truck at its maximum weight, but
does not take into account the amount of work being performed (work being the movement of cargo).”

Measured through the GEM lens of fuel efficiency, the per truck fuel economy benefit of lightweighting is in the range of 0.5% to 0.6% improvement in fuel efficiency per 1,000 lbs of weight reduction and EPA in fact notes that weight reduction is a “technology with a high cost that offers small benefit to the transportation sector” (80 FR 40223). However, this misses the real and fundamentally significant benefit of lightweighting to improve the overall freight efficiency of transportation operations. In this regard, lightweighting is the only technology being considered for Phase 2 inclusion in the GEM that confers this benefit. [EPA-HQ-OAR-2014-0827-1260-A1 p.4-5]

And what a benefit it is - For heavy duty trucks and trailers, the GEM methodology reflects that 340 pounds of every 1,000 lbs of weight reduction is translated to increased payload. Using the GEM’s 19 ton default payload for heavy duty trucks and trailers, an aluminum intensive combination tractor/trailer as modeled by the Ricardo Study noted above with 3300 lbs of aluminum lightweighting transports 3% more freight overall (3300 x .34)/(19 x 2000), equivalent to a 3% overall increase in freight efficiency and eliminating the need for one trip out of every 33 previously taken. [EPA-HQ-OAR-2014-0827-1260-A1 p.5]

For vocational trucks, the savings are similar as the GEM reflects that a 1000 lb weight reduction (assuming a smaller weight reduction as vocational trucks are smaller and lighter to begin with) would result in a 500 lb payload increase. This corresponds to a freight efficiency increase of 3.3% (1000 x 0.50)/(7.5 x 2000) and eliminating the need for one trip out of every 30 taken. [EPA-HQ-OAR-2014-0827-1260-A1 p.5]

Because the GEM as currently configured only looks at vehicle specific fuel efficiency and not at overall freight efficiency, the portion of lightweighting of an individual truck allocated to a payload increase is considered detrimental in the GEM methodology. This masks the true value of lightweighting’s benefit in terms of fuel efficiency and GHG emissions reduction at the freight efficiency level as it is not captured in the current GEM calculations and subsequent output. This must be corrected in the final rule and its accompanying GEM. The best way to do this would be to include the full credit for weight reduction in the GEM to account for the freight efficiency component of that weight reduction which results in the elimination of vehicle trips and the commensurate reduction in GHG emissions. [EPA-HQ-OAR-2014-0827-1260-A1 p.5]

Response:

We agree with Aluminum Association on the benefits of light weight material. We have enhanced the number of lightweighting components recognized in the regulations. The detailed list can be seen in 40 CFR 1037.520.

The agencies did not assess the impact of individual technologies in terms of freight efficiency of the entire sector. The metrics we use to evaluate a single vehicle is a freight efficiency metric – grams of CO₂ per ton-mile and gallons of fuel per 1000 ton-miles. Our split treatment of the weight reduction items recognizes that for a portion of the trips when the vehicle is at weight limit, that vehicle will be able to carry more payload.

Organization: American Automotive Policy Council

Adding Technologies to GEM
While the introduction of dual clutch heavy transmission may be a few years away from entry in the U.S. market, EPA needs to establish a procedure to add new fuel saving technologies to GEM. The process to add technologies must be clearly written and concise. The procedure should be vetted throughout the agencies, including EPA certification staff, and issued via guidance. Investing in new technologies can require hundreds of millions of dollars in up front funding. Furthermore, GEM, as proposed, provides no clear path towards incorporation of new, fuel saving technologies. [EPA-HQ-OAR-2014-0827-1238-A1 p.33]

While the feasibility of a heavy-duty dual clutch transmission may be debatable, the possibility of new technologies emerging that could and should be included in GEM is real. Hence the agencies needs to layout out a clear, concise, step by step process that OEM’s can follow to add technologies to the GEM pick list and the EPA certification staff can follow to approval or deny technology. Furthermore this process needs to be open and transparent to all parties. [EPA-HQ-OAR-2014-0827-1238-A1 p.33]

Simply discussing a process to add technologies to GEM in the draft RIA and assuming it can be used to make GEM technology changes post rulemaking is insufficient. The agencies need to add clear step-by-step guidelines with multiple examples using aero, driveline, axle, transmission, engine, aftertreatment, and climate control (heating and cooling technologies) that both industry and EPA can follow. [EPA-HQ-OAR-2014-0827-1238-A1 p.33]

Given the “newness of GEM” and the extreme difference in terms of speed and load demanded by the various urban, 55 mph, and 65 mph drive cycles vs the heavy-duty FTP additional flexibilities are needed to reflect in-use accessory load reduction. In addition to FEAD components discussed in the NPRM, other technologies that may not be fully reflected in the engine mapping process or underrepresented because of improper or unknown GEM assumptions need to be included. These include clutched, electric, variable speed, variable pressure coolant, fuel, engine oil, transmission oil, air conditioning and/or DEF pumps. Additionally, the agencies should consider adding generic powertrain and vehicle scaling features to GEM (aerodynamics, loads, etc.). [EPA-HQ-OAR-2014-0827-1238-A1 p.33]

AAPC believes that GEM credits for idle reduction technologies, such as neutral idle, idle shut down and stop-start, fall short of actual on-road CO2 benefits. [EPA-HQ-OAR-2014-0827-1898-A1 p.2]

Response:

We have considerably expand the technology improvement inputs to recognize many new technologies including various idle technologies. We also expand the test procedures that can detail the procedure of how these new technologies can be recognized. For example, all new technologies related to the engines will be recognized during the engine fuel map generation, including variable speed pumps on oil, fuel and water, as long as those components are part of the engines that are being tested. For transmission related new technology, it can be recognized by individual gear transmission efficiency tests or powertrain tests. As pointed out in Chapter 4.4.1.1 of the RIA, we do not model DCT directly. Rather, we model DCT as AMT.

Updates to modeled technologies
Changes to the representation of transmission, engine, and axle allow for more precise modeling of vehicle behavior in the GEM model. Additional vehicle technologies and greater acceptance of numeric
parameters (instead of Y/N) for technology inputs allows manufacturers greater representation of the vehicles they are actually putting on the road. [EPA-HQ-OAR-2014-0827-1896-A1 p.4]

Impact on the proposal

Modeling powertrain technology more accurately will help align GEM results with real world reductions. It will also allow for greater capture of incremental improvements. The proposal assumed fixed technology improvements—however, as is evident from sources like the Southwest Research Institute report, there will be continuous development of many of these technologies throughout the course of this rule. Because GEM can now better capture these more subtle technology improvements related to transmission efficiencies, etc., it is critical that the agencies tighten their 2024 and 2027 targets accordingly to ensure that the targets represent the “maximum feasible” and “technology forcing” standards. Similarly, the inclusion of technologies that the agencies did not originally model within the GEM model (e.g., tractor neutral idling) means that those targets should be tightened to recognize that these technologies can reduce fuel use from heavy-duty trucks. [EPA-HQ-OAR-2014-0827-1896-A1 p.4]

Response:

We have changed many technology improvement inputs from Y/N to %, allowing the user to input specific values for those technologies defined by 40 CFR 1037.520. These technologies are very well defined as part of the stringency development. Please see Preamble Sections III.D, IV.D, and V.C for discussions regarding the stringency of the tractor, trailer, and vocational vehicle standards.

Organization: BYD Motors

Further Refine Duty Cycles to More Fully Capture Technology Benefits

Despite significant improvement to the duty cycle, particularly for urban and multipurpose vehicles that spend much of the day parked or in transient operation, further improvements can be made to ensure that the broad spectrum of vocational vehicles is adequately represented and that the regulation drives the full spectrum of fuel consumption reduction technologies applicable to such a diverse fleet. [EPA-HQ-OAR-2014-0827-1182-A1 p.3]

Work trucks frequently experience idle time exceeding those of even the urban vehicle category. Furthermore, by setting stringency exclusively with the GEM model, the agencies have excluded fuel used for power take-off (PTO) operation at work sites and, in turn, technologies that would reduce this fuel use. The agencies have in Phase 2, as in Phase 1, a certification pathway that allows manufacturers to claim credit for hybrid and electric PTO; however, they did not include any uptake of this technology in the baseline assumptions, further undermining the stringency levels that should be assumed in vocational vehicles. [EPA-HQ-OAR-2014-0827-1182-A1 p.3]

Response:

We have made numerous changes to account for the benefits related to idle and PTO as part of input parameters for GEM, specifically targeting vocational sectors.
Organization: Daimler Trucks North America LLC

Use of rear axle efficiency test results to override GEM defaults – The agencies request comment on an optional axle efficiency test procedure to override the agencies simulated axle in GEM. 80 FR 40176. DTNA welcomes the option to override the GEM default value for axle efficiency based on the result of an axle efficiency test. This will be beneficial both to manufacturers and the agencies by providing better information about actual axle efficiencies than the default, literature value of 95.5%. While we appreciate the agencies’ efforts to define a new procedure to measure axle efficiency, we recommend instead aligning with the ACEA’s test protocol for axle efficiency measurement. Refer to Appendix D for ACEA’s Axle Test Method. [EPA-HQ-OAR-2014-0827-1164-A1 p.54]

Axles – The agencies request comment on the best way to recognize improved axle technology for vocational vehicles, either through a GEM calculation or a fixed assigned value. 80 FR 40299. Axle efficiency improvements whether it is lubrication or axle disconnect (6x2) should be rewarded with a GEM calculation or a fixed value. In the interest to keep a uniform approach across all vehicle subcategories we recommend adopting the proposed method for tractors, i.e. applying a fixed improvement value in the post-processing of GEM. [EPA-HQ-OAR-2014-0827-1164-A1 p.54]

Simulating Human Driver Behavior and Transmissions for Vehicle Certification - The EPA describes the complexity of its driver model on 80 FR 40184 and requests information on ideas like using transmission-specific shift logic and improved driver models. We at DTNA have modeled vehicles with different shift logic, from a simplified version to a complex one that required software in the loop. We found that for the EPA’s linehaul cycles, there was very little difference in the results for the different versions—the reason being that there is very little gear shifting involved in the EPA’s linehaul cycles. See the section on GEM, above. On vocational cycles, there could be significant differences, because the higher frequency of gear shifts. But the complexity of modeling all of the different drivers and the ways that their quirks impact shifting make it impossible to get one common driver model that both covers all of the quirks yet is generic enough to work in a regulatory setting. Therefore, we think that the agencies’ approach with the generic shift strategy and driver model is the correct approach. [EPA-HQ-OAR-2014-0827-1164-A1 p.63]

DCT Should Get No More Credit Than AMT – The agencies propose to assign a 2% benefit for dual-clutch transmissions. § 1037.520(f)(3). Despite having studied such transmissions, we do not see so large a FE benefit beyond the benefit that comes from the automated nature of the transmission. Therefore, we agree with the agencies’ proposal—as we understand it—that gives DCTs the same 2% benefit that AMTs get. If however we misunderstand and the DCT gets 2% plus the 2% for being automated, then we think the agencies’ approach is incorrect. [EPA-HQ-OAR-2014-0827-1164-A1 p.63]

Off-Cycle Technology Credits - The agencies propose to continue the process of innovative technology credits, now called off-cycle technology credits. We agree that this is an appropriate method of incentivizing development of FE technologies, even those that do not show FCRs on the GEM cycle or on a chassis dynamometer, given that a lot of the real world cannot be accurately represented on a chassis dynamometer. We also agree that the agencies should take the list of known off-cycle technologies, including predictive cruise control and tire inflation systems, and give manufacturers credit without forcing the manufacturers to go through the cumbersome off-cycle certification procedure. However, if a manufacturer makes a significant breakthrough, for example taking predictive technologies and developing one that can achieve significantly more than the 2% that the agencies currently propose to credit, then the manufacturer should be able to use the off-cycle credit procedure to demonstrate that delta and to get credit for it. [EPA-HQ-OAR-2014-0827-1164-A1 p.76]
Innovative and Off-Cycle Technology Credits - The agencies request comment on whether off-cycle technologies in the Phase 2 program should be limited by infrequent common use, in what model years, and what should be penetration rate to be considered not in common use. 80 FR 40158. First, as a preface, DTNA tried very hard for two years to get certification for off-cycle technologies (then called innovative technologies) that were not in common use at the start of Phase 1; we never achieved certification. For some technologies, the agencies objected that the technology was common enough at the beginning of Phase 1 that it could not be considered innovative. Leaving this to regulators' discretion after rulemaking seemed to open the door to the arbitrary decision that some technologies, which were not in common use at the start of the program, were in sufficiently common use to be denied innotech credits. As a solution to this, we propose that any technology be eligible for off-cycle credits if it is not included in GEM. Obviously, if a FE technology was invented only after start of Phase 2, it will be too new to be in GEM and should automatically be eligible for off-cycle credits. Similarly if there is a technology not invented at the time of the rulemaking but invented prior to the start of Phase 2, then it should automatically be eligible too. But even if the technology was invented and in use during the rulemaking or before, the fact that the agencies did not consider it for a pull-down menu-type credit should not prevent its eligibility. Any fuel savings are valid fuel savings. In short, with the agencies trying to capture as many technologies as possible with the pull-down menu credits, any that are omitted or that are not captured by GEM should be eligible for off-cycle credits. [EPA-HQ-OAR-2014-0827-1164-A1 p.76-77]

Innovative and Off-Cycle Technology Credits - On an appropriate penetration rate for a technology not to be considered in common use. 80 FR 40330. DTNA believes that any technology that provides measurable fuel savings and is not reflected in GEM should be eligible to be an accredited off-cycle technology. Especially in light of the ambitious CO2 reduction targets proposed by the EPA the ability to generate CO2 credits is very important and should further incentivize OEMs improve fuel efficiency. [EPA-HQ-OAR-2014-0827-1164-A1 p.77]

Innovative Technology and Off-Cycle Credits - Not granting any off-cycle credits for crash avoidance technologies, and also the possibility of adopting aspects of the light-duty off-cycle program. 80 FR 40158. DTNA believes that crash avoidance technologies have a tangible effect on FCR. Any reduction in crashes and the road congestion often associated with them will result in wasted fuel. NHTSA should grant off-cycle credits for crash avoidance technologies. DTNA agrees with the requirement for documentation for off-cycle requests so long as the requirement is straightforward and not unnecessarily complex. [EPA-HQ-OAR-2014-0827-1164-A1 p.77]

Off-cycle (innotech) burden in Phase 1 is too high; this is a better approach: DTNA favors to see as many technologies as possible to be recognized via separate fixed inputs into GEM. Beyond that DTNA fully supports the agencies' intention to provide a regulatory path for off-cycle technology credits as a complement to GEM. 80 FR 40330. However, following our experience with the inno-tech process in Phase 1, we urge the agencies to clearly define a clear path towards certification of a given technology. [redacted] For Phase 2 it is important to avoid scenarios like this. It should be feasible for OEMs to claim credits with a reasonable amount of effort, even at the expense of slight over crediting. Of course, good engineering judgement always has to be employed. It is important to remember that the agencies intend to credit similar technologies (with variable benefits) via predefined improvement factors in GEM. AMTs always allow the possibility to be operated manually and predictive cruise control technologies may never be active in a metropolitan area with dense infrastructure and high traffic density.[EPA-HQ-OAR-2014-0827-1164-A1 p.77-78]

Off-cycle (innotech) DF: in 1037.610(d)(7), the EPA proposes to require a demonstration of the in-use durability of the off-cycle technology. This is likely unnecessary or impracticable for many off-cycle
technologies. For example, if there is some technology like the future version of eCoast or Predictive Cruise Control, a programming-based technology, the technology does not degrade, so no demonstration is necessary. And for other technologies that are more hardware based (as opposed to software based), the demonstration may be impracticable or impossible, especially given the limited resources available to run test trucks for long mileages simply to look for deterioration. That is, trucks are designed for approximately a million miles of operation, with hardware components designed for similar operation (albeit perhaps with maintenance involved, as is allowed under the EPA's DF procedures for engines). There is no reason to believe that off-cycle technology would be any less robust than the rest of a vehicle. Then, to slow production and agency recognition of such technologies by mandating several hundred thousand miles of operation to validate a manufacturer's claim of durability is unnecessary. We recommend that the EPA apply a 'good engineering judgment' standard here, allowing a manufacturer to claim no deterioration (albeit, again, perhaps with maintenance required at prescribed intervals). If after introduction into commerce of such a technology, the agency has reason to believe the technology is not as durable as the manufacturer claimed, the agency could revoke certification of the technology or demand it be recalled and upgraded. 1037.610(d)(7) [EPA-HQ-OAR-2014-0827-1164-A1 p.78]

Describing post-processing technologies in 1037.205(b): it is not clear to us what level of detail would be required in describing the technologies listed in 1037.205(b), such as predictive cruise control. Additionally it is not clear whether a vehicle manufacturer could provide such information when the technology, again such as PCC, is supplied by an independent engine manufacturer. These are details that should be ironed out during the rulemaking process, as (in our experience) leaving this until after the rulemaking when manufacturers are trying to certify off-cycle technologies leads to months or years of back-and-forth on what information is required for certification. 1037.205(b) [EPA-HQ-OAR-2014-0827-1164-A1 p.78]

Predictive Cruise Control (PCC) is counted as a pull-down menu technology but eCoast, which provided huge fuel savings on Super Truck, is not. The agencies should correct this omission. At the least, the agencies should use a [redacted] value, which is representative of an average vehicle with eCoast. It is worth noting that the more aerodynamic a vehicle and/or the lower its rolling resistance, the more its eCoast will save fuel (as demonstrated by the DTNA Super Truck). If the agencies have the time, they should provide increased eCoast FCR benefits in GEM for the more aerodynamic vehicles (e.g., [redacted]% for eCoast on a Bin VII vehicle and [redacted].5% on a Bin VI, etc.). 1037.520(f) [EPA-HQ-OAR-2014-0827-1164-A1 p.80]

Response:

We appreciate many constructive comments from DTNA. Accordingly, we made many changes.

We do allow the rear axle efficiency tests result to override GEM defaults, which specifically address the benefits from 6x2 and lubricant, many advanced technologies related to axle.

We appreciate DTNA’s support for us to use generic shift strategy.

GEM will model DCTs as AMTs as DTNA suggested.

Although off-cycle credits will remain an option under Phase 2, the agencies have included many more technologies within GEM (so these are not off-cycle anymore, but rather already credited). These include predictive cruise control and tire inflation systems through % instead of N/Y option. Both predictive cruise control and neutral coast (eCoast) are defined as Intelligent Controls in the GEM input
file, which means that they can be all recognized as technology improvement inputs to get credit. How all those technology improvement inputs for off-cycle credit are used in GEM is defined in 40 CFR 1037.520(j).

**Organization:** Dana Holding Corporation

These comments specifically address the newly docketed Greenhouse Gas Emissions Model (GEM) P2v2.1 (EPA Docket No. EPA-HQ-OAR-2014-0827-1626), on which the agencies requested public comment. [EPA-HQ-OAR-2014-0827-1917-A1 p.1]

**Axle Efficiency Testing**

Dana fully supports the joint initiative by the National Highway Traffic Safety Administration and the Environmental Protection Agency to further reduce greenhouse gas (“GHG”) emissions and improve the fuel economy of medium- and heavy-duty vehicles as described in Alternative 3 of the proposed rule published in 80 FR 40137. On September 24, 2015, Dana submitted comments identifying our position related to the proposed rule and made several suggestions for consideration by the agencies during the process of promulgating a final rule. Dana remains committed to the views contained in our September 24, 2015, comments. Dana believes that various material changes have been made to the GEM since those comments were submitted that require the filing of these additional comments. [EPA-HQ-OAR-2014-0827-1917-A1 p.2]

Specifically, Dana notes that the agencies have adopted a “two-option” approach to determining axle efficiency within GEM P2v2.1. This new two-option approach will provide axle manufacturers with the choice to use either a very conservative default fixed axle efficiency that can be interpolated by ratio through a linear equation or, as a second option, to provide a full rear axle power-loss map obtained through standardized dynamometer testing. Given that the default efficiencies are very conservative and understate leading axle efficiency ratings, axle manufacturers like Dana are most likely to rely on the full dynamometer test to determine credits for the efficiencies designed into their proprietary axles. [EPA-HQ-OAR-2014-0827-1917-A1 p.2]

It is important to note that, given this new two-option approach, Dana supports the use of conservative default efficiency values to ensure that higher efficiency ratings are not awarded to axles that do not merit them. Our review of the GEM P2v2.1 shows that all default efficiency values are in fact conservative. As a result, Dana supports these efficiency values and related equations. [EPA-HQ-OAR-2014-0827-1917-A1 p.2]

Dana’s primary concerns are with the full dynamometer testing for rear axles. Our position remains the same as noted in our first set of comments on the proposed rule. It is Dana’s opinion that the standardized dynamometer testing would result in excessive complexity and documentation for fractions of a percent improvement in efficiency. It is also our opinion that various easily and visually identifiable features can serve as a less complicated checklist of efficiency credits with prescribed efficiency improvement values. A checklist approach with prescribed efficiency values for various features would be less complicated and allow axle manufacturers to focus on the development of innovative products rather than testing axles for the pure benefit of certification. [EPA-HQ-OAR-2014-0827-1917-A1 p.2]

As an axle manufacturer that is not vertically integrated within a vehicle manufacturer, Dana provides axles that are designed to meet the needs of a full range of customers. This results in extensive complexity within our product portfolio and requires us to provide customers with a number of axle offerings. For example, axle manufacturers (not vertically integrated within vehicle manufacturing
OEMs) serve the heavy-duty, on-highway line haul market with an array of axle families with multiple ratios for each axle family. Under the new GEM P2v2.1, leading axle manufacturers like Dana would need to conduct full dynamometer testing for their axles to ensure that they do not understate the efficiency values for their products by using the proposed conservative default values. Providing axle dynamometer testing for all axle families and each ratio will be extremely demanding on our human and capital resources with little resulting gain in achieving the proposed rule’s goals to reduce emissions and fuel consumption. Even minor changes to the axles would require recertification to ensure that efficiency values are stated correctly. Given the number of axle families produced by Dana, the various ratios offered within those axle families, and the numerous changes that occur on axles over their product life, the cost of testing for certification and recertification could be prohibitive. In addition to the cost of dyno-testing, there would be the opportunity cost of not utilizing those same human and capital resources for research, development, and advanced engineering programs that lead to innovative products that drive efficiency gains in our products and help improve the fuel efficiency of our customers’ vehicles. [EPA-HQ-OAR-2014-0827-1917-A1 p.2-3]

For the reasons noted above, we are suggesting a more simplistic approach to the full dynamometer bench testing. Rather than testing each ratio or variant of the axle within a product family, Dana suggests a combination of testing two book-end ratios for the product family and the development of an industry-acceptable mathematical formula to interpolate the remaining ratios. This will minimize the extent of the testing and balance the need to provide accurate axle efficiency values while not imposing costs that could limit our ability to develop innovative products to make the vehicles affected by the proposed rule more efficient. [EPA-HQ-OAR-2014-0827-1917-A1 p.3]

Full-time 6x2s, Part-time 6x2s, and Two-Speed Disconnecting Tandems

Class 8 on-highway line haul vehicles with 6x2 and part-time 6x2 configurations will clearly offer an option to help achieve the proposed rule’s GHG emissions and fuel-efficiency standards. At Dana, we are positioning our products to support both full-time and part-time 6x2s to accommodate the future market. Given the important role these configurations could play in meeting the proposed standards, we can agree with the agencies’ position not to offer a fixed 2.5% efficiency credit post GEM for 6x2 vehicles. [EPA-HQ-OAR-2014-0827-1917-A1 p.3]

The new two-option approach of using conservative default efficiency values or full power-loss efficiency maps within the GEM supports a more accurate approach. We can attest that the default efficiency values are in fact conservative. We also find that the mathematical equation used to interpolate ratio efficiency for 6x2 configurations is reasonable and uses a conservative 37 Nm loss for tag axles. [EPA-HQ-OAR-2014-0827-1917-A1 p.3]

Our review of the GEM P2v2.1 also concludes that it does not accommodate two-speed axles. As noted in our previous comments, Dana has developed a dual-range (two-speed), “disconnectable” tandem axle. This new axle innovation will operate as a traditional axle in 6x4 configuration with a higher numerical rear axle ratio to support the low-speed vehicle performance and safety. While approaching cruise speeds the tandem axle will automatically (without driver intervention) “disconnect” and no longer turn the inter-axle driveshaft, rear-rear pinion and ring-gear, therefore, operating fully on the forward of the rear axle. During this disconnected configuration, the axle operates at the equivalent efficiency of a 6x2 arrangement. Since the GEM does not allow for two-speed axles, we suggest that the GEM use the ratio that is expected to be engaged over the greatest driving distance to be used to determine axle efficiency and power-loss values. [EPA-HQ-OAR-2014-0827-1917-A1 p.3-4]

Automatic Tire Inflation Systems
In addition to driveline systems (steer axles, driveshafts and drive axles), Dana offers automatic tire inflation systems that can be used on the full range of vehicles affected by the proposed rule (class 2b – 8). The Spicer® Tire Optimization Management System is designed for use with steer and drive axles, ensuring that tires in all tractor positions are at their target inflation without depending on driver/human intervention. Dana’s automatic tire inflation (ATI) solution is one of a number of available systems in the commercial vehicle space that automatically keep tires at the appropriate inflation to reduce rolling resistance, and provide significant fuel economy benefits. [EPA-HQ-OAR-2014-0827-1917-A1 p.4]

Dana’s independent studies support the findings in Section II.C.1.(f) (80 FR 40187) of the proposed Phase 2 rule, highlighting that tire pressure monitoring systems cannot sufficiently guarantee the proper inflation of tires. These studies are supported by substantial fleet testimonials suggesting that monitoring only systems are too dependent on driver intervention to be effective, and even when used in combination with telematics, fleet managers typically only direct a truck in for unscheduled service if tires are at dangerously low pressures and at risk of blowout. Until tires reach this point, the benefits of reduced rolling resistance are typically not realized. Dana therefore agreed that the proposed rule did not assign an efficiency credit for tire pressure monitoring systems. We have learned that the agencies may now offer a 0.25% efficiency credit for tire pressure monitoring systems. For the reasons stated above, Dana does not support offering a 0.25% efficiency credit for tire pressure monitoring systems that require human intervention to pressurize the tire when signaling a low-pressure warning. [EPA-HQ-OAR-2014-0827-1917-A1 p.4]

While Dana supports the agencies’ findings related to providing post-simulation adjustments for class 7 and 8 tractors, the fuel economy benefits of reduced rolling resistance can be realized for all vehicles spending time on highway. As a result, Dana proposes that credit for automatic tire inflation systems be granted for all vehicle classes (2b-8) included in the rule, including credit for vocational vehicles as these vehicles tend to be on-highway between 40-60% of their life. [EPA-HQ-OAR-2014-0827-1917-A1 p.4]

Further, the proposed rule grants a 1% “reduction value” as a post-simulation adjustment for the use of ATI systems on drive axles in tractors (40 CFR 1037.520(f)(7) (80 FR 40631 of the proposed rule). Maintaining proper tire inflation of the front tires on the steer axles can also contribute to reduced rolling resistance, and improved fuel economy. Dana proposes an additional 0.25% credit be granted for tractors with ATI systems equipped on both steer and drive axles, for a total credit of 1.25%. [EPA-HQ-OAR-2014-0827-1917-A1 p.4]

**Automatic Tire Inflation & Deflation System Credit**

In addition to automatic tire inflation, the Spicer® Tire Optimization Management System will include an active deflate feature for an incremental fuel economy and safety benefit. In a recent OEM study, it was determined that tractors equipped with active inflate and deflate technology saw a 2% improvement in fuel economy as a result of making active modifications due to terrain, vehicle load, and duty-cycle. This level of sophistication is currently provided by Dana and is used in military and vocational vehicles. Dana is committed to bringing this technology to fruition in support of all on-highway tractors, and suggests that the agencies account for this enhanced solution in the final version of GEM by providing a 2% reduction value for active inflate and deflate systems. [EPA-HQ-OAR-2014-0827-1917-A1 p.4-5]

**Early Banking of Automatic Tire Inflation & Deflation System Credits**
As automatic tire inflation systems are currently available, Dana suggests that the agencies allow vehicle OEMs that adopt automatic tire inflation systems before the start of phase 2 to be able to bank the 1% - 2% (depending on whether the system includes active inflate and deflate features) credit for such systems during the phase 1 timeframe. Those credits could be banked for use within the MY2021 – MY2027 timeframe. [EPA-HQ-OAR-2014-0827-1917-A1 p.5]

Overall, Dana supports the changes made to GEM that are reflected in the new release (GEM P2v2.1). The changes support a more accurate approach and provide additional efficiency credits that reflect the important role axles and automatic tire inflation systems can play in meeting the proposed Phase 2 standards. Dana’s suggestions above aim to better balance the amount of axle testing with the anticipated value achieved by that testing. We believe that the suggestions provided above strike that balance. Dana’s commitment is to continue to provide innovative solutions that enable our customers to transport freight and people safely, efficiently and effectively. [EPA-HQ-OAR-2014-0827-1917-A1 p.5]

Response:

We appreciate Dana’s support on our axle two-option approach. In principle, we agree with Dana that rather than testing each ratio or variant of the axle within a product family, we could develop a combination of testing two book-end ratios for the product family and the development of an industry-acceptable mathematical formula to interpolate the remaining ratios. This methodology is adopted in the final rule in 40 CFR 1037.560.

GEM does allow two speed disconnecting tandems named as 6x4D, where the vehicle is simulated on the 55 and 65mph cycle as a 6x2 and as a 6x4 on the transient cycle. However, the axle ratio would still be the same for this two speed axle option, prompting OEM to select most commonly used axle ratio for GEM based on their driving condition. The main reason for this decision is that we believe that two speed axle is primarily used in tractor applications, where cruise speeds are pre-dominated. The cycle weighing on transient cycle is small compared to ones on two cruise speed cycles. As such, the lower axle ratio should be selected. This is not a perfect solution, but can greatly simplify GEM.

Taking into many other comments on tire pressure system, we recognize both TPMS and ATIS in Phase 2 GEM, though the effectiveness of TPMS is lower than ATIS to recognize the need for operator intervention. Please see Preamble Section III.D. 1.b for further discussion. Consistent with Dana’s recommendation, the agencies are providing early credits for ATIS (see 40 CFR 1037.150(y)).

Organization: Eaton Vehicle Group

Introduce the ability to overwrite GEM defaults with measured data: We recommend the certification procedure allow the GEM default transmission efficiencies to be overwritten with values measured on transmission efficiency test stands. This approach pulls through hardware improvements such as advanced lubrication and reduced friction similar to the measured axle efficiencies described in the NPRM. While the magnitude of these improvements is modest compared to those provided by controls, they are intrinsic to the transmission hardware and independent of its controls. Thus, the benefits can be exercised for all vehicles with the same transmission and without concerns over in-use tampering or family definitions. [EPA-HQ-OAR-2014-0827-1194-A1 p.3-4]

Overwriting GEM defaults with measured data

The NPRM defines two paths for certification: the use of “slightly conservative” transmission models and the powertrain test option. The latter makes sense to be used only for those transmissions that
implement advanced technologies not modeled in GEM, and where the benefits of transmission shift strategies and engine/transmission deep integration is significant. [EPA-HQ-OAR-2014-0827-1194-A1 p.11]

Rationale

For axle technologies, the NPRM has two different options: GEM “slightly conservative” models (power-loss or efficiency models, to be precise), and the potential to overwrite these models with a loss model that is linear in input shaft speed (so-called spin losses that have to do mostly with lubrication) and torque (losses that have to do mostly with gear contacts and friction of sliding surfaces). [EPA-HQ-OAR-2014-0827-1194-A1 p.11]

We recommend the agency allow a similar procedure for transmissions. The GEM default transmission efficiencies would be overwritten with values measured on transmission efficiency test stands for selected gears, and GEM defaults would be used for all other gears. A variant of this test is used in the draft European Commission VECTO simulation. [EPA-HQ-OAR-2014-0827-1194-A1 p.11]

Technical approach

The basis of this approach is to recognize that the transmission power loss in a given gear \( k \) is of the form: [EPA-HQ-OAR-2014-0827-1194-A1 p.11]

\[
\text{Transmission torque loss} = a_k w_{\text{input}} + B_k T_{\text{input}}
\]

The coefficient \( a_k \) is determined on a spin test by measuring the power loss of a transmission spun at a few different engine speeds \( w_{\text{input}} \) at the input shaft, but with no load on the output shaft. The coefficient \( B_k \) is calculated using the transmission in gear \( k \) between two dynamometers that load both the input shaft with torque and the output shaft with the corresponding torque to balance the system. In the second case, torque is measured at both inputs and outputs and the difference determines the torque loss, hence \( B_k \). It is important to run the test at two representative oil temperatures and the losses of the test stand itself need to be isolated from the losses of the transmission. [EPA-HQ-OAR-2014-0827-1194-A1 p.11]

[Figure 1 can be found p.12 of docket number EPA-HQ-OAR-2014-0827-1194-A1]

Note that the European VECTO approach is measuring data at many torque and RPM points, in some estimates at more than 1,300 test points per transmission. Such burden and precision are excessive, especially given that GEM and VECTO are run with generic controllers that introduce more significant errors than the actual power loss versus the bi-linear model above. [EPA-HQ-OAR-2014-0827-1194-A1 p.12]

We run such tests for development purposes to determine transmission efficiency. Based on that approach, we estimate that the unburdened costs of such tests are less than $40,000 per test. We have provided cost estimates based on actual expenses to the EPA [CBI data provided]. [EPA-HQ-OAR-2014-0827-1194-A1 p.12]

Limitation and compliance value

This approach pulls through hardware improvements such as advanced lubrication and reduced friction. While the magnitude of these improvements is modest compared to those provided by controls (5-10%
of the compliance gap for line haul tractors and 10-20% of the compliance gap for Vocational vehicles),
they are intrinsic to the transmission hardware and independent of its controls. Thus, the benefits can be
exercised for all vehicles with the same transmission and without any in-use tampering concerns or
powertrain family issues. For example, for an Eaton LAS 10-speed transmission approximately 2% fuel
reduction over GEM predictions can be captured with such an approach. However, for an MXP 18-
speed transmission the benefit is minimal because the most used gears are roughly 96% efficient and
98% efficient in direct applications (close to the GEM defaults). We have provided the EPA with
relevant data from several transmissions that show that \( f_3 = 0.02 \) in direct gear (98% efficiency) and
\( f_3 = 0.04 \) (96% efficiency) in other gears is a “slightly conservative” GEM setting [Jackson 2015 and CBI
data provided\(^1\), but for other transmissions the typical values range between 0.007 and 0.011 in direct
and 0.015 in the other relevant gears. For such transmissions, the benefit of overwriting GEM default
values results in 1-3% fuel consumption improvement. [EPA-HQ-OAR-2014-0827-1194-A1 p.12]

**Recommendation:** The EPA should introduce a transmission efficiency overwrite of GEM defaults
based on measured gearbox efficiency in select gears. [EPA-HQ-OAR-2014-0827-1194-A1 p.12]

---

We believe that the following are characteristics are critical to the success of GEM as a tool and to
realizing the improvements envisioned by the rule in an efficient way for the industry: [EPA-HQ-OAR-
- GEM results need to reproduce the technology trends in transmission technologies, so that GEM does

**Response:**

We have made many changes to address Eaton’s constructive comments. We do allow GEM default loss
for transmission to be overwritten by the OEM’s data.

**Organization:** Genthem, Inc.

All of our comments are directly addressing observed shortcomings and we are suggesting mechanisms
which would incentivize engine manufacturers to replace inefficient, mechanically driven accessories
with highly efficient and better controlled electrified accessories. Supertruck Program\(^1\) has shown that
such replacement is one of the basic approaches in further improving engine and overall vehicle fuel

**Comment #3. Provide a clear mechanism for off-cycle credits for waste heat recovery and other
alternative means to produce on-board electricity.** [EPA-HQ-OAR-2014-0827-1133-A1 p.4]

**Background from Draft**

“In particular, we project a more limited use of waste exhaust heat recovery systems in 2027, projecting
that about 10 percent of tractor engines will have turbocompounding systems, and an additional 15
percent of tractor engines would employ Rankine-cycle waste heat recovery. We do not project that
turbocompounding or Rankine-cycle waste heat recovery technology will be utilized in vocational engines. Although we see great potential for waste heat recovery systems to achieve significant fuel savings and CO2 emission reductions, we are not projecting that the technology could be available for more wide-spread use in this time frame.” [EPA-HQ-OAR-2014-0827-1133-A1 p.4]

Agencies are recognizing limited penetration of waste heat recovery and other energy harvesting technologies. It is justified to assume that implementation of Rankine-cycle waste heat recovery in vocational vehicles will remain to be limited due to complexity of the ORC equipment. This comment addresses the issue of off-cycle accounting for electricity production using innovative waste energy recovery and energy harvesting technologies which are producing electricity. [EPA-HQ-OAR-2014-0827-1133-A1 p.4]

**Proposed change:** Gentherm proposes a simplified mechanism to provide the off-cycle credits for fuel savings and emissions reduction by allowing the bench testing at component- or subsystem-level, and then using the results of the testing to calculate emission reduction and fuel saving coefficient in the GEM simulation. In general, we view implementation of an energy source which is not using additional fuel to generate electricity as a clean energy source which is reducing fuel consumption. Waste heat recovery is an example of such an energy source. We propose using similar approach in evaluating this benefit as in case of evaluating effect of electrification of accessories. Waste heat recovery or energy harvesting electrical source is substituting mechanically driven alternator. We propose a four-step calculation: [EPA-HQ-OAR-2014-0827-1133-A1 p.4]

1. **Step 1:** Benchtop evaluation of efficiency of efficiency of alternator (\(\eta_{\text{alternator}}\)). [EPA-HQ-OAR-2014-0827-1133-A1 p.4]

2. **Step 2:** Measurement of electrical power generated by a waste heat recovery device in the range of conditions matching the engine operating range \(\text{P}_{\text{WHR}}\). Calculate instantaneous energy saving \(\text{P}_{\text{saving}}\) as a result of implementation of waste heat energy source as: [EPA-HQ-OAR-2014-0827-1133-A1 p.5]

\[
\text{P}_{\text{saving}} = \text{BHP}_{\text{engine}} - \text{P}_{\text{WHR}}/\eta_{\text{alternator}}
\]

Using alternator efficiency in the denominator of term on the right side ensures appropriate accounting for downsizing of alternator as a result of additional electrical power generated by waste heat recovery device. [EPA-HQ-OAR-2014-0827-1133-A1 p.5]

3. **Step 3:** Use calculated net energy saving to calculate engine load reduction coefficient as: [EPA-HQ-OAR-2014-0827-1133-A1 p.5]

\[
K_{\text{WHR}} = (\text{average engine power in the regulatory cycle}) - \text{Average }\text{P}_{\text{saving}} \text{ in regulatory cycle}/(\text{average engine power in the regulatory cycle})
\]

4. **Step 4:** Apply calculated coefficient \(K_{\text{WHR}}\) in GEM simulation as an engine emission and fuel efficiency correction coefficient. [EPA-HQ-OAR-2014-0827-1133-A1 p.5]

The proposed process does not take in account duty cycle that would be observed while using waste heat recovery device. However, it stimulates engine manufacturers to design engines and exhaust systems in such a way that waste heat recovery devices can be optimally integrated. Waste heat recovery systems are the only type of devices that produce electricity without consuming any additional fuel. Making more electricity available without addition of larger, inefficient alternator encourages other energy beneficial choices such as downsizing of electrified accessories and developing new electrified
accessories. These devices are otherwise not taken in consideration during engine or powertrain test and are normally used in vehicles. [EPA-HQ-OAR-2014-0827-1133-A1 p.5]

1 The U.S. Supertruck program, expediting the development of advanced heavy duty vehicle efficiency technologies, O. Delgado and N. Lutsev, ICCT, 2014

Response

We appreciate the comments and suggestions on a new potential and simplified test procedure to recognize benefits from an accessory device. It should be clear that waste heat recovery technologies, such as Rankine cycle and turbo-compound, mentioned in our regulation is not an off-cycle credit. Its benefits are fully measureable by the dynamometer test procedure, and, in addition, it is part of the basis for the tractor standard and so would not be an off-cycle credit for that reason alone. In addition, any benefits due to technologies or components that can be measured through engine dynamometer tests as part of the engine fuel map procedure will be recognized by GEM. Technologies that cannot be measured through engine or powertrain test or are not part of technology improvement inputs used in GEM could be recognized by the innovative off-cycle credit, following the procedure defined as 40 CFR 1037.610.

Organization: Lubrizol Corporation

Axle and Transmission Lubricants

Higher-performing axle and transmission lubricants should also play an important role in helping the OEMs comply with the Phase 2 Rule. Providing the most effective incentives for the use of higher-efficiency axle and transmission lubricants will provide benefits throughout the recommended service interval of all trucks that use these fluids. In addition, because service intervals vary considerably across the range of applications covered by the Phase 2 Rule, additional consideration should be given to ensuring that this efficiency improvement remains after the initial required service interval and throughout the useful life of the vehicle or equipment. [EPA-HQ-OAR-2014-0827-1325-A1 p.5]

As currently drafted in the Phase 2 Proposal, OEMs will be incentivized to use higher-performing axle lubricants via a Greenhouse Gas Emissions Model (GEM) credit that will go to OEMs that use higher-performing axle lubricants in certifying their vehicles.9 More specifically, the Proposal provides a 0.5 percent CO2 emissions reduction value to OEMs that certify their vehicles with a qualifying axle lubricant.10 This will likely ensure widespread adoption of 75W90 axle lubricants, which will be a significant improvement over the status quo. [EPA-HQ-OAR-2014-0827-1325-A1 p.5]

While Lubrizol supports the adoption of a rear-axle efficiency test, eliminating ambiguities in the test procedure and providing a mechanism for additional GEM credits for axle lubricants that provide greater-than-0.5 percent efficiency improvements will make a very useful provision even more effective over the long run. We also recommend the adoption of incentives for higher-efficiency transmissions fluids (i.e., provisions to encourage higher-efficiency manual transmission fluids) and the inclusion of axle and transmission lubricants in the categories that can qualify for future Off-Cycle Technology Credits. [EPA-HQ-OAR-2014-0827-1325-A1 p.5]
We appreciate that the current Proposal will help ensure a significant improvement over the status quo. We have provided recommendations below that we believe will further strengthen the Proposal by clarifying language in the test procedure and further incentivizing or encouraging higher-efficiency axle and transmission lubricants. [EPA-HQ-OAR-2014-0827-1325-A1 p.5]

**Higher-Efficiency Axle and Transmission Lubricants**

While the Phase 2 Proposal does not regulate axle or transmission lubricants, it does include a number of provisions related to these lubricants. These include: [EPA-HQ-OAR-2014-0827-1325-A1 p.12]

- Low-friction axle lubricants: The Phase 2 Proposal maintains the current 0.5 percent default value for the CO2 and fuel consumption reductions provided for low-friction axle lubricants in the Greenhouse Gas Emission Model (GEM);[EPA-HQ-OAR-2014-0827-1325-A1 p.12]
- Rear-axle Efficiency Test (§1037.560(draft)): The Proposal seeks comment on a new test procedure to compare new lubricants to BASF Emgard FE 2986 and to identify superior performance at specified speed and torque values; and [EPA-HQ-OAR-2014-0827-1325-A1 p.13]
- Off-Cycle Technology Credits: If adopted, these could be used to provide additional credits to new axle lubricants and other advanced technologies that are not widely used and are not reflected in the GEM simulation tool even after the rule is finalized. [EPA-HQ-OAR-2014-0827-1325-A1 p.13]

**Lubrizol Supports the Proposed 0.5 Percent Default Value for Low-Friction Axle Lubricants, But Encourages EPA to Remove the Ambiguity in the Current Proposal**

Based on significant experience with speed-load testing in commercial vehicles, Lubrizol strongly supports including the 0.5 percent default value for low-friction axle lubricants in the Proposal. The current Proposal will likely ensure widespread adoption of 75W90 axle lubricants, which will be a significant improvement over the status quo. [EPA-HQ-OAR-2014-0827-1325-A1 p.13]

Under the current Proposal, a lubricant qualifies if it meets the specifications for BASF Emgard FE 2986 as described in “Emgard®FE 75W-90 Fuel Efficient Synthetic Gear Lubricant.” BASF Emgard FE 2986 is a good choice of baseline, but some consideration should be given to ensure it remains constant over the life of this rule. In addition, it is possible that a variety of 75W-90 fluids could meet the performance described, but not deliver the same efficiency improvement as BASF Emgard FE 2986. We recommend that EPA adopts a baseline that is based on a static formulation and include a defined procedure for equivalent, or improved, efficiency demonstration. Doing so will eliminate the risk that OEMs will be able to claim the 0.5% credit without actually delivering the efficiency benefit. [EPA-HQ-OAR-2014-0827-1325-A1 p.13]

We note that it is more accurate to call these lubricants “higher efficiency” than to call them “low-friction.” While lowering friction may be a necessary attribute of the higher-efficiency axle lubricants that will be in the market during the Phase 2 period, it is not a sufficient definition to ensure safe, efficient operation over the life of the vehicle, given the need to address churning losses and traction in all modes of operation. Thus, we suggest that the final Phase 2 Rule adopt a “High Efficiency” terminology, rather than continue the use of the “low-friction” phrase. [EPA-HQ-OAR-2014-0827-1325-A1 p.13]

**Lubrizol Supports the Adoption of a Rear-Axle Efficiency Test, but the Final Rule Should Eliminate the Ambiguity in the Proposal**
We strongly support the adoption of a new rear-axle efficiency test to evaluate new lubricants, and agree that the BASF Emgard FE 2986 is a good choice as the baseline lubricant for such a rear-axle efficiency test. We believe that this will help incentivize the use of axle lubricants that exceed the 0.5% default value and add value to the overall Phase 2 program. However, we are concerned that the proposed test is not defined in an unambiguous way. The final Phase 2 Rule should include three clarifications or changes to remove these ambiguities and improve the overall program. [EPA-HQ-OAR-2014-0827-1325-A1 p.13]

First, the baseline fluid should be unambiguously defined and should be used in all rear-axle efficiency testing. Given that developing new fluids requires a significant investment in time and resources, it is critical that the baseline fluid remains static so it can be relied upon as a reference constant throughout the Phase 2 Rule’s time frame. [EPA-HQ-OAR-2014-0827-1325-A1 p.14]

Second, we note that, within any given viscosity grade, there can be significant variations in efficiency and CO2 emissions. Therefore, we recommend that EPA provide a more consistent technical baseline than exists in the current draft. API specification, viscosity, and the exact fluid to be used are examples of details that should be clearly defined in any comparative test. [EPA-HQ-OAR-2014-0827-1325-A1 p.14]

Third, we also note that the proposed test design requires that the lubricant is equivalent or better than the Emgard baseline fluid at each and every of the many points in the test cycle. We are concerned that this approach applies a “one-strike baseball” test that will disqualify lubricants that provide better performance than the baseline fluid in most real-world conditions. [EPA-HQ-OAR-2014-0827-1325-A1 p.14]

Given that no axle or transmission spends equal time at each of the proposed conditions, we recommend an approach that weights the various results in each stage of the test and then converts them into an overall axle efficiency score. The overall axle efficiency score could then be used to provide additional GEM credits to axle lubricants that exceed the performance of the Emgard baseline fluid, i.e., beyond the 0.5 percent default value in the Proposal. Given that there is evidence that higher efficiencies are possible, doing so would create incentives for higher-efficiency axle lubricants to enter the market in years to come. [EPA-HQ-OAR-2014-0827-1325-A1 p.14]

**Lubrizol Supports Additional Credit for Higher-Efficiency Rear-Axle and Transmission Lubricants Through the Off-Cycle Technology Credit**

We encourage EPA to provide additional credit for rear-axle lubricants that exceed the 0.5 percent default value provided in the GEM. In addition to establishing a mechanism within the Rear-Axle Efficiency Test to provide such GEM credit, as discussed above, this can be done via the adoption of the proposed Off-Cycle Technology Credit. If the final Phase 2 Rule includes the Off-Cycle Technology Credit, we encourage EPA to unambiguously define the conditions and thresholds for demonstrating an efficiency gain that is greater than 0.5 percent, as well as the data or other proof that would be necessary to secure the additional credit. [EPA-HQ-OAR-2014-0827-1325-A1 p.14]

Because providing credits for the use of higher-efficiency axle and transmission lubricants will provide benefits throughout the useful life of all trucks that use these fluids, we also recommend that transmission lubricants be included in any future Off-Cycle Technology Credit. [EPA-HQ-OAR-2014-0827-1325-A1 p.15]

**Higher-Efficiency Lubricants for Manual Transmissions Can Provide Additional Improvements**
As noted above, the Proposal does not regulate transmission lubricants. It also provides no incentives (through the use of GEM credits or otherwise) for the use of higher-performing transmission lubricants. However, including provisions to encourage higher-efficiency manual transmission fluids in the final Phase 2 Rule will be very worthwhile. [EPA-HQ-OAR-2014-0827-1325-A1 p.15]

Lubrizol testing has found that significant efficiency improvements can be obtained through the use of high-performing transmission lubricants. Lubricant-based efficiency gains in the transmission can be similar in magnitude to those in axles. Like the axle test results noted above, this data is proprietary, but is based on years of rig testing involving significant capital investments.\textsuperscript{25} We are happy to discuss this data with you further upon request. [EPA-HQ-OAR-2014-0827-1325-A1 p.15]

We encourage the creation of GEM credits for lubricants that increase efficiency in manual transmissions. There are a number of ways to do this, including (i) creating a comparative test that provides credit for percentage improvements over a baseline fluid or (ii) providing some other mechanism that enables OEMs to validate equivalence to a designative test fluid. Lubrizol has test data and other information that it would be willing to share with EPA in order to assist in the creation of such GEM credits. [EPA-HQ-OAR-2014-0827-1325-A1 p.15]

**Summary of Axle and Transmission Comments**

Providing the most effective incentives for the use of higher-efficiency axle and transmission lubricants will provide significant benefits that will enhance the overall Phase 2 Rule. The current proposal will likely ensure widespread adoption of 75W90 axle lubricants, which will be a significant improvement over the status quo. However, eliminating the ambiguity in baseline fluid and the test procedure and providing a mechanism for additional GEM credits for axle lubricants that provide greater-than-0.5 percent efficiency improvements will make a very useful provision even more effective over the long run. Similarly, including provisions to encourage higher-efficiency manual transmission fluids is worth doing. [EPA-HQ-OAR-2014-0827-1325-A1 p.15]

---

\textsuperscript{25} Rig testing is a better way to isolate the efficiency improvements of one transmission fluid over another than in-use or chassis dynamometer testing.

**Response:**

We appreciate Lubrizol’s comments on both axle and transmission lubricants. In order to fully recognize the benefits resulted from lubricants, we allow the axle or transmission manufacturers or other manufacturers to perform their own tests to overwrite the default power loss table in GEM. In all of
these tests, benefits due to lubricants will be measured, and therefore the benefits due to lubricants can be recognized by GEM.

Organization: Meritor, Inc

Upgrade the GEM Baseline Axle-Efficiency Model

Meritor is concerned that a flat 95.5 percent axle efficiency as proposed in the rule is not representative of the “typical” 2017 axle upon which the baseline truck model is derived. In fact, when considering the breadth of the commercial truck segments that are being regulated, Meritor believes that 95.5 percent axle efficiency is artificially high, which would dis-incentivize the implementation of higher efficiency axles. For example a 95.5 percent efficient axle for a heavy haul application does not seem appropriate given the high numerical axle ratio. Chart 4.1 compares three common 40k GAWR tandem axles, each with a 3.55 ratio, for a typical North American linehaul application. [EPA-HQ-OAR-2014-0827-1254-A1 p.3]

Therefore, Meritor is requesting that the default axle efficiency in GEM be modified from the current flat 95.5 percent assumption in the current proposal to a ratio-sensitive axle-efficiency model which is more realistic, as illustrated in Chart 4.2, and appropriately supports the downspeeding trend. [EPA-HQ-OAR-2014-0827-1254-A1 p.4]

The GEM model already includes an input for axle ratio so establishing a relationship between axle ratio and efficiency seems relatively straightforward to implement into the model. It should also be noted that the default axle efficiency in the EU regulatory compliance model (VECTO) is currently ratio sensitive. [EPA-HQ-OAR-2014-0827-1254-A1 p.4]

Although Meritor is advocating a single, ratio-sensitive default-axle efficiency, we acknowledge that there may be alternate ways to implement this methodology. The following is a list of alternative axle-efficiency methods in preferential order: [EPA-HQ-OAR-2014-0827-1254-A1 p.5]

Linear Formula – Our preferred method is to calculate default axle efficiency for the bulk of the axle market using a formula based on a sloped line. Based on the chart above, we suggest the following formula: EffAxle = 99.56 – (1.54*RatioAxle), for ratios 2.15 to 4.11. For ratios outside of this range, the axle efficiency at the nearest limit can be assumed to be constant. For example, ratios less than 2.15 will assume the efficiency of the 2.15 ratio (96.2%) and ratios numerically higher than 4.11 will use the efficiency of 4.11 (93.2%). [EPA-HQ-OAR-2014-0827-1254-A1 p.5]

Linear Bi-modal – This simpler method, if less accurate method establishes two default axle efficiencies, one for low ratios and one for high ratios. This method mirrors the bi-modal nature of axle ratios in the actual market. [EPA-HQ-OAR-2014-0827-1254-A1 p.5]
Meritor’s bi-modal recommendation is: 

\[
\text{Eff}_{\text{Axle}} = 95.5\% \quad @ \text{Ratio}\text{Axle} \quad \text{Eff}_{\text{Axle}} = 94.1\% \quad @ \text{Ratio}\text{Axle} \geq 3
\] 

If a single number is necessary, then a more appropriate value based on the distribution of the market would be 94.8\% (the average of 95.5\% and 94.1\%).

It should be noted that all axle-efficiency recommendations detailed above include the use of BASF EmGuard® FE 2986 SAE 75W-90 or equivalent lube which is the current standard for the 0.5 percent high efficiency credit.

**Include Axle-Efficiency Map Input in GEM and Modify the Associated Axle Test.**

Meritor is supportive of an optional axle efficiency test that can be used to override the default GEM axle efficiency values. We believe this test option encourages continued development of high efficiency axles as it provides an established avenue to validate technologies and receive the appropriate fuel-efficiency credit throughout the lifetime of the regulation. Meritor acknowledges that we made several recommendations that influenced the axle efficiency test in the current proposal; we are now recommending an alternative that better aligns with the direction of the test procedure and axle mapping method from the proposed EU greenhouse gas simulation model known as VECTO. As such, Meritor proposes that the EU VECTO mapping method be considered as a starting point, and that the U.S. method be as consistent as is practical with that method.

First, output torque is the preferred test specification method as opposed to input torque for a final drive (the proposed procedure specifies input torque). A vehicle drive cycle dictates a common output – or, wheel torque profile – for a given macro vehicle specification, independent of axle ratio. Therefore, output torque will normalize the map across the spectrum of axle ratios. Also, it is difficult to test at true zero input torque as the output will be in a negative (coast mode) torque condition. If input torque is desirable for GEM as a forward-looking simulation type, GEM could internally convert an output-torque-based map to an input-torque-based map by considering both the axle ratio and the torque loss.

The map torque specification should account for the number of drive axles. For example, 6x2 and 4x2 drive axles should be tested at two times the output torque as a single-drive axle of a 6x4 configuration as it sees two times the torque in operation. A composite 6x4 drive-axle map should consist of the average of the front- and rear-drive axle-efficiency maps. This will normalize the maps such that an “X”x2-axle map will have the same grid density as a combined 6x4-axle map across the vehicle operating envelope.

The maximum mandatory output torque for the map should be limited to a reasonable level for two primary reasons:

Axle dynamometers used for efficiency testing require highly sensitive torque sensors to measure small torque losses through the final drive. This imposes practical limits on maximum torque as torque cells with adequate sensitivity have limited torque range.
Most of the operating torques on the GEM drive cycle are well below the peak torque for the transient drive cycle. [EPA-HQ-OAR-2014-0827-1254-A1 p.7]

A recommended maximum mandatory output torque is equivalent to 1.0 - 1.5 percent steady state grade torque at cruising speed for a Class 8 vehicle which is approximately 4000 N-m (2950 lb-ft) total wheel torque, or 2000 N-m (1475 lb-ft) for each drive axle of a 6x4 configuration. This is high enough to capture most of the operating points for both Cruise cycles (see Annex A). Note this is less than the maximum torque of the EU VECTO map proposal of 10,000 N-m which we find excessive. [EPA-HQ-OAR-2014-0827-1254-A1 p.7]

Meritor offers two recommendations for handling torque beyond the maximum mandatory standard output: [EPA-HQ-OAR-2014-0827-1254-A1 p.7]

Allow optional torque levels to be included in the map above the maximum mandatory torque, at standard increments. [EPA-HQ-OAR-2014-0827-1254-A1 p.7]

In the GEM simulation, extrapolate to torque levels above the map by assuming a linear relationship between torque loss and nominal torque at a given speed. This recommendation is based on the EU VECTO map proposal and on Meritor’s observation that torque loss is very linear with nominal torque (see Annex B). Note that the linear relationship assumption means that the axle efficiency will approach a constant maximum value at high torque, with the value being a simple function of the slope of the fitted line. [EPA-HQ-OAR-2014-0827-1254-A1 p.7]

Provision should be made to exclude map points above a given power. A rectangular torque/speed-map grid will include points at the high-torque/high-speed “corner” that exceed the maximum power of the powertrain (for example, the largest default GEM engine is rated at 455 hp [339kW]). These points are immaterial as they will never be encountered in operation. Therefore, the map should allow no entry or “NaN” (Not a Number) type entries for “excessive power” grid points. [EPA-HQ-OAR-2014-0827-1254-A1 p.7]

Table 5.1 below illustrates the EU VECTO axle map grid. On the whole it is adequate for North American purposes but the torque and speed granularity is rather fine, resulting in many cells and a heavy testing burden. Also, the mandatory maximum torque is rather high. A proposed map grid is given in Table 5.2 in which the torque and speed increments are larger but consistent with the EU VECTO map, and the mandatory maximum torque is lower. [EPA-HQ-OAR-2014-0827-1254-A1 p.7]

[Table 5.1, 'Reference EU VECTO Axle Map Grid', and Table 5.2, 'Proposed Axle Map Grid for Single Axle Efficiency Test', can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1254-A1]

In addition to the items noted above, other characteristics of the test method associated with map generation and usage should be either common with or as consistent as practical with EU VECTO for the intent of making axle map data portable between the U.S. and the EU. These elements include oil temperature, type, level, condition, and filtering; ambient temperature; torque and speed tolerances; torque cell temperature correction; run-in procedure; test torque-speed sequence; data sampling time, rate, averaging, and filtering; and “lumping” parameters and tolerances for grouping of axle maps. [EPA-HQ-OAR-2014-0827-1254-A1 p.9]

Resolve 0.5 percent Advanced Lube Credit with Axle-Efficiency Test Baseline Lube
With regard to the Advanced Lube Credit of 0.5 percent, Meritor is in favor of the concept, however, it is important to clarify a few matters prior to implementation of the rule as written. One concern is that BASF EmGuard FE 2986 SAE 75W-90 is designated as the baseline lubricant for the axle efficiency test but is also the baseline lubricant for the 0.5 percent “advanced lube” FE credit. As a result, if an axle supplier submits an axle map from an efficiency test, the results would include the advanced lube. When implemented in production, the OE would claim the axle efficiency as tested with the advanced lube and receive the 0.5 percent advanced lube credit, in effect double dipping. This cannot remain the case. One solution is to give the 0.5 percent advanced lube credit when using the default GEM axle efficiency, but eliminate the credit when using an axle-efficiency map. [EPA-HQ-OAR-2014-0827-1254-A1 p.9]

Also, there is no flexibility in the rule to get credit for an even more advanced lube except through off-cycle. We suggest allowing an axle test and the associated map using a more advanced lube than 2986 to provide a simple avenue for more advanced lubrication credits. [EPA-HQ-OAR-2014-0827-1254-A1 p.9]

It is important to note that if a 0.5 percent FE credit is to be given for the use of 2986, then our previous recommendations for baseline axle efficiency should be reduced by 0.45 percent accordingly (i.e. 99.56 is reduced to 99.11; 95.5% and 94.1% are reduced to 95.05% and 93.65% respectively; and 94.8% is reduced to 94.35%). [EPA-HQ-OAR-2014-0827-1254-A1 p.9]

Account for 2-Speed Axles

Although there is no regulatory framework regarding 2-Speed Axles, they are mentioned in the Regulatory Impact Analysis’ Technology Section 2.4.5.2 Gear Ratio (2-37) as a technology “many axle manufacturers are developing” to enhance vehicle performance. If that statement is true then it follows that 2-Speed Axles should be included in the regulation to better account for future market penetration. [EPA-HQ-OAR-2014-0827-1254-A1 p.11]

The first area that needs to be addressed with regards to 2-Speed Axles is fuel efficiency. A 2-Speed Axle can improve tractive force at low speeds and allow greater downspeeding at high speeds thereby potentially netting greater vehicle fuel efficiency however, it requires several more gears and bearings which will actually reduce axle efficiency. Meritor recommends that default axle efficiency of a 2-Speed Axle be reduced by 1 percent to prevent an artificial market incentive to a potentially less efficient axle configuration. Secondly, there needs to be some instruction on how to model a 2-Speed Axle in GEM. As written, GEM allows a single-axle ratio input but a 2-speed axle has two distinct ratios. Although a 2-speed axle can be used in conjunction with a transmission to double the number of gear ratios; that is not how this technology is being applied in North America. Rather, the 2-speed axle is being used to enable engine downspeeding by providing a very low downspeed axle ratio as well as a high torque “starting” ratio. Therefore, we suggest that GEM allow for an axle ratio input for each drive cycle in which the lower numerical axle ratio would apply to the 55- and 65-mph drive cycles and the higher numerical ratio would be applied to the transient drive cycle. [EPA-HQ-OAR-2014-0827-1254-A1 p.12]

Response:

We appreciate Meritor’s constructive comments on axle efficiency with a flat and fixed efficiency of 95.5% used in NPRM. Specifically, we appreciate very much that Meritor provided many highly valuable information on the axle performance and power loss tables to the agencies. As a result, we adopted their recommendations of using the power loss tables as default, and those default tables can be
replaced by a manufacturer’s measured values, and therefore, all technologies related to the axle, such as advanced lubricant, can be accounted for by this approach. GEM does allow two speed tandems named as 6x4D, which is only applied to 55 and 65mph cycle with 6x2 option, and then switch back to 6x4 once running the transient cycle. However, the axle ratio would be still the same for these two speed axle option, prompting OEM to select most commonly used axle ratio for GEM based on their driving condition. The main reason for this decision is that we believe that two speed axle is primarily used in tractor applications, where cruise speeds are pre-dominated. The cycle weighing on transient cycle is small compared to ones on two cruise speed cycles. As such, the lower axle ratio should be selected. This is not a perfect solution, but can greatly simplify GEM.

**Organization:** Odyne Systems LLC

*Modeling and Testing for the Full Workday*

Odyne understands the difficulty in modeling fuel efficiency improvements for hybrid technology within the GEM, as hybrid systems interact with the transmission, drivetrain, and engine, in addition to auxiliary activities beyond driving not currently modeled in the GEM. We appreciate EPA’s efforts to improve the accuracy of the GEM to account for real work driving. However, Odyne strongly believes that it is important to model the full day vocational vehicle duty cycle, including driving, idling, and stationary operation of truck-mounted equipment through a Power Take-off (PTO). [EPA-HQ-OAR-2014-0827-1239-A1 p.18-19]

Modeling the entire duty cycle would be consistent with efforts by CARB to understand the total emissions produced by the vehicle throughout the entire day. Since the GEM does not have a specific module for hybrid systems it is difficult to evaluate their impact on driving and stationary aspects of the full workday. Also it does not seem to properly account for all the differences in idle conditions, which are a large part of the full workday. We believe improvements to the accounting of hybrid systems and modeling of the full workday are necessary to properly developing emission standards and verifying emission savings. This needs to be handled separately from the hybrid PTO / e-PTO module in the GEM to account for idle time. Our system is active during the driving and stationary operation of the vehicle and provides unique benefits in both and when they are properly combined result in the real world benefits of a full workday. [EPA-HQ-OAR-2014-0827-1239-A1 p.19]

**Response:**

The agencies agree with comments from Odyne with regard to recognizing technologies that reduce emission while the vehicle is moving and at idle and because of this have modified 40 CFR 1036.540, 40 CFR 1037.540 and 40 CFR 1037.550 to allow for testing of these systems. 40 CFR 1036.540 and 40 CFR 1037.550 can be used to test hybrids and PHEV that use the stored energy to propel the vehicle. We added many features to recognize the benefits with various idle technologies. This has been done by the two idle cycles (parked idle and drive idle) and the PTO test. For electrified and PHEV PTO systems 40 CFR 1037.540 can be used to recognize the benefits of these systems, through an input to GEM.

**Organization:** Oshkosh Corporation

*Simulating Axles for Vehicle Certification* – The agencies request comment on whether or not we should finalize this test procedure and either require its use or allow its use optionally to determine an axle efficiency data table as an input to GEM, which would override the fixed axle efficiency we are proposing at this time. 80 FR 40185. We recommend that the EPA and NHTSA use the European test...
procedure, word for word and step by step. There should be the ability to input our own axle efficiency value if greater than the baseline value.[EPA-HQ-OAR-2014-0827-1164-A1 p.63]

Response:

Regarding the axle efficiency test, the agencies have reviewed the draft European test procedure but since it was not a final procedure that could be referenced, the agency have worked closely with major axle manufacturers and lubricant manufacturers to define a robust test procedure for measuring axle power losses. The agencies have worked to make the procedures overlap is as much as possible so that data from one procedure could be used for the other test procedure.

Organization: Truck & Engine Manufacturers Association (EMA)

Transmission Efficiencies

The currently available Phase 2 version of GEM uses default transmission efficiencies. However, those efficiencies for gear and pumping losses can be reduced by approximately 1% to 2% through design-specific actions to transmissions, and will vary from product-to-product. Accordingly, having a test method that can capture the product-specific performance and an optional transmission efficiency input for GEM would allow OEMs to determine and utilize the actual engineered GHG/FE benefits in Phase 2. The European agencies are working on a transmission efficiency test procedure that could be the starting point for the agencies in developing a Phase 2 option. EMA recommends that the same test procedure and data input formats that are being developed in Europe should be incorporated into Phase 2. [EPA-HQ-OAR-2014-0827-1269-A1 p.53]

Response:

In the final rule, we do allow the manufacturers the option to use their own tested power loss table to replace the agency’s default power loss table by following the test procedure 40 CFR 1036.565.

Organization: Volvo Group

Axle Efficiency Test

Volvo Group supports the option to test axle efficiency and offers comment on ensuring the test is run appropriately and consistently. In general, we suggest the test protocol should be reviewed jointly by the agencies working with the EMA Vehicle Measurement and Test Committee. [EPA-HQ-OAR-2014-0827-1290-A1 p.52]

We first note that the new axle break-in period is inadequate. Although we expect a longer break-in is needed, we do not have a specific recommendation at this time. [EPA-HQ-OAR-2014-0827-1290-A1 p.52]

Test targets should be based on output torque rather than input torque. Use of input torque will result in extremely high output torque for high axle ratios. Manufacturer axle torque ratings are not specified in a consistent manner and should not be the basis for test set-up. Maximum output torque should be based on the wheel slip torque on dry pavement at the legal load for the axle. Testing could be done in increments of axle slip torque, i.e. 25%, 50%, 75%, 100%. [EPA-HQ-OAR-2014-0827-1290-A1 p.52]
The accuracy of the average torque set point control within 1 N-m is tighter than it needs to be and may not be feasible. We expect that 5 N-m’s would not affect the efficiency result. The deviation of individual test points should also have a limited band, i.e. +/- 5% or 10%. [EPA-HQ-OAR-2014-0827-1290-A1 p.52]

Ambient temperature is irrelevant when oil temperature is controlled. In any case, maintaining ambient temperature between 20-30°C would require an unnecessary air conditioned facility. We recommend that the oil temperature measurement location be specified as the drain of the sump. Since the test result is an average of four runs at each torque and wheel speed, criteria should be established as to allowable variation between runs and to identify outlier data that should be discarded. [EPA-HQ-OAR-2014-0827-1290-A1 p.52]

The protocol requires testing 5 torque levels and 6 speeds, repeating each 4 times. This requires 120 test runs, and this is just for one axle ratio. Unless there is data showing significant variability within the 300 seconds run for each test point, it should not be necessary to repeat each test point four times. The 300 seconds of data could be parsed into 10 second test segments to establish efficiency variability. Alternatively, we could commission testing to determine variability at a given test point to see if the proposed protocol could be shortened. [EPA-HQ-OAR-2014-0827-1290-A1 p.52]

**Default Axle Efficiency Map**

The NoDA GEM release incorporates axle efficiency maps in place of a single axle efficiency number. A vehicle manufacturer has the option to use the default map provided within GEM, or to derive by test the axle efficiency map for the actual axles installed in the vehicle. If the default map is selected GEM uses the GEM_default_axle.m file to determine the axle efficiency based on a vehicle’s weight class, drive axle configuration, axle gear ratio. [EPA-HQ-OAR-2014-0827-1928-A1 p.18]

Where the default map is determined as a function of the vehicle’s axle configuration (e.g. 6x4), the Agency assumes that a dual-drive 6x4 configuration has a base spin loss torque 2.1 times that of a single drive 4x2 or 6x2 configuration. In addition, a 6x4 disconnect configuration uses a factor of 1.06 when operating in a 6x2 drive configuration. However, in a typical 6x4 configuration the front drive axle of the tandem has an additional gear mesh compared to the rear drive axle of the combination in order to accommodate the front axle’s output to the rear axle. In addition, the front drive axle incorporates an inter-axle differential or power divider. In the case of a single drive axle, the need for the additional gear mesh to accommodate the throughput to the second drive axle is eliminated, along with the inter-axle differential or power divider. Because of this, the front drive axle in a typical tandem will have a lower efficiency than the rear. [EPA-HQ-OAR-2014-0827-1928-A1 p.18-19]

As such, Volvo does not agree that the base spin loss torque of a tandem axle configuration, either disconnectable or full time, would be 2.1 times that of a single drive axle. Nor do we agree with the 1.06 factor applied to a 6x4 disconnect when operating in 6x2 mode, as a disconnectable 6x4 configuration would also have a front drive axle with a lower efficiency than the rear. For accuracy, Volvo suggests revision of the default axle map to accommodate these effects, as well as the ability within GEM to accommodate unique front and rear tandem drive axle efficiencies. [EPA-HQ-OAR-2014-0827-1928-A1 p.19]

**Axle Family Definition**

The proposed axle mapping test procedure requires axles to be split into families for which a test of the “parent” could apply. Volvo proposes that axle families be defined by the following attributes: [EPA-HQ-OAR-2014-0827-1928-A1 p.19]

1. Carrier family (typically driven by torque capacity)
2. Number of gear meshes
3. Inclusion of interaxle differential or power divider
4. Number of reductions (single reduction vs. double reduction)
Volvo also proposes that axles within a family be defined by a parent ratio that would either represent the worst efficiency map in the family, or that a default ratio efficiency factor be applied across all families as the EPA has done for the default axle map (gear_efficiency_norm as defined in the above noted default axle efficiency file). In addition, where a manufacturer believes their ratio efficiency numbers are better than the Agency’s default, they should be allowed to perform testing based on the proposed axle efficiency test procedure and use the resultant values. [EPA-HQ-OAR-2014-0827-1928-A1 p.19]

In order to eliminate unnecessary test burden, axle manufacturers should also be given the option to declare and test tandem axle families where the front and rear axles of a tandem are installed together in the vehicle. In this case tandem families would be defined by, at least: [EPA-HQ-OAR-2014-0827-1928-A1 p.19]
1. Carrier family (typically driven by torque capacity)
2. Number of reductions (single reduction vs. double reduction)

Additional Axle Efficiency Item of Note
It is not clear why the Agency has applied a factor of 1.65 to the base_spin_loss_torque_Nm parameter in GEM_default_axle.m. [EPA-HQ-OAR-2014-0827-1928-A1 p.19]

Transmission Efficiency
In the agencies’ summary of GEM P2V2.1 updates provided with the GEM release, it is noted that the agencies have revised the Automated Manual Transmission (AMT) and Automatic Transmission (AT) default gear efficiencies. For an AMT the default efficiencies were changed to 99.5% for direct drive and 96.5% for non-direct drive. For ATs the defaults were changed to 99.5% and 98.5% for direct drive and non-direct drive respectively. It is Volvo’s experience that mechanical efficiency of both a Manual Transmission and an AMT typically exceeds that of an AT. Therefore, Volvo requests the supporting data to understand these assumptions and the opportunity to work with the agencies to correct any erroneous values. In addition, Volvo does not agree with the assumption that all non-direct drive gears have the same efficiency and suggests a default file that accounts for each gear individually. [EPA-HQ-OAR-2014-0827-1928-A1 p.20]

The 2% difference between a manual and an AMT in our view is questionable. From a technology standpoint, a skilled driver should be able to obtain the same fuel efficiency as an AMT. So the difference is human (an unskilled or aggressive driver), not the technology. We have done simulations for highway cycles that supports they are equivalent or at most 0.5% worse, but clearly not 2%. [EPA-HQ-OAR-2014-0827-1928-A1 p.20]

Response:

Regarding the axle efficiency test, the agency has worked closely with major axle manufacturers and lubricant manufacturers to define a robust test procedure for measuring axle power losses. With respect to the break-in period the agencies believe leaving it up to good engineering judgement is a conservative position because axle losses typically decrease with additional break-in time. In addition to this the procedure has a specified repeatability requirement so if the axle has not been broke-in enough the repeatability specification will not be met, due to the axle losses changing with additional testing.

Based on comments the axle test procedure has be updated in the following ways:

- Test targets have been changed to output torque.
- Torque transducer accuracy requirements have been changed to ±0.2 % of the maximum axle input torque or output torque tested for loaded test points, and ±1 N-m of the maximum axle torque tested for unloaded test points.
• Stabilization and averaging period has been changed to a minimum of 10 seconds.

• Specify that the gear oil temperature must be measured at the drain of the sump.

• Axle family definition.

With the update to the stabilization and averaging time and the requirement of a minimum of 3 repeats the time to complete the testing has reduced significantly from the procedure that was published with the proposal to the rule.

The agencies have based the default axle losses on data from multiple axle manufacturers. Based on our analysis of this data the default axle losses are consistent with the manufacture data. In addition to this, the ability for an OEM to input the specific loss map for the axle being installed on the certifying vehicle, allows the actual losses of the axle to be used in GEM for vehicle certification.

On axle family comments, we ask the manufacturers to use good engineering judgment to divide your product line into axle or transmission families that are expected to have similar hardware, noting that efficiencies can differ across the members of a family.

Regarding transmission efficiency used in GEM, the mechanical efficiency we chose for both AT and AMT are based on the recommendations of transmission OEMs. In the final GEM, we further split the AMT gears into two groups for a total gear number larger than 10. When the gear number is smaller than 6, it will use 96% as the default efficiency, and when the gear number larger than 6, it will use 98% except 1:1 gear ratio. The reasons why MT has 2% worse than AMT in efficiency is based on the valuable inputs from one major transmission supplier. We believe that their recommendations reflect the reality.

### 2.4.2 Powertrain Testing

**Organization:** Truck & Engine Manufacturers Association (EMA)

Powertrain Test Requirements

The preliminary results obtained through the powertrain test are uncertain and unproven. It is unclear how child ratings are to be treated, how the powertrain test applies across different engine and vehicle configurations, and what specific test procedures apply. [EPA-HQ-OAR-2014-0827-1269-A1 p.39-40]

In addition, the proposed powertrain test is inadequately defined and fails to include a proper test protocol for managing a modern transmission. Specifically, testing in the lowest transmission gears is not feasible due to high torque and low RPMs. It also appears that the dynamometer inertial effects have not been accounted for. Other issues are likely to arise under the proposed powertrain test, but many manufacturers have not had the opportunity to run the test (which may not even be loadable into GEM as of yet) and so have not been able to complete a thorough evaluation. Such an in-depth evaluation should be undertaken before the agencies finalize the powertrain test procedures. [EPA-HQ-OAR-2014-0827-1269-A1 p.40]

**Organization:** Navistar, Inc.
We believe that the powertrain testing proposal and the subsequent stringency as related to the vocational vehicle segment are entirely unreasonable. The proposed powertrain testing method is a relatively new concept, and while it does show technical merit we believe that it should be included as an optional method for showing compliance. However, even if the powertrain alternative method were to be used as only an optional method there are significant issues and risks associated with this method that we wish to address. [EPA-HQ-OAR-2014-0827-1199-A1 p.34]

The first issue, and likely the most complicated to resolve, is the selection of the generic vehicles with which to test in a powertrain dynamometer. The variability in truck configurations sold in both the vocational and tractor market space will inevitably cause certain configurations to fall outside the bounds of the powertrain generic vehicle map. We foresee extrapolation outside the bounds of the test points as an unacceptable method of certification due to the large amounts of error that can arise from this method as already noted by EPA data. One might initially think that modification of the point selection technique could alleviate this problem; however, testing will be difficult as it will prove more difficult to derive the correct test points for certain powertrain families than others. If manufacturers are not able to ensure that the powertrain testing maps will ensure coverage of all vehicle configurations, this could limit both manufacture and customer choice in terms of vehicle configurations that are made available for sale. This limitation could lead to customers choosing vehicles that perform sub-optimally thereby leaving potential CO2 reductions on the table. [EPA-HQ-OAR-2014-0827-1199-A1 p.34-35]

The current nine point selection method for the powertrain testing points also requires testing of vehicle configurations that are entirely unreasonable. The selection of a vehicle to run at the minimum NTE exclusion speed at 65mph will result in either cruising engine speeds that are entirely too low when compared to real-world trucks, or will result in gearing down to run the GEM cycles thus resulting in higher engine speeds than intended. If the method was to be made optional and a range of vehicles were tested using a specific powertrain that would exhibit the sought-after deep integration benefits, we would request that the points be chosen in such a way as to cover the range of vehicles sold. [EPA-HQ-OAR-2014-0827-1199-A1 p.34-35]

Secondly, the family structure is ambiguously defined. Different manufacturers could take a widely different view on what constitutes a “common calibration attribute” thus lead to a certification process that is unnecessarily complex and burdensome. The RIA itself notes that “impact of transmissions including shifting strategies and numbers of gears, axle ratio to be minimal if the plots are designed in such a way that average engine speed (N) over average vehicle speed (V) defined as N/V is selected.” If this is the case, then it could be argued there is no need to separate the families in such a way. If this is the case it is potentially contradictory to the proposal’s sections on deep integration which makes the exact counter claim that significant fuel economy gains can be had through these types of changes. [EPA-HQ-OAR-2014-0827-1199-A1 p.35]

Because of these uncertainties, even if the powertrain testing procedure is used as an option, it should await the completion of the SAE technical procedure, currently under development. [EPA-HQ-OAR-2014-0827-1199-A1 p.35]

In order to address this issue we have undertaken a study of our own vehicle sales volumes and generated powertrain maps and fuel used values via an in-house simulation tool for all one year period of vehicles using a BSFC and a powertrain map. The trends we have seen from this study show that when applied to a whole vehicle population the powertrain testing issue shows inaccuracies that have not appeared in the limited testing performed. These issues are best described by having r-square values lower than .7 and .9 for the 55 and 65 GEM cycles respectively. [EPA-HQ-OAR-2014-0827-1199-A1 p.35]
It is also important to note that a powertrain test will be for a particular transmission calibration and engine calibration. The worst case calibration for the combination needs to be selected per the protocol requirements. Although it is uncertain whether a benefit can be demonstrated on a powertrain test that could meet the stringency requirement of 4-7%, it is even more unlikely that the worst case configuration will meet this aspect of the NPRM’s estimate. If transmission families are divided even further, which will further increase the test burden, there is an adverse consequence that these calibrations will be unable to be adjusted in the field. Because of an inability to modify the calibration, customers may order the powertrain that is NOT tested so as to preserve their resale value even if the tested combination provides better fuel economy. This will drive the opposite behavior from that desired by the regulation. For this reason, if powertrain testing is included in the final rule, the rule should allow powertrain modifications to ensure the customer can optimize for their application while still improving their fuel economy. [EPA-HQ-OAR-2014-0827-1199-A1 p.36]

Along the same lines, one could potentially see how the difference between GEM results and powertrain testing done thus far could be the result of inadequacies in the GEM modeling process. The combination of transmission efficiencies, differences in accessory loads (GEM uses constant power sink) and the lack of an engine transient torque model can all lead to a reduction in CO2 emissions that is not due to any inherent advantages in engineering development but is due instead unaccounted for pieces within the model. Although this requires additional test methodologies, we feel this is preferable to the test proliferation and mandatory inclusion of powertrain testing in the Proposed Rule. [EPA-HQ-OAR-2014-0827-1199-A1 p.36]

Finally, the implementation in GEM of the powertrain method has several structural issues. The method of calculation of N/V in the proposed rule is based solely on the axle ratio and tire size, as opposed to a true N/V (engine rpm/vehicle speed). The workgroup associated with this method and most of the analysis upon which the method is based has not yet even completed this methodology. While the same trends and results may hold true for both methods, insufficient work and time have been expended to verify this possibility. This method of accounting for N/V would seem to have little to no impact on 55 and 65 mph cycles with the current grade, because most of the cycle will be driven in a single gear. The general trend for these types of cycles will be that decreasing the N/V ratio, as calculated in the proposal, will result in a better CO2 number, e.g. down speeding. However, the ARB cycle, as well as other more urban type cycles can exhibit different characteristics and highly non-linear trends, depending on the cycle and powertrain under study. Accounting for N/V as done in the proposal will not represent these non-linearities. [EPA-HQ-OAR-2014-0827-1199-A1 p.36-37]

Further complicating these matters is that when certifying a combination via GEM with the powertrain option one is no longer certifying the actual vehicle configuration or powertrain family. Instead, the GEM model is run with a generic engine, and generic transmission, failing to account for the potentially differences in the number of gears, the transmission technology type, the size of the engine, and the operating range of the engine, among other factors. Since the N/V ratio is calculated using only the axle ratio and tire radius this could be viewed as a way of generating the required cycle work for use in the powertrain table lookup; except for the fact that the vehicle drive cycle, thus the total cycle work, can be impacted. This problem would further exacerbate itself should the new grade profiles presented in the NREL report be adopted, as the drivability and performance differences in powertrains would be more apparent. [EPA-HQ-OAR-2014-0827-1199-A1 p.37]

Finally, the method of calculating the gear efficiencies is based on finding the direct drive gear. The default powertrain scripts have a modifier of some “Fixed Axle/Specified * Gear Ratios,” so, unless the same axle as the Fixed Axle is used, there will be no direct drive gear and thus a penalty will be taken
on the GEM simulation for this vehicle. We view this as a bug that the agencies should address. [EPA-HQ-OAR-2014-0827-1199-A1 p.37]

Beyond everything we have mentioned, there is nothing in the record to show that powertrain testing will actually captures the benefit any better than GEM for vocational vehicles. At some point, however, a powertrain test method may be developed that, for some applications, could show results that are more sensitive than GEM. For that potential, we propose that if the powertrain option is kept, in any form, it be limited to an option for a defined application that is approved on a case-by-case basis, similar to the process for an off-cycle technology. [EPA-HQ-OAR-2014-0827-1199-A1 p.37]

The proposed powertrain certification test process used to leverage the deep integration of engine and transmission systems also fails to account for the inherent variability present in engine testing without the complexities of a transmission with a simulated or actual axle. Part 1037.550(g) calls for the development of a driver model to “mimic a human driver” which can comply with the statistical cycle validation criteria as presented in Table 4 of 1037.550. This expectation ignores the diverse range of Part 1065 capable engine/powertrain dynamometer test cell configurations currently available. [EPA-HQ-OAR-2014-0827-1199-A1 p.37]

The requirement to develop a driver model that mimics normal operation assumes that all transmissions will be either automatic or automated manual transmissions. Currently there are no provisions or available robotic drivers that can accommodate a manual transmission. This limitation effectively rules out an entire segment of medium duty and heavy duty transmissions currently available. If a technology becomes available whereby robotic manual transmission shift control is possible, a shift schedule and or logic map would need to be created either by the test facility or the engine/transmission manufacturer. [EPA-HQ-OAR-2014-0827-1199-A1 p.37-38]

The importance of a consistent and repeatable transmission shift schedule extends to either a manual or automatic transmission. If there are changes in these calibrations or other warm up control features, the vehicle certificate holder would be required to perform additional testing to demonstrate calibration transparency and compliance. This would in turn require the transmission OEM to continuously disclose any changes that could affect the CO2 result to the GHG certification holder, prior to implementation. This continuous disclosure requirement would have the net effect of increasing deployment cost, adding compliance margin and delaying implementation. [EPA-HQ-OAR-2014-0827-1199-A1 p.38]

This concern reinforces our overall concern that powertrain testing cannot yet capture benefits over the existing engine test in conjunction with GEM in a manner that does not increase variability. In short, as stated, we do not think it is ready for adoption, other than in a specific method that can be demonstrated as reliable to the agencies and that should only be included as an optional test. [EPA-HQ-OAR-2014-0827-1199-A1 p.38]

Organization: Allison Transmission, Inc.

Powertrain testing should be allowed as an optional certification method, however, EPA and NHTSA should not create incentives within this rulemaking for its use. EPA and NHTSA have seriously underestimated the costs of such testing. GEM must be modified to be reasonably accurate and suitable for certifying the large majority of vehicles; overreliance on powertrain testing could have several negative impacts including increased costs, and increased limits on consumer choice. [EPA-HQ-OAR-2014-0827-1284-A1 p.2-3]
EPA and NHTSA should credit other technologies not recognized in GEM or measured in powertrain testing such as load-based and grade-based shift algorithms and acceleration rate. [EPA-HQ-OAR-2014-0827-1284-A1 p.3]

EPA and NHTSA Must Not Require or Create Undue Incentives for Powertrain Testing

EPA and NHTSA are proposing to allow powertrain testing as an “optional certification path” but also request comment on whether the agencies should require such testing “more broadly.” While Allison supports retaining powertrain testing as an option, such testing should be the exception rather than the norm for certification. There are several reasons why this testing option should not be expanded. First, as EPA and NHTSA recognize, this type of testing has never before been used for vehicle certification. Instead, the Phase 1 rule only allowed for different certification under limited circumstances where normal testing procedures would not be adequate to measure emissions. [EPA-HQ-OAR-2014-0827-1284-A1 p.22]

Second, requiring powertrain testing in some circumstances or increasing the regulatory incentive for its use would substantially increase the cost of this regulatory program. As noted, EPA has estimated that the upgrade costs to an existing engine test cell is on the order of $1.2 million and new test facility in an existing building is estimated at $1.9 million; the estimated cost to test each powertrain family in a completed cell would be about $69,000. Given the large variety of vehicles in the vocational vehicle area, costs for such testing could add up to substantial amounts of money, especially in relation to smaller manufacturers who build different, specialized vehicle types. [EPA-HQ-OAR-2014-0827-1284-A1 p.23]

Third, the vocational vehicle space consists of highly varied vehicles that are tailored to meet the work needs of the vehicle. “Sub-optimizing” these configurations in order to fit within different powertrain families in order to avoid additional powertrain testing would lead to poorer fuel economy and more vehicles required to accomplish the same work. [EPA-HQ-OAR-2014-0827-1284-A1 p.23]

Finally, excessive powertrain testing could occur. For example, under the proposed regulation, Allison conventional planetary on-highway products would be classified into 10 unique transmission families. Allison hybrid transmissions would be classified into 6 unique hybrid transmission families. In 2014, in North America, Allison transmissions were used with over 30 different engine families. Thus, in combination with conventional and hybrid transmission families, there were at least 74 unique engine family/transmission family configurations. Moreover, most of these configurations are used in multiple regulatory classes which, per the test configuration proposal, would result in approximately 140 test configurations assuming a single calibration for each configuration and approximately 260 transmission family/maximum gear/engine family regulatory combinations assuming a single calibration for each configuration. Factoring in shift related calibrations, the number of unique test configurations would easily exceed 1,000. It is clearly not practical or cost-effective to conduct this level of powertrain testing each year. Thus, in order to limit the testing required, a likely result would be a reduction in consumer choices regarding vocational vehicle configurations. [EPA-HQ-OAR-2014-0827-1284-A1 p.23]

Altogether, it is critically important that GEM be reasonably accurate so the majority of vehicle configurations can be certified without powertrain testing. As discussed elsewhere in Section III, GEM does not accurately assess multiple features of ATs; this lack of accuracy creates a market disadvantage both by misinforming potential customers regarding the performance of ATs and literally “forcing” Allison to conduct powertrain testing in order to provide more accurate information regarding the performance of transmissions. In sum, Powertrain testing should be a tool that is used primarily for highly integrated powertrains that perform significantly better than non-integrated powertrains. It should
not become the de jure or de facto certification methodology. [EPA-HQ-OAR-2014-0827-1284-A1 p.23]

EPA and NHTSA must recognize that the net result of imposing powertrain testing requirements or including explicit or implicit incentives for such testing in the final rule could severely limit customer choices. This is because manufacturers seeking to avoid additional testing would have strong incentives not to specifically design systems that would either require powertrain testing or need such testing to properly account for emission improvements or efficiency gains. One concrete example of this is the Allison hybrids that are sold in transit buses. Based on the powertrain family definition, there would be 6 powertrain families to cover 2 hybrid models that work with 2 engines and are sold in Class 7 and Class 8 vehicles. Based on our current annual volume, doing 6 unique powertrain tests would result in a cost over $1000/unit, not covering the investment required for a powertrain test capability. Therefore, in order to better compete on price in the marketplace, a manufacturer might eliminate an offering to effectively reduce the need for powertrain testing, potentially at the expense of additional CO2 reductions. [EPA-HQ-OAR-2014-0827-1284-A1 p.24]

EPA and NHTSA Have Underestimated Costs of Powertrain Testing

Based on the Proposed Rule’s estimate of $70,000/test and the 140 unique powertrain configurations as described above, Allison estimates that it would need to bear an annual expense of at least $9.8 million just to test a single calibration for each configuration. Assuming one test facility and 3 tests per week, it would further require an entire year to test the 140 configurations. [EPA-HQ-OAR-2014-0827-1284-A1 p.24]

It is also unreasonable to assume a single calibration for each configuration would be acceptable so the costs would be even higher. The ability to accomplish such a testing regimen is unlikely due to test throughput, engine and transmission availability, and calibration readiness. Moreover, this level of testing would force many final powertrain configurations to be completed at least one year in advance of sales for the following year and force capital investment for multiple powertrain test cells. [EPA-HQ-OAR-2014-0827-1284-A1 p.24]

The vocational vehicle industry is highly horizontal. While the vehicle is configured by the vehicle OEM, the transmission and engine are often calibrated by the specific component supplier. Stock trucks are often built and configured to a specific vocation when sold from the dealer lot. Currently, the transmission reconfiguration is handled by the transmission supplier via their systems and tools. This will no longer be possible for powertrain tested configurations. Since the vehicle OEM factors the specific vehicle/transmission/calibration into their overall greenhouse gas compliance, they must approve and potentially manage calibration changes which will be a significant constraint to the industry and could ultimately eliminate stock truck sales. [EPA-HQ-OAR-2014-0827-1284-A1 p.24]

In the RIA Section 7.1.1.2, EPA has estimated that 11 powertrain test cells would be either constructed or upgraded. A second assumption is that 3 large manufacturers would each conduct 20 tests/year. It does not appear logical that 8 manufacturers would invest in the test capability and then not conduct a powertrain test. This puts into question the estimated costs of compliance or the assumptions regarding the frequency of powertrain testing. [EPA-HQ-OAR-2014-0827-1284-A1 p.24]

EPA has also assumed that 70% of vocational vehicles will undergo a powertrain test in 2027. Based on the 140 powertrain families (without shift calibrations) in our current product portfolio, Allison does not believe the assumption that 70% of vocational vehicles in 2027 could be achieved by conducting only
20 powertrain tests/year. Given this low estimate of the number of tests required, EPA and NHTSA’s estimates of resulting costs are therefore flawed. [EPA-HQ-OAR-2014-0827-1284-A1 p.25]

EPA and NHTSA Should Not Replace Powertrain Testing with European Union Efficiency Test

One concept that industry has suggested that EPA and NHTSA should explore is allowing manufacturers to input the European Union (“EU”) transmission efficiency data into GEM. Transmission efficiency data will be required for the EU Regulatory program either through transmission testing or extremely conservative calculations. [EPA-HQ-OAR-2014-0827-1284-A1 p.34]

Allison believes that fuel efficiency improvements that will be validated through powertrain testing will primarily come from the integrated controls of the engine and the transmission. Since transmission gear boxes are already relatively mechanically efficient, improvements in transmission efficiency will have a minimal effect on fuel consumption when compared to controls integration which determines where the engine operates in a given duty cycle. Allison also believes the overall testing costs of EU efficiency testing will not be less than powertrain testing due to Type Approval Authority involvement, long test duration and the quantity of transmission families. [EPA-HQ-OAR-2014-0827-1284-A1 p.34]

Allison is also concerned about the administrative burden that would be associated with compliance with both EU and US rules. Specifically, family definitions, alignment of certification calendars/frequency of testing, running changes, conformity of production and audits are areas where manufacturers would have manage the two extremely different regulatory programs. [EPA-HQ-OAR-2014-0827-1284-A1 p.34]

In summary, Allison believes that powertrain testing is a viable methodology to validate the GHG emissions/fuel efficiency of a powertrain and it should remain in Phase 2. The optional EU transmission testing is burdensome and offers only a minimal benefit, if such exists, when compared to the powertrain test. Therefore, Allison believes that EPA and NHTSA would be justified in relying solely on powertrain testing for validation. [EPA-HQ-OAR-2014-0827-1284-A1 p.34]

EPA Should Amend Proposed 40 C.F.R. 1037.231(b) Criteria for Powertrain Families

EPA and NHTSA are proposing to group powertrains in the same powertrain family if they share all of 11 different attributes. Allison is supportive of the attributes that have been defined in the proposed regulatory text to differentiate powertrain families. There are areas of the proposed regulations, however, that could benefit from further definition in order to increase the clarity of the Final Rule. Therefore, within the final regulatory text, the agencies should: [EPA-HQ-OAR-2014-0827-1284-A1 p.36]

1. Specify the type (and thereby the number) of clutches the proposed 40 C.F.R. 1037.231(b)(3) regulatory text refers to (e.g., starting clutches, friction plate clutches, dog clutches, torque converter lockup clutch, etc.). [EPA-HQ-OAR-2014-0827-1284-A1 p.36]

2. Specify the type of clutches in 40 C.F.R. 1037.231(b)(4) based on the clarification above in (1); [EPA-HQ-OAR-2014-0827-1284-A1 p.36]

3. Clarify that there are additional permissible architectures beyond those that are proposed in 40 C.F.R. 1037.231(b)(6)(i)-(iii) including combination of the identified architectures and Infinitely Variable. While this may be implied by the use of exempli gratia in the text of the regulatory
subparagraphs, EPA and NHTSA should not limit the type of architectures that are or may be available in future years; [EPA-HQ-OAR-2014-0827-1284-A1 p.36]

(4) Specify the energy storage capacity and rated output of hybrid technology at 40 C.F.R. 1037.231(b)(10) and (11)). [EPA-HQ-OAR-2014-0827-1284-A1 p.36]

(5) Clarify 40 C.F.R. 1037.231(b)(7) with respect to the number of forward gears and how this will be specified for different configurations (e.g., granny gears and secondary shift schedules). [EPA-HQ-OAR-2014-0827-1284-A1 p.36]

Comment on N/V Ratios on Powertrain Testing with CVTs

In Sections 1037.550 (h) (1) and 1037.550 (h) (2), the N/V determination appears to be on a fixed ratio gear reduction transmission. For continuously variable (CVT) and infinitely variable (IVT) transmissions that do not have a fixed engine speed at a set output speed, the procedure is not clear. Allison recommends the procedure be modified to use the lowest numerical gear that is available for a CVT or IVT transmission. Additional flexibility should be considered to allow a manufacturer to define the tire radius for the generic vehicle since there will be few axles available for some powertrains. [EPA-HQ-OAR-2014-0827-1284-A1 p.36]

Response to CARB Letter and Recommendations

With respect to the CARB letter on this matter, in order “to allow additional flexibility, ARB staff recommends allowing powertrain testing, as described in 40 Code of Federal Regulations 1037 as an option to chassis dynamometer testing. If this is done, we recommend that the Orange County Bus Cycle or UDDS cycle be used, along with another test cycle that the certifying party believes to be more representative of the specific vocational duty cycle of the hybrid vehicle.” [EPA-HQ-OAR-2014-0827-1284-A1 p.54-55]

CARB further estimates chassis testing costs at $30,000 not including vehicle pickup, delivery, or rental costs and recommends two options to relieve the cost of testing and the accessibility of test vehicles: [EPA-HQ-OAR-2014-0827-1284-A1 p.55]

1. If vehicle OEM is meeting Phase 2 GHG targets without the hybrids factored into their mix, then do not require the supplemental test. Instead, “U.S. EPA could require submittal of emission test data indicating NOx emissions are acceptable via another method, for example from Portable Emission Measurement Systems (PEMS) testing.” [EPA-HQ-OAR-2014-0827-1284-A1 p.55]

2. If vehicle OEM is making less than some threshold of hybrids (suggested number of vehicles is 500 vehicles per year) then do not require the supplemental test. Instead, “U.S. EPA could require submittal of emission test data indicating NOx emissions are acceptable via another method, for example from PEMS testing.”[EPA-HQ-OAR-2014-0827-1284-A1 p.55]

To better understand the impact of the CARB recommendations, Allison has used the ratio method calculation (from the Attachment section of the letter) along with data from the June 2015 NREL report NREL/TP-5400-62009 “Data Collection, Testing, and Analysis of Hybrid Electric Trucks and Buses Operating in California Fleets.” In our calculations, we find that all of the hybrid vehicles cited and tested in the NREL/TP-5400-62009 study would fail the supplemental NOx test which is computed as a combination of grams of NOx/bhp-hr and grams of NOx/mile. Sample calculations are detailed in the attached table. In this regard, it is important to note that the NREL study data was collected on vehicles
that had low kinetic intensity, and that a low kinetic intensity cycle does not reflect well on the benefits of a hybrid powertrain. Allison is very interested in similar studies involving high kinetic intensity, but we are not familiar with any studies of recent model year vintage that includes that type of data. [EPA-HQ-OAR-2014-0827-1284-A1 p.55]

When considering HD vehicles, Allison believes the ratio method presented by CARB is faulty. A more reasonable metric would be grams of NOx /ton-mile. In particular, for transit buses that are intended to displace multiple passenger vehicles (keeping such vehicles off the road in favor of large public transit vehicles), HD vehicles should be properly credited for the work being done to reduce overall vehicle-related emissions. Especially in the case of transit buses, an HD vehicle should not be penalized as if it were a single passenger commuter vehicle. [EPA-HQ-OAR-2014-0827-1284-A1 p.56]

In summary, Allison understands that CARB is attempting to rationalize hybrid NOx performance compared to conventional NOx performance at a vehicle level. Based on a lack of data to understand hybrid impacts on vehicle level NOx in high kinetic intensity applications, however, it is not possible to draw a conclusion this way, most especially with regard to a vehicle like a transit bus. Thus, implementation of the test protocol as proposed would be premature and unsupported in the record for this rulemaking. A more reasonable approach would be for EPA and NHTSA to gather additional data, conduct an analysis of the same and then, if necessary, propose a regulatory amendment that includes some factor of grams of NOx/ton-mile as opposed to grams of NOx/mile. [EPA-HQ-OAR-2014-0827-1284-A1 p.56]

Other Elements of CARB Memorandum

Despite recommending that EPA and NHTSA not include CARB recommendations Allison believes that understanding in-use NOx emissions concerns from HD hybrid vehicles is important to the future of the HD hybrid vehicle market. In this regard, Allison agrees with the following portions of the ARB memorandum: [EPA-HQ-OAR-2014-0827-1284-A1 p.57]

1. Computing a supplemental NOx value for a hybrid vehicle can be done with a hybrid powertrain test. [EPA-HQ-OAR-2014-0827-1284-A1 p.57]

2. If a vehicle OEM is meeting GHG targets without considering hybrids in its vehicle mix, then a supplemental NOx test is not required. [EPA-HQ-OAR-2014-0827-1284-A1 p.57]

3. If a vehicle is a produced by a low volume manufacturer, then a supplemental NOx test is not required. Allison suggests the threshold for an OEM should be 1,000 hybrid vehicles per year. [EPA-HQ-OAR-2014-0827-1284-A1 p.57]

4. Allison believes PEMs equipment should be used to gather in-use emissions data on a prescribed duty cycle, and that data should be considered for future rulemaking concerning a supplemental NOx test for HD hybrids. [EPA-HQ-OAR-2014-0827-1284-A1 p.57]

On the other hand, ARB states that a chassis dynamometer emissions test for HD truck can be run for “approximately $30,000 per test vehicle or hybrid engine family, excluding vehicle pick-up and delivery service.” Allison disagrees with this specific portion of the memorandum. Allison testing experience suggests that the cost to conduct this type of vehicle test could be at least double the ARB estimate.
Also, in cases of delegated assembly, the cost of producing/acquiring a test vehicle of the fidelity required for this type of testing is an additional burden beyond the cost of the test itself. The ARB memo also contains the provision “in order to allow additional flexibility, ARB staff recommends allowing powertrain testing.” While that may allow flexibility, the EPA estimated cost of that testing is $70,000 per powertrain family which is more than double the ARB estimate, albeit low, for a chassis test. [EPA-HQ-OAR-2014-0827-1284-A1 p.57]

CARB Recommendations Run Counter to Proposed Rule Advancement of Hybrid Technology

Allison would observe that the program that EPA has proposed to allow on-highway engines for specialty vehicles to be certified as non-road engines will provide meaningful advancement of the HD hybrid industry while maintaining a firm emissions standard. CARB’s proposal on NOx, however, appears to be directly at odds with this objective. The emission factor ratio application calculations essentially state that a given hybrid powertrain must equal -- or produce less -- NOx emissions than a conventional powertrain. But this requirement could easily result in hybrid powertrains that meet the NOx certification guidelines while at the same time emitting 25-35% more CO2 emissions. [EPA-HQ-OAR-2014-0827-1284-A1 p.57]

The underlying reason for this result is that hybrids have the tendency to cause engines to run at lower speeds than conventional powertrains. That is, the engines used in hybrids are certified on the FTP cycle which runs at speed/load points that are representative of a conventional powertrain that may have been used in the past. In the future, however, engines used in conventional vehicles with more transmission ranges will run at much slower speeds that the hybrid runs at today. It is expected that this migration to engine down speeding on all vehicles will have the side benefit of reducing NOx emissions on hybrid vehicles in use. [EPA-HQ-OAR-2014-0827-1284-A1 p.58]

Ultimately, Allison believes one solution could be changing the baseline FTP cycle to run closer to the lowered engine speed points that are commonly seen in the hybrid systems today and the conventional systems in the very near future. This kind of strategy will deliver both hybrid systems that reduce NOx as well as prepare for inevitable changes in conventional powertrains. Conversely, if changes in the test cycle are not made (and engine manufacturers choose to not optimize the SCR catalyst for the lower operating speeds of the hybrid) the hybrid manufacturer will be forced to sub-optimize the hybrid system. The sub-optimization of the hybrid will result in an estimated 20-30% reduction of the fuel economy gains associated with the hybrid system along with corresponding increases in CO2 emissions. [EPA-HQ-OAR-2014-0827-1284-A1 p.58]

42 The RIA estimates that industry-wide costs associated with the Proposed Rule would amount to only 6 upgraded and 5 new powertrain test facilities. These are projected to cost $16.6 million; operational costs for powertrain testing facilities would total $4.1 million per year, based on an estimate of 20 tests per year for three manufacturers. RIA at 7-6. Allison believes that these estimates are very conservative and do not fully account for the need for parties to do powertrain testing. Outside of vehicle certification per se, the Proposed Rule would drive additional powertrain testing throughout the industry (e.g., in the development of new products, in order to ensure compliance, to quantify potential emission reductions for potential purchasers, etc).

43 This number could potentially double with a second battery offering.

58 See Section III comments regarding secondary shift schedules.
90 This cycle is also sometimes referred to as the OCTA cycle.

92 Note, it is not clear from the CARB letter as to what duty cycle would apply in the PEMS testing in either situation.

**Organization:** Bendix Commercial Vehicle Systems, LLC

We request comment on whether the agencies should consider requiring powertrain testing more broadly. [EPA-HQ-OAR-2014-0827-1241-A1 p.2]

Similar to the comments on chassis dynamometers, Bendix does not believe that the agencies should require powertrain testing in lieu of the vehicle simulation approach being proposed. It is our belief that the associated costs of making it a requirement are not understood well enough to assess the financial impact and testing standards are not fully developed. However, we do believe that the use of powertrain testing will increase and the resulting data should be able to be used as input to GEM. [EPA-HQ-OAR-2014-0827-1241-A1 p.2]

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Powertrain testing**

The NPRM requests comment on “if the generic powertrains should be modified according to specific aspects of the actual powertrain. For example using the engine’s rated power to scale the generic engine’s torque curve.” For hybrid technologies, CARB staff recommends that U.S. EPA and NHTSA consider the effect of the hybrid system, e.g., the work performed by the electric motor, on the generic engine’s torque curve. Because the electric motor is sharing some of the vehicle load requirements, the engine torque map will be altered from its designed targets for similar total power requirement, at least for some operating regimes. If this is not properly accounted for by the powertrain testing procedures, inaccurate fuel economy and emissions test data may likely result. [EPA-HQ-OAR-2014-0827-1265-A1 p.88]

**Comment on Topic Where NPRM Requests Comment**

**Comment – Powertrain testing requirement**

The NPRM requests comment on whether U.S. EPA and NHTSA should require powertrain testing more broadly. CARB staff supports the proposed use of powertrain testing, and also supports future further exploration of powertrain and powerpack testing for certification use. The demands on the GEM simulation will be reduced as more of the engine/transmission interaction is demonstrated by physical operation in test cells. In this fashion, the detailed engine/transmission interaction behavior will be directly captured rather than being potentially ignored by simplifying assumptions in the GEM model. [EPA-HQ-OAR-2014-0827-1265-A1 p.113-114]

CARB staff anticipates that growth in powertrain testing will act to encourage collaborative information exchange between engine, transmission, and hybrid powertrain development groups. Maximization of the anticipated GHG savings from advanced powertrains cannot be realized without engine, transmission and hybrid powertrain development groups affecting the designs of each other’s products.
CARB staff sees adoption of a powertrain testing pathway for certification as a possible incentive in this collaborative direction. [EPA-HQ-OAR-2014-0827-1265-A1 p.114]

Comment on Topic Where NPRM Requests Comment

Comment – Powertrain testing in GEM (generic powertrain modification, transmission gear ratio scaling)

The NPRM requests comment on whether the generic powertrains should be modified according to specific aspects of the actual powertrain, for example by using the engine’s rated power to scale the generic engine’s torque curve. CARB staff believes the generic powertrains should be modified with actual powertrain data and support the proposed efforts to include further experimental data into the GEM simulation. The interpolation of powertrain test CO2 data for advanced powertrains allows the real104 | Page behavior of the powertrain control algorithms and actuator responses to more fully manifest in the GEM evaluation while also minimizing testing burden and avoiding the need to divulge detailed proprietary powertrain control algorithms. CARB staff support gear ratio scaling as it is in line with including all trivially available powertrain parameters in the GEM simulations. [EPA-HQ-OAR-2014-0827-1265-A1 p.115-116]

Comment on Topic Where NPRM Requests Comment

Comment – Hybrid charge sustaining operation - FTP or “City” Test and HFET or “Highway” Test: modifying the minimum and maximum allowable test vehicle accumulated mileage for both BEVs and PHEVs

The RIA requests comment on modifying the minimum and maximum allowable test vehicle accumulated mileage for both BEVs and PHEVs. CARB staff agrees with SAE’s test validity criterion of a 1 percent limit on net State of Charge compared to fuel energy. CARB staff agrees minimum and maximum test vehicle allowable mileage should have flexibility to account for unique usage and wear accumulation in plug-in and BEV vehicles. CARB staff recommends that deviations from the standard requirements be contingent on the certifying manufacturer submitting an engineering justification and the agency’s subsequent approval. [EPA-HQ-OAR-2014-0827-1265-A1 p.120]

Organization: Cummins, Inc.

Cummins supports the powertrain testing option [EPA-HQ-OAR-2014-0827-1298-A1 p.38]

The Phase 1 vehicle simulation utilized a generic, manual transmission model which did not capture the active nature of certain types of advanced transmissions such as automated manual transmissions (AMT) or automatic transmissions. For Phase 2, a powertrain testing option is proposed to evaluate the efficiency benefits of an integrated engine and active transmission system. Results of the powertrain test can be used in GEM in place of the engine fuel map and transmission model. Since both the engine and transmission contain highly complex controllers, a powertrain test recognizes the interaction between these two systems while avoiding the challenges associated with full vehicle testing and simulation. Furthermore, a powertrain test provides high fidelity measurement of fuel efficiency over powertrain
cycles and provides manufacturers with a clear path to demonstrate the benefits of optimized powertrain systems. [EPA-HQ-OAR-2014-0827-1298-A1 p.38]

The agencies proposed powertrain test in 40 CFR 1037.550 has been applied by Dykes and Dorobantu to a HD diesel engine and AMT. Dykes and Dorobantu demonstrated the benefits of the powertrain procedure in capturing the improvements that would not normally be recognized in simulation and engine testing. Cummins supports the option of a powertrain test to evaluate GHG/FE benefits obtained from an integrated engine and transmission. [EPA-HQ-OAR-2014-0827-1298-A1 p.39]

**Cummins supports powertrain families to limit the powertrain testing burden** [EPA-HQ-OAR-2014-0827-1298-A1 p.39]

While Cummins is still evaluating application of the powertrain testing option, there is some concern regarding the powertrain family structure proposed in 40 CFR 1037.231. Grouping similar powertrains into a family structure, analogous to engine families, helps reduce the certification and testing burden to manufacturers. However, if 70% of vocational vehicles require powertrain testing as the agencies have estimated, then the powertrain test burden due to the number of engine and transmission combinations likely exceeds the agencies’ assumptions. Cummins commits to working with vehicle OEMs, transmission manufacturers and the agencies to ensure a practical powertrain family structure is available for Phase 2. [EPA-HQ-OAR-2014-0827-1298-A1 p.39]

**Cummins supports powertrain engines included in engine families** [EPA-HQ-OAR-2014-0827-1298-A1 p.39]

Cummins supports allowing manufacturer’s engine families to contain engines used in powertrain families, which helps minimize proliferation of engine families in Phase 2. Cummins urges the agencies to clarify:

- Engines used in powertrains shall be included in the engine program ABT for CO2 emissions certified over the FTP and/or RMCSET cycles. [EPA-HQ-OAR-2014-0827-1298-A1 p.39]
- Powertrain CO2 emissions levels only apply to engine ratings tested as part of the powertrain system when considering SEA and in-use testing (see 40 CFR 1036.630(a)). Engine certifications submitted with fuel maps are only liable for CO2 emissions measured using the fuel map procedures. [EPA-HQ-OAR-2014-0827-1298-A1 p.39]

---

**Organization**: Daimler Trucks North America and Detroit Diesel Company

We continue to analyze these data to double-check ORNL’s work, but it is not clear to us what conclusions the agencies expected us to draw from all of these data. [EPA-HQ-OAR-2014-0827-1918-A2 p.4.]

**Organization**: Daimler Trucks North America LLC

Page 422 of 2127
Powertrain or Chassis Dyno Testing: The agencies discuss Powertrain testing extensively in the NPRM and we would like to provide our opinion. 1) We recommend the agencies completely remove the need for Powertrain testing, however, 2) if required, Powertrain testing as described risks not accurately capturing powertrain controls and shift strategy. The rule requires 9 different vehicle configurations. Of these 9 configurations, 8 are either at extremes of cycle work, or extremes of engine speed. Four are at extremes of both. While the final point may be considered a reasonable configuration, no consideration is given to a manufacturer’s recommended configuration, or a manufacturer’s specification guidelines on final drive ratio. This may upset a manufacturer’s powertrain control strategy – In the cases of low speed, causing the vehicle to spend too much time in top gear minus 1, increasing cycle CO2. In the case of maximum speed, the powertrain may spend too much time in top gear, and frequently operate in the peak fuel consumption point. This is unrealistic, and again, elevates cycle CO2. These extreme speeds may also cause a transmission or axle to run outside of their designed operating envelope. This may mean that they run in a worse section of their efficiency maps, compounding the CO2 penalty due to engine operating point and powertrain controls. Because the cycle CO2 is interpolated from these points, it is likely that a manufacturer’s best CO2 powertrain will be estimated to have higher cycle CO2 (from the interpolation) than if that particular powertrain configuration were tested. For example, if an OEM’s best powertrain were designed to operate at an optimum speed between the min NTE speed and B speed, the cycle CO2 measured in the powertrain test at the surrounding points would all be higher than the actual configuration. Therefore, it appears that sufficient resolution around actual configurations has been sacrificed to capture the breadth of all configurations, regardless of whether those configurations are allowed by the manufacturer. [EPA-HQ-OAR-2014-0827-1164-A1 p.64-65]

There is no need for powertrain testing for linehaul vehicles, rather we should be doing transmission efficiency test like the rear axle efficiency test: We recognize that the agencies attribute a significant amount of the projected CO2 reductions to using powertrain tests in order to show the benefits of engine and transmission (powertrain) integration. However, especially in the case of all tractor categories where the high speed cycles are weighted the highest we recommend that the agencies accept transmission efficiency testing in lieu of powertrain testing. Given the fact that most driving at high speeds incurs relatively few shift events, there is very little benefit to using powertrain testing as a means to show the benefits of improved shift strategies. The only exception would be neutral coast technologies which become more and more prevalent in the market. However, showing the benefits of i.e. DTNA's ECoast is very challenging on a test bench and would certainly not be feasible under the proposed Phase 2 powertrain test procedures. Similarly with vocational vehicle, a lot of the undefined “deep integration” benefit that the agencies seek can likely be found on a transmission efficiency test, in that manufacturers will be able to demonstrate improved gear efficiencies relative to those assumed in GEM. In our opinion it is more advantageous to capture transmission efficiency benefits with a dedicated transmission efficiency test than powertrain testing, because one transmission test can cover a broad range of powertrain configurations. Therefore, similar to our recommendation to align test procedures for axle efficiency with the ACEA approach we recommend aligning transmission test protocols as well. Given the global nature of the heavy duty truck industry DTNA would welcome the ability to leverage test results for global components in multiple regulatory areas of the world. [EPA-HQ-OAR-2014-0827-1164-A1 p.65]

Other Structures Considered: Powertrain Testing – The agencies propose powertrain testing and request comment regarding what key attributes should be considered when defining a transmission family. 80 FR 40178. DTNA recommends against powertrain testing as it is a burdensome approach to measure the same results that GEM is well-crafted to simulate. In particular, we recommend transmission mapping to get realistic transmission inputs. This would require one test per transmission, rather than multiple tests per transmission—at least one for each engine family, likely many more as a manufacturer will not be able to get much value from the worst-case transmission and engine rating
combination. We certainly will not be able to show the “deep integration” that the agencies expect when we are required to test worst-case configurations. So we will need to test a lot of variants, at the expense of a lot of money and time. Better is to use GEM with transmission inputs. [EPA-HQ-OAR-2014-0827-1164-A1 p.66] That said, if the agencies plan to incorporate powertrain testing, DTNA recommends that EPA include variants of automatic transmission torque converters. It is understood that changing torque converter design on an otherwise identical powertrain configuration can drastically affect engine operating points, and change the cycle fuel economy. This is due in part to what gear the TC locks up in, idle torque requirements, and slip. It appears that EPA just wants to know if there is a torque converter, and where it’s located. But we are not certain. We wish to work further with the agencies to understand your request and how we can work toward transmission mapping without need to define transmission “families” (particularly for powertrain testing). [EPA-HQ-OAR-2014-0827-1164-A1 p.66]

**Powertrain Testing** - If the generic powertrains should be modified according to specific aspects of the actual powertrain. - DTNA does not support that EPA promulgate rules that incentivize a preferred path for certification as it appears to have treated powertrain testing. 80 FR 40190. DTNA believes that full vehicle simulation using a verifiable suite of input values for key attributes is the most effective approach to Phase 2. Should EPA continue with offering the powertrain certification path, it should consider allowing manufacturers to establish the range of attributes that establish the matrix of configurations it plans to test. As manufacturers optimize their powertrain designs to specific applications, they should be allowed to configure the powertrain test matrix to closely bind the region of optimization. By doing so, the manufacturer can improve upon interpolation error that could otherwise be significant if the boundaries of the matrix are defined too widely as may be the case in EPAs proposed default configurations. [EPA-HQ-OAR-2014-0827-1164-A1 p.66] DTNA also questions the use of the criteria pollutant parent rating as the sole rating to establish fuel consumption characteristics for a family of ratings. It is clear that shifting patterns and engine operating speeds over a given drive cycle vary significantly with engine rating characteristics. EPA is encouraged to investigate how powertrain test results are affected as a function of engine rating. [EPA-HQ-OAR-2014-0827-1164-A1 p.66]

**Organization:** Eaton Vehicle Group

**Potential of powertrain testing:** Through prototype powertrain testing, we have data showing the incremental cost of testing is reasonable. For advanced vehicles there is no practical alternative because it is the proprietary shift logic and integrated engine-transmission controls that drive the differences between GEM-based predictions and real performance. Since the powertrain test results are a product of the engine and transmission controls, attention needs to be focused on maintaining the ability of authorized parties to modify calibrations in the field. [EPA-HQ-OAR-2014-0827-1194-A1 p.3]

**Importance of realistic GEM default values and baseline values:** GEM defaults need to be set at “slightly conservative” in all powertrain configurations. We believe there is still work to be done in choosing the default values. For transmission losses, it is important that a “slightly conservative” approach be taken so the relative ranking is preserved across different architectures. Fortunately, the EPA has developed a powertrain test capability at Southwest Research Institute and other locations, so it can collect real test data of 2015 powertrains and use this information to develop a consistent, data-driven set of MY2017 baseline assumptions and GEM defaults. [EPA-HQ-OAR-2014-0827-1194-A1 p.4]

Furthermore, we are pleased the EPA is developing a powertrain test option that accurately measures the fuel benefits of advanced technologies in realistic driving conditions. We believe that the EPA/NHTSA proposal to offer powertrain testing as an optional feature to measure the efficiencies of advanced
transmissions and powertrains is a critical expansion of its use in Phase 1 for hybrid certification. We believe the powertrain test option is an essential complement to model-based certification. The fact that the benefits of advanced transmissions and controls can be visible in the vehicle assessment, through the powertrain test option, enables OEM’s to achieve compliance though these technologies, in a cost-effective fashion. Coupled with the Averaging, Banking and Trading program proposed in the rule, it offers OEMs flexibility in achieving stringent standards and allows Eaton to bring advanced technologies to the market earlier, driving further emissions and CO2 reductions on an accelerated timeline. [EPA-HQ-OAR-2014-0827-1194-A1 p.5]

**Value of transmissions in GEM-based certification**

Advanced transmissions, deeply integrated powertrains, and the powertrain test option, deliver a significant part of the compliance burden without significant incremental product cost, complexity, weight or vehicle architecture changes. We have provided data to the EPA showing that 25-33% of the line haul tractor compliance gap between MY2017 and MY2027 can be covered through such technologies. [EPA-HQ-OAR-2014-0827-1194-A1 p.6]

Specifically, we have compared GEM simulations and powertrain tests of identically specified vehicles. For the GEM simulation, we used the engine fuel map and for the transmission we used actual gear ratios. In the powertrain test, we looked at both a normal powertrain configuration (450 HP ISX engine and an Eaton 10-speed LAS transmission without downspeeding), as well as the deeply integrated SmartAdvantage Powertrain (ISX engine with SmartTorque 2 communicating with an Eaton FAS high efficiency 10-speed transmission with increasingly more aggressive engine downspeeding). We observed a difference on average of 6.3% (and more than 8% in a particular vehicle combination) in the powertrain test versus the GEM prediction with the identical vehicle settings and appropriate engine fuel map and default transmission model. This difference is explained by the features present in the real hardware and controls but not modeled in GEM (e.g., the specific engine dynamics and controls, the dry sump technology and advanced shift strategy in the transmission, etc). These results show that through better engine transient controls transmission controls and architecture, the integration of the two components and advanced lubrication and efficiency treatments, it is possible to cover 25-33% of the line haul tractor compliance gap between MY2017 and MY2027 (6-8% improvement on a 22-24% target improvement). These results are described in [Dykes 2015, Stoltz 2014]1,2.[EPA-HQ-OAR-2014-0827-1194-A1 p.6-7]

Similarly, using the powertrain test methodology and comparing dual clutch transmissions in fuel economy mode versus incumbent technology in base mode, we have quantified the fuel advantage at 7-8%, numbers confirmed by test track tests. This shows that 33-50% of that gap in the vocational segment (14-16% improvement target can be covered by improvements in transmission efficiency and deep integration with the engine resulting in, e.g., minimizing idle losses and engine downspeeding. This value is realized assuming the GEM models are “slightly conservative” when simulating basic technologies. Specific results are presented in [Jackson 2015, Dykes 2015, Dorobantu 2014 and CBI data provided]3,1,4.[EPA-HQ-OAR-2014-0827-1194-A1 p.7]

**Powertrain testing**

The powertrain test option is applicable to advanced vehicle features where there is no practical alternative, because it is the proprietary shift logic and integrated engine/transmission controls that drive the difference between GEM-based predictions and the real performance. Since the powertrain test results are a product of the engine and transmission controls, attention needs to be focused on maintaining the ability of authorized parties to modify calibrations in the field, within certain limits.
Without such an option, the significant impact of controls cannot be accounted for in the vehicle certification, rendering the approach useless and leading to increased cost, weight and complexity of compliance by forcing hardware-only solutions. [EPA-HQ-OAR-2014-0827-1194-A1 p.7]

**Certification value**

As shown before, the powertrain test methodology applied to advanced transmissions and deep engine/transmission integration, can yield 6% fuel reduction in line haul tractors and 7-8% fuel reduction in vocational categories. The reductions account for engine and transmission dynamics not modeled in GEM, as well as mechanical efficiency improvements of advanced transmissions. This offers OEMs flexibility in achieving the tractor and vocational vehicle standards. [EPA-HQ-OAR-2014-0827-1194-A1 p.7]

**Powertrain families**

We agree with the EPA’s proposed definition of powertrain families and use of engineering judgment to determine the family and worst case representative. We believe that for our business, we will likely recommend splitting engine families into two groups; one with performance calibrations, the other with fuel efficient calibrations, so that the worst performing combination in each category will still provide significant certification to OEMs. We will stress that we do not believe there is significant value in powertrain testing to be applied across all powertrains. For example, using our portfolio today as a guide, we think only a few Eaton transmissions such as the FAS (as part of the SmartAdvantage package) or the Procision dual clutch (integrated with the ISB engine) will maximize the certification value through a powertrain test. For other transmissions that are mechanically more efficient than GEM defaults -such as our LAS 10-speed transmission -- we recommend a gearbox efficiency test only. Yet for another category of high performance transmissions -- the MXP 18-speed transmission, for example -- we would recommend GEM defaults. We also believe OEMs will select only higher volume powertrains for full powertrain testing, perhaps segregated into 2-3 families each. The RIA suggests that 70% of vocational powertrains will need to be powertrain tested for compliance. However, in terms of test burden, the appropriate metric is the number of distinct families that would need such testing, which needs an assessment. [EPA-HQ-OAR-2014-0827-1194-A1 p.7-8]

**Recommendation:** Continue evaluating the concept of powertrain families to assess the realistic test burden in the vocational space. [EPA-HQ-OAR-2014-0827-1194-A1 p.8]

**Powertrain test procedures**

We agree with the EPA description of the powertrain test procedure and we support the approach to mapping the powertrain space as a function of work and N/V ratio. We understand that the EPA is trying to define a single procedure that serves powertrain with and without the axle(s), and realizes this objective by specifying multiple tire radii. We are concerned that during a powertrain test, unrealistic an tire radius may be misinterpreted by either engine or transmission controllers resulting in erratic behavior. We believe that it is prudent to develop different (but equivalent) specifications for the powertrain test when a physical axle is present and when the axle is virtual. [EPA-HQ-OAR-2014-0827-1194-A1 p.8]

**Recommendation:** Allow an option to use either axle ratio or tire radius for the nine vehicle configuration setup for powertrain testing. Axle ratio can be used if the physical axle is not part of the powertrain test lab. If the physical axle is part of the setup than tire radius may be used. [EPA-HQ-OAR-2014-0827-1194-A1 p.8]
Powertrain cost estimates

A significant issue around using powertrain tests is the cost of the test, assuming there is no cost in running a GEM simulation using the GEM default transmission efficiency values. Based on two years of experience with two powertrain test cells, we estimate that the unburdened incremental costs of powertrain tests are below $10,000 for a test with an engine and a transmission that have been previously tested (i.e., fixtures, wire harnesses, etc. already exist), below $15,000 per test with a previously tested engine but new transmission family, and below $20,000 when a new engine is tested. The differences in costs are driven by the need to create new fixtures, harnesses, etc., and to calibrate the test cell. We have provided the EPA with a detailed cost analysis based on actual expenses [CBI data provided]. [EPA-HQ-OAR-2014-0827-1194-A1 p.8]

At Eaton, we have converted an engine emissions test cell as a medium-duty powertrain test for work under Phase 1, and a heavy-duty test cell for studying powertrain test options in Phase 2. The incremental costs of converting the cells (new simulation software and controls, replacing the engine dynamometer with a higher torque machine and additional wiring) over the cell’s emissions sensing system was under $1,000,000. We have provided the EPA with a cost analysis based on actual spend [CBI data provided]. [EPA-HQ-OAR-2014-0827-1194-A1 p.8]

Calibrations issues

There is a significant concern around the ability to perform adjustments and running changes to the transmission controller if the powertrain testing methodology is used. [EPA-HQ-OAR-2014-0827-1194-A1 p.8]

Eaton releases annually two software updates that are flashed (sometimes remotely) onto transmission controllers with the truck in the field. The bulk of these changes are bug fixes. Also, post-sale changes to the transmissions are made, mostly focused on adjusting shift durations and clutch engagement (usually not shift tables). These changes are essential to the correct functioning of the vehicle in areas such as low speed maneuverability when backing into a dock, and even to improving vehicle safety. It is important to recognize that most U.S., non-vertically integrated OEMs are not currently aware of these changes which are usually the responsibility of independent suppliers of engines, transmissions, and soon axles. [EPA-HQ-OAR-2014-0827-1194-A1 p.8-9]

Since the powertrain test results are a product of the engine and transmission controls, attention needs to be focused on maintaining the ability of authorized parties to modify calibrations in the field within certain limits. Without such an option, the significant impact of controls cannot be accounted for in the vehicle certification, rendering the approach useless and leading to increased cost, weight and complexity of compliance by forcing hardware-only solutions. The issue is not dissimilar to engine calibration adjustments, recently reported in the press to actually drive less fuel consumption by allowing fleets to optimize stock engine parameters. [EPA-HQ-OAR-2014-0827-1194-A1 p.9]

We believe the EPA is trying to avoid situations where OEMs might sell a “fuel economy package” and account for a significant CO2 credit at the sale, but then other parties change the calibration to “performance” which may impact adversely the CO2 emissions. [EPA-HQ-OAR-2014-0827-1194-A1 p.9]

Recommendation: The EPA considers a range of options. Willfully changing from a “fuel economy calibration” to a “performance calibration” during the regulatory useful life of a vehicle certified with powertrain tests would be illegal resulting in the agency having significant enforcement opportunities in
such unlikely scenarios. However, a constant re-testing of new settings or adopting a worse-case situation would also defeat the goals of the regulations. A compromise but clearly articulated solution based on either experience in light duty CAFE with multiple powertrain settings (“comfort” versus “sport” versus “eco” modes), and/or agreed upon limits in which adjustments can be made without re-testing, should be established by the EPA in the final rule. [EPA-HQ-OAR-2014-0827-1194-A1 p.9]

Importance of grade sensors

Modern transmissions have grade sensors and load sensor or estimators to determine the appropriate shift points. These tend to be proprietary algorithms as they dictate the quality and the feel of the shifts. A limitation of the powertrain test is that it cannot physically reproduce grades, and in some cases the load information is external to the powertrain (e.g., a vehicle level data and estimate). Grade is not important in the ARB cycle, but we have seen that it does make a substantial difference in the 65mph and 55mph cycles with the +/-2% grade proposed in the NPRM. Should that grade increase as the agency is suggesting up to +/-5% grade, the grade sensor data becomes a very significant part of the powertrain test. In our experience, the grade sensor is implemented as a pendulum and its readings are corrected for vehicle acceleration. Thus, in a test it will compensate for acceleration, tricking the controller into assuming a steep grade which will result in wrong gear selection. [EPA-HQ-OAR-2014-0827-1194-A1 p.9]

Recommendation: The EPA should allow the powertrain vehicle simulation to feed the simulated grade directly to the transmission controller, e.g., through an additional CAN signal, and allow a test version of the controller to accept that data instead of using its internal grade sensor. [EPA-HQ-OAR-2014-0827-1194-A1 p.9]

Simulated transmissions

An idea developed in the industry is to perform powertrain testing on an engine test stand with simulated transmission behavior. We do not agree with this approach for several reasons: First, the powertrain test should be used to give credit to transmission controls and integrated engine/transmissions controls. If the transmission is replaced by a model controller, that purpose is defeated. Second, the powertrain test is meant to reward advanced transmission technology which would not be seen in such a test. [EPA-HQ-OAR-2014-0827-1194-A1 p.10]

A variant of this request would be to run a transmission mechanical model in GEM, but replace the transmission logic with the actual transmission controller in a hardware-in-the-loop setting. Such an endeavor is feasible in development centers and the engine transmission communications would be captured by such a test. However, the controller-in-the-loop needs to be validated that it is functioning correctly, communicating with sensors, and correctly putting loads on simulated actuators. The validation of such an approach for regulatory reasons is open to interpretation and its interfaces are extremely complex. It could be argued that the powertrain itself is in fact hardware-in-the-loop and open to the same validation issues. That, however, is not the case because the powertrain has simple interfaces with the rest of the vehicle: CAN bus communications, one load at the prop-shaft, and a few well known electrical accessory loads. [EPA-HQ-OAR-2014-0827-1194-A1 p.10]

Recommendation: The EPA should not implement a simulated transmission in a powertrain test. [EPA-HQ-OAR-2014-0827-1194-A1 p.10]

GEM default values and baseline values
“Slightly conservative” GEM default efficiencies

GEM defaults need to be set to being “slightly conservative” in all powertrain configurations. As an objective measure, we recommend defining “slightly conservative” GEM predictions relative to a powertrain test of an identically configured vehicle using the steady state engine fuel map and corresponding gear ratios. [EPA-HQ-OAR-2014-0827-1194-A1 p.13]

The behavior of the GEM transmission model is mainly driven by the power-loss models and the assumed shift controls. We believe there is still work to be done in choosing the efficiency default values. For transmission losses, it is important that a “slightly conservative” approach be taken so the integrity of the certification process is maintained. This is further complicated by the fact that there are fundamentally two different transmissions architectures available in GEM that have different modeling assumptions. [EPA-HQ-OAR-2014-0827-1194-A1 p.13]

Data that the EPA shared recently with EMA and other powertrain manufactures is encouraging in terms of the correct ranking between architectures. The earlier version of GEM had significant issues with the relative ranking of various architectures in GEM versus their relative ranking in real world conditions or on the powertrain test. For example, when simulating in GEM for the Precision DCT and the automatic transmissions without fuel efficiency calibrations, were ranked as shown in the figure below where the measured quantity is g/ton-mile. However, the powertrain test results and the test-track simulation results showed the exact opposite trend. Furthermore, the effect of downspeeding the powertrain by simulating increasingly higher speed axles was correct for the DCT, AMT and MT architectures, but incorrect for the AT architecture. [EPA-HQ-OAR-2014-0827-1194-A1 p.13]

[Figure 2, 'An early version of GEM simulations where the results are counter to physics and hardware test data', can be found on p.13 of docket number EPA-HQ-OAR-2014-0827-1194-A1]

We also have data that shows that GEM is “optimistic” in terms of fuel consumption, rather than the needed “slightly conservative” even for manual and AMT transmissions. [EPA-HQ-OAR-2014-0827-1194-A1 p.14]

We have compared a few configurations using the early publicly available GEM version, as well as accessing computations with later development code shared by the EPA with the EMA and other industry participants. Our findings are as follows: [EPA-HQ-OAR-2014-0827-1194-A1 p.14]

There are modern transmissions on the market with the overall efficiencies of 98% in direct and 96% in other gears [CBA data provided].[EPA-HQ-OAR-2014-0827-1194-A1 p.14] There are significantly more mechanically efficient transmissions, such as the Eaton LAS 10-speed and the FAS 10-speed. Recognizing the contributions of such transmissions through either a powertrain test or overwriting the GEM defaults as described above provides an impetus to the industry to improve the technology. In the case of LAS, the GEM defaults understate the fuel consumption between 0.7% and 6.0% versus powertrain testing using different axle ratios at 55 mph and 65mph simulations with a slight grade (i.e., GEM is too optimistic instead of conservative in its fuel consumption predictions). Some of that difference is attributable to differences in shift controls and some is due to the loss model. However, these results point to a methodology to objectively tune GEM to “slightly conservative” predictions. [EPA-HQ-OAR-2014-0827-1194-A1 p.14] On the contrary, artificially inflating the default efficiencies removes the compliance incentive for better efficiency and would allow less efficient transmissions to claim fuel efficiency that is not real-world, defeating the purpose of the certification. [EPA-HQ-OAR-2014-0827-1194-A1 p.14] It is also critically important to establish a realistic baseline for the regulations using the GEM models, even if the relative change in stringency remains unchanged. We
agree with the EPA assessment that changing the standards numerical values (that are dependent on GEM tuning and choice of grade profiles in the duty cycle), while maintaining the relative stringency change in MY2021, MY2024 and MY2027 does not change the analysis of technology paths, their cost or their impact. However, it is important that the baseline is realistic because of the ability to compare against powertrain tests. [EPA-HQ-OAR-2014-0827-1194-A1 p.14]

If the baseline is too high, the standards will be automatically achieved by a simple exercise of GEM which defeats the purpose of the rule. If the baseline is too low, the standards become impossible to achieve in any powertrain test setting. Fortunately, the EPA has developed a powertrain test capability at Southwest Research Institute and other locations allowing it to collect real test data of MY2015-16 powertrains and to use these to develop the MY2017 baseline assumptions. In this way, the GEM model does not need to be tuned to road data but rather to very repeatable tests, strictly equivalent GEM, that exercise real powertrains. [EPA-HQ-OAR-2014-0827-1194-A1 p.14]

**Recommendation:** to resolve the issues of realistic baselines and “slightly conservative” GEM defaults, the EPA should consider selecting a few representative powertrains for the 2017 baseline whose performance settings are typical in the market today, and then use the SWRI powertrain test capability on vehicle configurations such that: [EPA-HQ-OAR-2014-0827-1194-A1 p.14]

GEM is tuned to reproduce the ranking of different transmission architectures when exercised over the same engine and vehicle, to avoid creating a “pull” for any particular technology based on GEM modeling assumptions and simplifications. [EPA-HQ-OAR-2014-0827-1194-A1 p.15] Ensure that GEM results are “slightly conservative” on the configurations where advanced transmission controls or deep engine/transmission integration are either nonexistent or disabled (e.g., fuel efficiency calibrations), and the degree of under-prediction is consistent across different transmission architectures. [EPA-HQ-OAR-2014-0827-1194-A1 p.15]

**Organization:** Eaton Vehicle Group

We believe that the following are characteristics are critical to the success of GEM as a tool and to realizing the improvements envisioned by the rule in an efficient way for the industry: [EPA-HQ-OAR-2014-0827-1875-A1 p.1]
- GEM needs the flexibility to include data-driven models as technology advances, so that GEM does not become a barrier to introducing new products. Powertrain test-based models and transmission power loss models are excellent options. [EPA-HQ-OAR-2014-0827-1875-A1 p.1]

- GEM test cycles need to be representative of real-life operations, and it is critical that GEM exercise the largest part of the powertrain modes. We believe the agency has developed a data-based approach that is statistically significant and achieves the needs [EPA-HQ-OAR-2014-0827-1875-A1 p.1]

Representation of powertrain technologies in GEM
Eaton has performed a number of simulations using GEM in both tractor-trailer and vocational vehicle mode. We noticed the following trends: [EPA-HQ-OAR-2014-0827-1875-A1 p.2]

- GEM correctly captured the effects of downspeeding engines through the combined effects of transmissions and axle ratios. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]
- GEM captured correctly the effects of gears designed for more down-sped operations [EPA-HQ-OAR-2014-0827-1875-A1 p.2]
- GEM captured correctly the differences between major transmissions architectures. For example, the impact on predictions of CO2 emissions of automatic, dual clutch and AMT transmissions are consistent with differences observed in powertrain tests or fuel tests when these technologies are compared. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]
- GEM captured correctly the impact of neutral-idle and start-stop technologies on automatic transmissions. When applied to automatic transmissions, they reproduce the effect of such transmissions to gain fuel efficiency and approach the efficiency of AMT and DCT transmissions with similar gear ratios. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]

Powertrain and efficiency test methodology
We have performed experiments with the powertrain test methodology outlined by the EPA, and have evaluated the applicability and consistency of the results. We have established that the powertrain test is reliable in predicting the performance of real transmissions and integrated engine-transmissions. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]

- The methodology for deriving the powertrain representation using 9 vehicle points and testing over the three cycles is sound. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]
- GEM simulations based on the powertrain test data recover the powertrain performance at the design points. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]
- The interpolation error is reasonable when comparing the powertrain test at a different test condition and comparing with the powertrain-based GEM model at that same condition. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]

Consistency between GEM prediction and hardware tests
We have also evaluated the ability of the powertrain test to quantify the advantage of advanced technology over a simulation using defaults [EPA-HQ-OAR-2014-0827-1875-A1 p.2]

- GEM simulation using transmissions default efficiencies is “slightly conservative.” We compared GEM outputs with the default transmission loss model to GEM outputs that overwrote the defaults with actual measured transmission losses. The calculations show a close match in the situation of an actual transmission in the market that is not optimized for efficiency. This allows us to conclude that the GEM default transmission losses are “slightly conservative,” in the sense that they predict correctly transmissions in the market that are not optimized for fuel economy. [EPA-HQ-OAR-2014-0827-1875-A1 p.2]
- Powertrain method quantifies correctly the benefits advanced technologies. We compared GEM predictions with default losses to powertrain tests of transmissions optimized for fuel economy. We found that the difference observed is correct and consistent with both hardware tests and fleet reports. The differences observed match and quantify, the effects of better mechanical efficiency, including dry sump, optimized shift points, and optimized engine-transmission response during shifts. We observed a
less than 1% uncertainty in the matching which we attribute to uncertainty in the auxiliary load used in the GEM assumptions and the hardware tests. [EPA-HQ-OAR-2014-0827-1875-A1 p.2-3]

**Organization:** Eaton Vehicle Group

Furthermore, we are pleased the EPA is developing a powertrain test option that accurately measures the fuel benefits of advanced technologies in realistic driving conditions. We believe that the EPA/NHTSA proposal to offer powertrain testing as an optional feature to measure the efficiencies of advanced transmissions and powertrains is a critical expansion of its use in Phase 1 for hybrid certification. We believe the powertrain test option is an essential complement to model-based certification. The fact that the benefits of advanced transmissions and controls can be visible in the vehicle assessment, through the powertrain test option, enables OEM’s to achieve compliance though these technologies, in a cost-effective fashion. Coupled with the Averaging, Banking and Trading program proposed in the rule, it offers OEMs flexibility in achieving stringent standards and allows Eaton to bring advanced technologies to the market earlier, driving further emissions and CO2 reductions on an accelerated timeline. [EPA-HQ-OAR-2014-0827-1194-A1 p.5]

**Organization:** Hino Motors, Ltd.

1. Cycle Average Mapping Test and Powertrain Test

With regard to the proposed test procedures on GHG emission test specified in 40 CFR part 1036, 1037 and 1065, Hino noticed some inconsistent testing frequencies from critical emission test. According to the proposal, set point frequency and validation frequency which are specified in 40 CFR part 1036.540(b)(5) and part 1037.550(1) and (k) are excessively high compared with those of measurement system response in 40 CFR part 1065.205, 1065.512(c) and 1065.514. [EPA-HQ-OAR-2014-0827-1877-A1 p.1]

| Table can be found on p.1 of docket number EPA-HQ-OAR-2014-0827-1877-A1 |
As shown in the table above, we found following issues. [EPA-HQ-OAR-2014-0827-1877-A1 p.2]
1. The response timing requirement in the GHG test is considerably fast and difficult to meet with existing test cell equipment.
2. The response timing requirement in the GHG test is not consistent with that of exhaust emission test specified in 40 CFR part 1065.

Request:
The same frequency which is proven in the FTP emission test for EPA emission test should be used in the GHG certification test. [EPA-HQ-OAR-2014-0827-1877-A1 p.2]

**Organization:** Navistar, Inc.

Navistar feels the following are key areas the agencies must address: [NHTSA-2014-0132-0094-A1 p.2]

- Powertrain testing should be optional, not mandatory, and the proposed protocol should be completely revised to be more representative of customer applications. [NHTSA-2014-0132-0094-A1 p.2]

**Organization:** PACCAR, Inc.

**Proposed Powertrain Integration Testing Requirements are Far More Burdensome than the Agencies Estimate**
The proposal also would require that any running changes to powertrain test family components that have, or may have, effects on fuel efficiency and GHG emissions must undergo powertrain integration testing before the running change could be implemented. This testing burden would make implementing necessary running changes extremely difficult, if not prohibitively expensive. [EPA-HQ-OAR-2014-0827-1204-A1 p.21]

PACCAR recommends that the agencies significantly reduce the powertrain integration testing burden by reducing penetration rates for vocational stringency determination and by limiting emissions measurements in the powertrain test cell to CO2, N2O and CH4, provided that criteria pollutants (NOx, CO, THC, PM etc.) are measured and reported as part of the engine certification process. PACCAR also recommends that the agencies provide increased flexibilities that will allow needed running changes and field fixes without the delay of additional testing and will work with the agencies to develop the best regulatory approach to support this need. [EPA-HQ-OAR-2014-0827-1204-A1 p.21]

As an additional note, the agencies’ early estimate is that the transmission would not be required for confirmatory and SEA testing of deep integration technologies. However, initial assessments indicate that the transmission will be needed if an SEA is performed because the engine torque output from the engine ECU does not reflect the engine performance at a given moment of time to the accuracy necessary to replicate the test without the transmission. [EPA-HQ-OAR-2014-0827-1204-A1 p.21]

Organization:  School Bus Manufacturers Technical Council

Powertrain Testing – The agencies have proposed powertrain testing and requested comments regarding what key attributes should be considered when defining a transmission family. SBMTC recommends against powertrain testing as it is a burdensome approach to measure the same results that GEM is well-crafted to simulate. SBMTC believes the best choice is to use GEM with both separate engine and transmission inputs. [EPA-HQ-OAR-2014-0827-1287-A1 p.1]

Organization:  Union of Concerned Scientists (UCS)

Automated manual transmissions allow for significant application for downspeeding, and some of this is captured in the updated GEM model. However, true powertrain integration can push these reductions even further by better matching torque to the vehicle’s operating conditions, as evidenced by the technical report published by Eaton and submitted to the docket (Dykes and Dorobantu 2015). In this report, the SmartAdvantage powertrain achieved a 3.4-percent improvement on the line-haul cycle and a 3.7-percent improvement on the regional-haul cycle. However, the GEM model would only capture the benefits of the top-gear being downsped by about 100 rpm. [EPA-HQ-OAR-2014-0827-1329-A2 p.11]

We calculated the impact of the 100-rpm downspeeding improvement in GEM using public data on the gear steps for the two transmissions (Eaton n.d., 2015) and the 2017 aerodynamic and tire coefficients. We’ve considered both the 2018 and 2027 final drive ratios to bound the problem — as mentioned above, the engine speed in 2018 is much higher than a typical engine today but is the default used by the agencies to set the regulations, while the 2027 final drive ratio leads to an engine cruise speed comparable to what the SmartAdvantage powertrain was designed for. This modeling shows that GEM is able to capture between 2.0- and 2.3-percent improvement on the line-haul cycle and just 1.6 to 2.0 percent on the regional cycle, well short of the 3.4- to 3.7-percent improvement shown in the powertrain test. Using the average result, this is 1.3-percent improvement from line-haul and 2.0-percent from day cab that is not being captured, and therefore not being incentivized, under the current regulation. [EPA-HQ-OAR-2014-0827-1329-A2 p.11-12]
Powertrain integration can provide significant fuel economy improvements, particularly in transient operation. Despite significant improvements, this is inadequately captured in the GEM model, and therefore the agencies should be moving towards a regulatory approach that captures transient operation better, such as the powertrain test. Furthermore, the agencies should ensure that the GEM model is not undercutting improvements measurable by powertrain testing by over crediting performance of conventional transmissions. [EPA-HQ-OAR-2014-0827-1329-A2 p.12]

Organization: Volvo Group

**Powertrain Testing**

We have had neither the time nor the resources necessary to adequately evaluate the powertrain test proposal. This is particularly troubling since much of the vocational efficiency improvement is based on “deep integration” of the powertrain that can only be demonstrated via powertrain testing. This procedure requires a thorough engineering investigation as is typically done within the EMA Emissions Measurement and Test Committee in cooperation with the agencies. In addition, a procedure for performing the powertrain testing should be established in 40 CFR Part 1065. The powertrain testing requirements in 1037.550 do not clearly define the hardware requirements for the test cell. The language is vague and could allow for inconsistent interpretation across the industry. At present, we can provide only a few observations based on a cursory review, without having had the opportunity to conduct any testing whatsoever. [EPA-HQ-OAR-2014-0827-1290-A1 p.39]

We first note that available dynamometers are not rated at the very high transmission output torque levels when in the lowest transmission gears. As an alternative, we propose to simulate the vehicle operation in the lowest gears while running in the lowest gear that maintains output torque below the dynamometer limits. Since work done while at these low speed is small, the measurement impact should be minimal. Upgrading dynamometers to have full torque capability for the proposed testing would require investment on the order of $1,000,000 per test cell. [EPA-HQ-OAR-2014-0827-1290-A1 p.40]

In order to properly manage transmission gear shifting, it is essential to provide the necessary inputs to the transmission controller. Currently our AMT requires road grade data that is acquired via a level sensor. This input must be simulated during the test. Without this input, the transmission controller would assume widely varying vehicle mass; and shifting would not be properly controlled. In the future, the transmission will utilize learned grade data from on-board GPS to optimize shifting on hills and we would expect this input data can also be simulated during the testing. [EPA-HQ-OAR-2014-0827-1290-A1 p.40]
In addition, the NPRM does not adequately define the test procedure. For instance, if a manual transmission were to be employed within a given powertrain family, the method of managing the testing is left largely to the manufacturer. This could result in an OEM employing a shift strategy for the test that would be un-realistic in the real world. This could serve to lessen the real-world benefit of auto shifting transmissions. At the same time, Volvo Group believes that the Powertrain Testing provision must include manual transmissions: otherwise the high power transmission efficiency benefits of manual transmissions could be misrepresented due to the forced usage of default GEM settings while less efficient technologies (i.e. torque converted automatics) may appear to offer an advantage, which is not real, but only a product of the test protocol. [EPA-HQ-OAR-2014-0827-1290-A1 p.40]

Volvo Group notes that while there has been a substantial penetration of auto-shifting transmissions, manual transmissions will continue to play a significant role especially in certain market segments for the foreseeable future. [EPA-HQ-OAR-2014-0827-1290-A1 p.40]

With regard to the axle, the measured axle efficiency should be an input to the powertrain test based on the results of the axle efficiency test, if available. [EPA-HQ-OAR-2014-0827-1290-A1 p.40]

A preferred alternative to the proposed powertrain testing procedure would be an engine test wherein the engines speed and torque is managed using the transmission control strategy such that the actual engine speed and torque is matched to how it would operate in the prescribed vehicle duty cycle. Measured axle and transmission efficiency in each gear or default values could be used as an input to the test. Volvo Group has demonstrated good correlation with vehicle tests using this method. [EPA-HQ-OAR-2014-0827-1290-A1 p.40]

**Powertrain Family Definition**

1037.231 states the definition and structure for powertrain families. The provision at 1037.231(a) (2) (7) states that the number of forward gears is a defining factor for a Powertrain Family. This largely implies that we would have to have a separate family for every transmission and engine combination and therefore no reason even to define families. This also implies that the amount of testing needed to certify using the powertrain family would prohibit the use of the procedure. Appendix 1 provides a list of transmissions currently offered by Volvo and Mack Trucks. This includes 24 different transmission offerings with unique numbers of gears and/or gear ratios. These can be paired with as many as four different engine sizes each with many unique calibrations resulting in hundreds of powertrain families, each needing to be separately tested to arrive at representative efficiency. [EPA-HQ-OAR-2014-0827-1290-A1 p.40-41]

Volvo Group believes that Powertrain Families should be defined by logical, higher order parameters, which do not over-constrain the product offering, thus promoting the usage of this method while not sacrificing accuracy. For instance, sub-families of transmissions could be created which share architecture, but do not have the identical number of forward gears or the identical ratios. The difference in emissions from two such systems would be small when operated on the regulated duty cycles. However the impact of such provisions would be large in allowing the industry to continue to offer the broad range of systems that are needed in the diverse applications of heavy duty vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.41]

**Organization:** Volvo Group

**Powertrain Test Data**
The agencies provided extensive data from testing performed at ORNL's (Oak Ridge National Lab) heavy duty powertrain test facility along with a summary of the results. However, it is difficult to understand all the results without more background on the testing and further discussion that has not been feasible during the NoDA review timeframe. The data set does not include key details like the transmission shift control schemes, engine torque curves, engine speed and torque plots, vehicle speed plot, transmission gear, engine fuel maps, etc. that would help explain some of the unexpected results. As a result, we are at a loss to explain possible inconsistencies with the data. For example, the number of times the truck will need to shift gears during the testing has an impact on fuel consumption that will vary with vehicle weight. [EPA-HQ-OAR-2014-0827-1928-A1 p.20]

It is unclear why fuel consumption data is presented with multiple readings for each unit tested, but with no explanation for the differences in these results that vary by as much as 7% for the same test. This certainly raises the question of which measurement methods are most accurate and meaningful and why they vary so much. [EPA-HQ-OAR-2014-0827-1928-A1 p.21]

The chart copied below is a comparison of 4 drive cycles at 41T (tons) with the 2.4 FD (final drive ratio) vs the 2.64FD and the 3.36FD respectively. [EPA-HQ-OAR-2014-0827-1928-A1 p.21]

[Figure 6 can be found on p.21 of docket number EPA-HQ-OAR-2014-0827-1928-A1]

The ARB cycle (transient) will include many shifts and speed changes and thus by conventional understanding the FC will be slightly or significantly worse depending on the shift count. There is also a concern that at 41T weight, the truck may not achieve the demanded speed during parts of the cycle and will run at full throttle during that time. But without knowing the shape of the fuel map, it is difficult to determine the validity and the magnitude of the reported differences in fuel consumption. The other vehicle weights in the study (19, 22, 32 tons) all show worse fuel consumption for the ARB cycle when the 2.4FD is used as compared to the other test ratios. This seems illogical, but without the shift strategy and other data, we cannot draw a conclusion about the validity of this result. [EPA-HQ-OAR-2014-0827-1928-A1 p.21]

The chart below provides the FC (fuel consumption) trends for the various FDs and weights on the 55 mph cycle. [EPA-HQ-OAR-2014-0827-1928-A1 p.21]

[Figure 7 can be found on p.22 of docket number EPA-HQ-OAR-2014-0827-1928-A1]

Use of the lower final drive ratios (2.4 vs the 2.64 for example) will normally reduce the engine speed on the drive cycle and should result in better FC, unless the transmission down-shifts to maintain engine speed and to increase torque to the axle. The expected lower FC is reflected here to some extent. An anomaly occurs at the 19T, 2.4FD vs the 2.64FD where FC increases by 0.75%. It does not make sense that the lighter vehicle would spend more time in a lower gear than a heavier vehicle with the same powertrain. Again, without the fuel map or shift logic it is difficult to say whether there is a reasonable explanation. The general trends seem to make sense given that as the FD decreases, the engine cruise speed also decreases resulting in a greater FC benefit at the cruise condition. [EPA-HQ-OAR-2014-0827-1928-A1 p.22]

The data for the 65mph cycle again yields trends that are in agreement with conventional intuition: decrease FD ratio; reduce engine speed at cruise; and decrease FC. However, in this chart the magnitude of the FC improvement are alarmingly high, particularly at the lower weights. [EPA-HQ-OAR-2014-0827-1928-A1 p.22]
The 19T 2.4FD has a 12% FC improvement over the 2.64FD. A truck with 2.4 FD, 512rev/mile drive tires, running at 65mph, and weighing 19T will have an engine speed of 1044 rpm. Conversely, the same spec with a 2.64FD will run at 1140 rpm, a difference of 96 rpm. Typically reducing engine speed by 100 rpm would result in around 2% reduction in fuel consumption, not 12%. By comparison, the 2.4FD vs 3.00FD yields an engine speed reduction of 250 rpm but only a 7% reduction in fuel consumption. Additionally, the 3.36FD shows a more than 16% reduction in FC as compared to the 2.4FD on the same weight. These values seem unreasonably high and illogical. Volvo cannot comment effectively without much more detailed data, but with the information given, these values are out of line with what Volvo would expect.

On the ARB cycle, the data shows that the 2.4FD is significantly worse than the other FD ratios with the exception of the 41T vehicle. The near 20% FC difference on this cycle is far too high. Volvo would expect a 5-10% difference to be more reasonable.

Although this testing provides valuable information on powertrain test variability, many of our concerns are not addressed. These include:

- Are the results logical and consistent with field experience? From the data, there are significant inconsistencies as already noted. This raises serious concern that a vehicle specified for optimum field fuel efficiency will perform poorly on powertrain testing, or vice-versa.

- What is the relative difference between powertrain test result and GEM simulation? This is not addressed since no comparison to GEM is provided. This is important to help us understand the need to run powertrain tests and the associated test burden.

- What is the impact of shift logic options on powertrain test results? This was not tested or at least not reported. As a result, we don’t know how programmable shift logic will be handled or its impact. This would have large impact on the number of powertrain tests that we need to run, on the limits we might need to set on operator adjustable parameters, and on our ability to reprogram transmissions to meet field requirements.

- What is the impact of engine power and torque rating on test results? Although, a range of 400-450 hp is tested, the data is not provided in summary form. In any case, we believe a wider range of power and torque needs to be evaluated.

- How will these results vary once the highway grade profiles are finalized? Since grade profile is as yet not firm, the testing does not address this issue.

- What improvement in fuel consumption should be expected from powertrain integration? We are very concerned that the level of improvement presented in the data significantly overstates what can be achieved and should not form the basis for expected stringency.

In conclusion, while the general trends from the powertrain test seem consistent with what Volvo would expect, the magnitudes of the FC differences are too large in many cases, especially where the final engine speed difference is relatively small. In some cases, the fuel consumption trend is also illogical. There may be reasonable explanations if much more detailed data were provided. Without further
investigation and explanation, Volvo is concerned that vehicles optimized for powertrain testing may perform poorly in actual applications and that the expected improvement from powertrain integration may be much greater than what can actually be achieved. In addition, we are left with little guidance as to the relative advantage of powertrain testing over GEM simulation, how many powertrain tests may ultimately be required, or the associated test burden. [EPA-HQ-OAR-2014-0827-1928-A1 p.24]

Response:

The agencies appreciate all the comments on the powertrain test method, including the many comments supporting the test as an optional certification path. EPA has heard the many comments on not overly relying on or incentivizing the powertrain procedure. Due to these comments the agencies have introduced the transmission efficiency test procedure. By introducing the transmission efficiency test procedure GEM can reflect the improvements to transmission efficiency across many vehicles without having to rely solely on the powertrain test. The method is particularly beneficial for the tractor sector where much of the benefit from the powertrain test was quantifying improvements to transmission efficiency. In addition to the transmission efficiency test procedure the agencies have also added the cycle average engine mapping procedure in 40 CFR 1036.540 to measure the transient fueling of the engine. With this change the benefits of improving transient fueling can be recognized without performing the powertrain test procedure, which further reduces the reliance on the procedure.

Validation of Powertrain Procedure

EMA’s objection to the powertrain test stated below:

*The preliminary results obtained through the powertrain test are uncertain and unproven.*

The agencies have modified the powertrain procedure for Phase 2, so that the output of the tests can be used in GEM without A to B testing for a wide range of vehicle configurations. The procedure has been tested and validated with testing at Oakridge National Laboratory (ORNL), Southwest Research Institute (SwRI) and two manufacture laboratories with parent and child ratings of the engine family. This testing has shown that the procedure can be implemented to meet all the requirements of the procedure including the speed regression of the dynamometer. From this testing the agencies have shown that the procedure is repeatable and accurate for measuring the benefits from integrated powertrains. The agencies have also observed that test-to-test variability of measured fuel of the procedure has a coefficient of variation (COV) less than 0.5%, which is at a level seen for engine testing, even though the procedure is testing the transmission with its own variability in addition to the engine. The figure below shows that powertrain testing compares on an absolute basis to chassis testing, but typical COV of chassis testing of heavy-duty vehicles is greater than 2%, due to the additional variability of the driver and the tires.
Regarding the use of default powertrains in GEM, the agencies have looked at this with the data collected at ORNL and have seen that GEM accurately interpolates the powertrain map even when a generic powertrain is used in GEM. The main benefit of using a default powertrain in GEM is that it gives a consistent process in GEM for all powertrains, including hybrids and transmission architectures that are not in GEM. For hybrids, the engine’s torque curve may not inform GEM of the total powertrain’s power, and for continuously variable transmissions there are no discrete gear ratios that can be put into GEM. Because of these reasons the agencies have chosen to use default powertrain parameters in GEM for vehicles that are certified with a powertrain map.

**Powertrain testing requirements**

The agencies agree that powertrain testing does add additional requirements over engine testing but our cost analysis outlined in detail in the RIA Chapter 2.9 and RIA Chapter 7.1 shows that for certain highly integrated powertrains the additional complexity and cost is justified by the benefit of being able to show the fuel savings of integrated powertrains and hybrids. As for the comments on high torque in lower gears the agencies have seen that dynamometers that are currently used for heavy-duty engine testing can be used for light-heavy and medium-heavy powertrain testing. Through our work at SwRI we have also shown that with the addition of a relatively inexpensive water brake the typical dynamometer used for heavy-duty engine testing can be adapted to test heavy-duty powertrains. One other thing to note on the torque requirements for powertrain testing is that the powertrain doesn’t stay in lowest gears long enough to produce the theoretical peak torque for those gears. The figure below shows the torque from the Cummins ISX - Eaton USP powertrain where the output speed is changing at different rates. In the first curve in red, the speed is defined by the vehicle model simulating a full throttle acceleration with a 30,000 kg vehicle. Comparing the peak torque of this test to a very slow ramp of 8 rpm/s the powertrain produces just over half the torque. Even when a 60,000 kg vehicle is simulated the peak torque is less than 70% of near theoretical torque of the powertrain in second gear.

---

33 Southwest Research Institute, July 2016 “Validation Testing for Phase 2 Greenhouse Gas Test Procedures and the Greenhouse Gas Emission Model (GEM) for Medium and Heavy-Duty Engines and Powertrains.”
**Figure 3 Comparison of theoretical torque to measured torque**

**Cost of powertrain testing**

See Section 6.3.3.2 for responses to comments on costs of powertrain testing for vocational vehicles.

**Updates to powertrain procedure from proposal**

Navistar’s comment on generic vehicles:

*The first issue, and likely the most complicated to resolve, is the selection of the generic vehicles with which to test in a powertrain dynamometer.*

Since the proposal the powertrain procedure has been updated to allow the manufacturer to choose the range of axles and tire sizes to test the powertrain with, to cover the full range of axles and tires that will be install on the vehicles with the powertrain. This will eliminate the problem of extrapolation while not requiring the powertrain to be tested with axles and tires that are not used with the powertrain in-use.

The agencies have also clarified 40 CFR 1037.550 to say that the vehicle model in the test cell shall run at a minimum of a 100 Hz but the dynamometer control frequency has to run at a minimum of 5 Hz.

As for the control frequency of the cycle average test procedure 40CFR 1036.540, the agencies thank you for your comment but are finalizing 10 Hz for both the cycle and the cycle validation. This is because the cycle is generated using GEM where the torque and speed change at rates of 10 Hz and higher due to transmission gear shifting and driver dynamics.

Eaton’s comment on sending grade signal to powertrain controllers:
The EPA should allow the powertrain vehicle simulation to feed the simulated grade directly to the transmission controller, e.g., through an additional CAN signal, and allow a test version of the controller to accept that data instead of using its internal grade sensor.

EPA agrees with Eaton’s comment that signal from the duty cycle including road grade should be sent to the powertrain controller if the data allows the powertrain to operate in a way that better reflects how the powertrain operates in-use.

Powertrain Family definition

Navistar’s comment on family definition:

Secondly, the family structure is ambiguously defined.

Based on all the comment received, the agencies have concluded that the powertrain family definition is appropriately defined after the clarifications to clutch type.

Allison’s comment on the number of families:

Finally, excessive powertrain testing could occur. For example, under the proposed regulation, Allison conventional planetary on-highway products would be classified into 10 unique transmission families. Allison hybrid transmissions would be classified into 6 unique hybrid transmission families. In 2014, in North America, Allison transmissions were used with over 30 different engine families. Thus, in combination with conventional and hybrid transmission families, there were at least 74 unique engine family/transmission family configurations.

After review all the comments on the penetration rates of powertrain testing and with the addition of the transmission efficiency test procedure the agencies are projecting lower penetration rates of powertrain testing. See chapter 2.9.3 of the RIA for the detailed discussion on penetration of powertrain testing.

The amount of testing is reduced by allowing manufacturers to override the default transmission power losses by performing the test defined in 40 CFR 1037.565. The agencies agree that the transmission efficiency test has comparable cost to the powertrain procedure but the results from the test are not limited to one engine family so the overall cost is significantly less than powertrain testing for transmissions that are paired with many engines.

With regard to Cummins comment “Powertrain CO2 emissions levels only apply to engine ratings tested as part of the powertrain system when considering SEA and in-use testing (see 40 CFR 1036.630(a)). Engine certifications submitted with fuel maps are only liable for CO2 emissions measured using the fuel map procedures.” the agencies have clarified in 40 CFR 1036.230 that an engine family can be divided into subfamilies where only the fuel map or powertrain map are certified with the applicable subfamily. 40 CFR 1036.630 has also been updated to clarify that SEA and in-use testing will only be done with the applicable test procedures (40 CFR 1036.535, 40 CFR 1036.540 or 40 CFR 1037.550) that apply to the subfamily.

With regard to Cummins comment, “Engines used in powertrains shall be included in the engine program ABT for CO2 emissions certified over the FTP and/or RMCSET cycles.” the agencies are not allowing powertrain results certified under 40 CFR 1036.630 to be included in the engine ABT program for CO2. This is because powertrain results generated according to 40 CFR 1037.550, are used for vehicle certification and not engine certification over the FTP or RMCSET cycles.

Modifications to calibrations
Eaton’s comment on running changes to calibrations:

There is a significant concern around the ability to perform adjustments and running changes to the transmission controller if the powertrain testing methodology is used.

The agencies share Eaton’s concern that using the powertrain test option should not limit the manufacturer’s ability to make running changes to the powertrain’s calibration that don’t effect fuel consumption. The agency has and will continue to work with manufacturers to streamline the process for these types of changes to the powertrain calibration.

Definition of powertrain N/V and work

For the powertrain procedure, N/V is defined by the axle ratio and tire size, because the main benefit of performing the powertrain test is to get credit for the shifting strategy of the integrated powertrain. If engine N/V is used then GEM determined N/V would be used to interpolate the powertrain map. For a powertrain that up-shifted early to operate the engine at lower engine speeds than in GEM, GEM would still be interpolating the powertrain map at the higher engine speed of the simulation. This problem becomes even more evident for hybrids where the engine N/V in GEM has no connection to the engine N/V in the powertrain procedure because GEM doesn’t model hybrids. For similar reasons work has also been defined at the output of the powertrain, so that the losses of the transmission in GEM do not affect how the powertrain map is interpolated. Using the output of the powertrain also simplifies the measurement since the speed and torque measurements during that powertrain test are made at the dynamometer.

ORNL Test Data

The agencies thank commenters for comments with regard to the test data that was submitted with the NODA. The agencies have docketed the final report that covers the details of how the data was collected. The title of the report is “Powertrain Test Procedure Development for EPA GHG Certification of Medium- and Heavy-Duty Engines and Vehicles.”

Powertrain testing of manual transmissions

The agencies are not allowing the powertrain procedure to be used for manual transmissions because the main purpose of the powertrain method is to recognize the integration of the transmission and engine. For improvements to the efficiency of manual transmissions the transmission efficiency procedure can be used.

2.5 Production Vehicle Testing for Comparison to GEM

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Annual production vehicle testing for comparison to GEM requirement, chassis dynamometer testing (cost and efficacy)

The NPRM requests comment on the proposed testing requirement for annual production vehicle testing. CARB staff supports requiring annual production vehicle testing, but wants to encourage sufficient chassis testing across the variety of vehicle types to verify that the GEM model remains robust over time in the face of shifting vehicle and engine technologies. CARB staff also prefers that the range
of technologies be represented rather than just those technologies present on the highest volume vehicle models. Restriction to only the highest volume models could blind this GEM evaluation to a large aggregate fraction of vehicle sales that will never individually rise to the popularity level necessary to qualify for chassis testing under the current vehicle selection criteria. CARB staff prefers there be some representation of non-highest-seller vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.116]

The “configuration” language is ambiguous. This GEM evaluation would be best served by spreading the sparse testing across five vehicle configurations that differ from each other as much as possible (transmission type and gearing, engine size, axle ratios, etc.) while selecting from widely used configurations. CARB staff seeks to avoid a situation where the meaning of a “configuration” is interpreted so strictly that all 12 most popular configurations, from which a manufacturer is allowed to select, may be essentially the same configuration with near trivial differences from GEM or actual GHG perspectives. [EPA-HQ-OAR-2014-0827-1265-A1 p.116] To address the concerns above, CARB staff recommends amending the regulatory language as described below: [EPA-HQ-OAR-2014-0827-1265-A1 p.117]

§ 1037.665 In-use tractor testing, perform in-use testing as described in this section.

(a) The following test requirements apply beginning in MY 2021:

1 or more models that you project to be among represent the diversity of your 12 highest-selling vehicle configurations for the given year.

This tractor based GEM evaluation avoids the vehicles most likely to stress the GEM model’s assumptions. Particularly avoided are vocational vehicles in heavily transient applications such as urban buses and solid waste collection vehicles, and vehicles with complex engine/transmission interactions such as advanced powertrain hybrids. CARB staff sees widespread deployment of electrified vocational vehicles (including hybrids) as central to meeting our GHG reduction goals thus lending importance to planning for their inclusion in future GEM model evaluations. CARB staff would prefer to see some representation of vocational and other non-tractor heavy-duty vehicle categories where the GEM model assumptions may not hold as well as for classic tractor vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.117]

The NPRM requests comment on the costs and efficacy of the requirement for manufacturers to annually chassis test three sleeper cab tractors and two day cab tractors and submit these data and GEM results. CARB staff feels that this testing requirement for comparison to the GEM model gathered from across the heavy-duty vehicle market is important for maintaining confidence in the certification simulation method as vehicle technology evolves. The limited amount of annual testing per manufacturer appears financially and operationally manageable while also providing an aggregate industry-wide dataset needed for evaluating correlation of actual emissions with GEM simulation results trends. [EPA-HQ-OAR-2014-0827-1265-A1 p.117]

The financial burden and operational limitation of available facilities are both eased by the relaxation of emissions measurement equipment specifications from those typical of engine emissions certification test cells. This allows any transient heavy-duty chassis dynamometer to be used by temporary placement of a PEMS unit next to it. [EPA-HQ-OAR-2014-0827-1265-A1 p.117] CARB staff agrees that for the purposes of this GEM evaluation the reduced instrumentation requirements of Subpart J are an acceptable cost savings and open many more potential chassis testing sites for consideration. [EPA-HQ-OAR-2014-0827-1265-A1 p.117]
Response:

The agencies agree with the comment from CARB that the vehicles that are chosen for chassis testing should reflect not only the high volume vehicles but also potentially cover the diversity of vehicles. For this reason 40 CFR 1037.665 has been written to allow the agencies to choose which vehicles are tested.

2.6 Use of GEM in Establishing Proposed Numerical Organization:

American Automotive Policy Council

Spark Ignition (Gasoline) GEM 2 implementation concerns

AAPC has completed detailed analysis of the Phase 2 GEM 2b-5 gasoline baseline and has concluded the baseline assumption of CO2 levels is underestimated and the resulting required improvements are overly stringent relative to other regulated segments and the agencies’ stated intentions. Per the summary table on the next page, the 2017MY baseline is underestimated by 10 – 15%. Further the overall Phase 2 gasoline GEM has a total CO2 reduction requirement of 29% with a required improvement of 20% in 2021MY alone. This is further exacerbated due to the lack of opportunities to build credits or phase-in to the standard prior to 2021MY. Class 2b/3 chassis certified products and planned Phase 2 GEM diesel standards appear to have been well studied and evaluated, but the Phase 2 gasoline GEM baseline and standards do not appear to have been evaluated with the same rigor. [EPA-HQ-OAR-2014-0827-1238-A1 p.31]

Tables of GEM baseline and percent improvement offsets can be found on p.32 of docket number EPA-HQ-OAR-2014-0827-1238-A1

AAPC requests that the Phase 2 GEM 2017MY gasoline baseline assumptions and standards be reevaluated based on a thorough analysis of all vocational vehicles with heavy-duty spark ignition engines, and we recommend the agencies set up a working group to validate GEM model assumptions and revise as additional data becomes available. [EPA-HQ-OAR-2014-0827-1238-A1 p.32]

§ 1036.535 Determining engine fuel maps and fuel consumption at idle

In previous comments submitted to the docket in response to the Proposed Rule, AAPC expressed concern about the baseline assumptions and standard stringency built into the revised Greenhouse Gas Emissions Model (GEM) for Phase 2 for Class 2b-5 Vocational Vehicles. In reviewing the data associated with the March 2 NoDA, AAPC was encouraged to see that EPA and NHTSA have conducted additional testing and model development work to better characterize these vehicles. Despite these improvements, AAPC believes there are still technical issues associated with the model and test procedures that must be addressed in order to have a successful and sustainable Phase 2 program for Vocational Vehicles. [EPA-HQ-OAR-2014-0827-1898-A1 p.2]

Highlights of the AAPC’s comments are as follows:

• Since the GEM model is still under active development, AAPC recommends that implementation of the GEM-based CO2 standards be postponed until 2023 to allow for public review and comment on a substantially completed GEM model. [EPA-HQ-OAR-2014-0827-1898-A1 p.2]

• The GEM 2 default assumptions for class 2b-5 truck aerodynamics, tire size, inertia weight, and axle ratio are not correct and need to be fixed to insure the model encourages manufacturers to implement technologies with real on-road CO2 benefits. [EPA-HQ-OAR-2014-0827-1898-A1 p.2]
• The baseline heavy-duty gasoline fuel map uploaded to the docket is not representative of real spark ignition engines and should be replaced with a map derived from actual engine testing. [EPA-HQ-OAR-2014-0827-1898-A1 p.2]

• Applying diesel-derived methodologies to spark ignition GEM vehicle categorization criteria is inappropriate. Unique spark ignition methods should be developed. [EPA-HQ-OAR-2014-0827-1898-A1 p.2]

Response:

Many of issues mentioned by AAPC have been resolved as indicated from their NODA comments. We also made a few changes on class 2b-5 configurations, such as CdA, Crr, and axle ratio and gasoline engine fuel map, after taking many constructive comments from public as well as many CBI from individual stakeholders. Many of these changes can be seen in Chapter 4.4.1.10 of the RIA. Please see the agencies’ response to the notice and comment of GEM in RTC Section 15.5.

Organization: Bendix Commercial Vehicle Systems, LLC

However, we encourage others to investigate this new approach in detail, and we request comment on whether or not the agencies should replace our proposed steady state operation representation of the engine in GEM with this alternative approach. [EPA-HQ-OAR-2014-0827-1241-A1 p.2]

As the agencies are aware, there are many simplifications made when only steady state fuel maps are used to simulate the engine fuel consumption in vehicle operation. Bendix believes that the GEM3 should be made flexible enough to accept engine data that has been collected via engine dyno testing over the GEM duty cycles over a range of simulated vehicle configurations which would include transient conditions. In addition, we believe engine accessories which are typically excluded from engine testing, should be included in the data collection. Examples include the engine cooling fan, air compressor, air conditioning compressor and power steering pump. [EPA-HQ-OAR-2014-0827-1241-A1 p.2-3]

Response:

We have made many improvements on GEM. On the transient condition, we introduced the cycle average approach to replace the steady-state engine fuel map to better and more accurately account for transient operations. The detailed test procedure can be seen in 40 CFR 1036.540. We do not believe that it would be a simple task or even practical to include all major vehicle accessory losses, such as engine cooling fan, air compressor, air conditioning compressor and power steering pump into the engine dynamometer. Rather, we continue using the pre-defined accessory loss into GEM, as in Phase 1 GEM. However, we did take a further step to first collect the accessory power loss data from engine and vehicle manufacturers, and then implement the values into GEM.

Organization: California Air Resources Board (CARB)

Support Comment

Comment – Fuel map requirements

U.S. EPA and NHTSA are proposing that engine manufacturers must certify fuel maps as part of their certification to engine standards, except in cases where they certify based on powertrain testing, and that engine manufacturers be required to provide these fuel maps to vehicle manufacturers beginning with
MY 2020 engines, since MY 2020 engines may be used in MY 2021 vehicles. Vehicle manufacturers may not develop their own fuel maps for engines they do not manufacturer. For Phase 2, GEM will allow the input of engines-specific fuel maps, which will increase accuracy. CARB staff supports these requirements as stated. [EPA-HQ-OAR-2014-0827-1265-A1 p.124-125]

Response:

Thank you for your support.

Organization: Cummins, Inc.

Cummins opposes use of a steady-state engine fuel map to provide engine information into GEM [EPA-HQ-OAR-2014-0827-1298-A1 p.22]

The agencies are proposing that engine manufacturers provide a very detailed steady-state fuel map to vehicle manufacturers to incorporate specific engine information into the vehicle simulation. The proposed steady-state engine fuel map is flawed for at least three reasons. First, the proposal requires engine manufacturers to release trade secret and confidential business information (CBI) to the public and competitors alike. Second, the proposed steady-state engine fuel map does not adequately represent true engine performance. Third, the proposed steady-state engine fuel map potentially gives CO2 credit at the cost of NOx emissions. Cummins understands the desire to include engine performance in the vehicle program, but in order to perform that function fairly and practically, some key principles must be met: [EPA-HQ-OAR-2014-0827-1298-A1 p.22-23]

- Manufacturers’ trade secrets and CBI must be protected. EPA has long recognized that manufacturers rely on EPA’s regulations (40 CFR Part 2) to protect proprietary information related to engine operation, such as steady-state fuel maps, calibrations and controls information, etc. submitted to the Agency as CBI. Cummins is aware of no circumstances in which the agencies have publicly released such information claimed confidential by a manufacturer. Whether disclosed in terms of CO2 or fueling values (which are directly correlatable), the proposed steady-state engine map would provide the public and competitors CBI that EPA and manufacturers have long held secret. [EPA-HQ-OAR-2014-0827-1298-A1 p.23]

Further, engine manufacturers have historically competed on the basis of optimizing fuel economy and criteria emissions control over the operating range of the engine. Requiring disclosure of steady-state fuel maps for vehicle certification in GEM would force engine manufacturers (who are not always the vehicle manufacturer) to divulge proprietary information, well ahead of production, to competing manufacturers. Those competitors could use the trade secret information to gain an unfair advantage by exploiting the research and development efforts of the engine manufacturer rather than investing their own resources in developing and optimizing such systems. Forcing that disclosure violates the principles of market integrity that have been the cornerstone of EPA regulations for decades and reduces marketplace competition, providing a disservice to the customers. A reasonable alternative to protect CBI contained in steady-state engine maps is the cycle-average map approach discussed below. [EPA-HQ-OAR-2014-0827-1298-A1 p.23]

- The engine information should be accurate, including accurately representing transient engine performance. In order to meet the accuracy need, the engine should be evaluated in a manner consistent with how it will be used in the vehicle regulation, such as transient operation simulated across a range of vehicle configurations. The steady-state engine fuel map does not
meet this requirement. Transient engine operation is not well represented by the steady-state engine fuel map as indicated by the agencies’ use of a transient correction factor and described in more detail below. The appropriateness of the transient correction factor for all engines and engine technologies until 2030 is questionable, especially considering the implementation of model-based controls in this timeframe as recognized and projected by the agencies in this proposal. [EPA-HQ-OAR-2014-0827-1298-A1 p.23]

- The CO2 evaluation of the engine for use in the vehicle program should be consistent with the criteria emissions regulation protocol. If the protocol for generating credit for engine CO2 in the vehicle program is not consistent with the protocol for engine regulation for NOx, then manufacturers will have an incentive to create systems that perform well on CO2 at the expense of NOx when certified separately and differently for CO2. These systems will not drive both NOx and CO2 control in the real world. Conversely, the cycle-average map, as discussed below, provides the opportunity in the future to re-align both transient and steady-state GHG and criteria emissions, thus addressing this issue. [EPA-HQ-OAR-2014-0827-1298-A1 p.24]

The agencies should implement the alternative ("cycle-average") map approach in lieu of the steady-state fuel map in the final rule [EPA-HQ-OAR-2014-0827-1298-A1 p.24]

In the Preamble (see 80 FR 40179), the agencies request comment on replacing the steady-state fuel map with an alternative mapping approach that tests the engine over “the GEM duty cycles over a range of vehicle configurations.” The result of this testing is a set of “cycle-average map” CO2 values that can be used in GEM to represent the engine. EPA has been working with a group of companies to develop and validate the cycle-average map approach, described in the Draft RIA at Section 3.10, and results show good correlation between this alternative method and experimental results (see Figure 12). Further details of the cycle-average map validation work can be found in Zhang et al.22 and Salemme et al.23. [EPA-HQ-OAR-2014-0827-1298-A1 p.24]

The use of cycle-average CO2 values resolves many of the issues identified above with the steady-state engine fuel map. The benefits of the cycle-average approach are: [EPA-HQ-OAR-2014-0827-1298-A1 p.24]

- Disclosure of CO2 over the cycle-average map does not expose manufacturers’ CBI that would put them at a competitive disadvantage. Cycle-average test results have historically been reported to the agencies and available to the public. The CO2 values from the cycle average map approach are a collection of cycle test results and can be treated the same. [EPA-HQ-OAR-2014-0827-1298-A1 p.24]

- It is more accurate. This approach is inherently testing the engine through a transient drive cycle, so the engine is operating as it will in the vehicle, with all of the transient controls in operation on realistic maneuvers. Including transient behavior in the cycle-average map approach removes the need for a transient correction factor that is necessary with the steady-state engine fuel map and the concerns and difficulty with determining the correct factor. Figure 12 compares the correlation of the two mapping approaches to the measured values. The cycle-average map approach shows good accuracy without the need for a transient correction factor. [EPA-HQ-OAR-2014-0827-1298-A1 p.25][Figure 12 can be found on p.25 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

- Auditing of the cycle-average CO2 values can be accomplished by using any one of the pre-defined vehicle configurations. This approach defines a clear and consistent audit test cycle for manufacturers to evaluate production variation and product improvement changes. [EPA-HQ-OAR-2014-0827-1298-A1 p.25]
The cycle-average map provides a framework of transient engine testing that could be utilized in the future to link criteria emissions and GHG certification approaches. For example, current engine FTP and RMCSET cycles could be replaced with cycles generated using predefined vehicles, and both criteria emissions and GHG/FE engine standards could be established over these cycles. Such a change should only be undertaken if both engine criteria emissions and GHG/FE are simultaneously shifted to the new certification cycles to maintain the linkage between all engine emissions. [EPA-HQ-OAR-2014-0827-1298-A1 p.26]

The engine cycle-average map approach utilizes a similar mapping approach as the agencies proposed for the powertrain test option. This provides consistency in the evaluation of engines and powertrains used in the vehicle program. [EPA-HQ-OAR-2014-0827-1298-A1 p.26]

Cummins does not support this hybrid approach as issues with the steady-state engine fuel map, mentioned earlier, will remain (e.g., pre-production disclosure of CBI to competitors). Cummins urges the agencies to implement the cycle-average map as the sole engine mapping approach for Phase 2 in the Final Rule, and we commit to continued collaboration to refine the cycle-average mapping procedures. [EPA-HQ-OAR-2014-0827-1298-A1 p.26]

*Cummins does not support requiring a fuel map for MY20 engines used in MY21 vehicles [EPA-HQ-OAR-2014-0827-1298-A1 p.27]*

Cummins opposes requiring MY20 engines to generate engine fuel maps. The agencies’ proposal attempts to address MY mismatch between engines and vehicles that occurs in practice today. This requirement may effectively pull forward the MY21 engine standards as MY21 vehicles with MY20 engines would still be expected to meet vehicle standards that are premised on MY21 compliant engines. To account for this, vehicle manufacturers may require engine makers’ MY20 engines to perform at MY21 standards to ensure vehicle fleet compliance. Similar situations will also occur at the MY24 and MY27 standard changes. Cummins is willing to work with the agencies and industry on a better remedy for MY mismatch that will not disrupt market dynamics and inadvertently pull ahead engine standards. [EPA-HQ-OAR-2014-0827-1298-A1 p.27]

*Cummins supports the option of a generic fuel map in GEM that can be overridden by vehicle manufacturers [EPA-HQ-OAR-2014-0827-1298-A1 p.40]*

In the Preamble, the agencies request comments on providing default GEM maps for vehicle certification (80 FR 40184): [EPA-HQ-OAR-2014-0827-1298-A1 p.40]

*We also request comment as to whether or not the agencies should provide default generic engine maps in GEM for Phase 2 and allow manufacturers to optionally override these generic maps with their own maps, which would be generated according to our proposed engine dynamometer steady-state test procedure. [EPA-HQ-OAR-2014-0827-1298-A1 p.40]*

Cummins supports this provision as it helps maintain the integrity of the engine ABT program. For example, an engine manufacturer can elect to certify some engines using CO2 credits. Since the engine program ABT has already accounted for the excess CO2 emissions, there is no need to also account for the engine CO2 emissions levels in the vehicle program. Therefore, allowing a manufacturer to apply a default map would preserve the value of engine credits and ABT program. [EPA-HQ-OAR-2014-0827-1298-A1 p.41]
Response:

We have made significant changes on the engine fuel map used for GEM since NPRM. First of all, as Cummins urges, the final rule uses the cycle average approach to replace the steady state engine fuel map for the transient ARB cycle in GEM runs, and allows manufacturers the option to either use the cycle average approach or steady state engine fuel maps during the simulation of the 55 mph and 65 mph cruise cycles in GEM.

Manufacturers that certify vocational vehicles to the custom-chassis standards are required to use the agencies’ default engine fuel maps, and they are not allowed to overwrite the default fuel maps with their own maps. The certification of all other vocational vehicles and tractors requires the use of the actual fuel map in GEM.

Regarding fuel map for MY20 engines used in MY21 vehicles, we have decided that it would be more appropriate to harmonize the engine and vehicle model years, starting in MY 2021 so that vehicle manufacturers will not need fuel maps for MY 2020 engines (see 40 CFR 1037.150(n) and the definition of “model year” in 40 CFR 1037.801). Thus, we are not finalizing the requirement to provide fuel maps for MY 2020 engines. However, we are requiring fuel maps for all MY 2021 engines, even those (e.g., small businesses) for which the Phase 2 engine and vehicle standards have been delayed. See 40 CFR 1036.150(n).

Organization: Cummins, Inc.

II. Engine Fuel Map Input to GEM

1. Cummins supports use of a cycle average map for evaluating the ARB transient cycle in GEM in the final rule

In the time since the proposal, EPA and manufacturers have completed significant additional testing and analysis to validate the use of a cycle average fuel map as input to the Greenhouse Gas Emissions Model (GEM) used for vehicle certification. The NODA contains some of the new data related to the cycle average approach originally described in the NPRM, including test results from Southwest Research Institute (SwRI) in EPA-HQ-OAR-2014-0827-1619 and NHTSA-2014-0132-0184 on more engine models (Cummins ISB and Navistar N13 engines) and ratings (ISB 300 and 200 hp) and comparisons of various numerical methods for using the cycle average map to predict engine fuel consumption across a variety of vehicle configurations. [EPA-HQ-OAR-2014-0827-1927-A1 p.2]

The results from SwRI and from other EPA and industry tests continue to show that the cycle average map is accurate in predicting engine fuel consumption on the ARB transient cycle and that robust numerical methods such as global regression models can be implemented in GEM. As a result, the latest version P2v2.1 of GEM released with the NODA at EPA-HQ-OAR-2014-0827-1626 and NHTSA-
2014-0132-0181 now accepts a cycle average map as the fuel map input for evaluating vehicles over the ARB transient cycle. [EPA-HQ-OAR-2014-0827-1927-A1 p.2]

As noted in our NPRM comments, Cummins supports using a cycle average map for evaluating vehicles over the ARB transient cycle in GEM in the final rule. Because the cycle average map consists of data obtained from running the engine on transient cycles, it is more accurate than using a steady state engine fuel map and removes the need for the 1.05 transient correction factor proposed by the agencies in the NRPM. The cycle average fuel map should be the only engine fuel map allowed for evaluating the ARB transient cycle. [EPA-HQ-OAR-2014-0827-1927-A1 p.1-2]

2. *Cummins supports use of a cycle average map for evaluating the 55 and 65 mph cruise cycles in GEM in the final rule*

The latest version of GEM released with the NODA still requires a steady state engine fuel map for evaluating vehicles on the 55 and 65 mph cruise cycles. As noted in our NPRM comments, Cummins opposes the use of a steady state map due to issues such as requiring engine manufacturers to provide such trade secret and confidential business information (CBI) to competitors and the public and also poor accuracy on current and future engines. Transient accuracy can be addressed by moving to the cycle average map for the ARB transient cycle as discussed above, but disclosure of CBI is still an issue that warrants fully removing the steady state map as a required input to GEM from the final rule. The cycle average map is a reasonable alternative to address the competitive disadvantage that could result from requiring disclosure of a steady state map. [EPA-HQ-OAR-2014-0827-1927-A1 p.3]

EPA or other stakeholders have expressed the following concerns with using the cycle average map approach for the GEM cruise cycles: [EPA-HQ-OAR-2014-0827-1927-A1 p.3]

- **Accuracy on child ratings**
- **N/V overlap on generic vehicles** (where N/V is the ratio of average engine speed to average vehicle speed)
- **Issues with vehicles that cannot follow the cycles**
- **Other needs for a steady state map within GEM**

Each of these concerns will be addressed here, including presenting additional data or recommendations for resolving them such that the cycle average map can be implemented for the GEM cruise cycles in the final rule. [EPA-HQ-OAR-2014-0827-1927-A1 p.3]

(a) **Accuracy on child ratings**

EPA expressed concern with accuracy of the cycle average map for child ratings for 55 and 65 mph cruise cycles based on results of the testing performed by SwRI on the Cummins ISB 200 hp rating. That analysis used the cycle average map created from the “parent” ISB 300 hp engine to simulate the performance of the “child” ISB 200 hp engine and found poor correlation between measured and predicted results for the ISB 200 on the cruise cycles. However, when Cummins compared steady state fuel maps for the ISB 300 and ISB 200, we discovered the two ratings had different fuel rates for the same speed and load points. The analysis released in the NODA did not assess the steady state map performance on the ISB child rating. Cummins’ own analysis shows that performance of the cycle average map on the cruise cycles is similar to the steady state map when the same certification process
of applying the parent map to the child rating is applied in both cases. See Figure 1 which compares the
ISB 200 fuel consumption using the ISB 300 parent steady state map to the ISB 200 fuel consumption
using the ISB 300 parent cycle average map. [EPA-HQ-OAR-2014-0827-1927-A1 p.3-4]

[Figure 1 can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

Another issue contributing to poor correlation is due to the vehicle configurations chosen to assess the
ISB cycle average map on the 65 mph cruise cycle. Four of the six additional vehicle configurations
chosen to evaluate accuracy (different from the generic vehicle definitions used to generate the map
itself), shown in Figure 2, had unrealistically low axle ratios such that the vehicles did not meet
Cummins recommended gearing guidelines. These unrealistic configurations are not valid vehicles to

[Figure 2 can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

No cruise cycle concerns were raised regarding performance of the cycle average map for the ISB
parent rating. Figures 3 and 4 show good correlation associated with using the cycle average map
approach for the parent ISB 300 rating on the cruise cycles. Cycle average map accuracy is as good as
or better than the steady state map. [EPA-HQ-OAR-2014-0827-1927-A1 p.5]

[Figure 3 can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

[Figure 4 can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

To further evaluate child rating accuracy, Cummins recently completed testing of a Cummins ISL
engine. Figures 5 and 6 again show good accuracy using the cycle average map on the parent rating, the
ISL 450 hp, for the cruise cycles. [EPA-HQ-OAR-2014-0827-1927-A1 p.6]

[Figure 5 can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

[Figure 6 can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

When we used the procedure which would be used in the certification process to apply the ISL 450
parent maps to an ISL 300 hp child rating, the GEM output was equivalent between the cycle average
map and the steady state fuel map approaches, as shown in Figure 7. [EPA-HQ-OAR-2014-0827-1927-
A1 p.7]

[Figure 7 can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

(b) N/V overlap on generic vehicles Some stakeholders have encountered issues with the proposed
generic vehicle definitions used to generate the 55 mph engine cycles for populating the cycle average
map with results over an appropriate range of N/V. The N/V of a lower axle ratio vehicle configuration
has “overlapped” with the N/V of a higher axle ratio vehicle configuration, resulting in poor coverage in
N/V space by the cycle average map. (While the lower axle ratio vehicles are included to reach lower
N/V values, in some cases the lower axle ratio results in a change in shifting that causes a higher N/V
which overlaps with the N/V of the higher axle ratio). [EPA-HQ-OAR-2014-0827-1927-A1 p.8]

Some revision of the generic vehicle definitions is needed. Currently, axle ratio for each test cycle is
calculated based on running at 65 mph in top gear at various defined engine speeds. Those same axle
ratios are also applied in generating the 55 mph cycles. Revising the definitions to use a different axle ratio calculation based on 55 mph in top gear (instead of 65 mph) can prevent N/V overlap for the 55 mph cycle. Considering the purpose of defining generic vehicles is to develop the cycle average map over a suitable range of engine operation, revising the definitions in this way is appropriate. [EPA-HQ-OAR-2014-0827-1927-A1 p.8]

Cummins demonstrates successful use of the revised definitions in Figure 8, which shows an improvement in the range of N/V covered and no overlap compared to the generic vehicle definitions from the NPRM. [EPA-HQ-OAR-2014-0827-1927-A1 p.8] [Figure 8 can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

(c) Issues with vehicles that cannot follow the cycles Other cycle average map accuracy issues can be traced to vehicle configurations that do not follow the cycle. For example, certain vehicle specifications are not geared to run at 65 or even 55 mph. Since such a vehicle is likely to be a low speed/urban vocational vehicle, the weightings of the cruise cycles would be low. These vehicles should not be used to assess cycle average map accuracy on the cruise cycles and would need to be handled uniquely for certification. The question of whether a 65 mph cycle should be used to certify a vehicle that cannot run 65 mph is valid no matter what fuel map approach is used. [EPA-HQ-OAR-2014-0827-1927-A1 p.9]

(d) Other needs for a steady state map within GEM Other arguments that have been stated for requiring an engine-specific steady state map in GEM are that it is necessary for GEM to execute shift logic or to generate the engine speed and torque cycles for cycle average mapping. Cummins has completed analysis to show that for these purposes, using a generic steady state map has minimal effect on vehicle fuel consumption or engine cycle work and N/V compared to using an engine-specific steady state map. [EPA-HQ-OAR-2014-0827-1927-A1 p.9]

Cummins ran GEM for eight vehicle configurations to compare the GEM output when the transmission used an engine-specific steady state map for shifting versus when the transmission used a generic steady state map for shifting. The two maps were different in their shapes and fuel consumption values. The maximum differences in GEM outputs for two key parameters are shown in Figure 9. There is no significant change in vehicle fuel consumption when the generic steady state map is used to execute shift logic in GEM. [EPA-HQ-OAR-2014-0827-1927-A1 p.9] [Figure 9 can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

Cummins also investigated the impact of using a generic steady state fuel map in GEM for generating the engine speed and torque cycles needed to create cycle average maps. Figures 10-12 show no significant changes in N/V or cycle work space compared to using an engine-specific steady state map. Many of the points align exactly, and any slight movement of points is inconsequential because the purpose is to generate the map, not to hit a specific target N/V or cycle work. These two analyses confirm that an engine-specific steady state map is not needed in GEM. A generic steady state map is sufficient and a reasonable alternative that would not require manufacturers to disclose CBI. [EPA-HQ-OAR-2014-0827-1927-A1 p.10] [Figures 10-12 can be found on p.10-11 of docket number EPA-HQ-OAR-2014-0827-1927-A1]

Cummins sees no technical or policy reasons for the agencies to require a steady state fuel map as an input to GEM. Cummins is also not aware of any progress in protecting the confidentiality of a manufacturer’s steady state engine fuel map. Given the unresolved issues with requiring disclosure of CBI associated with the steady state map, we urge the agencies to implement only the cycle average
map in the final rule. If the agencies do not remove the steady state map as a required input to GEM, they should at least allow engine manufacturers the option of providing a cycle average map for evaluating the 55 and 65 mph cruise cycles instead of a steady state map. With such an option, use of a generic steady state fuel map should also be allowed for executing shifting within GEM and generating engine cycles. [EPA-HQ-OAR-2014-0827-1927-A1 p.12]

Finally, using the cycle average approach to represent the engine in GEM cruise cycles is consistent with the powertrain test option, which has already been proposed to use cycle average maps to evaluate both the transient and cruise GEM cycles. [EPA-HQ-OAR-2014-0827-1927-A1 p.12]

III. Conclusion

Significant progress has been made by the agencies and industry in answering open questions outlined in the NPRM and elsewhere regarding the cycle average map approach. Its accuracy has been validated across multiple engine models including child ratings. The cycle average map has been shown to be just as accurate (and more accurate in the case of transients) as a steady state map. Additionally, robust regression models have been developed for predicting points inside and outside the mapped regions, and improvements related to generic vehicle definitions and vehicles that cannot follow the cycles are being discussed. Cummins remains committed to collaborating with the agencies and industry to finalize a rule that fully and successfully implements the cycle average map approach. [EPA-HQ-OAR-2014-0827-1927-A1 p.12]

Response:

In the final rule, we use cycle average approach to replace steady state engine fuel map for the transient ARB cycle in GEM runs, and then we allow manufacturers to have an option to either use the cycle average approach or steady state engine fuel maps for certification using GEM. The testing data obtained from many different engines show that the regression model used for cycle average approach can be effectively used to address parent/child rating issues. We also recognize the issue with N/V overlap, specifically on 55mph cruise speed cycle. Consequently, we allow different axle ratio between 55 and 65mph cycles. Most of technical information and improvements on parent/child rating, N/V overlap and steady state maps issues can be seen in details from SAE paper 2016-01-8018. These improvements were also reflected in the changes made to 40 CFR 1036.540.

With regard to vehicles that cannot meet the trace, these vehicles map qualify to be except from the vehicle standards if they meet the requirements defined in 40 CFR 1037.631. One of the criteria of this section is that the vehicle has a maximum speed at or below 54 mi/hr.

For vehicles that use the cycle average mapping procedure in 40 CFR 1036.540 for the cruise cycle the steady-state fuel map that is needed by GEM for the shift strategy is defined in the Appendix of 40 CFR part 1036.

Organization: Daimler Trucks North America and Detroit Diesel Company

[Redacted]

Here is the engine the agencies assumed:

[Figure can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1918-A2]

[Redacted]

In short, we have significant concerns about the agencies’ standards for the gasoline powered HDVs. [EPA-HQ-OAR-2014-0827-1918-A2 p.4]

Response:

The agencies’ 2018 baseline engine fuel map was developed based on a 2015 MY HD gasoline engine with low pressure loop exhaust gas recirculation (LPL-EGR) and cam phasing technology, which could be representative of a technology baseline in 2018 MY. EGR can improve efficiency in several ways. It enables full-map stoichiometric operation, improves the ratio of specific heats of the working fluid, lowers heat loss in-cylinder due to reduced combustion temperatures and reduces knock tendency which allows more favorable combustion phasing and/or an increase in compression ratio. All of these effects can be observed in the test cell. Cam phasing was altered from baseline cam timing based upon our EGR experience. At low loads, normal to late cam phasing was used. At mid-loads, late cam phasing was used. Cam phasing for high loads was selected for best volumetric efficiency. Because of these technologies applied to the existing engine, the characteristics of the fuel map have be altered from the 2015 MY fuel map. We believe that this engine technology package only represents one of many potential paths to achieve the gasoline vocational vehicle standard. More detailed explanation and derivation on the gasoline engine map can be seen in the SwRI final report titled “Validation Testing for Phase 2 Greenhouse Gas Test Procedures and The Greenhouse Gas Emissions Model (GEM) for Medium- and Heavy Duty Engines and Powertrains” [EPA-HQ-OAR-2014-0827].

Organization: Daimler Trucks North America LLC

GEM Software Bugs - The agencies request for us to identify GEM software bugs, which would lead EPA to make additional changed to GEM before the Final Rule. 80 FR 40191. We have worked extensively with the agencies since the NPRM’s publication and have shown them some bugs. We continue to find them, however, due to the complexity of the program and the fact that the agencies continue to change it. We strongly recommend that the agencies try to lock down GEM then set a thirty day period for GEM power users to test this new version and submit comments. [EPA-HQ-OAR-2014-0827-1164-A1 p.43]

Fuel map measurement - The agencies propose a procedure for measuring fuel maps for use in GEM. We agree with this procedure. [EPA-HQ-OAR-2014-0827-1164-A1 p.44]

Response:

We appreciate DTNA’s comments. We have been considering all comments obtained from all of our stakeholders through multiple GEM power user releases including pre-NODA and post-NODA releases,
allowing users to have ample notices and time to respond and help the agencies to debug GEM. This process allows us to lock down a version that can model vehicles in a most realistic way. Please see the agencies’ response in RTC Section 15.5 regarding the notice and comment of GEM versions.

**Organization:** Eaton Vehicle Group

**Performance-based standards**

The EPA has adopted a computer model simulation approach to vehicle certification that in principle drives performance-based standards. However, we recognize that it is impossible to simulate all technologies that contribute to fuel efficiency and that at some point a limit is reached between the accuracy of physics-based models coded in GEM, their fundamental modeling assumptions, and the quality of measured data in the lab. These limit the ability to measure the performance of some technologies (e.g., predictive controls or the effect of automation on drivers). Other technologies become either computationally intractable or require a complex modeling framework that make model validation impossible (e.g., sophisticated engine and shift controls). Furthermore, it is impossible to predict all of the technologies that might be relevant to certification through 2030. We believe the powertrain test can be used to quantify the benefits of many technologies. In rare cases, such as predictive powertrain management, post-processing the GEM results is appropriate with a “slightly conservative” offset based on industry best practice (sometimes referred to as “Drop-down menus”). However, these should rarely be used so they do not compete unfairly with technologies that should legitimately be recognized through a powertrain test.

We recognize the need to expedite the certification process and simplify the test and administrative burden. It may be tempting to achieve these goals through higher use of “drop-down menus.” We are concerned that such an approach may drive the wrong technologies in the market by chipping away from the performance-based standards approach and replacing it with a features-based approach. Higher grades in the regulatory cycles and the consistent treatment of manual drivers described below are examples of how the “drop-down menu” or post-GEM simulation feature-based efficiency credits may be avoided.

**Response:**

We agree that the powertrain test can be used as one of the most effective approaches to quantify the benefits of many technologies. We also recognize that it would still be expensive to use this approach to quantify all technologies if we use alternatives to simplify the process with a simpler and effective approach. That is the reason why we derived an approach using technology improvement inputs in GEM to account for those technologies that cannot be easily modeled but whose effectiveness can be quantified today without the need to be evaluated with the powertrain test or other test method. Detailed technology improvement inputs are included in 40 CFR 1037.520(j). We have carefully considered the public comments as well as CBI to determine the value of the technology improvement inputs that we adopted. We are confident that those values for the technology improvement inputs used in GEM can simplify the process to recognize those technologies. However, as the commenter states, it is impossible to predict all of the technologies that may be relevant in the future years. Therefore, the agencies are maintaining the off-cycle credit provisions (see 40 CFR 1036.610 and 1037.610).

**Organization:** GILLIG LLC
GILLIG is very concerned with the timing required for the proposed certification process and the impact it would have on our business, employee jobs, delivery of replacement buses to municipalities, jobs at those municipalities, and those who use public transportation daily. Although not addressed in the proposed rule, it would make sense to us that the engine fuel maps that we would enter into GEM would be from fully certified engines. It is common that certification for our engines has come in Q4 and many of those in December of the year preceding the engine model year change. We see acquiring these fuel maps, running GEM, submitting our request for our vehicle certificates of conformance, EPA processing of those submissions and subsequent granting of the certificates extremely difficult to accomplish in time for an early vehicle model year changeover. Delay of these certifications will also delay processing of our applications for CARB EO’s. Not having certified vehicle configurations to build would bring transit bus production at GILLIG to a standstill, delay delivery of replacement buses to municipalities responsible for sustaining transportation services, impact jobs at those municipalities, inconvenience those who travel and depend on public transportation, and be financially devastating for our business and our employees. We request the Agencies consider eliminating the Phase 2 proposal for entering engine fuel maps in GEM and consider continuing the Phase 1 approach using a standard engine in GEM for transit buses. [EPA-HQ-OAR-2014-0827-1156-A1 p.5]

Response:

The final rule includes several provisions to address the timing concerns raised by the commenter. Manufacturers of transit bus chassis have the option in the final rule to certify to the custom-chassis standards which use a default engine fuel map defined by the agencies in GEM. In addition, the agencies have harmonized the vehicle model years to align with the engine model years (see 40 CFR 1037.150(n) and the definition of “model year” in 40 CFR 1037.801). Finally, the agencies streamlined the certification requirements during the application of certification and only require GEM simulations of ten vehicle configurations covering the range of CO\textsubscript{2} emissions expected during the year’s production (see 40 CFR 1037.205(o)).

Additional response to GILLIG’s related comments regarding stockpiling are included in RTC Section 13.2.5.

Organization: Isuzu Motors Limited

(1) GEM model results are inaccurate compared to actual (real world) test results due to rolling resistance and Aerodynamic Value (CdA) being a fixed number in GEM. These physical parameters can vary for different vehicles and applications. Therefore Isuzu believes CdA needs to be reconsidered for all truck classifications and we are willing to meet with the agencies to discuss our results. [EPA-HQ-OAR-2014-0827-1263-A1 p.2]

Response:

We have validated GEM against many testing data, including extensive comparisons over vehicle chassis dynamometer, powertrain tests, and real world driving conditions over two very well controlled trucks. The detailed comparisons and discussion can be seen in Chapter 4 of the RIA.

Please see the agencies’ response to CdA for vocational vehicles in RTC Section 6.2.1.
Organization: Navistar, Inc.

As the Proposed Rule is currently structured the engine standard is effectively pulled ahead of its nominal start date. Engine fuel maps are now part of the GEM input process. That means, to run GEM for each individual vehicle, and to determine fleet-wide averages for overall compliance, a compliant fuel map for an engine must be available. Of necessity, therefore, this pulls ahead the requirement to develop the MY2021 engine since the fuel map is a key component that must be developed well before MY2021. Essentially, manufacturers have to obtain the fuel map for the engine we believe a full 15 months before the actual standard comes into effect in model year 2021. The result is effectively a staggered compliance deadline, which differs by engine and vehicle. [EPA-HQ-OAR-2014-0827-1199-A1 p.7]

The data requirements of GEM cannot effectively drive the compliance dates. First, this would have obvious lead time implications where less than four years lead time and three years of stability is provided. This is as applicable for the second and third tier implementation dates as for the first. Second, it essentially renders much of the Preamble NPRM misleading at best. For instance, the NPRM states that “[E]PA considered proposing Phase 2 standards that would begin before MY 2021—that is with less lead time.” The NPRM also states that, with regard to the engine standard, the “EPA determined that earlier model year standards would not be appropriate, especially given the value of harmonizing the NHTSA and EPA standards.” And yet, as a practical matter, that is exactly what the Proposed Rule does—namely provide less lead time—since the regulation effectively forces development of that engine at least one year prior to 2021. Navistar agrees with EPA that a requirement that effectively forces the industry to develop a compliant engine 15 months prior to the nominal effective period is not appropriate. To do so would be arbitrary and capricious. [EPA-HQ-OAR-2014-0827-1199-A1 p.8]

Moreover, for a vehicle manufacturer that acquires engines from a third party supplier, the vehicle manufacturer is left at the mercy of the third party manufacturer. The Proposed Regulation requires the manufacturer provide MY2020 fuel maps, but the MY2019 maps will also be needed for the first few months of calendar 2020 (MY2021 for the vehicle). There is no requirement, however, that a third party supplier to provide a MY2021 compliant engine within the regulation. Similarly, this could drive the costs up for engines if third party manufacturers charge higher prices to deliver engines or fuel maps significantly ahead of the regulatory deadline. Using the engine model year to define the GHG model year for both engine and vehicle will ensure that the standards align for a given vehicle. [EPA-HQ-OAR-2014-0827-1199-A1 p.8]

In addition, the model year definition will cause significant disruption in certain industries, school bus manufacturing in particular. School buses are ordered and manufactured on a specific schedule that is dictated by the school year. In most cases, the buses are ordered for delivery over a short period in the summer, between school years. As a result, common industry practice is to have a nominal model year for school buses that can be a full model year before other vehicles. To change this would cause significant disruption which could, among other things, impact the resale value of the vehicles due to a potential model year skip or overlap as manufacturers are forced to adjust model years. In recognition of this and other pre-existing industry standards, the agencies should adopt a provision that allows model year modifications where there are specific industry conditions that justify a departure from normal model year designations or to recognize a “regulatory only” model year for certain vehicle classes. [EPA-HQ-OAR-2014-0827-1199-A1 p.8]

One of the primary concerns with the fuel mapping approach—namely its impact on timing—is addressed elsewhere in these Comments. Navistar also opposes the adoption of a cycle average map in this
Proposed Rule. This is not actually proposed within the NPRM, but is discussed generally in the RIA. We have, as a result, have not seen the regulatory language that would implement the procedure and, frankly, do not fully understand what the procedure would involve. As a result, almost by definition, the agencies should not proceed with adopting such a procedure without further opportunity for notice and comment, including disclosure of the potential language. Regarding the uncertainties of this approach, we could not have stated them any better than the agencies in this quote from the RIA: [EPA-HQ-OAR-2014-0827-1199-A1 p.19]

The following questions are only a subset of the questions that need to be answered:[EPA-HQ-OAR-2014-0827-1199-A1 p.19-20]

-How does this alternative approach address parent and child rating? Would nine points be adequate to cover the practical range of the vehicle operation on the road?

-How can this approach address those points that may be out of map ranges with much higher or lower N/V?

-What kinds of numerical schemes, interpolation or surface fitting, shall be used to interpolate those points that are located between testing points?

-What the numerical scheme shall be used to extrapolate those points outside the maps?

-How robust are these numerical schemes?

-Can what we have learned so far be applied to other engines?

-How the single engineering certification point shall be selected among the number of engine tests?

These are all excellent, very much open, questions that we feel preclude the option of this alternative being adopted during this rulemaking. They are also not fully reflective of the other questions that may be raised by this alternative. [EPA-HQ-OAR-2014-0827-1199-A1 p.20]

Though these questions remain open, the insights we have gathered so far indicate that this may be a highly burdensome procedure. Analysis of prior year’s sales data shows that the alternative engine mapping approach would require almost three times as many engine tests as the proposed BSFC map approach. The increase in the number of tests is due to the fact that engines can be used across vehicle classifications and, as currently defined, would require a separate test for each vehicle sub-family (class 8 tractor and vocational, class 2b-7 vocational, and Class 8 HH). By contrast, the BSFC map approach requires one engine test and that map is applicable across all vehicles without the need for extrapolation of points outside the generic vehicle test points. In addition, Navistar is not in favor of measuring NOx or other constituents not directly addressed by this rulemaking. In this regard, we fully agree with EMA’s comments on this point. [EPA-HQ-OAR-2014-0827-1199-A1 p.20]

Response:

We have decided that it would be more appropriate to harmonize the engine and vehicle model years, starting in MY 2021 so that vehicle manufacturers will not need fuel maps for MY 2020 engines (see 40
CFR 1037.150(n) and the definition of “model year” in 40 CFR 1037.801)). Thus, we are not finalizing the requirement to provide fuel maps for MY 2020 engines. However, we are requiring fuel maps for all MY 2021 engines, even those (e.g., small businesses) for which the Phase 2 engine and vehicle standards have been delayed. See 40 CFR 1036.150(n).

We understand Navistar concerns on cycle average approach. However, we initiated this approach in the fall of 2014, in collaboration with five manufactures, one of which was Navistar. Since then, we have received strong support from most of the major engine and HD vehicle manufacturers. More importantly, significant progresses have been made in both the engine dynamometer tests and the test procedure development. Six different engine platforms including Cummins ISX, ISB, ISL engines, Navistar N13 engines, Volvo D13 engines and a Ford gasoline engine, some of which were conducted at the manufacturer’s site. Parent and child ratings were also extensively tested. More information on cycle average approach related to parent/child rating, N/V overlap issues, and the accuracy of the regression models can be seen in details from the SAE paper 2016-01-8018. All the results point to the same direction – cycle average approach is more accurate than the steady state map approach, specifically in the transient cycle even with a transient correction factor. Regarding test burden, we have reduced numbers of the engine test points to determine the steady state fuel map used with the two cruise cycles in GEM from 143 in the NPRM to 100 points in the final rule, thus reducing significantly the test burden. In addition to reducing the number of steady-state test points 40 CFR 1036.540 allows test points to be consolidated so that only 9 points are needed to cover the full range of vehicles the engine will be installed in. According to our assessment, we expect that the cycle average approach testing time plus the steady state engine fuel map testing time based on the procedures adopted for the final rule to be similar in the time that would have been required to conduct the steady state fuel mapping process included in the NPRM. With regard to the question if 9 points are enough, this was looked at with the test data collected Oakridge National Laboratory and doubling the number of points from 9 to 18 had minor effect on the accuracy of the method. In summary, we believe that use of cycle average approach is the best approach with respect to evaluating performance on the transient cycle, and a reasonable alternative for evaluating steady state cycle performance. With this change, we removed the transient correction factor proposed in NPRM.

Organization: PACCAR, Inc.

Engine Mapping for Vehicle Assessments in GEM May Need Revision
PACCAR has reviewed both the primary Steady-State Fuel Map approach and the alternative Cycle Average approach for generating fueling data that would be used in GEM’s vehicle assessment. Advantages and disadvantages with both were found. [EPA-HQ-OAR-2014-0827-1204-A1 p.21]

PACCAR will continue to work with the agencies to assess these methods and ensure that unintended consequences are avoided. [EPA-HQ-OAR-2014-0827-1204-A1 p.22]

The alternate method provides a viable option of quantifying CO2 for specific vehicle configurations using the Phase 2 GEM model, but has some concerns as detailed below. As noted in the draft Regulatory Impact Analysis (RIA), the method can only be applied to each specific cycle. That is, the

35 Memos to Docket, “Test Procedure Review with Cummins, Volvo, Navistar, Paccar, Daimler Eaton and Allison.”

36 Oakridge National Laboratory, July 2016, paragraph 2.2.2 of “Powertrain Test Procedure Development for EPA GHG Certification of Medium- and Heavy-Duty Engines and Vehicles”
transient, 55 MPH, and 65 MPH cycles must each have a separate CO2 surface generated and used independently. The range of input values provided for the nine (9) sample configurations provided in Table 3-32 in the draft RIA requires more study to verify that it sufficiently spans the operating space in terms of N/V (engine RPM per km/h) and cycle work (horsepower hour) for all available vehicle configurations. It is recommended that the range of axle ratios and especially CdA values be expanded slightly. In particular, vehicle configurations having higher cycle work than those shown in the draft RIA must be accounted for. [EPA-HQ-OAR-2014-0827-1204-A1 p.22]

Response:

We appreciate Paccar’s support on this matter. We did consider Paccar’s specific recommendations on increasing the axle ratio range and CdA values to make the cycle average approach more robust, and consequently we revise the test procedure to reflect these changes (40 CFR Part 1036.540). As Paccar is aware, we initiated this approach in the fall of 2014. Since then, we have received strong support from most of the major engine and HD vehicle manufacturers. More importantly, significant progresses have been made in both the engine dynamometer tests and the test procedure development\textsuperscript{35}. Six different engine platforms including Cummins ISX, ISB, ISL engines, Navistar N13 engines, Volvo D13 engines and a Ford gasoline engine, some of which were conducted at the manufacturer’s site. Parent and child ratings were also extensively tested. More information on cycle average approach related to parent/child rating, N/V overlap issues, and the accuracy of the regression models can be seen in details from the SAE paper 2016-01-8018\textsuperscript{34}. All the results point to the same direction – cycle average approach is more accurate than the steady state map approach, specifically in the transient cycle even with a transient correction factor. Regarding test burden, we have reduced numbers of the engine test points to determine the steady state fuel map used with the two cruise cycles in GEM from 143 in the NPRM to 100 points in the final rule, thus reducing significantly the test burden. According to our assessment, we expect that the cycle average approach testing time plus the steady state engine fuel map testing time based on the procedures adopted for the final rule to be similar in the time that would have been required to conduct the steady state fuel mapping process included in the NPRM. In summary, we believe that use of cycle average approach is the best approach with respect to evaluating performance on the transient cycle, and a reasonable alternative for evaluating steady state cycle performance. With this change, we removed the transient correction factor proposed in NPRM.

Organization: Truck & Engine Manufacturers Association (EMA)

Cycle-Average Engine Map

The agencies have requested comment on a potential alternative to the proposed 143-point steady-state engine fuel map, referred to as a “cycle-average map,” in an effort to address confidentiality, accuracy, and other concerns relating to the proposed 143-point map approach. (See 80 FR at 40193, and RIA Section 3.10). Open questions around the treatment of child engine ratings, applicability across various engine/vehicle configurations, and test procedures for the alternative approach are being assessed by several manufacturers and the agencies. EMA is evaluating the concept. [EPA-HQ-OAR-2014-0827-1269-A1 p.26]

Response:

Regarding cycle average engine map, we initiated this approach in the fall of 2014. Since then, we have received strong support from most of the major engine and HD vehicle manufacturers. More importantly, significant progresses have been made in both the engine dynamometer tests and the test procedure development\textsuperscript{35}. Six different engine platforms including Cummins ISX, ISB, ISL engines,
Navistar N13 engines, Volvo D13 engines and a Ford gasoline engine, some of which were conducted at the manufacturer’s site. Parent and child ratings were also extensively tested. More information on cycle average approach related to parent/child rating, N/V overlap issues, and the accuracy of the regression models can be seen in details from the SAE paper 2016-01-8018. All the results point to the same direction – cycle average approach is more accurate than the steady state map approach, specifically in the transient cycle even with a transient correction factor. Regarding test burden, we have reduced numbers of the engine test points to determine the steady state fuel map used with the two cruise cycles in GEM from 143 in the NPRM to 100 points in the final rule, thus reducing significantly the test burden. According to our assessment, we expect that the cycle average approach testing time plus the steady state engine fuel map testing time based on the procedures adopted for the final rule to be similar in the time that would have been required to conduct the steady state fuel mapping process included in the NPRM. In summary, we believe that use of cycle average approach is the best approach with respect to evaluating performance on the transient cycle, and a reasonable alternative for evaluating steady state cycle performance. With this change, we removed the transient correction factor proposed in NPRM.

**Organization:** Truck & Engine Manufacturers Association (EMA)

### 4. Default Engines in GEM

The updated version of GEM does not include generic engine fuel maps for 2021, 2024 and 2027. Manufacturers need the generic fuel maps to evaluate the vehicle-level custom chassis vocational vehicle technology packages outlined in EPA’s February 12, 2016, memorandum, which was released with the NODA. Additionally, the generic engine fuel maps are needed to evaluate the GEM output improvements from vehicle technologies that will be deployed in other vehicle categories. To isolate and assess the GEM contributions from different vehicle technologies, manufacturers must be able to input a generic engine fuel map for each stringency step in the proposed regulation.

**Response:**

We have provided adequate notice on the GEM features and detailed source code with multiple power user pre-NODA and post NODA releases, allowing users to understand how the engine fuel maps are interacted with vehicles. Please see the agencies’ responses to the GEM releases in RTC Section 15.5. Providing generic engine fuel maps would not help the manufacturers to understand how the engine would contribute the total vehicle performance for the primary vocational vehicle and tractor programs. Rather, users can use their own engine fuel maps to achieve the same goal. In addition, releasing 2021, 2024 and 2027 maps to public means that we will release the engine standards for the final rule before the rule is signed. For the vehicle-level custom chassis vocational vehicle, we provided the default engine fuel maps.

**Organization:** Volvo Group

**Engine Mapping**

The engine fuel and torque map used in GEM is truncated above the maximum mapping test speed as shown in the plot below. To properly evaluate urban vehicles that are gear bound below 65 MPH, the torque and fuel map should be extended linearly to zero at the high idle point for each engine. Otherwise vehicle speed for a gear-bound driveline is truncated and will not run on the governor droop under light
load conditions (such as moderate down-hill) as is the case in actual operation. [EPA-HQ-OAR-2014-0827-1290-A1 p.52-53]

Alternative Engine Certification via Cycle Average Method

EPA has been working with a number of manufacturers (not including Volvo Group) for more than a year on an alternative process to conventional engine mapping. A conventional engine fuel map has been used for many years by all manufacturers for vehicle simulation. This is the method proposed in NPRM section 1036.535. Given our long experience with vehicle simulation using this type of fuel map, we are confident that we understand how the method works and its limitations. One such limitation is variation between transient fuel consumption and the steady state consumption measured in the mapping process. We had previously discussed the possibility to run a typical engine transient test which could be the FTP or a test based on a typical vehicle set-up using the GEM ARB cycle output (engine torque and speed vs. time) to establish the engine’s transient efficiency that could be compared to the output using the steady state map to establish a transient correction factor. [EPA-HQ-OAR-2014-0827-1290-A1 p.53]

Further extension of these ideas led to the concept of eliminating the steady state fuel map and establishing a new concept wherein the engine is tested over a number of cycles based on GEM output for a range of vehicle load factors, driveline set-ups, and each of the regulatory duty cycles (ARB, 55 MPH, 65 MPH). The result is a matrix of 27 engine test cycles (3 load factors x 3 drivelines x 3 duty cycles). This output is used to create a 3 dimensional map plotting cycle work, cycle average engine fuel consumption, and N/V (average ratio of engine speed to vehicle speed based on GEM output for each cycle). [EPA-HQ-OAR-2014-0827-1290-A1 p.53]

Volvo Group recently began investigating this proposal because EPA stated that they are seriously considering this method or possibly a “hybrid method” where cycle average is used for the ARB transient cycle and conventional fuel mapping is used for highway cycles with constant speed targets. Our efforts have been hampered because the method is not clearly documented in any one place in EPA’s proposal that allows for complete analysis and comment. There is no test description with regulatory details. Instead, limited discussion is found in the RIA and certain technical papers. We also have received some limited information from discussions with various regulatory staff. Based on this information, we have attempted to glean what we believe is a somewhat representative picture of the intended process. From this, we provide some preliminary comments on our observations. We note, however, that Volvo Group has not been provided sufficient information to comment fully or adequately on this provision. [EPA-HQ-OAR-2014-0827-1290-A1 p.53-54]

It is unclear how the “parent” rating within an engine family should be defined when using this process. Whereas a maximum torque rating would typically produce the best brake specific fuel consumption (BSFC) on an engine emissions test cycle, it may well result in the highest fuel consumption on a vehicle cycle based test. Also, we question how various transmission types might impact the results. We can envision a vehicle with a transmission with many gears or even a continuously variable transmission that would operate an engine over a very narrow operating speed range. We could also envision a similar vehicle with a transmission with few gears that required the engine to operate over a wide speed range but with an axle ratio that resulted in the same N/V as the first vehicle. These two vehicles would have similar cycle work and similar N/V but significantly different engine operation and efficiency. Yet this method would simulate both with the same efficiency. We do not believe the testing has adequately addressed the range of possible drivetrains and efficiency outcomes. [EPA-HQ-OAR-2014-0827-1290-A1 p.54]
Because GEM does not include an engine torque response function, torque changes in the GEM output are instantaneous. But real engines have a torque lag due to the need to develop boost from the turbocharger and to manage emissions. Hence the engines cannot actually follow the engine cycle output from GEM. This means that the engine test results in somewhat lower cycle work than the GEM output. [EPA-HQ-OAR-2014-0827-1290-A1 p.54]

GEM shift management resulted in the engine running at speeds well below low idle where the engine would stall out. The Agency recommended that we ignore these test areas and run at the closest speed and load that the engine could sustain. [EPA-HQ-OAR-2014-0827-1290-A1 p.54]

Using the vehicle configurations prescribed to develop the engine test cycles resulted in GEM downshifting (appropriately) at low axle ratio on the 55 MPH cycle. This resulted in an N/V that essentially overlaid the 65 MPH cycle with a higher axle ratio which (appropriately) ran in top gear. This, in turn, resulted in the software being forced to extrapolate into an N/V and cycle work range that was never tested resulting in inaccurate results when tested against a vehicle driveline that was not part of the mapping matrix. [EPA-HQ-OAR-2014-0827-1290-A1 p.54]

All these results were shared with EPA and quite possibly corrections can be devised. Nonetheless, we have little doubt that additional issues will surface as the full range of transmissions, axles, engines and vehicle configurations are run through this method. Our conclusion is that the method is not adequately developed to be used as the test method in the final rule. We note in particular that EPA has failed to provide adequate notice of the method, and an adequate description of what it is proposing, sufficient to allow for meaningful comment. [EPA-HQ-OAR-2014-0827-1290-A1 p.54]

If the agencies intend to pursue this approach, it must be done as a revision to the final rule or perhaps as a technical amendment, when and if it is thoroughly tested and demonstrated to be effective and robust. In addition, any change of this magnitude will have a significant effect on the GEM outcomes. Regulatory standards must be adjusted if such a change is promulgated. [EPA-HQ-OAR-2014-0827-1290-A1 p.54-55]

Response:

The full torque curves for all the engine fuel maps includes zero torque point at the highest possible engine speed. We added transient torque response to the engine model in GEM. The torque response is determine from the engine’s displacement and the torque curve of the parent engine rating of the engine family. We also significantly improved GEM’s shifting strategy when operating at low idle speed. We improve our test procedure to mitigate N/V overlap issues in 40 CFR part 1036.540.

Regarding cycle average engine map, we initiated this approach in the fall of 2014. Since then, we have received strong support from most of the major engine and HD vehicle manufacturers. More importantly, significant progresses have been made in both the engine dynamometer tests and the test procedure development. Six different engine platforms including Cummins ISX, ISB, ISL engines, Navistar N13 engines, Volvo D13 engines and a Ford gasoline engine, some of which were conducted at the manufacturer’s site. Parent and child ratings were also extensively tested. More information on cycle average approach related to parent/child rating, N/V overlap issues, and the accuracy of the regression models can be seen in details from the SAE paper 2016-01-8018. All the results point to the same direction – cycle average approach is more accurate than the steady state map approach, specifically in the transient cycle even with a transient correction factor. Regarding test burden, we have reduced numbers of the engine test points to determine the steady state fuel map used with the two cruise cycles in GEM from 143 in the NPRM to 100 points in the final rule, thus reducing significantly
the test burden. According to our assessment, we expect that the cycle average approach testing time plus the steady state engine fuel map testing time based on the procedures adopted for the final rule to be similar in the time that would have been required to conduct the steady state fuel mapping process included in the NPRM. In summary, we believe that use of cycle average approach is the best approach with respect to evaluating performance on the transient cycle, and a reasonable alternative for evaluating steady state cycle performance. With this change, we removed the transient correction factor proposed in NPRM.

Please see the agencies’ responses related to GEM notice and comment in RTC Section 15.5
3 Test Procedures and Engine

3.1 General Comments

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

The draft proposal calls for a whole vehicle and separate engine standard. The final regulations should not include an engine standard that OEMs will have a difficult time complying with. It is a consolidated market place and an overly stringent standard could lead to monopoly pricing. An overly stringent engine standard could also lead to the very boom bust cycle we are seeking to avoid. There is nothing in this regulation to prevent OEMs from investing in more efficient engines and gaining credits that could be applied to meet stringency requirements. OEMs should be free to meet the stringency standards in the way that best suits their business model. These regulations rightfully should offer pathways on how to meet the standard but should not dictate the path a given company takes. [EPA-HQ-OAR-2014-0827-1248-A2 p.9-10]

**Organization:** Mass Comment Campaign sponsored by anonymous 1 (email) - (23)

Specifically, I ask for stronger engine standards to further reduce climate pollution and protect our children and families. Please finalize engine standards several times stronger than the weak standards proposed. [EPA-HQ-OAR-2014-0827-1341-A1 p.1]

With stronger engine standards that take effect no later than model year 2024, our communities will be better protected from the harmful pollution emitted by big freight trucks and buses. [EPA-HQ-OAR-2014-0827-1341-A1 p.1]

**Organization:** Mass Comment Campaign sponsored by Sierra Club (email) - (26,917)

It is critical that the agencies strengthen these standards, particularly the engine standard, to ensure efficiency improvements throughout freight trucks. [EPA-HQ-OAR-2014-0827-0814-A1 p.1]

**Organization:** Motor & Equipment Manufacturers Association (MEMA)

**Maintain Existing Regulatory Framework** [EPA-HQ-OAR-2014-0827-1274-A1 p.2]

**Provide More Flexibilities to Ensure Engine Technologies are Utilized** [EPA-HQ-OAR-2014-0827-1274-A1 p.4]

There may be some opportunities to further drive innovation and technology for engines that are still achievable in the Phase 2 timeframe. Under different aspects of the NPRM, the agencies did propose various ways to try and better represent real-world service applications and MEMA commends these revisions to the Phase 2 program. For example, under the engine component of the proposed rule, the agencies did make some adjustments to the Phase 2 SET cycle weighting. The agencies acknowledge that the task to represent all real-world applications is difficult and they seek feedback from stakeholders on ways to achieve as broad a representation as possible, while still allowing for the recognition of real-world service and the beneficial impacts from various technologies and systems. With regards to the SET cycle, MEMA believes the agencies’ revisions are generally tracking in the right direction and we do not take issue with the test procedures themselves. As an example, real world
engines operate at a lower operating RPM levels than what the proposed test cycle emphasizes (with a lower operating RPM range, the result is a gap between real world operations and test settings). MEMA encourages the agencies to identify potential gaps and make them as small as possible. Bringing the gap closer to real-world operating conditions will help the agencies avoid either unintentionally disincentivizing operational improvements that could have real impact on optimizing engine efficiencies or, conversely, potentially drive technologies that do not result in CO2 reductions. [EPA-HQ-OAR-2014-0827-1274-A1 p.5]

MEMA anticipates that some of our member companies will address these issues more specifically in their comments. [EPA-HQ-OAR-2014-0827-1274-A1 p.5]

**Organization:** Navistar, Inc.

Navistar feels the following are key areas the agencies must address: [NHTSA-2014-0132-0094-A1 p.2]

- Engine standards must be adjusted to account for the cumulative impact of the various requirements, including N2O, and their feasibility is also predicated on the stability of other emission requirements, such as NOx. [NHTSA-2014-0132-0094-A1 p.2]

**Organization:** Robert Bosch LLC

Bosch also opposes the proposed rule’s uneven handling of vocational vehicle engines. Just as there should be technology neutrality in the HD pickup truck and van sector, so, too, should there be neutrality under Phase 2 for vocational vehicle engines. [EPA-HQ-OAR-2014-0827-1466-A2 p.8]

**Response:**

As reflected later in the context of more detailed comments, the agencies recognize the need to balance the benefits of establishing stringent engine standards against the risks of setting standards that are too stringent. This is true both in the context of the diesel engine standards by themselves and in the context of the SI engine standards relative to the diesel engine standards.

### 3.2 Regulatory Structure - Separate Engine Standards

**Organization:** Achates Power, Inc.

We recognize the importance of a separate engine efficiency standards, for a number of reasons: [NHTSA-2014-0132-0049-A1 p.2]

- The EPA has a robust compliance program based on engine testing, making it straightforward to hold engine manufacturers accountable. Without a separate engine standard, in-use compliance becomes more subjective. Having clearly defined compliance responsibilities is important to both the government agencies and market participants. [NHTSA-2014-0132-0049-A1 p.2]
- Engine standards for CO2 require engine manufacturers to optimize engines for both efficiency and for non-CO2 emissions, particularly for NO emissions given the strong counter-dependency between engine-out NO, and fuel consumption. By requiring engine to meet both NO, and CO2 standards, manufacturers will include technologies that optimize for both rather than alternative
calibrations that would trade lower NOx emissions for higher CO2 emissions depending on how the engine and vehicle is tested. [NHTSA-2014-0132-0049-A1 p.2]

- Because engine fuel consumption can vary significantly between transient and steady-state operations, only steady-state engine date is required for chassis certification. The separate engine standard for vocational vehicles provides the only measure of engine fuel consumption under transient conditions. [NHTSA-2014-0132-0049-A1 p.2]

- A separate engine standard enables the federal agencies to exempt certain vehicle classes from some or all of the vehicle standards without foregoing efficiency improvements. [NHTSA-2014-0132-0049-A1 p.2]

To be effective in achieving these benefits, however, the separate engine standard must not only be commercially acceptable and reasonable, but also meaningful. The new MDV and HDV standards are designed to 'spur innovation, encouraging the development of and deployment of existing and advanced cost-effective technologies for a new generation of cleaner, more fuel-efficient commercial trucks....' The standard are meant to be set 'not only on currently available technologies but also on utilization of technologies now under development or not yet widely deployed while providing significant lead time to assure adequate time to develop, test, and phase in these [technologies].' [NHTSA-2014-0132-0049-A1 p.2-3] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.287.]

**Organization:** Advanced Engine System Institute (AESI)

AESI is pleased that the Agency has proposed to retain the basic regulatory structure used in Phase 1, including a separate engine standard and similar testing and certification procedures. Our industry has invested heavily in research and systems to deliver cost-effective greenhouse gas reductions to meet the Phase 1 schedule while meeting the 2010 standards for NOx and PM. Retaining a separate engine standard with the appropriate compliance enforcement will help ensure the long term environmental integrity of the program. [EPA-HQ-OAR-2014-0827-1152-A1 p.1] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.289.]

**Organization:** American Automotive Policy Council

Model Approach for Vocational Vehicles while AAPC has concerns about the technical details of the proposed Phase 2 GEM model which will be detailed below, we believe that a model-based approach that looks at the powertrain and chassis as a whole can be an effective way to drive CO2 and fuel consumption improvements through the vocational vehicle fleet. While engine standards should be maintained as a “no-backsliding” provision (hold engine standards at 2017 levels), the inclusion of the engine, transmission, and chassis as a system in a more sophisticated GEM model more accurately reflects the ways in which manufacturers deliver on-road CO2 and fuel consumption benefits to their customers. [EPA-HQ-OAR-2014-0827-1238-A1 p.31]

Conceptually, this could be an improvement over the Phase 1 approach in which only tire rolling resistance was reflected in the model for vocational vehicles and key components such as transmissions were not included at all. Assuming our concerns with the technical details of the model can be addressed, an accurate GEM model-based approach will drive efficiency improvements to engines, transmissions, and chassis technologies. [EPA-HQ-OAR-2014-0827-1238-A1 p.31]

**Organization:** Association for the Work Truck Industry (NTEA)
**Regulatory Structure**

The NTEA supports the Agencies’ structural approach to the rules. It is logical to separate out the four vehicle categories as they tend to be both built and utilized in different manners. Of the categories, vocational trucks will be the most diverse vehicle population, as noted by the possible chassis, body and equipment configurations available in the marketplace. This diversity also continues in the manufacture process. [EPA-HQ-OAR-2014-0827-1187-A1 p.2]

**Organization:** Autocar, LLC

**Autocar Supports Separate Engine and Vehicle Standards**

Autocar supports the Agencies’ proposal to maintain separate engine and vehicle standards in Phase 2 for vocational vehicles. For Low-speed/Frequent-stop Vehicles in particular, the engine offers the greatest potential for reducing GHG emissions and fuel consumption. Such vehicles have no opportunity for fuel consumption improvement though aerodynamics and other highway-speed technologies. Maintaining standards at the engine level facilitates the Agencies’ and Autocar’s proposed exemptions and exceptions for certain vehicle and manufacturer types without foregoing the engine improvements, ensuring positive environmental impact across a broader range of applications. [EPA-HQ-OAR-2014-0827-1233-A1 p.16]

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Separate engine and vehicle standards**

The NPRM requests comment on the choice to maintain separate engine and vehicle standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.29]

CARB staff strongly agrees with U.S. EPA and NHTSA’s choice to maintain separate engine standards for the following reasons.

- Engine standards directly address the source of GHG emissions and ensure some efficiency improvements at the engine level will be achieved over the useful life of the vehicle. Without an engine standard, some vehicle manufacturers could elect to rely more heavily on vehicle technologies to meet emission standards. These technologies may prove to be less effective at reducing emissions as the vehicles’ vocation changes over time. For example, line-haul tractors with aerodynamic technologies would see less of a benefit from the aerodynamic technologies if placed into local-haul service by a second owner. [EPA-HQ-OAR-2014-0827-1265-A1 p.30]

- Separate engine standards based on the direct measurement of GHG emissions from engines can be directly verified for compliance using existing engine test protocols: U.S. EPA’s heavy-duty engine ramped-modal Supplemental Emission Test (SET) and heavy-duty engine transient emissions test, i.e., the Federal Test procedure (FTP). [EPA-HQ-OAR-2014-0827-1265-A1 p.30]

- The SET and FTP would continue to be used to certify heavy-duty engines to GHG emission standards, as well as the criteria pollutant emission standards. This provides a direct link between the
GHG emission measurement and NOx emission measurement methods for certification. [EPA-HQ-OAR-2014-0827-1265-A1 p.30]

**Comment on Topic Where NPRM Requests Comment**

**Comment – Full vehicle simulation approach (advantages and disadvantages)**

The NPRM requests comment on the proposed approach for full vehicle simulation. CARB staff generally supports the proposed full vehicle simulation approach, and is in favor of GEM including additional subsystems to provide manufacturers greater design flexibility and incentivize the development of vehicles that fully realize the GHG benefits of well-integrated systems. [EPA-HQ-OAR-2014-0827-1265-A1 p.103]

Additionally, the NPRM requests comment on whether the Phase 2 full vehicle simulation proposal, which potentially requires engine manufacturers to disclose proprietary engine performance information to vehicle manufacturers long before production, would enable the “reverse engineering” of engine manufacturers’ intellectual property, and if so, what steps U.S. EPA and NHTSA could take to address this issue. While CARB staff recognizes that this proposed approach will likely require engine manufacturers to disclose more detailed engine design and performance information early in production cycles, certainly earlier than currently occurs, CARB staff believes this will be a positive development that will facilitate better engine, component, and vehicle integration necessary for achieving maximum, cost-effective fuel efficiency improvements and GHG benefits. [EPA-HQ-OAR-2014-0827-1265-A1 p.103]

**Comment on Topic Where NPRM Requests Comment**

**Comment – Chassis dynamometer test procedure**

The NPRM requests comment on whether a chassis dynamometer test procedure should be required in lieu of the proposed vehicle simulation approach. CARB staff supports chassis testing for vehicles that are already emissions certified on chassis dynamometers and provisions for similar vehicles that can also be tested using widely available chassis dynamometer testing resources, as proposed in the NPRM. These are the lighter end of the heavy-duty vehicle range. [EPA-HQ-OAR-2014-0827-1265-A1 p.113]

The NPRM’s proposed chassis dynamometer testing requirements will expand the data set of chassis dynamometer emissions measurements, which will help provide data needed to evaluate vehicle integration success. CARB staff believes chassis dynamometer testing is critical for assessing engine, powertrain, and vehicle integration effects on GHG emission levels. For its own testing needs, CARB staff is committed to developing a robust in-house test program by aggressively working to expand its heavy-duty chassis dynamometer testing capacity for the comparison of chassis data with simulation, PEMS, and engine/powertrain test data. [EPA-HQ-OAR-2014-0827-1265-A1 p.113]

20 See page 40195 of the NPRM for more details of the technology

21 See page 40195 to 40196 of the NPRM for more details of the technology

**Organization:** Caterpillar Inc.
PROMOTE INNOVATION—FOCUS ON FULL VEHICLE OPTIMIZATION BY ELIMINATING ENGINE-BASED STANDARDS

As we examine new, fuel-saving technologies for heavy-duty vehicles, Caterpillar believes vehicle manufacturers must be allowed to focus design efforts on the complete vehicle in order to optimize fuel economy, without the incremental constraint of engine-based standards. Based on our extensive experiences with nonroad equipment, both the opportunities and magnitude of vehicle GHG reductions significantly outweigh possible engine-based GHG reductions. A total systems perspective, considering application variability and appropriately tailoring technologies, provides a broader landscape to advance the optimization of fuel efficiency, productivity, and cost – factors which all lead to a win-win result for both the environment and customers. [EPA-HQ-OAR-2014-0827-1189-A1 p.3]

As an efficiency and productivity proof point, this total systems approach has allowed Caterpillar to be recognized as a major innovator of fuel-saving and GHG-reducing technologies in nonroad equipment. For example, our Caterpillar model 336E H hydraulic hybrid excavator has been demonstrated through a grant from the California Energy Commission to reduce fuel consumption by 30 percent on a per-ton basis. Similarly, our Caterpillar D7E track-type tractor was awarded the 2008 EPA Clean Air Excellence Award for reducing fuel consumption by 10 to 30 percent (depending on work load/cycle) and increasing dozing efficiency by 25 percent (cubic yards moved/gallon of fuel) compared to previous models. These are just two examples of where a system focus rather than an engine focus resulted in substantial efficiency gains. [EPA-HQ-OAR-2014-0827-1189-A1 p.3]

From a cost efficiency perspective, vehicle-based GHG reductions are expected to be lower cost than engine-based reductions. Cost is a key customer buying criteria. The engine should not be treated differently from a GHG perspective than any other vehicle component. There are many components and design selections that must be made on a vehicle. If the EPA constrained each component to certain parameters, (i.e. engine, transmissions, driveshaft, axles, differential, rims, tires, cab, HVAC, APU, etc.) the likely result is that vehicle design would be tightly controlled using components that have essentially been prescribed by EPA. Vehicle manufacturers would have to focus vehicle design efforts on ensuring each individual component met EPA standards rather than spending development efforts on optimizing the system as a whole. The cost of GHG reduction would be higher, and the amount of GHG reduction achievable would be hindered. [EPA-HQ-OAR-2014-0827-1189-A1 p.3]

We urge EPA to allow vehicle manufacturers to fully optimize the entire vehicle as this greatly improves GHG opportunities, and decreases the cost of such reductions. [EPA-HQ-OAR-2014-0827-1189-A1 p.3]

Organization: Caterpillar Inc., et al.

Engines are best evaluated based on how they operate in the vehicle, considering the engine size and power output, the vehicle power demand, and the driveline characteristics – that is, by the full vehicle approach. The engine’s operating efficiency is fully accounted for in the complete vehicle evaluation, rendering separate engine standards redundant. The Agencies, however, have proposed in the NPRM to establish separate engine standards. It’s absolutely essential that the Agencies avoid setting overly stringent engine standards to avoid repeating the market disruptions the industry experienced when introducing diesel particulate (DPF) technology in 2007. To this end, we are opposed to any decrease in the engine standards as proposed. [EPA-HQ-OAR-2014-0827-1215-A1 p.4]

Organization: Cummins, Inc.
The Agencies recognize that separate engine standards have been successfully used to “achieve emissions reductions from complete vehicles that operate on road,” while providing a “well-established, representative, and robust set of engine test procedures” for emissions compliance enforcement (80 FR 40147, 40181). Using the same protocols for criteria and GHG emissions ensures linkage between all pollutants, forcing consideration of all constituents when optimizing engine performance and emissions. With differing certification cycles, one could trade-off GHG improvement at the expense of nitrogen oxides (NO\textsubscript{x}) increases. Such a situation would undermine regulatory integrity and environmental benefits from criteria emission reductions achieved over the years. Furthermore, engine certification captures both steady-state and transient behavior that is absent in the vehicle program. Advantages of separate engine standards are identified in the Preamble (80 FR 40181-182) and detailed further in Cummins oral arguments\textsuperscript{1} and comments to NHTSA\textsuperscript{3}. [EPA-HQ-OAR-2014-0827-1298-A1 p.6]

For Phase 2, EPA and NHTSA are proposing to maintain dividing the commercial vehicle industry into three categories (combination tractors, vocational vehicles and HD pickups and vans), while continuing separate engine and vehicle standards for combination tractors and vocational vehicles. The Phase 2 regulatory proposal adds a fourth category for trailers to establish standards for this component of tractor vehicles. Cummins fully supports this regulatory structure, especially the separate engine program. [EPA-HQ-OAR-2014-0827-1298-A1 p.6]

Engine standards also acknowledge the non-integrated nature of the commercial vehicle market and allow for multiple suppliers of engines and powertrain options for a given vehicle original equipment manufacturer (OEM). Customers can continue to buy a common certified engine and use it in a wide range of vehicle applications, ensuring emissions reductions and economic and regulatory efficiencies across the diversity of vehicles that exist in the marketplace. [EPA-HQ-OAR-2014-0827-1298-A1 p.6-7]

Cummins opposes features of the proposed rule that undermine regulatory integrity [EPA-HQ-OAR-2014-0827-1298-A1 p.7]

Regulatory integrity means that the intended improvements in emissions are assigned appropriately and directly to the engine and vehicle, are realized in real-world use and can be physically verified and enforced. [EPA-HQ-OAR-2014-0827-1298-A1 p.7]

The biggest threat to regulatory integrity is a disconnect between engine NO\textsubscript{x} and CO\textsubscript{2} regulations. This can arise in several ways, including: (a) different test protocols for each pollutant; (b) significant engine operation outside the criteria-emission Not-To-Exceed (NTE) zone; (c) implicit engine emissions stringency at the vehicle level that is not recognized in engine testing; and (d) lack of robust means to assure compliance in-use and to link NO\textsubscript{x} with CO\textsubscript{2} at the vehicle level. [EPA-HQ-OAR-2014-0827-1298-A1 p.7]

[Figure 1 can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

The 55 MPH cycle is outside the NTE zone, suggesting that future vehicles are expected to operate a considerable amount of time outside of this emissions control zone. This means a vehicle could emit higher NO\textsubscript{x} emissions which would not be assessed during the in-use enforcement program. Furthermore, since the NTE region is tied to the engine torque curve, there is an incentive for engine manufacturers to skew the torque curve to higher speeds to draw the NO\textsubscript{x} NTE zone farther away from the cruising engine speed. This concern could be addressed in a future criteria emissions rulemaking by expanding the NTE zone as defined in 40 CFR 86.1370(b) for engines with transmissions such as Continuously Variable Transmissions (CVT). [EPA-HQ-OAR-2014-0827-1298-A1 p.8-9]
Cummins cautions the Agencies against this approach. First, implicit engine stringency in the vehicle program decouples engine CO2 improvements from compliance with standards for oxides of nitrogen (NOx). This threatens the regulatory integrity of the rule by creating a structure in which in-use NOx emissions can be increased by operation outside expected NOx regulatory limits while in-use CO2 emissions are reduced. Second, it allows trading of directly measurable and enforceable improvements at the engine level for less certain and unenforceable improvements at the vehicle level. Third, implied standards lack the regulatory clarity required for focused and sustained innovation in engine technology. For these reasons, required engine CO2 reductions should be explicit in the engine standard, and engine procedures should continue to link CO2 with criteria emissions. [EPA-HQ-OAR-2014-0827-1298-A1 p.10 and 12] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.47-48.]

(d) The vehicle standard in Phase 2 employs computer simulation to calculate the integrated effect of all component improvements. This is useful for all applications but also problematic for translating apparent benefits for line-haul trucks into real-world effects. To be sure, there are “vehicle”-level technologies that will convey real CO2 benefit, but there are no existing integrated-vehicle test protocols that can be used to validate real-world performance and assure in-use compliance. For this reason, all CO2 reduction that is expected and required from the engine should be assigned explicitly to the engine in the engine standard. It can be physically verified and enforced with protocols that have been honed by EPA and industry over three decades. And by using these established engine certification protocols for both CO2 and criteria emissions, regulators can also assure continued compliance with current and future criteria emission standards as greenhouse gases are reduced. This is an especially important point to protect against increases in NOx emissions as CO2 is being reduced and to ensure CO2 reductions are protected as future reductions in NOx emissions are contemplated. [EPA-HQ-OAR-2014-0827-1298-A1 p.12-13]

In addition to enabling direct assurance of performance, assignment of all required engine CO2 reductions explicitly in the engine standard also provides clear direction to engine manufacturers for technology investment and innovation required to meet future GHG goals. [EPA-HQ-OAR-2014-0827-1298-A1 p.13]

1 See Appendix A for the full text of the testimony. [p.44 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

3 See Appendix B. [p.48 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

4 Criteria emissions are HD exhaust emissions controlled under the Clean Air Act and include oxides of nitrogen (NOx), particulate matter (PM), hydrocarbons (HC) and carbon monoxide (CO).

Organization: Daimler Trucks North America LLC

Basing vehicle and engine standards on the same technologies - EPA requests comment on whether the engine and vehicle standards should be based on the same projected technologies. 80 FR 40191. DTNA has maintained that the best approach to Phase 2 is for the standards to be based on complete vehicle fuel efficiency wherein technologies that are applied to the engine are integral to complete vehicle package. The separation of standards between the engine and the vehicle creates a number of

Page 472 of 2127
problems. The most significant problem (which EPA has attempted to at least partially correct with their proposed revisions to the SET test procedure) is the problem of defining an engine test cycle that truly represents the engine operation across a range of powertrain configurations anticipated when Phase 2 takes effect and for powertrains beyond that time. Clearly, no such cycle exists since differing power train designs will result in differing engine operating points. Consequently, the level of improvement from a given technology that is projected onto a fixed engine test cycle will differ from the level of improvement when the technology is projected in simulation across a range of vehicle configurations. This leads to the problem that as powertrains diverge actual engine operation from the fixed test cycle, and as the stringency of the engine certification standards increases, engine manufacturers become driven to apply technologies to improve efficiency on the test cycle but which may derive little benefit in real use. For these reasons and others that DTNA believes that complete vehicle certification where the actual fuel map is included in the simulation is the strongly preferred path. DTNA agrees that engine and vehicle standards should be based on the same technologies but that the magnitude of improvements of each for a given technology need to consider where in the engines operating map the improvements are realized and the differences in how the test cycles operate the engine within the operating map. [EPA-HQ-OAR-2014-0827-1164-A1 p.15]

Mutual exclusivity of engine standard and GEM: EPA states that the use of a fuel map in GEM should eliminate concerns that a separate engine standard and a full vehicle standard are mutually exclusive. 80 FR 40180. While the inclusion of the engine map in GEM helps alleviate some concerns, the existence of the separate engine standard still carries with it this concern. An engine improvement can conflict with a vehicle improvement despite the engine being in GEM. For example, if an engine manufacturer optimizes the engine around the A speed such that vehicles using that engine can be very heavily downspeeded, the result will likely be lower fuel consumption on the road and in GEM—even if the A-speed optimization harmed B and C speed fuel consumption to a greater extent. It is possible to see technologies that show in-vehicle/real-world improvements that do not show up on the cycle. If this means that the engine OEM with the better real-world performing engine does not meet the standard, then either way the cost of this engine has to increase which means in reality a less expensive and less efficient engine becomes more attractive. The agencies should recognize when an engine configuration results in improved on-road fuel efficiency but worse engine dynamometer test results, and the agencies should exempt such engines from strict compliance with the engine test standards—knowing that the ultimate concern is fuel consumption and GHG emissions on real roads not in a test cell. [EPA-HQ-OAR-2014-0827-1164-A1 p.15-16]

Preface - DTNA fundamentally disagrees that separate engine standards are needed in Phase 2 but nonetheless provides comments in response to EPA’s request for comment on engine-side stringency. 80 FR 40156. [EPA-HQ-OAR-2014-0827-1164-A1 P.19]

Other Structures Considered: Chassis Dyno Testing – The agencies request comment on whether a chassis dynamometer test procedure should be required in lieu of the vehicle simulation approach being proposed. 80 FR 40178. EPA requests comment regarding the alternative of chassis dynamometer testing in lieu of the simulation approach that is proposed (80 FR 40178). DTNA is strongly in favor of the proposed simulation approach for multiple reasons many of which led EPA to the conclusion that a simulation approach was most appropriate in Phase 1, and now again in Phase 2. Chassis dynamometer testing as a path for vehicle certification is highly impractical considering the tremendous burden of testing the large number of powertrain and vehicle variants as compared to the simulation approach. [EPA-HQ-OAR-2014-0827-1164-A1 p.67]
More on EPA Alternatives - The agencies have presented a sufficiently wide range of alternatives representing various approaches to further regulating the heavy-duty industry, with the exception of one alternative that was not presented and should be – namely not having a separate engine standard. The agencies should add to their current discussions on the pros and cons of maintaining a separate engine standard, and add an alternative that estimates the benefits and costs of not including a separate engine standard. An additional alternative could be presented on including an anti-backsliding engine standard as opposed to the technology-forcing standard proposed in Alternative 3/the preferred approach. [EPA-HQ-OAR-2014-0827-1164-A1 p.73]

Technology neutral standards: The EPA proposes technology neutral standards. We agree that this is the right approach. Prescribing technology to vehicle manufacturers is not the right role for the EPA. That said, the agencies should recognize that—although they purport to create technology neutral standards—in creating a separate engine standard alongside a vehicle standard, the agencies depart from technology neutrality, forcing technology onto the engine even if the same net emissions impact on-road could be achieved through vehicle-side technologies. We recommend that, upon a showing from a manufacturer that a vehicle-side technology creates extra emission reductions beyond those necessary for vehicle-side compliance, that the manufacturer be able to convert those extra emission reductions into an engine-side credit (and vice versa). Only with such an allowance will the agencies truly achieve the technology neutrality that they claim their regulations have. [EPA-HQ-OAR-2014-0827-1164-A1 p.116]

Organization:  Daimler Trucks North America, Navistar Inc., Paccar Inc., and the Volvo Group

Recommendation

EPA and NHTSA should not increase the engine efficiency targets proposed in the NPRM. As a fundamental principle, separate engine standards provide no environmental or energy efficiency benefit because the GHG reduction benefits are calculated only with the engine incorporated into the vehicle. Therefore increasing the stringency of a separate engine standard provides no direct environmental benefit. [EPA-HQ-OAR-2014-0827-1894-A1 p.3

Consequently, the separate engine standards should be set at a level that avoids unintended consequences. EPA and NHTSA should recognize the importance of considering the engine as an integrated part of a complete vehicle. With this approach, the agencies can avoid forcing engine optimization on fixed test cycles that do not, and cannot, replicate how the engine operates in each vehicle. [EPA-HQ-OAR-2014-0827-1894-A1 p.3

The conflicting arguments in the subject paper demonstrate that overly stringent separate engine standards are inappropriate, unnecessary, and counterproductive. As we have argued, it is fundamental that the engine influence on the vehicle (size, weight, cooling demand, and cost) and the vehicle influence on the engine (power demand, gearing, and controls) must be considered. Furthermore, from a purely economic perspective, OEMs should be able to develop and choose the efficiency technologies that best fit with their capabilities and expertise to meet regulatory GHG objectives and customer requirements. This will increase competition and innovative approaches while providing optimized products with greater market acceptance. EPA should support this and acknowledge that the engine specific regulation is meant to ensure a level of improvement to be achieved with minimal potential tradeoffs on other vehicle efficiency features, and to ensure some continued link to criteria emissions testing. [EPA-HQ-OAR-2014-0827-1894-A1 p.4-5]

Conclusion:
Furthermore, there is no efficiency or GHG contribution from a separate engine standard that is not already included in the complete vehicle standard. The logical and appropriate conclusion is that engine improvements should be driven from the complete vehicle standard and any separate engine standard should represent a level that can be achieved without compromise in vehicle efficiency or lowest total cost of vehicle operation, not an aggressive limit that forces manufacturer to focus on the engine over other potential efficiencies. EPA and NHTSA have accomplished this in their phase 2 proposal. These engine targets should not be made more stringent. [EPA-HQ-OAR-2014-0827-1894-A1 p.20]

**Organization:** Eaton Vehicle Group

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, pp. 38-39.]

Eaton believes that the separate engine and vehicle standards found in Phase 1 should be maintained in Phase 2. The separate standards reflect the reality of the commercial vehicle market, drive adoption of efficient technologies, and provide a structure that is proven and accepted in the U.S. market today.

**Organization:** Engine Research Center

I applaud the agencies in recognizing the importance of a separate engine efficiency standards, for a number of reasons: [EPA-HQ-OAR-2014-0827-1141-A1 p.1]

• The EPA has a robust compliance program based on engine testing, making it straightforward to hold engine manufacturers accountable. Without a separate engine standard, in-use compliance becomes more subjective. Having clearly defined compliance responsibilities is important to both the government agencies and market participants. [EPA-HQ-OAR-2014-0827-1141-A1 p.1]

• Engine standards for CO2 require engine manufacturers to optimize engines for both efficiency and for non-CO2 emissions, particularly for NOx emissions given the strong counter-dependency between engine-out NOx and fuel consumption. By requiring engine to meet both NOx and CO2 standards, manufacturers will include technologies that optimize for both rather than alternative calibrations that would trade lower NOx emissions for higher CO2 emissions depending on how the engine and vehicle is tested. [EPA-HQ-OAR-2014-0827-1141-A1 p.2]

• Because engine fuel consumption can vary significantly between transient and steady state operations, only steady-state engine data is required for chassis certification. The separate engine standard for vocational vehicles provides the only measure of engine fuel consumption under transient conditions. [EPA-HQ-OAR-2014-0827-1141-A1 p.2]

• A separate engine standard enables the federal agencies to exempt certain vehicle classes from some or all of the vehicle standards without foregoing efficiency improvements. [EPA-HQ-OAR-2014-0827-1141-A1 p.2]

**Organization:** Environmental Defense Fund (EDF)

1. **Strong engine standards are critical to a meaningful program**

We reiterate our strong support for the Agencies’ proposed structure of the rule – separate engine standards are imperative to drive innovative engine technology and provide proven, measureable and
durable real-world emissions reductions. However, these benefits can only be realized through robust engine standards. Weak standards, as proposed by the Agencies, do not drive advanced technologies and fall short of unlocking the full capabilities of existing technologies. Additionally, limited engine standards do not take advantage of the robust in-use enforcement provisions of the engine program. These provisions provide high confidence that GHG reductions demonstrated on new engines actually occur in the real world. In order to secure the significant benefits afforded by separate engine standards, the Agencies’ must finalize far more meaningful standards that drive technology and allow for robust enforcement. [EPA-HQ-OAR-2014-0827-1886-A1 p.3]

**EDF supports a separate engine standard as a key element of a strong rule**

EDF fully supports the proposed inclusion of a separate engine performance standard and full vehicle performance standard. An engine performance standard for each vehicle class is an essential element of a well-designed heavy-duty fuel efficiency program for several reasons. First, engine standards provide proven, measureable and durable real-world emissions reductions. Engine standards also help to drive development of advanced engine technologies, which can provide a significant proportion of total vehicle fuel efficiency potential. An engine standard also allows EPA and manufacturers to simultaneously evaluate oxides of nitrogen (NOx) and carbon dioxide (CO2) emissions, ensuring efficiency improvements do not result in higher NOx emissions and vice versa. We encourage the agencies to finalize a robust separate engine standard (see Section VI below). In addition to an engine standard, EDF supports a rigorous full vehicle standard to drive technology advancements across the rest of the vehicle, including the transmission, aerodynamic improvements, idle reduction, and more. [EPA-HQ-OAR-2014-0827-1312-A1 p.15]

**Organization:** Honeywell Transportation System (HTS)

We strongly support the separate engine standard reflected in the current proposal, as we believe a vehicle-only standard creates problems of sustainability and enforcement. For example, while tractor aerodynamic solutions can provide a tangible benefit for applications that travel long distances at sustained speeds, studies¹ have shown that these require precise adjustment which can be adversely affected in real world situations (aftermarket modifications, improper adjustment) and could negatively impact payload capability due to the increased weight. This increases an operator’s maintenance costs, increases compliance complexity for Original Equipment Manufacturers (OEMs), and creates enforcement challenges for the agencies due to additional application-specific testing, diagnostic, and inspection criteria. [EPA-HQ-OAR-2014-0827-1230-A1 p.2]

**Organization:** Manufacturers of Emission Controls Association (MECA)

MECA strongly supports EPA’s decision to retain the Phase 2 regulatory structure based on separate engine and vehicle standards that has been proven effective under the Phase 1 heavy-duty GHG standards. [EPA-HQ-OAR-2014-0827-1210-A3 p.3] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p.96.]] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.211.]]

**Organization:** Motor & Equipment Manufacturers Association (MEMA)
Although we recognize that many vehicle manufacturers are recommending elimination of the separate engine standard and removal of the alternative engine mapping approach, MEMA represents many suppliers that provide technologies that will have a direct impact at achieving the NPRM targets by having separate vehicle and engine requirements. Therefore, we support retaining separate vehicle and engine requirements to provide continuity of the standards’ regulatory structures and strike a balance between compliance and market latitude. Additionally, the longer timeframe of the Phase 2 standards provides the industry foresight to develop the technologies needed to continue to meet the standards, particularly during the middle and latter stages of the rule. These approaches are vital to the long-term success of the standards. [EPA-HQ-OAR-2014-0827-1274-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.193.]]

Organization: National Association of Clean Air Agencies (NACAA)

We strongly endorse the continued inclusion of separate but complementary standards for engines and whole vehicles – this is a fundamental aspect of the rule. [EPA-HQ-OAR-2014-0827-1157-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.51.]]

Separate engine standards are critical for the Phase 2 program because they directly address the source of GHG emissions and ensure that engine manufacturers will incorporate some level of engine efficiency improvements that will reduce GHG emissions over the useful life of the vehicle. Engine test procedures and methods have been refined over decades of implementation and provide high certainty that verifiable emission reductions will occur when engines are in use. Separate engine standards are also important because engine GHG emission levels can be directly verified through the existing engine certification test protocols: the Supplemental Emission Test (SET) and Federal Test Procedure (FTP). The SET and FTP used to certify engines to GHG and criteria pollutant emission standards, such as for oxides of nitrogen (NOx), provide a direct link between GHG and NOx emission measurement methods. Further, separate engine standards prompt development of advanced engine technologies that, in turn, can offer a substantial improvement in a vehicle’s fuel efficiency. In the absence of separate engine standards, some vehicle manufacturers may rely more heavily on vehicle improvements, such as aerodynamic technologies, that are less effective at reducing fuel consumption and emissions, particularly as vehicles change vocations, or functions, over time. [EPA-HQ-OAR-2014-0827-1157-A1 p.2]

Organization: National Automobile Dealers Association (NADA)

As with Phase 1, the Phase 2 proposal includes separate standards for tractor and vocational engines. The goal of the diesel engine mandates is to reduce GHG emissions and fuel consumption by some 4 percent over Phase 1. Consequently, 4.2 of the 24 percent improvement sought for large tractors and 4 of the 16 percent improvement for vocational vehicles must come from engine improvements by MY 2027. [EPA-HQ-OAR-2014-0827-1309-A1 p.10]

The Phase 2 proposal's long list of potential improvements for compression (CI) and spark ignition (SI) engines generally fall into the categories of combustion optimization, improved air handling, reduced friction, improved emissions after-treatment, and waste heat recovery. NADA/ATD recognizes that most, if not all, OEMs will rely on engine performance improvements to achieve compliance with the Phase 2 program. But, NADA/ATD is concerned that some of these strategies could involve disproportionately high costs as measured on a unit of benefit realized basis. Consequently, ATD urges EPA and NHTSA to: [EPA-HQ-OAR-2014-0827-1309-A1 p.10]
1. Not to include engine-only mandates in the final rule. Manufacturers should have the ability to choose the most cost-effective compliance strategies from the basket of all available options. [EPA-HQ-OAR-2014-0827-1309-A1 p.10]

2. Alternatively, engine-specific mandates should be designed only to prevent back-sliding from the Phase 1 MY 2018 standards. Moreover, manufacturers involved in both engine and vehicle manufacturing should be free to apply credits generated by “over performing” with “non-engine” strategies against their engine compliance obligations, and should be able to provide credits generated in one vehicle class or category against their compliance obligations for another. Providing OEMs with such flexibility will maximize compliance and economic efficiencies, bringing to market the most affordable compliant vehicles and engines. Since a gallon of fuel is a gallon of fuel and a gram of GHGs is a gram of GHGs, what matters most is the performance outcome, not how compliance is achieved. [EPA-HQ-OAR-2014-0827-1309-A1 p.10]

11 Advanced technology strategies include: SI engines: cylinder deactivation, direct injection, turbocharging/downsizing, and cooled exhaust gas recirculation. CI: automatic transmissions, hybridization,

Organization: Natural Resources Defense Council (NRDC)

NRDC also supports the agencies’ proposal to maintain separate engine standards. NRDC believes that the separate standard is necessary to ensure that all feasible and cost-effective advancements are made in the engine to lower carbon pollution and fuel consumption. As we noted previously, there are important opportunities for advancements in tractor engines and vocational gasoline engines. NRDC agrees with the agencies that there are advantages with maintaining separate engine standards including consistent testing with non-GHG emissions requirements that will prevent any trade-offs between carbon dioxide and emissions such as nitrogen oxides. [EPA-HQ-OAR-2014-0827-1220-A1 p.6]

Organization: Power Solutions International (PSI)

We applaud the agencies recognition for the need to have separate efficiency standards applicable to engines. Engine manufacturers are required to meet criteria emission standards and imposing the GHG emission standards on the engine allows manufacturers the opportunity to optimize the engine for fuel efficiency while developing the engine to meet criteria emissions, specifically, NOx, NMHC and CO. [EPA-HQ-OAR-2014-0827-1161-A1 p.1]

1 http://www.epa.gov/otaq/documents/eng-cert/on-hwy-2014e.xls, 2015 and 2016MY files posted appear to be incomplete

Organization: Shahed, SM

I applaud the agencies in recognizing the importance of a separate engine efficiency standards, for a number of reasons: [NHTSA-2014-0132-0033-A1 p.1]
• The EPA has a robust compliance program based on engine testing, making it straightforward to hold engine manufacturers accountable. Without a separate engine standard, in-use compliance becomes more subjective. Having clearly defined compliance responsibilities is important to both the government agencies and market participants. [NHTSA-2014-0132-0033-A1 p.1]

• Engine standards for CO2 require engine manufacturers to optimize engines for both efficiency and for non-CO2 emissions, particularly for NOx emissions given the strong counter-dependency between engine-out NOx and fuel consumption. By requiring engine to meet both NOx and CO2 standards, manufacturers will include technologies that optimize for both rather than alternative calibrations that would trade lower NOx emissions for higher CO2 emissions depending on how the engine and vehicle is tested. [NHTSA-2014-0132-0033-A1 p.1-2]

• Because engine fuel consumption can vary significantly between transient and steady-state operations, only steady-state engine date is required for chassis certification. The separate engine standard for vocational vehicles provides the only measure of engine fuel consumption under transient conditions. [NHTSA-2014-0132-0033-A1 p.2]

• A separate engine standard enables the federal agencies to exempt certain vehicle classes from some or all of the vehicle standards without foregoing efficiency improvements. [NHTSA-2014-0132-0033-A1 p.2]

To be effective in achieving these benefits, however, the separate engine standard must not only be commercially acceptable and reasonable, but also meaningful. The new MDV and HDV standards are designed to “spur innovation, encouraging the development of and deployment of existing and advanced cost-effective technologies for a new generation of cleaner, more fuel-efficient commercial trucks….“ The standard are meant to be set “not only on currently available technologies but also on utilization of technologies now under development or not yet widely deployed while providing significant lead time to assure adequate time to develop, test, and phase in these [technologies].” [NHTSA-2014-0132-0033-A1 p.2]

Organization: South Coast Air Quality Management District (SCAQMD)

In addition, we strongly support having separate emissions standards for engines and full vehicles. Without separate standards, there are no guarantees that even modest enhancements that will provide engine efficiency improvements to reduce greenhouse gas emissions over the useful life of the vehicle are made. As an example, with the recent certification of a 8.9 liter natural gas engine (see Attachment 2 and discussion below), the engine manufacturer implemented a modest enhancement of having closed crankcase ventilation system, which resulted in lower methane emissions. Other technology enhancements that can potentially result in lowering greenhouse gas emissions including improvements in combustion efficiencies, can lead to lowered greenhouse gas emissions directly from the engine. [EPA-HQ-OAR-2014-0827-1181-A1 p.2]

[Attachment 2 can be found on p.15 of this docket]

Organization: Union of Concerned Scientists (UCS)

THE NEED FOR SEPARATE ENGINE STANDARD
We agree with the agencies’ proposed structure of the rule, with separate standards for both heavy-duty engines and the vehicles that use these engines, for three reasons: 1) verifiable emissions; 2) compatibility with criteria emissions regulations; and 3) ensured investment in efficiency technologies.

While ultimately the emissions of use occur at the vehicle level, the current regulations are measured by simulation with the GEM model, not a true full vehicle test. Therefore, the engine standard provides the closest measure of true real world emissions reductions. Furthermore, unlike many other technologies which may not last the lifetime of the vehicle, such as low-rolling resistance tires or some aerodynamic add-ons, the engine cannot be tampered with nor replaced without meeting a similar level of efficiency. This helps set a guaranteed threshold of fuel savings and global warming emissions reductions throughout the entire vehicle lifetime without relying solely upon the agencies’ ability to enforce the regulations.

Currently, manufacturers must already perform a separate engine test to certify compliance with existing criteria pollution standards. Therefore, an engine test adds no additional test burden. Furthermore, this helps to ensure that vehicles are achieving reductions in global warming emissions without compromising criteria pollution standards. In addition to the engine standard test procedure, in the agencies’ proposed vehicle standard, engines used in GEM must already go through an additional engine map certification—we therefore recommend that the agencies collect this additional data on the criteria emissions during this engine mapping procedure to inform future pollution standards and further ensure that vehicles continue to achieve reductions in both criteria and global warming emissions.

The structure of the tractor market also lends itself to a separate engine standard. The largest supplier of tractor engines is independent of the four vehicle manufacturers because of the long-standing desire for vehicle purchasers to fully customize vehicles down to the precise engine, transmission, and axles offered by all suppliers. Currently, the vehicle manufacturers are split between those who are more vertically integrated and those who continue to operate in the way that the market has traditionally behaved. Given this heterogeneous network of suppliers, a separate standard for engines helps ensure that all vehicle manufacturers will be able to rely on technology innovation from individual suppliers by providing the overall certainty that a distributed marketplace cannot. This is exceptionally important in the case of engines, which have significant complexity and heightened research costs compared to many other aspects of the vehicle. This will help ensure that vehicle purchasers will continue to have a wide assortment of compliant, customizable vehicles from all makes.

Organization: Volvo Group

We fully agree that evaluating vehicle technology as an integrated package is the only effective way to approximate real world results. The Agencies’ proposal provides appropriate credits to promote development and deployment of many important efficiency technologies. Since the engine is fully included in the vehicle evaluation, there is no need for, or benefit from, setting separate engine standards.

Complete Vehicle Regulation

Volvo Group greatly appreciates that the proposed rule incorporates a complete vehicle approach utilizing a vehicle simulation (GEM) that incorporates the engine, driveline, and other key inputs that impact efficiency. GEM determines the fuel consumption and GHG emissions over an assigned road
cycle for each vehicle type. The customer’s choice of aero fairings, tire type, engine, powertrain, and other details are entered as inputs to the tool, and the output is compared to the regulated target for that vehicle category for the purpose of credit tracking and averaging. This type of modeling has been done successfully by all major heavy-duty vehicle manufacturers, by Argonne National Lab, and in the regulatory vehicle model (GEM) proposed for the Phase 2 rule. It is a proven technique that correlates well with on-road testing. In fact, modeling is a much more accurate approach than in-use or chassis dyno testing to measure efficiency differences between vehicles because test variables, such as driver differences, traffic, wind, and weather, are eliminated. Even in chassis dyno testing, driver variability is significant, key load factors (rolling resistance and aerodynamics) must be measured and simulated, and testers must compensate for tires interacting with dyno rollers. Simulation offers the most efficient, accurate, robust and repeatable means for assessing vehicle efficiency, and is therefore the ideal tool for certification to efficiency and GHG standards. [EPA-HQ-OAR-2014-0827-1290-A1 p.13-14]

Engines should not be Separately Regulated

In the Phase 1 rule, the engine is separately regulated and not included in the vehicle evaluation. Engine efficiency is measured on the test cycles developed some 30 years ago for criteria emissions evaluation, cycles that no longer reflect how engines operate in today’s vehicles. These tests do not consider the size and power output of the engine relative to the vehicle’s power demand, the installation impact of the engine system, or the impact of the powertrain on how the engine operates. Instead, each engine’s test points are based on its power and torque capability. A larger engine is tested at higher power and torque, regardless of the actual power needed for vehicles in which it will be installed. [EPA-HQ-OAR-2014-0827-1290-A1 p.14]

In recent years, Class 8 tractors (the vehicles that consume most of the commercial fleet fuel) are increasingly using automated manual transmissions or AMTs. These transmissions retain the high efficiency of a manual gearbox but use computer control to precisely and automatically shift gears without the driver operating a clutch or shift lever. Some of these, including the Volvo I-shift and Mack M-drive, sense vehicle load and road grade to optimize shifts points for maximum efficiency. Because shifting is fully automatic, drivers are no longer troubled if a downshift is required on a road grade. This has allowed the industry to increase fuel efficiency by running a lower overall gear ratio, thereby slowing the engine down at typical highway speeds. Engines have been re-optimized to increase low speed torque and to maximize efficiency at these lower speeds. This is one example of vehicle technology changing how engines operate that is reflected in a complete vehicle regulation but not in a separate engine test. The regulatory engine test cycles, even considering the reweighted RMC, would reward optimizing the engine for higher speeds where it rarely even operates in today’s trucks. An engine optimized for the regulatory cycles gets higher efficiency in the regulatory test but potentially worse efficiency on the road in service. [EPA-HQ-OAR-2014-0827-1290-A1 p.14]

In addition, as improvements are made to the aerodynamic of tractors and trailers, as tire rolling resistance is reduced, and as accessory loads are reduced, the cruise power demand of vehicles is reduced. This reduced power demand could allow for use of smaller engines or further down-speeding the engine. But bigger engines tend to be more efficient on separate engine tests due to fundamental engine thermodynamics while smaller engines tend to do better on vehicle efficiency because they operate closer to their peak efficiency torque and speed, in addition to the advantages they offer in weight and limiting inefficient driving habits. [EPA-HQ-OAR-2014-0827-1290-A1 p.14]

Perhaps the most significant problem with separately regulating an engine is the failure to consider the installation impacts of the engine and related technology. Bigger engines obviously take up more space and demand more cooling capacity that can only be efficiently provided by forcing ram air through the
radiator and charge air cooler. One of the proposed engine efficiency technologies is known as Rankine waste heat recovery. This system is much like a steam engine, using a working fluid that is pumped under pressure through a heat exchanger (or boiler) in the exhaust gas to boil the fluid. The pressurized gas is expanded through a turbine or other mechanical device to produce power that must be delivered back to the vehicle’s powertrain either mechanically through a complex gear train or electrically via a generator-motor system. The expanded gas must then be cooled back to liquid state using a condenser prior to re-entering the pumping stage. Beyond the obvious complexity, the whole system adds weight and requires space on the vehicle. Both space requirements and weight distribution can force tractor manufacturers to extend the wheel base, which may increase the trailer gap (particularly for day cabs and short sleepers) resulting in increased aerodynamic drag. Equally concerning is the substantial increase in cooling required by the condenser, resulting in further increase in aerodynamic drag that can negate any benefits of the engine efficiency. Another issue with this type system is the substantial lag time between increased power demand and power availability due to the thermal inertia of the system. In sum, the system can deliver measurable efficiency in an engine test, but may not deliver in the vehicle. The whole industry is evaluating the merits of waste heat recovery, but a lot of research is still needed to determine if this technology is worthy of industrialization. Only then should manufacturers commit to the intensive effort to make this technology reliable, durable, and cost-effective. Even so, it will only work well when it is fully developed and when it is applied with the appropriate engine and vehicle combinations to maximize its efficiency and minimize negative vehicle impacts. [EPA-HQ-OAR-2014-0827-1290-A1 p.14-15]

Engines should only be evaluated based on how they operate in vehicles, not on a fixed cycle in a test cell. Proponents of engine efficiency regulation argue that such testing is more accurate and verifiable than a complete vehicle approach. They fail to consider, however, that, the correlation between these engine tests and the desired in-use fuel efficiency is tenuous at best and may even be inverted. There is little value to highly accurate measurement of a parameter that does not correlate well with the desired goal. When the engine is measured as part of the full vehicle approach, its efficiency is mapped at more than 100 points (compared to only 13 test points in the tractor engine test) that feed into a vehicle model that exercises the engine at the speed and load points dictated by the vehicle’s power demand and drivetrain running on an appropriate road cycle, i.e. like it actually runs in the vehicle. [EPA-HQ-OAR-2014-0827-1290-A1 p.15]

Some have argued that it is important to include a separate engine standard so that manufacturers don’t neglect enhancement opportunities from the component that actually burns the fuel. The problem is that engineers have been squeezing blood from this stone for decades; this is precisely why the next level of research is aimed at evaluating technologies as exotic as waste heat recovery to eke out a few more percent from a highly mature technology. The fact that OEMs are doing this is strong evidence that OEMs are not neglecting and would not neglect engine technology without the specter of an engine standard. Furthermore, technologies integrated into the engine itself have to operate in the harshest environment found on the vehicle; if such measures are unnecessary, it does not make sense for EPA to insist that manufacturers integrate new technology into this environment. This is especially true in this rulemaking, where other opportunities for efficiency improvement exist elsewhere on the vehicle. In fact, any competitive manufacturer must look at all efficiency technologies and select those that deliver the highest customer value and meet regulatory requirements for the complete vehicle. This is amply demonstrated in the automobile market, where engine improvements are a huge part of the technology deployed to meet regulated efficiency without any requirement specifically regulating engines. [EPA-HQ-OAR-2014-0827-1290-A1 p.15]

Aside from the technical issues related to engine efficiency regulation, we note the typically high cost associated with complex engine system development and deployment. These costs include engineering
development, product cost, and manufacturing costs. More concerning however, are on-going costs and operational impacts associated with maintenance and down-time. Such costs and impacts have typically been grossly underestimated by regulators, yet they are the primary reasons customers have been reluctant to purchase such technologies. [EPA-HQ-OAR-2014-0827-1290-A1 p.15-16]

We note that there is no benefit accrued from regulating engine efficiency once the engine has been fully accounted for in the vehicle efficiency evaluation. Unlike the current (Phase 1) rule, wherein the engine is isolated from the vehicle, all benefits accrued under the Phase 2 proposal are based on reductions in fuel used and GHGs emitted from complete vehicles. There is no basis or justification for continued engine regulation. The Agencies have failed to do any assessment of the cost of engine efficiency regulation considering the loss of vehicle design flexibility, on-going testing and reporting requirements, and increased total cost of operation for vehicles. However, since there is no assignable benefit to regulating engines, any cost cannot be justified. [EPA-HQ-OAR-2014-0827-1290-A1 p.16]

Engine Efficiency

Recognizing that the Agencies have chosen to include a separate engine efficiency regulation, we encourage them not to increase stringency beyond the proposed levels. Maintaining engine stringency at these levels pushes the envelope of engine technology without forcing the many negative consequences we have outlined in these comments. Furthermore, we are very concerned that an engine manufacturer could generate significant credits (for example by selling alternatively fueled engines) so that they could avoid selling undesirable, complex, expensive engine technology, while competitors, lacking such credits, would be pushed out of the market. [EPA-HQ-OAR-2014-0827-1290-A1 p.19-20]

Response:

Separate Engine Standards

The agencies receive many comments on the proposed regulatory structure, primarily related to the need for separate engine standards. Those supporting the separate engine standards largely agreed with the agencies’ reasons given in the NPRM (80 FR 40181), that they would:

- Enhance the agencies’ compliance efforts
- Maintain a connection between GHGs and criteria pollutants (such as NOx)
- Measure transient fuel consumption control
- Enable simpler vehicle requirements for small volume and specialty vehicles

With respect to the compliance advantages, we also see a benefit to having a compliance program that is not entirely dependent upon computer simulations. ACEEE also supported separate engine standards “to set out direct, multiyear targets for engine performance sufficient to promote substantial, sustained investment in engine efficiency.” They argued that if “the only signal to improve engine efficiency is filtered through the lens of whole vehicle efficiency, there will remain uncertainly about how much of the improvement will fall to the engine.”

Those opposing separate engine standards did not dispute these advantages. Instead they expressed concerns similar to those the agencies discussed in the NPRM. However, commenters opposing separate engine standards appear to actually oppose separate engine standards that are too stringent rather than separate engine standards per se. Volvo acknowledged that the proposed stringency would not cause the adverse consequences. We addressed this issue in the NPRM (80 FR 40182):
Note that commenters opposing separate engine standards should also be careful distinguish between concerns related to the stringency of the proposed engine standards, from concerns inherent to any separate engine standards whatsoever. When meeting with manufacturers prior to this proposal, the agencies heard many concerns about the potential problems with separate engines standards that were actually concerns about separate engine standards that are too stringent. However, we see these as two different issues. The agencies do recognize that setting engine standards at a high stringency could increase the cost to comply with the vehicle standard, if lower-cost vehicle technologies are available. Additionally, the agencies recognize that setting engine standards at a high stringency may promote the use of large-displacement engines, which have inherent heat transfer and efficiency advantages over smaller displacement engines over the engine test cycles, though a smaller engine may be more efficient for a given vehicle application. Thus we encourage commenters supporting the separate engine standards to address the possibility of unintended consequences such as these.

In addition, the agencies pointed out that:

In the past there has been some confusion about the Phase 1 separate engine standards somehow preventing the recognition of engine-vehicle optimization that vehicle manufacturers perform to minimize a vehicle’s overall fuel consumption. It was not the existence of separate engine standards that prevented recognition of this optimization. Rather it was that the agencies did not allow manufacturers to enter input into GEM that characterized unique engine performance. For Phase 2 we are proposing to require that manufacturers input such data because we intend GEM to recognize this engine-vehicle optimization. The continuation of separate engine standards in Phase 2 does not undermine in any way the recognition of this optimization in GEM.

To address these opposing comments, it is helpful to consider them in the context of three relative engine stringency scenarios. For each scenario, the engine stringency is compared to levels vehicle manufacturers would choose if there were no separate engine standards.

1. For the first case, assume the engine standards were low enough that they required less technology than vehicle manufacturers would choose to apply to meet the vehicle standards. In this scenario, the concerns raised in the opposing comments would not apply. However, the benefits of having separate engine standards would occur.

2. For the second case, assume the engine standards were set so they required the same technology that vehicle manufacturers would choose to apply to meet the vehicle standards. Like the first scenario, the concerns raised in the opposing comments would not apply, but the benefits of having separate engine standards would occur.

3. For the third case, assume the engine standards were set stringent enough that they required more technology than vehicle manufacturers would choose to apply to meet the vehicle standards. Only in this scenario, would the concerns raised in the opposing comments would apply. However, since the benefits of having separate engine standards would also occur, the agencies would need to balance these against one another.

In neither the first case nor the second case would the concerns raised in the comments apply at all, so they clearly could not justify sacrificing the benefits of having separate engine standards (benefits which commenters did not dispute) under those scenarios. Thus, only under the third scenario would the
opposing comments be relevant. This is the concern raised by the vehicle OEMs. However, the agencies do not believe the standards being set are too stringent. As described elsewhere, the tractor and vocational vehicle standards are stringent, technology-forcing standards that will require vehicle manufacturers to make extensive use of available engine and vehicle technologies, including integration of the two. Although the feasibility analyses for those vehicle standards project some technological flexibility for vehicle manufacturers, we believe it to be very unlikely that manufacturers would be able to achieve the final vehicle standards with engines that significantly exceed the engine standards.

It is important to also note that we project the engine standards to be both feasible and very cost-effective. Caterpillar claimed that engine-based controls are expected to be more expensive than vehicle-based controls. We disagree. For example, we project the 2027 heavy heavy-duty tractor standards to cost $1,579 per engine to achieve a 5.1% reduction, which is comparable to the cost-effectiveness of other projected vehicle standards. Thus, if a vehicle manufacturer were to identify some less expensive vehicle technologies, it is not clear that the vehicle manufacturer’s preferred path would be to scale back these cost-effective engine reductions.

Volvo overstates the risks associated with the regulatory engine test cycles, when they argue that the reweighted RMCSET would reward optimizing tractor engines for higher speeds than are common in today’s trucks. This ignores the full range of the impacts of engine speeds, including those associated with the shape of the torque curve. We do not believe manufacturers will intentionally sacrifice in-use fuel efficiency to gain a false benefit on the engine test cycle.

Finally, even if having separate engine standards resulted in marginally higher costs than would have occurred without engine standards, the benefits of having the separate standards would still justify the costs. Therefore, the agencies are finalizing separate engine standards.

Including Engines in GEM

The agencies are finalizing the regulatory structure that includes both separate engine standards and a recognition of engine fuel maps in GEM. Some commenters expressed explicit support for including engine fuel maps in GEM to achieve full vehicle simulation. In addition, other commenters who focused their structural comments on the need for separate engine standards generally did not oppose the inclusion of engine fuel maps in GEM.

Some of the arguments raised in opposition to separate engines standards seemed to assume that having separate engine standards precluded including engine technologies in GEM. However, the final structure accomplishes both.

Chassis Testing

We are finalizing the proposed chassis testing requirements, which will:

- Continue to require chassis-testing for certification of complete HD pickups and vans.
- Add a new requirement for tractor manufacturers to perform demonstration chassis testing on a small sample of production tractors.

CARB supported expanded use of chassis testing. However, Daimler commented that chassis dynamometer is highly impractical. While we understand the potential benefits of expanded chassis testing, we also recognize the practical obstacles to widespread chassis testing. We believe the requirements being finalized strike the proper balance.
Other Regulatory Structure Issues

It is worth noting that the agencies regard the standards for pickups and vans, vocational vehicles, tractors, trailers and engines as independent of each other, functioning sensibly on their own. Thus, for example, the standard for tractors is not dependent on the engine standards (engine standards are separately implemented by engine dynamometer testing, whereas the tractor standards are implemented via GEM); the trailer standard has no relation to the vocational vehicle standard (these are separate averaging sets even after ABT is available for trailers). Also, the NHTSA fuel consumption standards are independent of the EPA greenhouse gas standards and vice versa. Each standard implements, and is justified by, each agency’s respective and distinct statutory authority. See preamble Section I.E. and Delta Construction Co. v. EPA, 783 F. 3d 1291, 1297-98 (D.C. Cir. 2015). The agencies therefore regard each of these standards as legally severable.

Although the FRM generally discusses these components separately by category, many if not all the subcategories are also legally severable. Certainly, anything separated by an averaging set would be equally severable. For example, standards for heavy heavy-duty engines and vehicles are independent of the standards for smaller engines and vehicles.

EPA has also issued engine standards for greenhouse gases other than CO\(_2\), namely N\(_2\)O and CH\(_4\). These standards are independent of the engine CO\(_2\) standards. Those CO\(_2\) standards function identically whether or not there were the standards for N\(_2\)O and CH\(_4\), and vice versa.

Finally, EPA has taken certain final actions which are exclusive to EPA programs. These include actions relating to rebuilt engines used in new chassis (i.e. glider vehicles) and certain additional actions described in Section XIII of the Preamble to the final rule. These actions are independent of the greenhouse gas standards. (The final rule indicates that glider vehicles must meet greenhouse gas standards, but the rules are structured so this requirement functions independently of the requirements providing allowances for usage of engines not meeting criteria pollutant standards for the model year the glider vehicle is assembled.)

3.3 Proposed Engine Standards for CO\(_2\) and Fuel Consumption

EPA and NHTSA project that CO\(_2\) emissions and fuel consumption reductions can be feasibly and cost-effectively met through technological improvements to diesel engines. The agencies also discussed several alternatives in the proposal. When considering alternatives, it is necessary to evaluate the impact of a regulation in terms of CO\(_2\) emission reductions, fuel consumption reductions, technical feasibility and technology costs. However, it is also necessary to consider other aspects related to feasibility and cost, such as manufacturers’ research and development resources, the impact on purchase price, and the impact on purchasers. Manufacturers are limited in their ability to develop and implement new technologies due to their human resources and budget constraints. This has a direct impact on the amount of lead time that is required to meet any new standards.

The agencies received some general comments on the overall stringency of the proposed Phase 2 diesel engine standards. Several entities encouraged the agencies to adopt more stringent standards, while other commenters cautioned the agencies from adopting final standards that are more stringent than those proposed. The agencies considered all of the general comments associated with the proposed

---

37 GEM requires a measured engine fuel map, which would also be collected using an engine dynamometer; the mapping procedure is independent of the engine standards.
engine standards and the more detailed comments. We believe there is merit in many of the detailed comments and these are discussed in detail below. Instead of merely choosing from among the proposed alternatives, the agencies have developed a set of final engine standards that reflect our reevaluation of the technologies, as well as the test procedures. Readers are encouraged to see Chapter 2 of the RIA (especially Chapters 2.6 and 2.7) which includes more detailed discussions of each technology, updated to reflect new information provided in the comments.

As can be seen from the comments, there is uncertainty and a wide range of opinions regarding the extent to which these technologies can be applied to heavy-duty engines. Vehicle manufacturers tended to take the conservative position for each technology and argue that the agencies should not project effectiveness or adoption rates beyond that which is certain. Many other commenters took a more optimistic view and argued for the agencies to assume that each potential technology will be highly effective. However the agencies believe the most likely outcome will be that some technologies will work out better than expected while others will be slightly more challenging than projected. Thus, the agencies have tended to make balanced projections for the various technologies, although some may be slightly optimistic while others are somewhat conservative. We believe the overall effect of this approach will be standards that achieve large reductions with minimal reliability risks to the industry.

Although the standards are stringent and technology-forcing (since they are based in part on technologies not fully commercialized at this moment), the agencies project manufacturers will have some technological flexibility. However, it is important to emphasize that we expect this flexibility to be constrained by manufacturers’ financial abilities to invest in the new technologies. The choice is less likely to be between doing more or less, and more likely to be between how heavily to invest in each technology. Manufacturers will probably also need to make choices between developing technologies themselves, and purchasing technologies developed by suppliers.

The individual comments on the engine standards and responses are presented below. These responses to the individual comments must be read in the context of the preceding paragraphs, which explains that the agencies balanced the feasibility, costs, benefits, and risks for the various technologies. For example, without this context, responses to comments arguing for more stringent standards could be misread to question the feasibility of the standards. Such responses necessarily focus on the challenges that engine manufacturers will face in improving their engines, and may not emphasize that the standards are nevertheless feasible.

Because so many of these comments address the “stringency” of the engine standards, it is also worth noting the three different ways in which the term “stringency” can be used. It can refer to the level of technology required to meet the standards. It can also refer to the percent reduction from the baseline. When used in this context, it is critical to also consider the test procedures associated with the numerical standards. As is discussed the responses below, changes to the baselines and the test procedures being made for the FRM have resulted in numerically lower emission standards. However, the agencies generally do not consider these changes to be true changes in stringency because they are independent of the projected technology. Nevertheless, we are also projecting the feasibility of increasing technological effectiveness and adoption, which represents a true increase in the stringency of the standards.

The proposal issued jointly by EPA and the National Highway Transportation Safety Administration (“the Agencies”) in June 2015 failed to adequately take into account existing and emerging technologies from suppliers like us. The proposed 4.1% heavy-duty engine efficiency improvement does not reflect
the full potential of available technologies on the shelf today, nor does it take into account the current state of advanced engine technology development. Indeed, it falls below the historical competitive pace of improvement achieved in the absence of regulation. The Agencies are proposing a standard that is less than half the improvement required under Phase 1, with more than twice the lead time to comply. Manufacturers have already demonstrated, with on the road trucks, the potential to reduce fuel consumption and CO2 emissions from engines used in heavy-haul and line-haul applications by more than 15 percent. Consequently, the standards as proposed are missing a unique opportunity to promote the further development and encourage the deployment of promising advanced technologies. [EPA-HQ-OAR-2014-0827-1762-A2 p.1]

More stringent engine standards are imperative to scale the fuel-saving solutions our companies are creating today. This rulemaking should set the regulatory landscape to drive American innovation further, not just to maintain the status quo. If the agencies choose to push innovation, our companies and others will be able to bring new, cost-effective solutions to market. We urge the Agencies to adopt increased engine stringency standards consistent with the demonstrated capabilities of emerging technologies. Such standards should be set for vocational vehicles and for heavy-duty trucks and vans while providing for adequate incentives and averaging, banking, and trading flexibility. [EPA-HQ-OAR-2014-0827-1762-A2 p.1]

Compared to Phase 1, the proposed Phase 2 standards only require a 4% reduction in fuel consumption and CO2 emissions of engines through 2027. This 4% requirement may be met with technology that has already been demonstrated. If the standard is set too low, it presents a risk that the agencies’ goal of spurring development and deployment of advanced technology may not be met, and it may render the separate engine requirement largely meaningless. [NHTSA-2014-0132-0049-A1 p.3]

We respectfully recommend the Phase 2 engine standard require a greater reduction in fuel consumption. Enough promising technologies and time exist to provide compliance at a cost increase that meets the payback scenarios outlined in the proposed standard. A more stringent standard will spur more earnest evaluation and development of promising new technologies that provide the required efficiency improvement in a cost-effective manner to spur even faster adoption of the new generation of commercial vehicle technology. Based on extensive testing and measured results, we estimate that the heavy duty version of our opposed piston engine will have 15% lower cycle average fuel consumption that the Phase 1 standards. Nearly all the advanced engine technologies being developed in the Department of Energy’s SuperTruck program and independently by leading OEMs and suppliers can be applied to the opposed piston engine for further efficiency improvement. As a result, we propose that at least a 15% decrease in cycle average fuel consumption compared to the Phase 1 standard be required for Phase 2. [NHTSA-2014-0132-0049-A1 p.3]

Response:
In response to comment, the agencies have made a number of changes from the proposal. On the vocational side, we changed the baseline engine to reflect the most recent certification data, making vocational engine standards more stringent numerically than proposed, while relying on performance of similar technologies to those proposed to develop the stringency of the final standard. The detailed vocational engine standard stringency and the baseline to which that stringency is applied is described fully in Chapter 2.7.4 of the RIA. The final tractor engine standards likewise reflect some changes from proposal. We increased the dis-synergy factor from 0.85 to 0.9, and, for the final MY 2027 standard, increased the projected market penetration for WHR Rankine cycle technology from 15% to 25%, and included down speed benefits on the engine. As a result, the projected improvements over the baseline for the 2027 tractor engine standards increased from 4.2% estimated at proposal to 5.1%. Chapters 2.3 and 2.7 of the RIA provide detailed justification of these changes from the proposal. With respect to comments referring to even greater engine improvements under the DOE SuperTruck program, those technology demonstrations only focus on a single operating point in an R/D environment. However, since these engines do not operate at a single operating point in use, we necessarily considered 13 composite modes in deriving standard stringency. This stringency, not surprisingly, is less than that based on a single, optimized operating point.

**Organization:** Advanced Engine System Institute (AESI)

There appears to be ample evidence to indicate that, of the options considered by the agencies, Alternative 4's timeline comes closest to striking the right balance though it does appear greater reductions than the 4.2% in the proposal could well be feasible now and still be quite cost-effective. There are now a multitude of technologies, including waste heat recovery, turbo-compounding, advanced downspeeding, hybridization, etc. that can be ready to deploy in the Alternative 4 timeframe or sooner at still reasonable cost, provided the right policy or market signal and some combination of incentives or credits. EPA may want to consider whether such incentives or credits, particularly in an era of low fuel prices, might expedite the development and commercialization of these technologies and promote earlier and more cost-effective achievement of the program goals. If the Agency chooses not to adopt a technology-driving engine standard in this rulemaking cycle, it may make sense to incorporate a Mid-term Review or evaluation of engine related technologies in the not too distant future so the standards can be adjusted and updated to keep pace with innovation and the growing need to reduce carbon emissions. [EPA-HQ-OAR-2014-0827-1152-A1 p.2] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.290-291.]

Our members have been working with the Department of Energy's Super Truck program to demonstrate the magnitude of carbon dioxide reductions that engine and vehicle technologies can deliver while improving criteria pollution control systems. From this advanced research and development program as well as the independent investment our companies are making with EPA and the California Air Resources Board at the Southwest Research Institute, we are increasingly confident that there is a fuel economy/greenhouse gas optimization 'bonus' to be realized from integrating rapidly emerging and cost-effective NOx control strategies into heavy-duty manufacturers' engines and powertrain designs. [EPA-HQ-OAR-2014-0827-1152-A1 p.] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.291.]

There no longer needs to be the once evident tradeoff between engine efficiency and tailpipe NOx emissions. The presentation attached (attachment 1) illustrates many of the newest NOx and GHG reducing technologies and the continually declining NOx emissions rates of the more recent and more efficient engine certifications. Basically, as engine manufacturers have been, with the able assistance of AESI companies, certifying their engines to tighter criteria pollutant standards and simultaneously
integrating carbon emissions reduction as a design priority, both categories of pollution have been dropping. However, without the appropriate policy signal, the newest and most promising NOx control technologies may not manifest on the right timescale to comport with the Phase 2 proposal and thus could leave significant fuel economy gains until a future time. [EPA-HQ-OAR-2014-0827-1152-A1 p.2]

Because California, as well as other states, continues and will continue to have very serious ozone nonattainment problems due mainly to NOx pollution from vehicles, that state is seriously considering an additional 90% reduction in NOx emissions beyond the 2010 standards for medium and heavy duty vehicles. Should that state, states in the Ozone Transport Commission region or the Northeast, or EPA, choose to formally adopt that standard, AESI members will work very hard with our customers to ensure that that standard can be achieved and to realize the optimization ‘bonus’ that would make fuel economy/greenhouse gas targets easier to achieve. [EPA-HQ-OAR-2014-0827-1152-A1 p.2-3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.291-292.]]

Response:

In response to comment, the agencies have made a number of changes from the proposal. On the vocational side, we changed the baseline engine to reflect the most recent certification data, making vocational engine standards more stringent numerically than those proposed, and then determining standard stringency to reflect performance of technologies similar to those on which the proposed standard was predicated. See RIA chapter 2.7.4. As noted in the previous response, we also made certain changes in the tractor engine standard following proposal, with the result that the projected improvements over the baseline for the 2027 tractor engine standards increased from 4.2% estimated at proposal to 5.1%. Chapters 2.3 and 2.7 of the RIA provide detailed justification of these changes from proposal. We have responded in the previous comment to arguments that standard stringency should reflect the results of the SuperTruck program, and why such stringency is not fully representative of in use drive cycles or performance.

We envision that future NOx reduction will be possible with minimal to no effect on fuel consumption, especially if the reductions in NOx are achieved via optimizations of NOx aftertreatment that improve overall NOx reduction efficiency across all operating ranges. See e.g. RTC Response 15.8.1.

Organization: Alliance of Automobile Manufacturers and Association of Global Automakers

While we support implementation of consistent IRAF procedures and methodologies, we do not support the inclusion of CO2 into IRAF emissions calculations and reporting for any vehicle or engine segment. [EPA-HQ-OAR-2014-0827-1271-A1 p.10]

Response:

Please see Response 3.3.4 for a more detailed discussion of infrequent regeneration adjustment factors (IRAFs). As there stated, we do not believe inclusion of IRAF CO2 emissions significantly impact the stringency of these standards because manufacturers have already made great progress in reducing the frequency and impact of regeneration emissions since 2007. Rather, the agencies are including IRAF CO2 emissions for Phase 2 to prevent these emissions from increasing in the future to the point where they would otherwise become significant. In their comments on the NPRM, manufacturers qualitatively acknowledged the likely already small and decreasing magnitude of IRAF CO2 emissions in their comments. For example, EMA stated, “the rates of infrequent regenerations have been going down since the adoption of the Phase 1 standards” and that IRAF “contributions are minor.” Nevertheless, we believe it is prudent to begin accounting for regeneration emissions to discourage manufacturers from adopting
criteria emissions compliance strategies that could reverse this trend. Manufacturers expressed concern about the additional test burden, but the only additional requirement would be to measure and report CO₂ emissions for the same tests they are already performing to determine IRAFs for other pollutants.

At the time of the proposal, we did not specifically adjust baseline levels to include additional IRAF emissions because we believed them to be negligible and decreasing. Commenters opposing this proposed provision provided no data to dispute this belief. We continue to believe that regeneration strategies can be engineered to maintain these negligible rates. Note, however, the agencies did consider potential IRAF impacts when establishing the final FTP and SET baselines. Highway operation includes enough high temperature operation to make active regenerations unnecessary. Furthermore, recent improvements in exhaust after-treatment catalyst formulations and exhaust temperature thermal management strategies, such as intake air throttling, minimize CO₂ IRAF impacts during non-highway operation, where active regeneration might be required.

**Organization:** Allison Transmission, Inc.

EPA and NHTSA Should Not Incentivize Larger Engines

EPA and NHTSA have expressed concern that setting engine standards at high stringency could produce counterproductive results, e.g., that such standards “may promote the use of large displacement engines, which have inherent heat transfer and efficiency advantages over smaller displacement engines over the engine test cycles, though a smaller engine may be more efficient for a given vehicle application.” In general, Allison supports the proposal to maintain separate engine standards. However, Allison shares the agencies’ concerns that if standards are too stringent then incentives could be created to use larger engines in order to pass certification tests. [EPA-HQ-OAR-2014-0827-1284-A1 p.16]

Specifically, we would note that power shifting Allison ATs actively enable the use of smaller engines -- in place of larger engines for AMT/MT equipped powertrains -- while achieving the same amount of work in the same amount of time. A documented customer fleet test over a 1 year period of time comparing an 11L engine/AMT vs 7L engine/Allison AT on same daily route, indicates the same level of performance at GVW and 22% better fuel economy for the 7L engine/Allison powertrain. The parameters and results of this testing are submitted below: [EPA-HQ-OAR-2014-0827-1284-A1 p.16]

- Two 42,000 lb GVW pickup and delivery trucks, identical except for power pack and rear axle [EPA-HQ-OAR-2014-0827-1284-A1 p.16]
- Same daily route over 1 year period in service [EPA-HQ-OAR-2014-0827-1284-A1 p.16]
- AT vehicle with smaller engine achieved 28% better fuel economy (equivalent to 22% reduction in fuel consumption) with equivalent performance to AMT vehicle with larger engine [EPA-HQ-OAR-2014-0827-1284-A1 p.17]

[Table, 'Results of Performance Testing Between Smaller and Larger Engines', can be found on p.17 of docket number EPA-HQ-OAR-2014-0827-1284-A1]
Response:

We understand Allison’s concern. We do not believe that the current engine standards would incentivize large displacement engines. As a matter of fact, the engine technology road map we are adopting as a potential compliance pathway includes a path for the engine downsizing together with down speeding. See RIA Chapter 2.3.9 and Table 2-11 in that chapter. In addition, we believe including the fuel map in GEM provides a strong incentive to not oversize engines.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Separate engine standards

ACEEE has supported maintaining standards for tractor and vocational truck engines in Phase 2. The primary reason for such standards in our view is to set out direct, multi-year targets for engine performance sufficient to promote substantial, sustained investment in engine efficiency. So long as the only signal to improve engine efficiency is filtered through the lens of whole vehicle efficiency, there will remain uncertainty about how much of the improvement will fall to the engine. This is especially problematic for engines not produced by vehicle OEMs, which play a prominent role in the U.S. market. [EPA-HQ-OAR-2014-0827-1280-A1 p.8]

The 4.2% engine efficiency improvement over the 2017 standard proposed by the agencies for 2027 represents such a modest gain as to undermine the argument for the engine standard. An engine standard that achieves 10% fuel consumption reduction by 2027, which we recommend in these comments, has a much clearer justification. Other rationales cited for engine standards include ensuring that criteria pollutant and greenhouse gas emissions for engines remain linked, so that these two types of emissions can be brought down in tandem. However, given the proposed changes to the weighting of the test point in the supplemental emissions test (SET) cycle for engines and the possibility that engine certification will move to a drive-cycle-based approach, the link between GHG and criteria pollutant testing may be in jeopardy even assuming the separate engine standard is maintained. EPA should consider adjustments to the criteria emissions program at the earliest opportunity to address this issue and ensure that reductions in one set of pollutant emissions do not come at the expense of reductions in the other. [EPA-HQ-OAR-2014-0827-1280-A1 p.8-9]

Recommendations: Separate engine standards

- Maintain separate engine standards in Phase 2, as proposed, but require substantially greater improvements in fuel efficiency. [EPA-HQ-OAR-2014-0827-1280-A1 p.9]
- Adjust the criteria pollutant emissions program for engines as needed to ensure that both these emissions and GHG emissions decline in tandem. [EPA-HQ-OAR-2014-0827-1280-A1 p.9]

Engine standards for tractor trucks

Revised weighting of SET cycle test points; baseline engine efficiency [EPA-HQ-OAR-2014-0827-1280-A1 p.9]

The agencies propose to change the weighting of the SET cycle test points in the Phase 2. The re-weighting would result in a higher percent (33% higher) of time spent at low engine speed points (A and B speeds) than is reflected in the current SET (p. 40192). This increase in the weights of A and B speeds means greater weight to points of low brake-specific fuel consumption and consequently show lower
ACEEE supports this revised weighting for SET, because it better represents the real-world operation of today’s long-haul trucks. In a presentation in 2014, the Daimler Truck North America (DTNA) shared data on the operating points of a 2010 model year DD15 heavy-duty diesel engine in on-road testing. The majority of the data points for that truck were clustered around A and B speeds and rarely reached C speeds in its operation. Volvo Group, in another presentation, presented the on-road engine operation of about 600 line-haul trucks covering 82 million miles, where these trucks spent most of their time under 1500 rpm engine speed. Note that most of these trucks are rated at 1800 rpm or more. Therefore, increasing the weighting of A and B points of the SET cycle and reducing the weighting of C points in the Phase 2 certification protocol is appropriate.

Recommendation: Revision of tractor engine baseline

- Adjust the 2017 tractor engine baselines to reflect the reweighting of SET points.

Stringency of the tractor engine standard

The Phase 2 proposal calls for only 4.2% efficiency gains for tractor truck engines by 2027 (p. 40197). In fact, given that the Phase 2 baseline efficiency level does not reflect the engine cycle test points’ new weighting, as discussed above, the actual improvement the proposal represents is even less than 4%. In terms both of the importance of greater engine efficiency and the technologies available to increase that efficiency, the proposal is far too timid.

Both the overall and the annual rate of improvement for medium and heavy heavy-duty engines in Phase 2 are lower than those in Phase 1, as shown in table 1. Phase 1 is being implemented in six years, from 2011-2017, while Phase 2 would be implemented over ten years, from 2017-2027. The Phase 1 rule, adopted in 2011, mandates some improvement from its pre-Phase 1 baseline in 2014, the first year of compliance. The Phase 2 rule also mandates some improvement in 2021, the first year of compliance, from the 2017 baseline.

[Table 1 can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1280-A1]

Improved combustion, engine airflow improvement, friction and parasitic loss reduction, and waste heat recovery are the major technologies in the agencies’ Phase 2 package. The agencies understate the benefits of these technologies in three ways:

1. the effectiveness numbers for some of the technologies are low;
2. the penetration levels for some technologies, especially waste heat recovery, are low; [EPA-HQ-OAR-2014-0827-1280-A1 p.10]
3. the agencies apply an unexplained discounting of the benefits of engine technologies when they are combined, which lowers the effectiveness of the package. [EPA-HQ-OAR-2014-0827-1280-A1 p.10]

Consequently, the increase in tractor engine efficiency called for in the proposal is much too small. These issues will be discussed in the following paragraphs, leading to our recommendations regarding the stringency of Phase 2 standards for heavy-duty diesel engines used in tractor trucks. [EPA-HQ-OAR-2014-0827-1280-A1 p.10]

- Any discounting of the benefits of technology packages to account for overlapping benefits should be based on the specifics of the technologies in the packages. [EPA-HQ-OAR-2014-0827-1280-A1 p.12]
- The standards for tractor track engines should require reductions of at least 9% in 2024 and 10% in 2027, rather than the much lower levels called for in the proposal. [EPA-HQ-OAR-2014-0827-1280-A1 p.12]

- Require at least 6% reduction in fuel consumption for gasoline engines in vocational applications in 2027 to reflect the availability of further friction reduction, turbo downsizing, and variable valve lift/actuation. [EPA-HQ-OAR-2014-0827-1280-A1 p.14]
- Strengthen the proposed standards for diesel engines used in vocational vehicles by 3% in 2024 and 4% in 2027. [EPA-HQ-OAR-2014-0827-1280-A1 p.14]

Response:

This comment contains constructive suggestions. However, as detailed in the RIA, we believe a 10% increase in 2027 is beyond what will be feasible in this time frame industry-wide. Data cited by the commenter mainly relies on the literature, including DOE Supertruck programs, which are not directly applicable. The values from the literature are single optimal operating points, not operation over the entire engine map. Further, those values were demonstrated in an R/D environment. In contrast, we must consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point. Technology effectiveness is also not additive. Chapter 2.7.5 of the RIA details justifications of the dis-synergy factor used in the rule. These justifications were also supported by many industry comments, such as the reports made by four major vehicle OEMs (EPA-HQ-OAR-2014-0827-1894) as well as other comments made by individual vehicle OEMs (Daimler Truck North America and Navistar). The technology effectiveness of WHR in Rankine cycle, which we project to be less effective than what this (and other) commenters recommended, were directly obtained from credible, but CBI information, and also reflect the recommendation from a leading engine manufacturer. It is critical to derive the standards based on the agencies’ weighting factors over 13 modes, vehicle weight, and three vehicle certification cycles. Thus, the adjusted values for stringency are typically much smaller than the values seen in the literature. Having said that, we have made changes to increase the stringency of the standards from those proposed. In the final rule, we also readjusted the
baseline of the tractor engine standards to reflect the reweighting impact. See Response 3.3.3 below. Chapter 2.7.4 of the RIA discusses the change in the baseline. We made a few other key changes to engine standard analysis. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the 2027 tractor engine standards’ projected stringency over the baseline increased from 4.2% to 5.1%. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase. We also readjusted the baseline for the vocational engine standards, and strengthened the vocational engine standards to reflect certain differences in estimated technology effectiveness and projection rates from proposal. See RIA Chapter 2.7.9 for projected compliance pathway for the final standard.

---

2 2013 Diesel Truck Index

**Organization:** American Council for an Energy-Efficient Economy (ACEEE) et al.

**Vocational engine certification**

Since the public comment closed on the proposal, certification data for a number of new heavy-duty engines have been made public. Conventional diesel engines from Cummins,\(^{18}\) Detroit Diesel,\(^{19}\) Hino,\(^{20}\) and PACCAR\(^{21}\) in medium- and heavy-duty vocational applications could all be certified in 2016 to the proposed 2027 standard. [EPA-HQ-OAR-2014-0827-1896-A1 p.6]

**Impact on proposal**

That an assortment of engine families certified for the 2016 model year from a breadth of manufacturers already achieve the 2027 fleet-average standard in their respective classes indicates that the agencies have set far too weak a standard for vocational engines. This, in turn, leads to weakened vocational vehicle standards, since these engines are incorporated into GEM for compliance. We expect based on careful examination of recent engine certification data that the agencies will adjust greenhouse gas emission and fuel consumption targets downward in 2027 to more appropriately account for where the technology is today and what it can achieve more than a decade hence. [EPA-HQ-OAR-2014-0827-1896-A1 p.6]

---

18 Cummins 2016 8.9L MHDD diesel engine (GCEXH05040LAV): FCL = 553 g/bhp-hr, compared to a proposed 2027 MHDD standard of 553 g/bhp-hr. Certified to vocational applications (ISL9).

19 Detroit Diesel 2016 14.8L HHDD diesel engine (GDDXH14.8EAD): FCL = 517 g/bhp-hr, compared to a 2027 HHDD standard of 533 g/bhp-hr. Certified to vocational and tractor applications (DD15).

20 Hino 2016 7.7L MHDD diesel engine (GHMXH07.7JWU): FCL = 538 g/bhp-hr, compared to a proposed 2027 standard of 553 g/bhp-hr. Certified to vocational applications (J08E-WU).

21 PACCAR 2016 10.8L HHDD diesel engine (GPCRH10.8M01): FCL = 509 g/bhp-hr, compared to a proposed 2027 standard of 533 g/bhp-hr. Certified to vocational and tractor applications (MX-11).
Response:

We have significantly adjusted the FTP baseline CO₂ emission levels taking into account the new certification data. Chapter 2.7.4 of the RIA details the methodology of how these baseline changes reflect the certification data referenced by the commenter. See also Response 3.3.3 below.

Organization: American Gas Association (AGA) et al.

We Strongly Support Preserving the Compliance Pathway Flexibility

In the HD Phase 1 Rule,² the agencies adopted provisions that allowed original equipment manufacturers (OEMs) to offset any nitrous oxide (N2O) and methane emissions above the standard with carbon dioxide (CO2) emissions below the standard. Under this approach, an OEM would convert measured N2O and methane emissions levels generated on the engine certification test cycle into a CO2-equivalent credit.³

We strongly support the maintenance of this provision in the Phase 2 Proposal. Doing so preserves the valuable compliance pathway flexibility for cross-pollutant trading of methane, N2O, and CO₂. We further note that this flexibility is not only beneficial to the OEMs in the natural gas sector that use it to offset methane emissions with CO2-equivalent credits, but it is also a necessity for some diesel engine OEMs who use the provision to offset high N2O emissions with CO2-equivalent credits. [EPA-HQ-OAR-2014-0827-1223-A1 p.2]

We Support the Maintenance of a Common Regulatory Structure for all Fuel Types

We support the common regulatory structure for all fuel types and support the continuation of separate standards for spark-ignition and compression-ignition engines, as was established in the HD Phase 1 Rule.²³ We raise concerns with any proposal to modify the regulatory structure to distinguish among the fuels used in those categories, and commend the agencies on not doing so in the Phase 2 Proposal. With respect to the proposed changes to the certification of natural gas engines, we agree with agencies in their assessment that these changes are merely clarifications that ratify the status quo. [EPA-HQ-OAR-2014-0827-1223-A1 p.5]

Response:

We appreciate your support on the compliance pathway flexibility and the maintenance of a common regulatory structure for all fuel types.
**Organization:** American Power Group Inc. (APG)

As the proposed CO2 standards Heavy-Heavy Duty-Tractor/Vocational reflect Fuel Economy (FE) increases manifested through both engine efficiency and vehicle efficiency improvements (tires, aero, etc.), and as the CO2 exhaust emission values are determined by engine dynamometer tests (RMC13: HHD-line haul Tractor or FTP-HDT: HHD-Vocational), how is the EPA proposing to reflect the vehicle efficiency improvements within the respective M.Y. engine dyna test procedures? Will there be a modification to the test parameters and/or a correction factor applied? The previous answer (6 Aug, 2015) was 'EPA did not propose to reflect vehicle efficiency improvements in the engine dynamometer test procedures'. Although we understand the given answer, the question remains, if vehicle efficiency improvements are to be employed to increase FE and reduce CO2 emissions, how can this be accounted for in the results of a dynamometer emission test? To not correct for vehicle efficiency affects effectively places the burden of all F.E. increase on the engine alone. [EPA-HQ-OAR-2014-0827-1197-A1 p.4]

**Response:**

We did not propose to reflect vehicle efficiency improvements in the engine dynamometer test procedures or adopt any such provisions in the final rule. Any vehicle related technologies that can have an impact on the vehicle will be recognized and accounted for exclusively by the vehicle standards.

**Organization:** American Trucking Association (ATA)

The actual stringency in the proposed rule is much greater than what EPA has indicated due to errors in EPA’s baselines and testing protocols, such as: [EPA-HQ-OAR-2014-0827-1243-A1 p.13]

- Compliance margins are not provided for engine fuel map audits requiring OEMs to over-design (if plausible) beyond their certification levels to ensure passing routine audits. [EPA-HQ-OAR-2014-0827-1243-A1 p.13]

In summary, these issues create impossible hurdles that could not be met within the framework of the rule and the agencies must work with OEMs to rectify these matters. [EPA-HQ-OAR-2014-0827-1243-A1 p.13]

**Response:**

As described elsewhere in the final rule, each of these factors been considered in the final analysis. First, although the agencies revised both the SET and FTP baselines, these changes had no impact on standard stringency. The changes reflect only the baseline from which stringency is calculated. See Response 3.3.3. Second, the final standards do account for a compliance margin. See Section 1.4.3 of this RTC.

**Organization:** Bay Area Air Quality Management District (BAAQMD)

The proposed EPA/DOT Phase 2 rule-making can help us pursue both our air quality and GHG emission reduction goals. To ensure the maximum benefits are achieved from this joint-rule-making effort, we would like to offer the following suggestions.

Consider more stringent engine emissions standards that reflect the technologies currently available in the mass market and those that are now being developed and tested. The current proposal improves engine
GHG emissions by 4% compared to the final Phase 1 standards, but we believe more stringent standards are technically feasible. [EPA-HQ-OAR-2014-0827-1136-A1 p.2]

Response:

In the final rule, we readjusted the baseline of the tractor engine standards to reflect the reweighting impact of the SET. Chapter 2.7.4 of the RIA and Response 3.3.3 detail the change in the SET baseline. We made a few key changes on engine standards. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the 2027 tractor engine standards’ projected stringency over the baseline increased from 4.2% to 5.1%. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase. We also strengthened the vocational engine standards.

Organization:  Bendix Commercial Vehicle Systems, LLC

We request comment on whether or not a chassis dynamometer test procedure should be required in lieu of the vehicle simulation approach we are proposing. [EPA-HQ-OAR-2014-0827-1241-A1 p.2]

Bendix does not believe that the agencies should require chassis dynamometer testing in lieu of the vehicle simulation approach being proposed. At the time of this rule making, there simply aren’t enough chassis dynamometers available to make it a requirement and it is our belief that the associated costs of making it a requirement are not understood well enough to assess the financial impact. However, we do believe that the use of chassis dynamometer testing will increase to assess the vehicle benefits of many new technologies and the resulting data should be able to be used as input to GEM. [EPA-HQ-OAR-2014-0827-1241-A1 p.2]

Response:

We are not requiring chassis dynamometer certification.

Organization:  Center for Biological Diversity

Engine Standards

There is clearly large potential for greater engine improvements than those currently proposed. Engine standards are particularly important because these are the most verifiable reductions and central to achieving overall vehicle efficiency. Diesel engines are more efficient than gas engines, and currently separate standards are applied to gas and diesel engines. [EPA-HQ-OAR-2014-0827-1460-A1 p.7]

Response:

In the final rule, we readjusted the baseline of the engine standards to reflect the SET reweighting impact. Chapter 2.7.4 of the RIA details the change in the tractor engine baseline. We made a few key changes to the final engine standards. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in
2027, and include down speed benefits for engines. As a result of this, the tractor engine standards’
projected stringency over the baseline increased from 4.2% to 5.1%. Chapters 2.3 and 2.7 of the RIA
detail the justification of this increase. We also strengthened the vocational engine standards from
proposal.

Organization: Cummins, Inc.

There is a discrepancy between the proposed engine standards and the Agencies’ projection of engine
capability as implemented in the engine maps used in GEM. Figure 2 shows results of an analysis of the
HD tractor engine maps. When these maps are used with the Agencies’ expected class 8 high roof sleeper
cab vehicle technology packages for 2021, 2024 and 2027, the engine map performance on the GEM
cycles is better than the engine standard. This result is an implied engine stringency where engine CO2
reduction is driven by the vehicle program with no accompanying NO\textsubscript{x} control. The Agencies should set
the engine standard at the expected performance of the engine as represented by the engine maps which
define the engine capability. [EPA-HQ-OAR-2014-0827-1298-A1 p.9]

[Figure 2 can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

Also, the Agencies have assumed engine downspeeding in the vehicle program technology packages.
However, no downspeeding has been assumed in the engine program. An engine optimized for
downspeeding usually has a lower rated speed, plus the peak torque is higher and occurs at a lower speed.
These changes have not been considered by the Agencies. Figures 3-6 from the Draft RIA show that the
torque curves have not been changed for any of the future expected engines. The RMCSET points
therefore have not changed, so no expectation of downspeeding performance is considered in the engine
standard setting. As stated in our oral comments: [EPA-HQ-OAR-2014-0827-1298-A1 p.10]

[Figures 3-6, 4, 5 and 6 can be found on p.10-12 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

Cummins supports the proposed alternative fuel source categorization [EPA-HQ-OAR-2014-0827-1298-
A1 p.27]

The Agencies are proposing that all engines, that are not gasoline-fueled and are intended for MHD or
HHD service classes, must meet the compression-ignition ("diesel") emission standards. This designation
applies regardless of whether an engine is normally considered a spark-ignited engine. Cummins supports
this provision as it provides a fuel neutral assessment and consistent certification requirements relative to
emission standards, including NTE, and certification cycles. [EPA-HQ-OAR-2014-0827-1298-A1 p.27]

The Preamble (80 FR 40158, 40207) further indicates that this new designation for alternative-fueled
MHD and HHD engines also applies for criteria emissions. Cummins agrees with this clarification as it
maintains alignment between criteria emission and GHG certification for engines. The Agencies should
clearly define this within the standard setting parts for criteria emissions. [EPA-HQ-OAR-2014-0827-
1298-A1 p.27]

Cummins opposes IRAF requirements for CO2 emissions [EPA-HQ-OAR-2014-0827-1298-A1 p.27]

For reasons outlined in EMA’s comments, Cummins opposes IRAF requirements for CO2 emissions.
[EPA-HQ-OAR-2014-0827-1298-A1 p.27]

Cummins requests that the Agencies more clearly explain the methodology for setting the engine
Additional clarification from the Agencies is needed for the following: [EPA-HQ-OAR-2014-0827-1298-A1 p.35]

(a) It appears the reweighted RMCSET was not correctly accounted for in determining the engine standard levels. Table 4 shows results from an analysis of the engine maps created by the Agencies to represent future engine technology. The new RMCSET weightings reduce CO2 by 1.8%. This impact is not accounted for in the standard values which appear to assume the Phase 1 RMCSET weightings. Cummins asks for clarification on this discrepancy. [EPA-HQ-OAR-2014-0827-1298-A1 p.35]

[Table 4 can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

Response:

At proposal, there was indeed an incorrect discrepancy between the proposed engine standards and the agencies’ projection of engine capability as used in the GEM. This was an error that has been corrected. The final engine standards for MY 2021 and 2024 use estimates of technology efficiency which are identical to those used in GEM, and which reflect downspeeding of engines. As the commenter suggests, the engine standard is set at the expected performance of the engine as represented by the engine maps which define the engine capability. See Chapter 2.8.4.1 of the RIA. However, as discussed in Section II.D.(2)(e) of the Preamble, vehicle manufacturers can use a broader mix of engine designs to achieve an average engine performance significantly better than what is required by the engine standards, and the MY 2027 vehicle standards reflect engine platform improvements (which are amenable to measurement in GEM), without forcing each manufacturer to achieve these additional reductions for the engine standards.

We appreciate Cummins’ support for the proposed alternative fuel source categorization.

With regard to Cummins’ comment endorsing the EMA position that inclusion of CO2 in IRAFs changes standard stringency, we do not believe this will significantly impact the stringency of these standards because manufacturers have already made great progress in reducing the frequency and impact of regeneration emissions since 2007. Rather, the agencies are including IRAF CO2 emissions for Phase 2 to prevent these emissions from increasing in the future to the point where they would otherwise become significant. In their comments on the NPRM, manufacturers qualitatively acknowledged the likely already small and decreasing magnitude of IRAF CO2 emissions in their comments. For example, EMA stated, “the rates of infrequent regenerations have been going down since the adoption of the Phase 1 standards” and that IRAF “contributions are minor.” Nevertheless, we believe it is prudent to begin accounting for regeneration emissions to discourage manufacturers from adopting criteria emissions compliance strategies that could reverse this trend. Manufacturers expressed concern about the additional test burden, but the only additional requirement would be to measure and report CO2 emissions for the same tests they are already performing to determine IRAFs for other pollutants.

At the time of the proposal, we did not specifically adjust baseline levels to include additional IRAF emissions because we believed them to be negligible and decreasing. Commenters opposing this proposed provision provided no data to dispute this belief. We continue to believe that regeneration strategies can be engineered to maintain these negligible rates. Note, however, the agencies did consider potential IRAF impacts when establishing the final FTP and SET baselines. Highway operation includes enough high temperature operation to make active regenerations unnecessary. Furthermore, recent improvements in exhaust after-treatment catalyst formulations and exhaust temperature thermal management strategies, such as intake air throttling, minimize CO2 IRAF impacts during non-highway operation, where active regeneration might be required. Finally, as is discussed in Section II.D(2), recent
significant efficiency improvements over the FTP cycle suggest that FTP emissions may actually be even lower than we have estimated in our updated FTP baselines, which would provide additional margin for manufacturers to manage any minor CO₂ IRAF impacts that may occur. See also Response 3.3.4.

We have considerably expanded the explanation on the methodology for setting engine standards described in Chapter 2.7 of the RIA. This commenter, as well as commenters from the NGO community, noted the error in not accounting for the Phase 2 reweighted of SET modes in the baseline. Consequently, we adjusted the baseline engine standards based on the new weighting factors of 13 SET modes. See Response 3.3.3.

**Organization:** Daimler Trucks North America and Detroit Diesel Company

- And two additional documents posted to the docket, Feasibility Assessment of Future Efficiency Improvement for Class 8 Diesel Tractor Engines, by Michael P. Walsh and Stephen J. Charlton, plus its Addendum:

Daimler would like to reiterate that engine standards are unnecessary, given the stringent full vehicle standards. But if there are going to be standards, then 1) the agencies are correct to reweight the RMC test conditions as proposed in the NPRM and 2) the agencies’ proposed stringencies (in the NPRM) are essentially at the limit of what is achievable on an engine test. In particular, the paper by Messrs. Walsh and Charlton dramatically mischaracterizes what is possible and errs in important details about the current state of technology. Moreover, in the Addendum, when Walsh and Charlton state 1) that Super Truck is “an important source of data [from which] a technology assessment could be made” and 2) that the SwRI report “was found to be overly conservative in its assessment of the available technologies,” the authors are stating as fact what are really opinions not consistent with the actual state of technology. We tested DTNA’s Super Truck on the road, on test tracks, and in simulation enough to know this: Walsh and Charlton inaccurately conclude that Super Truck demonstrates a suite of technologies ready for series production. Rather, through our extensive expertise in demonstrating the most efficient truck on the road, we learned that many of the technologies simply are not feasible for series production; they are suited to a lab and no more. For more details, we refer the agencies to our detailed comments about this paper, jointly submitted through an additional memo to the docket by Daimler, Navistar, Paccar, and Volvo.

As previously stated, DTNA has invested heavily in its engine, transmission, aftertreatment and controls technologies to maintain a fuel efficiency leadership position in the marketplace while at the same time meeting or exceeding mandated CO₂ emissions reductions. It is important to note that many of the technology improvements included in EPA’s analysis (in its preamble and regulatory impact analysis) of potential improvements beyond the 2017 model year have already been implemented in order to meet reductions required to meet 2017 requirements. EPA should not be projecting improvements for Phase 2 based on improvements that had already been implemented to meet Phase 1. The reason behind this flaw in EPAs analysis is brought to light in the regulatory impact analysis where EPA makes note on many occasions that its projected improvements (used to derive the improvements noted in the above tables) were based on improvements that manufacturers projected in its Super Truck programs. For example, improvements projected in DTNA’s program were estimates based on a 2009 model year engine baseline. Multiple improvements to DTNA engine injection systems, turbochargers and aftertreatment have since been made in order to achieve CO₂ certification levels at or marginally below 2017 SET standards.

[Large portion of below text is redacted]
Fuel Maps Developed by EPA for Stringency Assessment - EPA requested comment regarding the fuel maps it had developed using projections of fuel efficiency improvements from various technologies. DTNA has reviewed fuel maps EPA had developed for the 2021, 2024 and 2027 model years and formulated recommendations regarding modifications that EPA should consider when finalizing the Phase 2 rule. [EPA-HQ-OAR-2014-0827-1164-A1 p.49]

As described elsewhere in DTNA’s comments, EPA’s projections of fuel efficiency improvements are very aggressive compared to levels that DTNA expects to be achievable in the Phase 2 timeframe. As DTNA has explained to the agency, the EPA had based its projected efficiency improvements from estimates that used a baseline case that preceded the 2017 model year baseline used for the Phase 2 fuel map analysis. Consequently, it appears that EPA has overestimated the how much improvement remains available since a portion of the improvements from the older baseline engine were already applied in order to reach 2017 required levels. DTNA recommends that EPA revisit its estimate improvements to make sure that they had not overestimated remaining improvements which would appear to be the case given the very low 174 g/kW-hr levels in the 1100 RPM / 1600 N-M region of the fuel map. [EPA-HQ-OAR-2014-0827-1164-A1 p.49]

[redacted]

This observation stresses the importance of allowing, as proposed in Phase 2, that as manufacturers design drivetrains to operate engines in their most efficient speed and torque regions, manufacturers be able to input to GEM their actual torque curves and actual fuel efficiency characteristics. [EPA-HQ-OAR-2014-0827-1164-A1 p.49-50]

Response:

Although we disagree with DTNA and DDC’s comments on separate engine standards, we largely agree with many of their comments on the reports by Michael P. Walsh and Stephen J. Charlton, plus its Addendum further addressing the Walsh and Charlton reports. As noted in other responses, the SuperTruck program tests under a single mode, and under what Daimler properly characterizes as ‘lab conditions’ for many of these results.

While we appreciate DTNA’s comments on various technologies EPA proposed as a basis for the engine standard, we believe that much of the data and emission values quoted by DTNA are overly conservative. Our values were based on many data sources, not just from public data sources, but also many CBI sources from OEMs. On the other hand, our technology effectiveness is still below what many other stakeholders have urged, including one major engine OEM that recommended a much higher reduction rate. The 174 g/kw-hr BSFC mentioned by DTNA is the peak efficiency and is only equivalent to 48% BTE, which is far lower than what DOE SuperTruck programs, which have already demonstrated 50-51% peak BTE under some conditions. (Although the agencies do not consider the SuperTruck program to be a sufficient basis for determining overall standard stringency due to its unrepresentativeness, the program is a valid basis for demonstrating peak technology efficiency.) We believe that the engine standards we are adopting represent the most achievable reductions for the given time frame on an industry-wide basis at reasonable cost.

Organization: Daimler Trucks North America LLC

2. Engine CO2 Test

i. Establishing separate standards for child ratings or only for parents
The agencies should not set Phase 2 CO2 and fuel consumption standards for the other ratings (often called the child ratings) within an engine family. EPA requests comment from manufacturers regarding continuation of the Phase 1 approach to GHG certification of an engine family wherein the GHG certification of the parent and child ratings was based on emissions results from testing of the parent rating. 80 FR 40206. DTNA supports the continuation of this Phase 1 approach for certification of parent and child ratings and the Phase 1 requirement that a minimum percentage of the family actual sales volume be below certified levels. DTNA agrees that by including the actual fuel map and rating specific full load curve in the GEM simulation, the range of engine ratings are appropriately represented in the vehicle certification. [EPA-HQ-OAR-2014-0827-1164-A1 p.16]

ii. IRAF

IRAF – The agencies propose to include CO2 emissions and fuel consumption due to regeneration over the FTP and RMC as cycles as determined in the infrequently regenerating aftertreatment devices (IRAF) provisions in 40 CFR 1065.680. 80 FR 40193. EPA also requests comment regarding its proposed Phase 2 modification to include emissions contribution from infrequently regenerating aftertreatment devices (IRAF) in calculation of final CO2 emissions over the SET and FTP test cycles. In Phase 1 EPA excluded IRAF contribution based on its correct understanding that (in the context of Phase 1 stringency) such contributions are minor, and that competitive pressures would drive manufacturers to continue to seek ways to minimize frequency of regeneration and its associated fuel efficiency penalty. DTNA believes that the rationale for excluding IRAF in Phase 1 is equally valid for Phase 2. DTNA does not foresee circumstances in which manufacturers would seek to increase IRAF associated fuel consumption penalties. In fact, the proposed fuel efficiency improvements are more than likely to pressure manufacturers towards developing engines at higher in cylinder NOx levels which are beneficial to passive regeneration of diesel particulate filters, and lower particulate emissions levels due to the natural tradeoff between NOx and particulates. [EPA-HQ-OAR-2014-0827-1164-A1 p.16]

Consequently the need for active regenerations and the associated IRAF impact on fuel consumption can be expected to decrease. DTNA recommends that for the above reasons and in light of both mitigating the vastly increased burden of Phase 2 regulations, that EPA maintains the Phase 1 approach of excluding IRAF effects in the testing and data processing for Phase 2. Should EPA choose to move forward on its proposed path of including IRAFs in its Phase 2 regulation, DTNA suggests that in light of the demanding stringency of Phase 2 regulations, the associated effective increase in stringency due to inclusion of IRAFs be accounted for and avoided by raising the 2017 baseline CO2 levels and Phase 2 engine standards by an appropriate amount. [EPA-HQ-OAR-2014-0827-1164-A1 p.16-17]

iii. DF

DF - EPA requests comments regarding the appropriateness of continuing the practice of engine manufacturers adopting assigned DFs for CO2 emissions. 80 FR 40206. During Phase 1 discussions DTNA shared data from laboratory and field tests with EPA to demonstrate the in-use fuel efficiency performance of its products. These data illustrated that fuel efficiency remains stable over the course of high mileage testing and thereby support EPA’s rationale of allowing manufacturers to adopt a 0.0 g/bhp-h additive deterioration factor for CO2 emissions. DTNA agrees that it is prudent for EPA to consider, subject to good engineering judgement, allowing the same assigned DF for advance or off-cycle technologies. [EPA-HQ-OAR-2014-0827-1164-A1 p.17]

iv. Reweighting of RMC
RMC reweighting and engine stringency. EPA requests comments regarding proposed changes to the test methodology for determining CO2 emissions levels for engines certified to proposed tractor standards. 80 FR 40192. DTNA, as is stated elsewhere in these comments, strongly recommends elimination of both FTP and SET engine standards in the GHG Phase 2 program for many reasons, one of which is that fixed engine cycles currently and in the future will inadequately reflect actual engine operation across a range of applications, and over time as drivetrain designs evolve. Both of these shortfalls can be addressed by using a complete vehicle approach. That said, DTNA applauds EPA’s effort to improve the alignment between the tractor certification SET test cycle and engine operating conditions so that the test cycle is more reflective of how engines operate in line haul tractor operation. DTNA has gone on record on numerous occasions, and has presented data to the regulators, informing that the weighting scheme currently applied in the SET protocol is inappropriate as a measure of CO2 emissions for GHG regulations. A mismatch between operating points of the certification test cycle and the operating points in actual operation is problematic because it can cause engine manufacturers to develop technologies for the purpose of meeting regulatory requirements that do not provide the benefit in the real world that regulators intended and that end users will nonetheless end up paying for. Regulators must seek to correctly align regulatory requirements to actual operation so as to avoid such unintended consequences and the associated waste of manufacturers engineering efforts and cost to end users for technologies that provide little real world benefit. The example provided below illustrates that the operation at “C-speed” in the current SET protocol grossly overemphasizes the negligible operation that occurs in actual operation at high engine speeds. Over the past decade, vehicle and engine manufacturers, in their drive for improved efficiencies, have developed their products and educated end users to operate their products at lower engine speeds to improve fuel efficiency and reduce operating costs. This has resulted, as depicted in the example, in dominant operation in the A-speed and B-speed regions. Clearly, the proposed changes to increase weighting of the lower A-speed and B-speed points are appropriate and necessary for the GHG Phase 2 test cycle to better reflect actual operation of today’s vehicles. Further, in shifting emphasis away from C-speed operation, EPA proposes to shift weighting to the lower A-speed of the SET. DTNA agrees that moving the weighting in this manner, as opposed for example to B-speed operation, is appropriate consideration of the likely continued trend towards more efficient drivetrain designs that encourage operation at lower engine speeds in its NAFTA line-haul applications. [EPA-HQ-OAR-2014-0827-1164-A1 p.18-19]

[The graphics, plots of the RMC and actual measured engine operation, showing very little C-speed operation, can be found on p.19 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

- **Reduced Parasitics** - Variable Speed Coolant Pumps - DTNA has realized parasitic load reduction through the development and introduction of variable speed coolant pumps on its production DD13 and DD15 engine families. The benefits of this technology are dependent on the application but are realized when cooling demands require less than full flow capacity of the coolant pump, which in most applications is a considerable percentage of operating time. High duty cycle applications, such as those for which the DD16 engine is targeted, do not benefit as much since cooling system demands are greater. Consequently the DD16 family does not include this feature. This technology is already implemented and cannot be included in projections for the future. [EPA-HQ-OAR-2014-0827-1164-A1 p.21]

- **Aftertreatment** - EPA estimates potential benefit of 0.5% due to future aftertreatment design improvements to reduce backpressure in conjunction with improved aftertreatment NOx reduction performance to handle higher engine out NOx levels that are a natural outcome of retuning for improved combustion. DTNA has completed a redesign of its aftertreatment system for its 2016 model year products with consideration for improved backpressure by introducing improved substrates. However, requirements for improved NOx reduction performance via improved DEF mixing directionally work against backpressure reduction resulting in negligible difference in final backpressure performance. As
development is pressed to further combustion improvements for CO2 reduction it will be a challenge to maintain or avoid further increases in backpressure in the future. It may be anticipated that in order to achieve fuel efficiency improvements proposed by EPA, aftertreatment system redesign may be required to convert even higher NOx flux from engines that are tuned to higher NOx levels to achieve fuel efficiency goals while at the same time meeting packaging and weight design constraints driven by needs for improved vehicle efficiency. Substrate manufacturers continue to develop improved materials intended to improve pressure drop characteristics which may help to avoid additional backpressure increases. [redacted]. [EPA-HQ-OAR-2014-0827-1164-A1 p.21-22]

· **Downsizing** - DTNA offers heavy-heavy duty engine products that span a range of displacements from 12.8L to 15.6L and has considerable experience in developing these products for maximum efficiency across a range of applications. Our experience supports that within this product range, the optimum displacement for in-use fuel efficiency for fleet applications (which because of their high volume, account for a significant fraction of Class 8 fuel consumed) is the DD15 (14.8L displacement). DTNA expects that trends in current and future drivetrain designs will continue to highlight the DD15 displacement as the fuel economy leader. It is well known and discussed elsewhere that drivetrain design trends are evolving towards ever decreasing engine operating speeds. At higher engine speeds and moderate-light loads, there is a theoretical efficiency advantage of a smaller displacement engine since a smaller fraction of the fuel burned is lost to overcoming parasitic losses to smaller contact surfaces of rotating and sliding components. However, with downspeeding, as engine operating speeds are reduced, overall friction losses are reduced and the friction advantage of the smaller engine diminishes. In concert with reduced operating speeds, the engine torque capacity must increase to achieve required power levels demanded of the vehicle so as to avoid loss in gradeability and the operator’s over the road performance (route time). As a result, since the smaller displacement engine has less capability to produce the necessary high torque levels it is less capable of downspeeding without compromising either durability or performance. Consequently DTNA suggests that downsized engines not be considered to provide a fuel efficiency benefit. [EPA-HQ-OAR-2014-0827-1164-A1 p.22]

· **Model Based Control (MBC)** – EPA projects a very significant 2% efficiency improvement due to implementation of MBC when operating over transient conditions. DTNA has expended considerable effort to successfully apply the principles of model based controls to multiple systems. MBC approaches are or have been used to control engine coolant temperature, turbocharger inlet temperature, peak firing pressure and EGR systems amongst others. Extensive research has also been applied to combustion and emissions control using MBC approaches, seeking improvements over transient operation to reach steady state efficiency levels. Extensive work to generate data has shown that controls system improvements can only compensate for a fraction of the negative efficiency impacts of hardware dependent turbo lag, gas transport delays and thermal inertias. We have found that small efficiency improvements during transients may be reached, once again, at the cost of increased NOx levels. DTNA has learned that implementation of Neural Network approaches and on-line optimization carries computational demands that far exceed existing and foreseeable system capacity. While fuel efficiency gains from MBC are anticipated to be [redacted] we believe that continued MBC refinement can lead to improved transient torque response, thermal protection and transient particulate control. [EPA-HQ-OAR-2014-0827-1164-A1 p.22-23]

· **General Engine Compliance Margins** - EPA requests comment from manufacturers regarding continued declaration of FCLs above the measured levels during certification of engines to future GHG standards as was the case for DTNA’s Phase 1 heavy-heavy duty engines. 80 FR 40195. DTNA’s FCLs included compliance margin for measurement variability to ensure compliance during possible EPA confirmatory testing. DTNA is likely to continue to include compliance margin in the future and recommends that EPA considers, in setting its future standards that manufacturers will need to set FCLs above measured levels for this reason. [EPA-HQ-OAR-2014-0827-1164-A1 p.23]
5. CO2 from Urea SCR Systems

**CO2 from Urea SCR Systems** – Comments are requested by (80 FR 40193) regarding its Phase 2 proposal to allow manufacturers to downward adjust its gaseous emission measurement based engine fuel map points by the amount of CO2 that is generated by the consumption of urea. The consumption of urea would be averaged during each sampling period to calculate the correction. EPA estimates that up to 1% of an engine’s CO2 emissions may be derived from the consumption of urea. The agencies further explained that it would apply this correction with any engines for which the engine manufacturer applied the correction for its fuel maps during certification. DTNA supports that manufacturers should be allowed to downward correct its Carbon mass balance based fuel consumption measurements by the amount contributed by DEF consumption on the condition that EPA and manufacturers work together to define measurement procedures for urea consumption that reliably and repeatedly produce satisfactorily accurate results. It is appropriate that EPA would apply the same adjustments when assessing a manufacturers fuel maps in an audit or confirmatory test scenario. Although EPA states that it does not propose a urea contribution correction to engine CO2 emissions that are measured over the SET or FTP for certification purposes, it requests comment (80 FR 40193) regarding both doing so, and regarding the magnitude of such an adjustment. EPA suggests that commensurate with a downward adjustment of reported CO2 levels, the CO2 standards themselves should also be reduced by a fixed amount of 1 – 2 g/bhp-h. DTNA does not support either the offset of manufacturer’s certified CO2 levels or the downward adjustment of standards for CO2 contribution related to urea consumption. Manufacturers will vary in their approaches to NOx control strategies and consequently the urea contributions to CO2 emissions will vary. It would be inappropriate for EPA to assume a given downward adjustment in standards when any given magnitude of adjustment would not be appropriate given that there is likely to be a range depending on manufacturers DEF based control strategies. DTNA recommends no change to the Phase 1 practice of including CO2 from all sources in the certified CO2 levels for an engine, thus making the manufacturer accountable for its design philosophy for NOx control, DEF injection and its consequences to CO2 emissions. [EPA-HQ-OAR-2014-0827-1164-A1 p.24]

7. NOx

**Forcing** decreased tailpipe NOx comes with the tradeoff of increased GHG emissions - Reduction in tailpipe brake specific NOx emissions has classically been achieved at the cost of degraded engine efficiency and higher CO2 emissions. Even with the addition of highly effective NOx aftertreatment, this tradeoff continues to exist as is evidenced by industry efforts to improve NOx aftertreatment performance in order to optimize combustion for higher efficiency at higher engine out NOx levels. A Continued push for reduced engine out NOx emissions should be avoided in consideration of basic fuel efficiency compromises. Since ultimately the emissions level of a vehicle travelling over the road is a function of both the brake specific emissions of the engine and the road load required of the vehicle, a highly effective approach to reducing emissions of both CO2 and NOx is to improve the efficiency of the vehicle so that less power is required of the engine. Improvements in tire rolling resistance, cab aerodynamics, trailer aerodynamics all contribute to reductions in required road load and should be carefully accounted for in evaluating GHG Phase 2 positive contribution to NOx emissions reductions. In summary, the EPA should work with us to understand the tradeoffs—and likely increase in GHG emissions—that would occur if the agency decided to seek lower engine-out NOx; and the EPA should recognize the decreased NOx benefit from improved vehicle drag. [EPA-HQ-OAR-2014-0827-1164-A1 p.28]

**Alternate CO2 Standards** - The agencies ask whether the alternate CO2 allowance, used for non-SCR engines in Phase 1, should be eliminated. We think that the standard is no longer needed, as it was primarily intended to help [redacted] prior to its adoption of SCR. Now, the agencies should eliminate the option. 80 FR 40206. [EPA-HQ-OAR-2014-0827-1164-A1 p.30]
Response:

We will use the same approach as Phase 1 for certification between parent and child ratings as the commenter suggests. We do not believe inclusion of CO\textsubscript{2} into IRAF will significantly impact the stringency of these standards because manufacturers have already made great progress in reducing the impact of regeneration emissions since 2007. Nevertheless, we believe it is prudent to begin accounting for regeneration emissions to discourage manufacturers from adopting compliance strategies that could reverse this trend. See Response 3.3.4.

We appreciate DNTA’s positive comments on DF and SET reweighting. While we also appreciate DTNA’s comments on various technologies EPA proposed for the engine standard setting, we believe that much of the data and emission values quoted by DTNA are overly conservative. Our values were based on many data sources, not just from public data sources, but also many CBI sources from OEMs. On the other hand, our technology effectiveness is still below what many other stakeholders have proposed, including one major engine OEM that recommended a much higher reduction rate. We believe that the engine standards we are adopting represent the most achievable reductions for the given time frame on an industry-wide basis. For diesel engines utilizing urea SCR emission control systems for NO\textsubscript{X} reduction, the agencies will allow, but not require, correction of the final engine (and powertrain) fuel maps to account for the contribution of CO\textsubscript{2} from the urea injected into the exhaust. We understand DNTA’s concerns on NO\textsubscript{X} trade-off with CO\textsubscript{2} and we will take into consideration any effect on CO\textsubscript{2} emissions when developing any future NO\textsubscript{X} standards.

Organization: Daimler Trucks North America, Navistar Inc., Paccar Inc., and the Volvo Group

Reasons for Additional Comment Submission

Since the close of the formal comment period on October 1, 2015, there continues to be important discussion and reaction to the proposed greenhouse gas emissions stringency for engines separate from the complete vehicle requirements. In particular, a paper by Steven Charlton and Michael Walsh\textsuperscript{1} (the “Charlton/Walsh Paper”) submitted to the docket calls for a sizable increase in engine stringency citing various sources to support its contentions. The arguments in that paper are highly speculative, unsubstantiated, misleading and/or inaccurate, and must not form the basis for increased stringency.

The purpose of this document, submitted by the commercial vehicle OEMs, is to provide the Agencies with the best technical data and assessments as input to the GHG and Fuel Efficiency Phase 2 regulations.

Background Statement

The major heavy-duty truck manufacturers have invested heavily in fuel efficiency for many years, driven by the competitive demand for lowest commercial vehicle operating cost. We are fully supportive of sensible heavy duty GHG and efficiency regulations that reduce fuel consumption in real-world operations while meeting market requirements including adequate payback, durability, and reliability. Furthermore, regulations should invite open competition to deliver maximum benefits to vehicle purchasers at least cost, thereby incentivizing purchase of the most efficient vehicles and maximizing benefits to society. Regulations should not favor one vehicle manufacturer or supplier over another, nor should they focus on one vehicle subsystem over another, recognizing that manufacturers and suppliers may have differing levels of focus and expertise. While one manufacturer may choose to focus on highly advanced engine technology, others may choose to focus on vehicle aerodynamics, powertrain
integration, advanced vehicle controls, or any combination of these and other technologies. EPA has consistently recognized the importance preserving competition and encouraging innovative efforts for meeting stringent emissions standards, rather than forcing all manufacturers into using the same technological path. Setting separate engine standards based on the upper limits of advanced research would force all manufacturers to dedicate their limited resources on this with no assurance of success. Conversely, allowing manufacturers to focus on a wider variety of technologies will drive broader innovation and ultimately identify new opportunities for efficiency. [EPA-HQ-OAR-2014-0827-1894-A1 p.2-3]

**Recommendation**

EPA and NHTSA should not increase the engine efficiency targets proposed in the NPRM. As a fundamental principle, separate engine standards provide no environmental or energy efficiency benefit because the GHG reduction benefits are calculated only with the engine incorporated into the vehicle. Therefore increasing the stringency of a separate engine standard provides no direct environmental benefit. [EPA-HQ-OAR-2014-0827-1894-A1 p.3]

Consequently, the separate engine standards should be set at a level that avoids unintended consequences. EPA and NHTSA should recognize the importance of considering the engine as an integrated part of a complete vehicle. With this approach, the agencies can avoid forcing engine optimization on fixed test cycles that do not, and cannot, replicate how the engine operates in each vehicle. [EPA-HQ-OAR-2014-0827-1894-A1 p.3]

By driving engine efficiency as part of the complete vehicle, manufacturers must optimize the engine for the actual engine operation, dictated by the vehicle power demand, powertrain, and controls. At the same time, manufacturers will be able to consider the impact of engine size, weight, and cooling demand on the vehicle efficiency when making optimal design tradeoffs, while avoiding the negative consequences of far-reaching engine standards as proposed in the Charlton/Walsh Paper and that the Agencies identified in the NPRM. [EPA-HQ-OAR-2014-0827-1894-A1 p.3]

A vehicle has many different subsystems and components that a vehicle OEM can innovate, design and integrate to optimize overall vehicle fuel economy. Vehicle efficiency obtained through system integration is far more significant than any single subsystem or component efficiency. In fact, two components that each have lower efficiency than their baseline counterparts can be combined and integrated to produce higher overall system efficiency through vehicle integration. We can illustrate this by considering just two components from a vehicle as an example, the engine and the transmission. [EPA-HQ-OAR-2014-0827-1894-A1 p.3]

While continuously variable transmissions (CVT) have not been demonstrated as viable technology for the HD highway market, the concept can be helpful in this illustrative example. From a component perspective, a CVT has lower average mechanical efficiency than a traditional, discrete ratio, counter-rotating transmission. However the CVT eliminates the existing fixed relationship between vehicle and engine speed. This enables the engine to be operated at its peak efficiency point for a requested power demand. Combine this with an engine that is designed and tuned specifically to be integrated to the CVT, and the result is a more efficient vehicle. This same engine would be optimized for operation with a CVT rather than the standard FTP cycle. As such, this same engine would however have lower overall efficiency when measured over the standardized test cycles than a typical engine, when compared on a component basis. However, the integration of these two so-called “less-efficient” components yields a vehicle that is more efficient than the combination of the two standard, baseline components. Furthermore, in addition to fuel economy improvements, the CVT with a compatibly optimized engine...
could potentially reduce criteria emissions through engine/aftertreatment performance improvements. The flexibility of decoupling engine speed from vehicle speed enables the vehicle to avoid areas of the engine speed-torque map that have poor aftertreatment efficiency during real-world operation. This improves overall aftertreatment performance, further reducing real-world vehicle emissions in addition to CO2 reduction. [EPA-HQ-OAR-2014-0827-1894-A1 p.3-4]

EPA must allow manufacturers to innovate solutions that optimize vehicle efficiency for real-world situations rather than forcing manufacturers to optimize components under lab environments. Constraining vehicle design by mandating the use of certain components is extremely counter-productive for fuel efficiency. While such constraints may benefit a subset of component manufacturers, there would be an unintended detrimental cost in fuel economy and environmental impact. Furthermore vehicle purchasers would ultimately and unfairly bear the higher financial costs. There is no technical, environmental, or financial common sense in driving small improvements in engine efficiency standards when they will potentially limit the ability to achieve vehicle efficiency improvements. Vehicle manufacturers must be allowed broad choices of solutions in order to encourage innovation and thus produce the most efficient vehicles possible. [EPA-HQ-OAR-2014-0827-1894-A1 p.4]

As mentioned in the subject paper, the 21 CTP report on US Department of Energy commercial vehicle programs states, “The engine systems Goal 1 of a 50% BTE for an emissions compliant engine has been achieved. Two of the four SuperTruck teams have successfully demonstrated BTE greater than 50% in on-road tests using commercial, ultra-low-sulfur diesel fuel.” This statement is misleading for a number of reasons: [EPA-HQ-OAR-2014-0827-1894-A1 p.13-14]

• The 50% BTE is achieved at a single operating point, not on a test cycle that reflects the engine’s operating range. [EPA-HQ-OAR-2014-0827-1894-A1 p.14]

• NOx emissions are demonstrated at 0.2 g/bhp-hr only on a new, single engine. No margin is provided for variability, deterioration, OBD, or in-use requirements. It is incorrect to characterize these engines as being emissions compliant. [EPA-HQ-OAR-2014-0827-1894-A1 p.14]

• These engines are designed for optimum fuel efficiency with compromises made to life expectancy and reliability, and were intended only for short-term demonstration, and without commercially acceptable constraints on cost. [EPA-HQ-OAR-2014-0827-1894-A1 p.14]

Note that in SuperTruck 2 (a follow-up initiative launched by DOE for manufacturers to further demonstrate efficiency technologies), DOE has proposed only lab demonstration of the target 55% BTE. DOE clearly recognizes that the proposed pathways are extremely tenuous, do not account for in-vehicle operation, and have never even been laboratory demonstrated with a complete engine (vs. a single cylinder approximation). The technologies discussed in this section of the paper are simply an overview of the menu of approaches, none of which are proven feasible. The only engines that have ever approached 55% BTE are huge ship engines running with unlimited cooling water, unlimited NOx, and controlled steady state duty cycles. These engines deploy multiple waste heat recovery systems to generate electricity that is counted into the BTE, even though not converted back to mechanical propulsion. It is not reasonable to expect a truck engine to achieve this level of efficiency, given the many constraints and requirements. [EPA-HQ-OAR-2014-0827-1894-A1 p.14]

Conclusion:

Furthermore, there is no efficiency or GHG contribution from a separate engine standard that is not already included in the complete vehicle standard. The logical and appropriate conclusion is that engine
improvements should be driven from the complete vehicle standard and any separate engine standard should represent a level that can be achieved without compromise in vehicle efficiency or lowest total cost of vehicle operation, not an aggressive limit that forces manufacturer to focus on the engine over other potential efficiencies. EPA and NHTSA have accomplished this in their phase 2 proposal. These engine targets should not be made more stringent. [EPA-HQ-OAR-2014-0827-1894-A1 p.20]

1 http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2014-0827-1237

Response:

We understand the principle behind the comments made by these four major vehicle OEMs. While we believe that the separate engine standard is necessary, we agree they should not be set in way that would prevent optimization of the engines for the vehicles. However, we believe they overstated the significance of this issue. Certain technologies may perform better in the vehicle than over the engine test cycle, but these marginal differences do not equate to actually preventing manufacturers from optimizing either engine or vehicle efficiencies for in-use emissions. The commenters also ignore the role emission averaging can play in this process by allowing different degrees of optimization across engines.

In regard to the comments on component-by-component optimization, we also understand the principles behind these comments. Our vehicle standards promote total vehicle optimization, which is realized by our certification tool - GEM. GEM allows all individual components, such as advanced engine technologies that can be measured through the engine dynamometer, advanced aero-dynamic technology, tire rolling resistance, and efficient transmission and axle design into a seamless package that is modeled and certified in a systematic manner. The only component that is required to comply with an individual standard is the engine component, which is recognized by separate engine standards. Section II.B.2.b of Preamble details the justifications surrounding why we need the separate engine standards. As can be seen, we fully recognize the pros and cons of having separate engine standards, and we believe that this level of component optimization is appropriate and reasonable.

Organization: Environmental Defense Fund (EDF)

Engine standards must be strengthened

As stated above, engine standards provide proven, measureable and durable real-world emissions reductions. Engine technologies can also provide a significant portion of total vehicle fuel efficiency potential. And because combination tractors and vocational trucks account for about 85 percent of fuel use in the medium and heavy-duty sector, establishing a robust engine standard to drive technologies in those classes is critical. [EPA-HQ-OAR-2014-0827-1312-A1 p.27]

Unfortunately, the Agencies have proposed a 4.1 percent engine efficiency improvement over Phase 1 for diesel engines, which falls far short of what is technologically feasible. These proposed standards are not technology forcing considering the current state of advanced engine technology development, nor do they reflect the full potential of available technologies on the shelf today. It is clear that the proposed engine standards do not meet the Agencies’ statutory requirements for appropriate and maximum feasible standards. [EPA-HQ-OAR-2014-0827-1312-A1 p.27]

The administrative record does not support the Agencies conclusion in the Preamble that they have taken “a more technology-forcing approach than in Phase 1, predicated on use of both off-the-shelf technologies
and emerging technologies that are not yet in widespread use.” The proposed standards can be met with today’s technologies – manufacturers need not rely on any advanced technologies; by definition, they are not technology forcing. The Agencies finalized a 9 percent engine improvement in the Phase 1 rule to be implemented between 2014 and 2018. In comparison, the proposed 4.1 percent improvement is less than half of the improvement required under Phase 1, and the Agencies are proposing to give manufacturers more than twice as long. And because the proposed standards will not be fully implemented until 2027, they preclude the opportunity to set more meaningful standards until 2030 under NHTSA’s statutory requirements for lead-time. [EPA-HQ-OAR-2014-0827-1312-A1 p.28]

A recent report by Walsh et. al. performed an exhaustive literature review, and critiqued the methodology and assumptions used by the Agencies in their determination of stringency. The study found “the Agencies to be overly conservative in their assessment of technology effectiveness, cost/retail price and adoption rates, which is reflected in the relaxed HD tractor engine standards proposed.” Based on the recommendations of the report, EDF requests that the Agencies set significantly more stringent Phase 2 engine standards that are consistent with the Clean Air Act’s 202(a) technology forcing authority. [EPA-HQ-OAR-2014-0827-1312-A1 p.28]

Proposed engine standards are weaker in the real-world than rulemaking documents claim

Although the proposed engine standards will nominally achieve a 4.1 percent emission and fuel consumption reduction, in reality they are equivalent to a 2.1 to 3.1 percent reduction because of the effects of the proposed test procedure changes. [EPA-HQ-OAR-2014-0827-1312-A1 p.28]

The Supplemental Engine Test (SET) was adopted as the sole test cycle for GHG compliance determinations in EPA’s medium- and heavy-duty Phase 1 GHG rule finalized in September 2011. In Phase 2, the Agencies are proposing to revise the cycle weighting for CO2 compliance testing purposes, based on the belief that the revised weighting would make the SET more representative. The proposed cycle re-weighting is shown in Figure 1 below. The Agencies increased the weighting of the A speed from 23% to 45% and reduced the C speed from 23% to 5%. The B speed weighting remained essentially unchanged. [EPA-HQ-OAR-2014-0827-1312-A1 p.28]

The fuel consumption of a heavy-duty tractor engine would usually be lower at the A speed than the B or C speeds. Consequently, an engine tested on the re-weighted cycle would have approximately 1 to 2% lower CO2 emissions as compared to levels measured on the existing cycle. The proposed cycle re-weighting therefore relaxes the standards, and the Agencies should account for this effect in the setting of the engine standards. [EPA-HQ-OAR-2014-0827-1312-A1 P.29]

Proposed engine standards do not reflect the compliance potential of existing and emerging technologies

In summary, the Walsh et. al. study found that EPA and NHTSA’s proposed standards do not reflect the current state of existing and emerging engine technology development. The analysis found that significant progress in improving engine fuel efficiency has already been demonstrated by all manufacturers participating in the DOE SuperTruck Program. In fact, manufacturers have demonstrated with on-the-road trucks the potential to reduce CO2 emissions from the engine by 15 to 20%. A wide range of heavy-duty engine technologies have been improved upon or developed, and applied successfully to demonstration trucks in the SuperTruck Program. These technologies include combustion/closed cycle efficiency improvements, air handling/open cycle efficiency improvements, friction and parasitic loss reduction, downspeeding, and waste heat recovery. And both Volvo and Cummins have already
demonstrated at least 48% BTE on their demonstration vehicles without advanced technologies like waste heat recovery (“WHR”), compared to the proposed standard of 44.6% BTE (441gCO2/bhp-hr). [EPA-HQ-OAR-2014-0827-1312-A1 p.29-30]

Furthermore, the most recent NAS report, which conducted an in-depth progress assessment of the SuperTruck program, concluded “the engine systems Goal 1 of a 50% brake thermal efficiency (BTE) for an emissions compliant engine has been achieved.” A 50% BTE level implies an engine CO2 standard of 390 g/bhp-hr or a 15% emissions reduction compared to 2017 levels. NAS also concluded “a pathway to achieve 55% is being developed.” Figure 2 below graphically shows the Phase 1 and proposed Phase 2 emission standards (expressed as BTE) and, for reference, the assessments of NAS, SwRI, and the results of the SuperTruck program. [EPA-HQ-OAR-2014-0827-1312-A1 p.30]

As can be seen from Figure 1, the proposed engine standards fall significantly short of what is projected as possible by NAS and is already being demonstrated within the SuperTruck program. Data from the SuperTruck teams from Daimler, Navistar, Volvo, and Cummins/Peterbilt is highly relevant to the development of the engine standard and the Agencies must appropriately consider this information in developing final engine standards. The DOE program has resulted in more than $375 million dollars being invested in research, development, and demonstration vehicles, and was specifically designed to integrate emerging advanced technologies into over-the-road line-haul trucks, in order to demonstrate significant reductions in GHG and fuel consumption in real-world freight operations. The freight efficiency results obtained to date over mixed drive cycles clearly indicate that a significantly stronger engine standard is feasible. [EPA-HQ-OAR-2014-0827-1312-A1 p.30-31]

Technology feasibility assessment is overly conservative

As discussed above, the proposed standards will not facilitate development of advanced technologies. The weak standards proposed by the Agencies are the result of an analysis that is overly conservative in its assessment of technology effectiveness, technology penetration rates, cost projections, and the application of a “dis-synergy” factor to discount technology effectiveness. Nearly all of the engine technology effectiveness values used by the Agencies were underestimated. In some cases, the Agencies used lower effectiveness estimates than SwRI’s research study projected. (The SwRI study was funded by NHTSA and was a key technical support reference for the proposal). In other cases, the effectiveness values assigned were lower than publically available industry estimates. For example, the Agencies estimated that friction and parasitic loss reductions would result in a 1.4% efficiency improvement. In contrast, the SwRI study estimates more than a 4% improvement and some industry estimates are even higher. As another example, the Agencies projected a 3.6% efficiency improvement for WHR, whereas the latest information reported by Cummins shows that an improvement of 5 to 6.5% is possible. The Agencies fail to adequately justify the use of lower estimates in the rulemaking record. [EPA-HQ-OAR-2014-0827-1312-A1 p.31-32]

The Agencies also assumed constant effectiveness for all of the individual technologies between 2021 and 2030. This assumption means that no performance improvements are projected during the 9-year period over which the standards are being phased in. In contrast, real world experience would suggest that manufacturers and suppliers would continue developing and refining their engine technologies and therefore effectiveness would improve. We recommend that the Agencies properly account for these

The Agencies’ technology penetration assumptions are also problematic. As mentioned above and demonstrated in Table II-6 below from the Preamble, the Agencies are relying substantially on existing engine technologies. Because many of these technologies are already on the road and have proven to be cost effective, the Agencies should accelerate the penetration of existing technologies earlier than 2024. [EPA-HQ-OAR-2014-0827-1312-A1 p.32]

[Table II-6 can be found on p.32 of docket number EPA-HQ-OAR-2014-0827-1312-A1]

The last column in the table shows the very small penetration rates assigned for more advanced technologies, such as WHR and turbo compounding. These minimal penetration rates combined with weak standards do not drive the technologies. Moreover, other advanced combustion technologies are not included on the list. Between 2024 and 2027, the Agencies are only requiring an additional 5% penetration for existing technologies, no additional penetration for turbo compounding, and a 10% increase for WHR. As a consequence, a negligible increase of only 0.5% in stringency is added in 2027. It is critical that the Agencies assume a much more realistic deployment of advanced technologies to finalize a rule that is truly technology forcing. Beyond 2024, there is a tremendous opportunity for the Agencies to set transformational standards that will result in significant additional CO2 reductions compared to those projected for the proposal. [EPA-HQ-OAR-2014-0827-1312-A1 p.32]

Another example of the conservative nature of the Agencies’ analysis is the derivation of cost for WHR systems. NHTSA hired Tetra Tech, Inc. (“TTI”) to work with SwRI to study the cost of the key technologies for reducing CO2 and fuel consumption. TTI relied on existing literature for cost information: a 2009 NESCAFF/ICCT study and a 2009 TIAX study. Other secondary sources (NAS and NHTSA) were referenced. However, these sources also heavily relied on the NESCAFF/ICCT and TIAX studies. Not only are the data sources dated, the costs were created for a 2009 WHR system that has little in common with the state-of-the-art systems demonstrated today by the SuperTruck program. [EPA-HQ-OAR-2014-0827-1312-A1 p.33]

In addition, the Agencies assumed that WHR was on the flat portion of the cost learning curve, an inappropriate assumption for this emerging technology. The Agencies’ explanation for this assumption is as follows: [EPA-HQ-OAR-2014-0827-1312-A1 p.33]

“We consider this technology to be on the flat portion of the learning curve (curve 12) because although waste heat recovery is a new technology and in the 2015 to 2017 timeframe remains, perhaps, on the steeper portion of the learning curve, applying such rapid learning effects to the cost estimate we have would result in costs too low in the MY2024 to 2027 timeframe.” [EPA-HQ-OAR-2014-0827-1312-A1 p.33]

The agencies have not provided a reasonable explanation for declining to apply the cost curve in the way that they themselves recognized was appropriate. As a consequence, EPA and NHTSA’s technology cost estimates are biased on the high side, reducing the stringency of the standard. [EPA-HQ-OAR-2014-0827-1312-A1 p.33]

The agencies use of a “dis-synergy” factor is likewise not well supported. Theoretically, a dis-synergy factor is intended to account for the fact that some technologies may negatively impact the performance of other technologies. However, a positive – or synergistic – effect can also occur. And for some technologies such as friction reduction and turbo efficiency improvements, one would expect no effect.
Therefore, it is not appropriate to apply a dis-synergistic value across the board. [EPA-HQ-OAR-2014-0827-1312-A1 p.33]

When determining synergistic and dis-synergistic effects, it is important to account for the specific combination of technologies under consideration, and apply values for each situation. Instead, the Agencies applied a uniform 25% discount in 2021 and a 15% discount in 2024 and 2027 across all technologies. This fails to credit efficiency benefits of some technology combinations. Furthermore, the Agencies provide no explanation for the derivation or justification for the use of the dis-synergy factors in the rulemaking record. Nor do they provide any evidence to support their proposed approach, which EDF considers inappropriate given that many of the technologies on EPA’s list may not even have dis-synergistic effects. [EPA-HQ-OAR-2014-0827-1312-A1 p.33-34]

In summary, EPA and NHTSA made overly conservative assumptions on almost every critical input that went into the derivation of the proposed engine standards. This results in standards that provide minor incremental improvement over 2017 engine designs despite cost-effective available technologies and more than 12 years of lead time. We respectfully urge the Agencies to correct these deficiencies in their analysis, which would more that double the stringency of the proposed standards. [EPA-HQ-OAR-2014-0827-1312-A1 p.34]

**Recommended engine standards**

Based on the literature review and analysis performed by Walsh et. al., and the extensive technology analyses performed by ACEEE, UCS and ICCT, we are strongly recommending that the Agencies consider the following performance-based standards for line-haul and heavy-haul applications, which consume the majority of the fuel in the medium- and heavy-duty truck category: [EPA-HQ-OAR-2014-0827-1312-A1 p.34]

**a) Engine standards**

- Model Year 2027 and beyond HD Tractor Engines 390 gCO2/bhp-hr (50.4% BTE)
- Model Year 2024-26 HD Tractor Engines 405 gCO2/bhp-hr (48.5% BTE)
- Model Year 2021-23 HD Tractor Engines 435 gCO2/bhp-hr (45.1% BTE) [EPA-HQ-OAR-2014-0827-1312-A1 p.34]

Robust engine standards are needed to drive emissions and fuel consumption reductions across the entire vehicle. The technology is clearly available to meet these standards in the time frames suggested. [EPA-HQ-OAR-2014-0827-1312-A1 p.34]

The 12-year lead-time the Agencies are providing for compliance is more than sufficient for manufacturers to develop and successfully deploy the advanced engine technologies needed to meet more stringent standards. In fact, the lead-time is extraordinarily long when compared to most past Agency actions over the last 40 years. At minimum, the Agencies could consider conducting a biennial review as was done for the 2007/2010 HD criteria pollutant rule. These reviews were conducted biennially, and reviewed the development status of the advanced technologies that were in question, specifically diesel NOx adsorbers. At the end of each review cycle, EPA publically released a report that discussed the status of the technology development and any implications concerning rule implementation. [EPA-HQ-OAR-2014-0827-1312-A1 p.34-35]

We reiterate our strong support for the Agencies’ proposed structure of the rule – separate engine standards are imperative to drive innovative engine technology and provide proven, measureable and durable real-world emissions reductions. However, these benefits can only be realized through robust engine standards. Weak standards, as proposed by the Agencies, do not drive advanced technologies and fall short of unlocking the full capabilities of existing technologies. Additionally, limited engine standards do not take advantage of the robust in-use enforcement provisions of the engine program. These provisions provide high confidence that GHG reductions demonstrated on new engines actually occur in the real world. In order to secure the significant benefits afforded by separate engine standards, the Agencies’ must finalize far more meaningful standards that drive technology and allow for robust enforcement. [EPA-HQ-OAR-2014-0827-1886-A1 p.3]

a. Proposed engine standards are clearly not technology forcing and should be significantly strengthened in the final rule.

1. Strong engine standards are critical to a meaningful program
The NODA states that the proposal “intended to” base standards “not only on currently available technologies but also on utilization of technologies now under development or not yet widely deployed.” However, this is clearly not the case. The Agencies proposed a meager 4.1 percent engine efficiency improvement over Phase 1 for Class 8 diesel engines. (In-use they are equivalent to only a 2.1 to 3.1 percent reduction because of proposed updates to the test procedure.) The proposed standards are not technology forcing because they do not reflect the full potential of available technologies on the shelf today, nor do they fully consider the current state of advanced engine technology development, as shown below. [EPA-HQ-OAR-2014-0827-1886-A1 p.3]

i. Numerous model year 2016 medium-heavy-duty and heavy-heavy-duty vocational truck engines are already in compliance with EPA’s proposed 2027 CO2 standards

Recent heavy-duty certification data posted by the California Air Resources Board (CARB) on their website show that at least four medium-heavy-duty and heavy-heavy-duty vocational truck engines from four different manufacturers (Detroit Diesel, PACCAR, Hino, and Cummins) already meet the proposed 2027 engine standards. The data made publically available by CARB are certificates of compliance (Executive Orders) for the 2016 model year. Table 1 below compares the certified levels of these engines to the proposed 2027 CO2 standards for vocational truck engines. [EPA-HQ-OAR-2014-0827-1886-A1 p.3-4]

[Table 1 can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1886-A1]

The table clearly shows that these 2016 engines are already in compliance with the 2027 standards – more than a decade before they are required. And several of the current engines are significantly cleaner than the proposed levels. This is compelling evidence that the agencies have proposed extraordinarily weak standards for vocational engines, and the standards are not consistent with the CAA’s technology-forcing mandate. In fact, the 2016 certification data demonstrates that the 2027 standards will not require technologies beyond those already being applied to today’s production engines. It is critical that the Agencies more accurately reflect the true capabilities of today’s engines into their analysis and set meaningful 2027 engine standards that drive the adoption of more advanced technologies. Given that more than a decade lead-time is being provided, the standards must go well beyond what were proposed in order to be reconciled with EPA’s technology-forcing authority and NHTSA’s maximum feasible mandate. [EPA-HQ-OAR-2014-0827-1886-A1 p.4]

ii. More recent assessments of Waste Heat Recovery should be considered by the Agencies

In our comments, submitted to the docket on October 1, 2015, we highlighted our concerns with the Agencies’ conservative analysis of the potential of waste heat recovery (WHR) - an engine technology that can provide a step-change reduction in CO2 emissions. The data sources that the Agencies relied upon to project WHR costs were dated, the system design assumed had little in common with the latest designs planned for production, and cost learning curve assumptions were flawed. Taken together, these factors bias WHR cost on the high side, which in turn resulted in very low proposed penetration rates of the technology and therefore reduced stringency of the program. A recent white paper analysis performed by John Wall, recently retired Chief Technology Officer for Cummins Engine Company, reinforces this view (attached as Appendix A). [Appendix A can be found in docket number EPA-HQ-OAR-2014-0827-1886-A2][EPA-HQ-OAR-2014-0827-1886-A1 p.4-5]

Wall’s paper describes WHR as “a significant enabling technology to drive CO2 reductions.” His analysis found that “new WHR architectures reduce the projected cost of WHR to less than half the cost numbers presented in the Phase 2 NPRM.” This result was achieved even without applying a learning curve to the
cost projections. The white paper further concludes, “this substantially lower cost estimate should allow EPA to consider a more significant penetration of WHR technology with acceptable cost effectiveness.”

It is critically important that the Agencies’ final rule stringency determinations take into account the latest and most relevant data and analysis related to WHR and other technologies, and in doing so, significantly increase the stringency of the tractor engine standard. [EPA-HQ-OAR-2014-0827-1886-A1 p.5]

iii. Additional data provided in NODA does not change need for more robust engine standards

In a 2015 report, (submitted to the docket during the initial comment period) leading engine experts Walsh and Charlton performed an exhaustive literature review of engine technology, and critiqued the methodology and assumptions used by the Agencies in their determination of stringency. The study concluded that the “agencies have underestimated the potential of key technologies when setting the GHG emission and fuel consumption standard for HD tractor engines,” and therefore “the standards set for HD tractor engines fall well short of being “technology advancing.” Walsh et. al. made specific recommendations for stronger and more appropriate standards, which EDF cited in our 2015 comments to the docket. [EPA-HQ-OAR-2014-0827-1886-A1 p.5]

As part of the NODA, the agencies are seeking comment on a Southwest Research Institute (SwRI) Report titled “Commercial Medium- and Heavy-Duty Fuel Efficiency Technology Study – Report #2.” According to the agencies, an independent peer review of the initial report identified errors that were corrected and a final report was released as part of the NODA. After reviewing the final SwRI peer-reviewed report, Walsh and Charlton found that 1) the report was “overly conservative in its assessment of the available technologies, especially waste heat recovery (WHR),” 2) the report contained “non-data based speculation and opinion for technologies in question that have been demonstrated in both the test cell and in over-the-road trucks,” and 3) “the final report from SWRI, containing only minor corrections, does not alter the recommendations made by [us].” Based on their review and the above conclusions, the authors “continue to recommend the adoption of more challenging limit standards for CO2 in the Phase 2 rule: [EPA-HQ-OAR-2014-0827-1886-A1 p.5-6]

MY 2027 and beyond HD Tractor Engines 390 gCO2/HP-hr (50.4% BTE)

MY 2024-2026 HD Tractor Engines 405 gCO2/HP-hr (48.5% BTE)

MY 2021-2023 HD Tractor Engines 435 gCO2/HP-hr (45.1% BTE)

Again, EDF supports the conclusions and recommendations made by Walsh and Charlton – two of the nation’s leading experts on heavy-duty truck engine technology. [EPA-HQ-OAR-2014-0827-1886-A1 p.6]

b. Robust final engine standards are needed to provide enforcement

As recently exemplified by Volkswagen, in-use testing requirements and enforcement are critical to achieving real-world emissions reductions. One of the most cost-effective ways to safeguard emissions reductions is through the use of robust engine standards. The existing heavy-duty engine testing and in-use compliance requirements have evolved over decades, making them very rigorous and providing verifiable proof that in-use engine emission reductions are real. Despite the assurances afforded by engine standards, the Agencies have instead allocated most of the Phase 2 stringency to model-based vehicle standards that do not currently include in-use compliance and enforcement requirements. The agencies should instead finalize far stronger engine standards to capitalize on the existing strong engine compliance and enforcement provisions, which will provide high assurance that emission reductions
required by the standards are achieved in-use. Since the real world benefits of engine fuel economy improvements can readily be monitored and enforced, those improvements should be of the highest priority. [EPA-HQ-OAR-2014-0827-1886-A1 p.6]

13 Walsh and Charlton, Feasibility Assessment of Future Efficiency Improvement for Class 8 Diesel Tractor Engines, Consultant Report, (September 2015).

Response:

We appreciate EDF’s constructive comments. The commenter is correct that the SET baseline at proposal failed to account for the reweighted SET modes in Phase 2 (One OEM pointed out this same error). The agencies have corrected this error in developing the SET baseline for the final rule. See Response 3.3.3. We also made a significant adjustment to the FTP vocational baseline engine emission values based on the latest certification data (initially brought to the agencies’ attention by this commenter). We also have reassessed the costs of WHR and have revised the cost downward from that estimated at proposal. These reductions largely reflect the agencies’ judgment that the WHR system considered at proposal had
certain components and aspects not actually needed. This judgment is consistent with CBI information from one of the engine manufacturers as well as information from other credible sources. The detailed process of the adjustment of the baseline values can be found in Chapter 2.7.4 of the RIA and RTC Response 3.3.3, and the cost related to WHR is in Chapters 2.7.6, 2.7.8, 2.7.10, and 2.11.2.15 of the RIA. We have made certain other changes from proposal which have the effect of increasing the stringency of the engine standards including: increasing the dis-synergy factor from 0.85 to 0.9 in 2027, increasing the market penetration for WHR Rankine cycle technology from 15% to 25% for a tractor engine in 2027, and including down speed benefits as part of the projected compliance pathway. This resulted in an increase from 4.2% to 5.1% for the tractor engine standards in 2027 compared to the proposed rule. Chapters 2.3 and 2.7 of the RIA detail the justification for these changes.

We respectfully disagree with many of EDF’s arguments for even more aggressive engine stringency standards for the final rule. Their argument is largely based on the report from Walsh/Charlton. We have reviewed the responsive report from four major vehicle OEMs (EPA-HQ-OAR-2014-0827-1894) as well as other comments made by individual vehicle OEMs (Daimler Truck North America and Navistar). In these reports, they rebut all points made by EDF, specifically as they pertain to the Walsh/Charlton report.

When taking the vehicle OEMs’ comments into consideration:

- We disagree with EDF’s comments that our standards are not technology forcing. We believe that implying that the standards we were proposing were too low and stating that a 9 percent reduction from Phase 1 is achievable, is simply misleading. The driving forces behind this is that improvements in technology effectiveness cannot be extrapolated in a linear way as it is constrained by the law of thermodynamics. A good summary report that highlights the limitation of engine efficiency improvement can be found at: http://www1.eere.energy.gov/vehiclesandfuels/pdfs/deer_2011/wednesday/presentations/deer11_ edwards.pdf. Any further incremental improvements will require tremendous engineering efforts with high cost and unreliability. Furthermore, NOx emissions always act as one of major constraints for further improvement in engine efficiency. In our final rule, the peak thermal efficiency of the tractor engine is approaching 50%, which is in the range of the DOE SuperTruck program. DOE acknowledged (Roland Gravel, 2016 SAE Government/Industry Meeting, January 21, 2016) that there were significant differences between the technologies developed by DOE through the SuperTruck program and technologies used to comply with regulations, and many of technologies developed under the SuperTruck program still have a long way to reach production level. Despite these challenges, we have significantly adjusted our standards for both tractor and vocational engines to make this rule even more stringent compared to the NPRM, as explained in the initial part of this response.

- We disagree with the approach taken by EDF regarding the technology effectiveness derived from DOE’s Supertruck program and NAS’s report. It appears that EDF took a single value out of the literature, which was primarily based on peak values. In contrast, we considered the stringency over 13 composite modes (i.e. accounted for actual in-use driving patterns), where the reduction achievable is (not surprisingly) much lower than from the single most efficient point.

- We believe that the technology effectiveness used in our rule is consistent with the SwRI report, specifically with respect to friction when making an apples-to-apples comparison. In order to make such a comparison, the certification cycle weighting and certification vehicle weight must be used for this evaluation.
• We do not believe that the effectiveness we set for WHR is conservative. As a matter of fact, the effectiveness used in our rulemaking was directly from the same engine manufacturer that EDF and Walsh/Charlton quoted, and is consistent with this engine manufacturer’s expectations in terms of reductions. In addition, we did consider recent technology information obtained from one of the engine manufacturers. Consequently, we increased the estimated market penetration from 15% to 25% in 2027, thus increasing the estimated contribution from WHR used to set standard stringency in the final rule.

• We do not think that there is any positive synergy effect when putting all technologies into one package, while the dis-synergy effect is always present. Please see the detailed explanation and justifications regarding this matter in Chapter 2.7.5 of the RIA. We have significantly expanded the explanation of the dis-synergy effect in this final rule and we did increase the dis-synergy factor from 0.85 to 0.9 in 2027.

• We do not believe that the SwRI reports are too conservative, specifically as they pertain to their estimate on WHR effectiveness. The projections from these reports is in line with what EDF mentioned in their comments, which is about 4%. Although SwRI’s evaluation of the technology is not entirely based on test data, the methodology used is defensible because it incorporates the use of a state-of-the-art simulation tool box to model the technology effectiveness. This modeling approach is even more important as it is not possible for the agencies to evaluate all possible technologies under test cell or real-world driving conditions. Therefore, the assumptions used in running simulations must be largely based on literature values in conjunction with limited testing data.

Organization: Honeywell Transportation System (HTS)

Technology Available for Greater GHG Reduction with Strong Payback

While the new SET cycle weighting factors introduced in the proposal more accurately reflect real-world use of heavy duty long haul truck engines, they also result in a “calculated” fuel consumption reduction of between one half and one percent. This “baseline shift” is not reflected in the current proposal, which means that the “actual” required engine efficiency improvement from 2017 to 2027 (a period marked by no planned changes in NOx or particulate matter (PM) emissions) is between 3.2 percent and 3.7 percent, resulting in an annualized reduction rate of only 0.35 percent per year. According to industry sources2 in the period between 1980 and 1999 (a period with relatively few new NOx and PM rules), heavy duty engine OEMs were reducing fuel consumption at an annualized rate of 0.8 percent. This rate of development was not driven by regulatory pressures, but rather was motivated by the desire of engine OEMs to offer reduced operating costs to their customers in a highly competitive truck sales environment. Based on this precedent, and discussions with our OEM customers, HTS believes that in a stable NOx and PM regulatory environment, competitive pressure will drive engine OEMs to reduce fuel consumption at a rate that is higher than is reflected in the current engine-level proposal and more in line with historical performance. We therefore believe that a more stringent regulation could be met without being overly burdensome on engine manufacturers, the trucking industry and consumers. [EPA-HQ-OAR-2014-0827-1230-A1 p.2-3]

Therefore, HTS recommends that the engine-level standard be moved to Alternative 4, with a 4.2 percent improvement over the 2017 baseline effective in 2024, and a 7 to 10 percent improvement over the 2017 baseline by 2027. [EPA-HQ-OAR-2014-0827-1230-A1 p.3]
We appreciate that revised weighting factors for the SET cycle CO2 emissions for the heavy-duty tractor engine standards have been included in the proposal. These revised weighting factors better represent real-world operating conditions of long-haul trucks with minimal additional complexity. However, the new weighting factors effectively represent a regulatory downspeeding of engines, and we estimate this will result in a cycle-weighted fuel consumption improvement of approximately 1 percent, with no changes made to the actual engine. This essentially means that 2021 model year engines only need to be .5 percent more efficient than the 2017 baseline, a .12 percent per year improvement over a 4-year time period. This is well below the industry’s historical continuous improvement rate of change in efficiency. The new weighting factors have a similar impact on subsequent emissions reduction levels.

For this reason, we believe there is room to make the engine-level CO2 reduction larger than is reflected in the current proposal, without the need for widespread adoption of advanced technologies like Rankine Cycle waste heat recovery. Honeywell can help provide data and work with the EPA to refine the inputs to models to better reflect the improvements that air systems technology can provide in order to enable this.

Response:

The agencies have corrected the tractor engine baseline for the final rule to reflect the reweighting of the 13 modes of the SET. The agencies have also increased the stringency of the engine standard over that proposed. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase. The agencies have calculated stringency from revised baselines which (particularly for the FTP baseline) reflect historic improvements in engine performance consistent with the commenter’s suggestion.

Organization: National Association of Clean Air Agencies (NACAA)

Toward this end, we believe the proposed engine standards must be strengthened. Others—including the California Air Resources Board (CARB), engine makers and independent non-governmental organizations—have suggested engine efficiency can be improved significantly more than the modest 4.2 percent proposed by EPA. Recent work by the Southwest Research Institute, West Virginia University, the U.S. Department of Energy’s SuperTruck teams and Cummins, the largest manufacturer of heavy-duty truck engines, all indicates the feasibility of engine GHG reductions in the Phase 2 timeframe at levels more than twice that included in the proposal. Further, these analyses, as well as those of EPA, indicate that technologies to achieve this degree of improvement are currently available and highly cost effective. In conjunction with increasing engine standards, we also recommend that EPA increase the corresponding whole-vehicle standards to capitalize on the full emission reduction potential of efficiency-improving technologies. We believe it is imperative that EPA strengthen the engine and vehicle standards in the final rule to reflect this. [EPA-HQ-OAR-2014-0827-1157-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.53.]]
We have made the standards more stringent from those proposed. See earlier comment responses and Chapters 2.3 and 2.7 of the RIA, which detail the justification for this increase.

Organization: Natural Resources Defense Council (NRDC)

Setting strong, long-term national limits on motor vehicle global warming pollution and fuel efficiency standards is a necessary and important action for the U.S. to meet nation targets for reducing greenhouse gas (GHG) emissions. It is appropriate and necessary that President Obama has made medium- and heavy-duty vehicle GHG and fuel consumption standards an integral part of his Climate Action Plan.

Medium- and heavy-duty vehicle performance standards are an essential component of a comprehensive strategy to cut U.S. global warming pollution and oil consumption. The transportation sector is responsible for approximately a third of the nation’s greenhouse gas emissions and 70 percent of total oil demand. Highway medium- and heavy-duty vehicles are second only to light-duty vehicles in total fuel consumption and global warming pollution within the transportation sector. According to the agencies, medium and heavy trucks consume 20 percent of the oil used in the transportation sector and emit about 20 percent of transportation sector global warming pollution. Yet these trucks represent only about 5 percent of the vehicles on the roads.

The process of setting the Phase 2 medium- and heavy-duty vehicle standards extends a record of success that started with the model year 2012-2016 light-duty vehicle GHG and fuel economy standards. The Phase 2 truck standards address both the need for the National Highway Traffic Safety Administration to set fuel efficiency standards under the Energy Independence and Security Act of 2007 and the requirement for U.S. Environmental Protection Agency to regulate emissions of greenhouse gases under the Clean Air Act.

The Phase 2 proposed rule is a very important step forward but it should be strengthened to maximize the environmental, security and economic benefits. Below, we recommend actions the agencies should take to improve the proposal to better meet the Administration’s overall energy and climate security goals and address the imperative that we dramatically reduce carbon pollution.

---

1 On March 31, 2015, the U.S. submitted its target to the United Nations Framework Convention on Climate Change to reduce GHG emissions by 26-28% below 2005 levels by 2025.

Ibid.

Response:

We appreciate your comments, and we believe that our final rule will indeed meet the Administration’s overall energy and climate security goals and address the imperative that we dramatically reduce carbon pollution.

Organization: Navistar, Inc.

We believe the inclusion of CO2 emissions from IRAF’s as part of the existing certification test procedure would be both non representative of the in-service activity and increase the aggregate certification burden. In addition the inclusion of CO2 IRAFs may actually increase CO2 emissions in service as manufacturers balance the certification penalties against reduced DPF backpressure between regenerations. [EPA-HQ-OAR-2014-0827-1199-A1 p.22]

The agencies’ acknowledged that “manufacturers have already made great progress in reducing the impact of regeneration emissions since 2007.” Since the onset of use of regenerative DPFs emission increases have been practically nil. Currently regeneration rates are driven more by timer based algorithms for soot removal and desulfurization rather than demand based DPF loading. Many in-service line haul fleets have reported intervals of thousands of miles between regenerations due in large part to passive regeneration. By including the fuel consumed during regeneration there will be a natural tendency for manufacturers to reduce the frequency and duration of regenerations to avoid the implications of regeneration fuel penalty. However this approach can have the unintended consequence of increasing DPF backpressure and pumping losses absent increased passive regeneration, which can have a direct and negative impact on fuel economy. [EPA-HQ-OAR-2014-0827-1199-A1 p.22]

As engine out NOx levels increase in order to improve base engine fuel economy there will be an associated increase in passive regeneration, which will only further reduce regeneration frequency. As aftertreatment systems improve with each generation, they become more operationally efficient. Manufacturers need the flexibility to size and operate their systems to maximize the aggregate fuel economy without increasing the regulatory burden, not to mention the risks to component durability or to customer fuel economy. We would therefore recommend that Phase 1 requirements be extended to Phase 2. [EPA-HQ-OAR-2014-0827-1199-A1 p.22-23]

VI. Response to Comments on Engine Standards

In light of discussions with EPA for a realistic rule, Navistar feels that it must comment additionally on comments by other commenters as well as other documents recently placed in the docket, specifically a document by a Mr. Walsh and Mr. Charlton. While EPA chose not to seek further comment as part of the NODA, Navistar feels that the issues raised in those materials are important enough to highlight in these additional comments. Primarily, we feel it is important to respond to comments that we find are technically inaccurate and misleading. Walsh and Charlton based their recommendations of increased
engine stringency on the achievements of participants of the Department of Energy (“DOE”) - funded SuperTruck program, of which Navistar is an awardee. [EPA-HQ-OAR-2014-0827-1919-A2 p.8-9]

The basic premise of the SuperTruck initiative was to demonstrate 50% freight efficiency improvement at 65 mph and to demonstrate 50% engine BTE at the vehicle’s cruise point. The participants demonstrated a wide range of technologies in order to achieve these objectives. However, it is a technology development program and by definition limited to a specific operating condition or cycle. Furthermore, the technologies are highly experimental, have not been vetted for commercialization, and thus, are not all likely to be ready for production in the foreseeable future. Therefore, we want to give the EPA as much information as possible to develop a realistic and successful implementation of the Phase 2 regulations. [EPA-HQ-OAR-2014-0827-1919-A2 p.9]

Walsh and Charlton’s claims and recommendations were summarized as 11 major findings and are focused on tractor engines. In the proposed Phase 2 regulations, these engines are certified in the ramp modal cycle (RMC) for CO2 and the FTP for the other GHG constituents. The NPRM also proposed a reweighing of the modes in this cycle that departs from that used for criteria pollutants, but that aim to align the engine standard to the real world or in-vehicle usage of these engines. In the following, Navistar highlights the major concerns with the authors’ findings. [EPA-HQ-OAR-2014-0827-1919-A2 p.9]

Finding 1 & 2 & 7: The authors erroneously attempt to use the achievement of SuperTruck as evidence for further stringency on the engine standard. SuperTruck achievement of 50% or greater BTE for the engine is a single point demonstration, as opposed to the cycle demonstration (RMC) required for GHG certification of an engine. This is very clearly shown in Figure 5 of their paper, where the authors highlight the region that is used in the SuperTruck demonstration overlaid with the RMC modes: this is a very small subset of the test cycles used in the regulatory framework. Furthermore, systems on the demonstrator engines are not all production feasible. These SuperTruck programs are unconstrained to the limitations of production feasible solutions. SuperTruck programs are not required to deliver production requirements of full tailpipe compliance (deterioration factors, NTE), On-Board Diagnostics as well as all other regulatory requirements of other constituents (NOx, N2O, and CH4) or with the level of robustness necessary for production feasible systems. [EPA-HQ-OAR-2014-0827-1919-A2 p.9]

Figure 1 shows a typical tractor engine map. This is the 2018MY representative tractor map available in the EPA Phase II GEM model that is used to set the baseline for the GHG Phase 2 regulations. The modes for the RMC are overlaid and show the weighting (by size) as proposed in the NPRM. From this figure it is clear that the authors have extrapolated the achievements of SuperTruck in their recommendation of 50% BTE in the RMC cycle. At the A-speed, which is the highest weighted speed, the BTE of a typical engine that meets 2017MY GHG will range from 39% at the lower torque to a maximum of 46% at the 75% load point. In order for such an engine to meet a composite number of 50% with the assumption of a flat map, the part load points would need to improve over 11% efficiency points and this is without the appropriate engineering margins. Furthermore, the assumption of a flat map is counter to the physics and the optimization of the systems that support the function of the engine as is demonstrated by what EPA considers state-of-the-art today. Within the space of the RMC cycle, excluding the idle point, BTE ranges from 34% to the maximum already stated of 46%. Hence, in the event that a manufacturer had to design for the 50% BTE, the engine would have to significantly exceed the achievements of the SuperTruck program by having the cruise point be well above 50% BTE and even exceeding the secondary objective of a pathway to 55% BTE as shown in Figure 2. Figure 2 is a hypothetical map using the realistic shape of the engine map that mathematically results in 50.5% BTE for the RMC with GHG Phase 2 weighting. Production margins, hence, would dictate a peak efficiency of 60% to achieve Charlton and Walsh proposed stringency. In Navistar’s opinion, the recommendation by Charlton and Walsh is based on misleading premises and not physically possible. [EPA-HQ-OAR-2014-0827-1919-A2 p.9-10]
Finding 3: Unlike the claim by Charlton and Walsh, significant improvements in both engine and aftertreatment technologies will have to be implemented in order to achieve the currently proposed engine targets included in the GHG Phase 2 NPRM. The authors only focus on the stringency of CO2 in this claim, and throughout the paper, and treat the engine standard as a standalone requirement in the rule. They fail to account for the implications of the rule as a whole: consideration of the implication of the other regulated GHG constituents, known future pressures to reduce NOx for which the NPRM protects (inclusion of IRAF, etc) and the engine in the context of the vehicle regulation. Per our comments submitted to the NPRM docket, the rule in its full context represents 10% efficiency improvement over the MY2017 engines, which have yet to make it to the marketplace and themselves represent over 3% improvement over the MY2014 engines. [EPA-HQ-OAR-2014-0827-1919-A2 p.11]

The addition of the manufacturer specified fuel maps to the vehicle standards in Phase 2 and expanded selective enforcement audit (SEA) programs will drive additional stringency on the engine to account for compliance and production margin (shown in Figure 3 as a dotted green line). The reweighting of the RMC cycle is critical and without it the engine, as a standalone component, and its technologies would not align with the vehicle standard (or GEM). Again, as shown in the author’s Figure 5, the reweighting is closer to real world operation (NESCAUM cycle) and will drive technologies that will have significant impact on the real world CO2 as opposed to just meeting a generic standard on a dynamometer. [EPA-HQ-OAR-2014-0827-1919-A2 p.11]

The combined Phase 1 and Phase 2 rules in essence result in over 10% improvement in engine efficiency in the span of 13 years. However, when other components of the GHG Phase 2 regulation are taken into account, the full impact of this rule is about 17% improvement in that span even with the reweighting of the RMC. [EPA-HQ-OAR-2014-0827-1919-A2 p.12]

Finding 10: Charlton and Walsh argue against the reweighting of the RMC because it breaks the linkage with criteria pollutant cycles. They contradict themselves with such an argument. The intent of the rule is to address climate change and they recommend increased stringency without the reweighting of the RMC cycle to achieve this change. However, numerous studies and databases exist that document the usage of engines in the tractor applications in the line-haul sector, and these were the basis of the reweight. Though heavy-duty vehicles only represent 4% of the vehicles on the road, they consume about 18% of the fuel in the US and the line-haul sector represents over 60% of that. Therefore, in order to enact the necessary climate change the improvements need to be realized in real-world representative cycles. [EPA-HQ-OAR-2014-0827-1919-A2 p.14]
The authors site the unintended consequences to criteria pollutants as a counter argument, not acknowledging that current regulations already tightly control the engines emission of criteria pollutants. Beyond the dynamometer cycle demonstration, there are Not-To-Exceed requirements. The NTE requirement, added in 2007, regulates the pollutant output of an engine at a maximum of, for example, 1.5 times the standard for 2010, for a wide range of ambient conditions and altitude. There are also the On-Board Diagnostic (OBD) requirements introduced for all HD diesel engine in 2013. This requires that the engine’s control systems detect malfunctioning components of the emission control systems (EGR valves, injectors, etc.) throughout the useful life for the engine. In addition, the CO2 regulatory impact for the Phase 2 regulation is only captured from the Vehicle standards which operate closer to real world with the GEM cycles. [EPA-HQ-OAR-2014-0827-1919-A2 p.14]

In conclusion, Navistar supports the implementation of a realistic, impactful and commercially feasible rule. The Proposed Rule is of such complexity, and carries such widespread ramifications for the industry that commenting on the inaccuracies represented in the paper by Charlton and Walsh is critical. They fail to acknowledge and explain that the achievements of the SuperTruck program are limited to a very small subset of an engine map and are not representative of the certification RMC cycle. The stringency that they recommend is not physically possible and requires engine peak efficiencies > 58% BTE, something that was not demonstrated in the SuperTruck program or in the pathways. Downspeeding is correctly accounted for in the vehicle portion of the standard as it requires the full powertrain definition in order to achieve the gains. WHR systems are in the infancy of development with no commercially feasible implementation at the current time and has dis-synergy with the rule itself. The agencies have adequately account for its penetration in the lifetime of this rule. [EPA-HQ-OAR-2014-0827-1919-A2 p.15]

To create the hypothetical engine that forms the baseline for the vocational engine in GEM, the agencies constructed a hypothetical engine map. This was not derived from an actual in-use engine. Our current analysis of this hypothetical map shows a shift in the baseline from actual, real-world engines. That is, the theoretical starting point, the MY17 standards, has changed. The baseline engine maps within GEM for the vocational vehicle are not aligned with current 2017MY compliant engines and hence, set up an unrealistic baseline for the vocational vehicle standard. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

Navistar took one of its MY2017 CO2 compliant engine families and created an engine map for use in the Phase 2 version of GEM. Comparing the tested engine map to the 2018MY baseline maps the tested engines showed differences ranging between 1 to 5% in the cruise part of the map and around 10% in the “acceleration” part of the map for the 345hp engine map to 10% to 15% differences for the 350hp engine map. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

The problematic areas of the hypothetical vocation baseline engine include the following: [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

- The EPA 345 hp HD generic engine map has an uncharacteristic shape where the minimum BSFC points is at 9% of maximum power. Other hypothetical engines show 80% of maximum power. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]
- The 270 hp MD hypothetical engine is flawed as well. Comparison with actual compliant MY2017 engines show that the hypothetical engines were 10% higher in fuel consumption than the real-world engines. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

Ultimately, this discrepancy must be corrected. Navistar will separately provide proprietary information to EPA showing this concern in greater detail. All manufacturers should begin from the same starting line, the actual MY2017 emission performance of the engines. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]
11 EPA-HQ-OAR-2014-0827-1237. EPA also placed a powerpoint presentation delivered to EPA by the same authors in the docket.

12 Participants at the Transportation Combustion Engine Efficiency Colloquium found that, with money as no object, 60% BTE is the maximum efficiency possible for current engine configurations. See K. Edwards, et al., Defining Engine Efficiency Limits, presentation at 17th DEER Conference 3-6 October 2011. Available at http://energy.gov/sites/prod/files/2014/03/f8/deer11 edwards.pdf

Response:

We do not believe inclusion of CO$_2$ into IRAF will significantly impact the stringency of these standards because manufacturers have already made great progress in reducing the impact of regeneration emissions since 2007. Nevertheless, we believe it is prudent to begin accounting for regeneration emissions to discourage manufacturers from adopting compliance strategies that could reverse this trend. See Response 3.3.4.

We appreciate Navistar’s comments on a document by Mr. Walsh and Mr. Charlton. We largely agree with these arguments. Specifically, we agree that the peak thermal efficiency deduced by the Walsh/Charlton reports would not be realistic. We agree that use of the SuperTruck program data can be misleading because data sources are limited to a very small subset of the engine map and are not representative of the certification RMC cycle. The technology path for downspeeding proposed by the Walsh/Charlton report is not practical, because while the peak torque of the engine moves down to an engine speed of around 800 rpm, the required high boost pressure cannot be maintained due to the engine’s low speed. We agree that there may be a trade-off between some of the technologies used for NOx reduction and those used for fuel economy improvements (although we do not believe the NOx control and fuel consumption improvements are mutually exclusive (see, e.g. RTC Section 15.8.1)).

All the agencies’ baseline engines are developed based on real life in-use engines. In the final rule, we have combined a 345hp engine with a 350hp engine as one engine, which will be applied to both tractor and vocational vehicles. In combining these two engines the minimum brake specific fuel consumption point is now in line with the other baseline engines and is located at approximately 70% of peak engine power. We also made changes to the 270hp baseline engine fuel map. However, it should be pointed out that the engine for the baseline 270hp rating engine was 7 liter based, and is much smaller than the Navistar 9 liter engine. As a result, the engine sweet spot and the rated speed are also appreciably different. On the other hand, the 350hp engine used by the agencies is 11 liter based, and is bigger than Navistar’s N10 engine. Depending on the vehicle configurations, such as transmission, and axle ratio, the engine operating points in terms of engine speed and load can be so different between two different engines, resulting in different values of CO$_2$ g/hp-hr. Although we did not provide the baseline values, we made the best efforts to supply those vocational vehicle baseline values in the later power user release version provided for comment.

Organization:  Northeast States for Coordinated Air Use Management (NESCAUM)

The engine standard should be stronger.

The proposal would reduce fuel consumption from engines by 4.2 percent, which is far short of what is achievable over the coming decade. We note that at least one engine manufacturer has indicated potential engine efficiency improvements of 15 percent or more even with advanced NOx controls. Moreover,
EPA’s estimates for both the effectiveness and likely market penetration of engine efficiency technology improvements are far too conservative, according to analyses performed by CARB and ICCT. [EPA-HQ-OAR-2014-0827-1221-A1 p.2] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.138.]

Response:

See response to EDF above noting both the increased stringency in the final engine standards from those proposed, and explanation of why more stringent standards are either not feasible or unreasonable.

Organization: Shahed, SM

The proposed Phase 2 standards only require a 4% reduction in fuel consumption and CO2 emissions of engines, compared to Phase 1, through 2027, a requirement that may well be met with already demonstrated technology. If the standard is set too low, it presents a risk that the agencies’ goal of spurring development and deployment of advanced technology may not be met, and it may render the separate engine requirement largely meaningless. [NHTSA-2014-0132-0033-A1 p.2]

The EPA has a long and successful history of setting technology forcing standards. I respectfully suggest the Phase 2 engine standard can require a larger reduction in fuel consumption to become at least “technology encouraging” if not “technology forcing.” Enough promising technologies and time exist to provide compliance at a cost increase that meets the payback scenarios outlined in the proposed standard. Based on my experience and judgment, I support anywhere between 10% and 15% fuel consumption reduction for Phase 2 heavy engine standards, depending on how ambitious the regulators want to be. [NHTSA-2014-0132-0033-A1 p.2]

Response:

We made a few key changes on engine standards. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the projected market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the tractor engine standards’ projected stringency over the baseline increased from 4.2% to 5.1%. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase.

It should be pointed out that while the literature, specifically from the DOE SuperTruck program, demonstrates more reduction on the engine side, the technology demonstrations only focus on a single
operating point. In contrast, we consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point.

Organization: Sierra Club

Strengthen the engine standard

The engine standards finalized in this rule will influence the engine technologies adopted over the next 15 years. Unfortunately, the proposed standards only require roughly a 4 percent improvement in engine efficiency, far short of what can be achieved. Organizations such as the American Council for an Energy-Efficient Economy have noted that a 10 percent increase in engine efficiency is possible over the timeframe of the rule. We urge you to strengthen the engine standard to ensure continued gains in engine efficiency in the years to come. [EPA-HQ-OAR-2014-0827-1277-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.189]]

Response:

As detailed in the RIA, we believe the 10% increase in 2027 is beyond what is feasible in this time frame industry-wide. Data cited by the commenter mainly relies on the literature, including DOE SuperTruck programs, which are not directly applicable. The values from the literature are single optimal operating points and not operation over the entire engine map. Further, those values were demonstrated in an R/D environment. In contrast, we must consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point. Technology effectiveness is also not additive. Chapter 2.7.5 of the RIA details justifications of dis-synergy used in the rule. These justifications were also supported by many industry comments, such as the reports made by four major vehicle OEMs (EPA-HQ-OAR-2014-0827-1894) as well as other comments made by individual vehicle OEMs (Daimler Truck North America and Navistar). The technology effectiveness of WHR in Rankine cycle used by the agencies, which we project to be less effective than what commenters recommended, were directly obtained from credible, but CBI information, based on the recommendation from a leading engine manufacturer. It is critical to derive the standards based on the agencies’ weighting factors over 13 modes, vehicle weight, and three vehicle certification cycles. Thus, the adjusted values for stringency are typically much smaller than the values seen in the literature. Having said that, we have made changes to strengthen the standards from those proposed. In the final rule, we did readjust the baseline of the tractor engine standards to reflect the SET reweighting impact. Chapter 2.7.4 of the RIA and Response 3.3.3 discuss the change in the baseline. We made a few other key changes to engine standard analysis. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the 2027 tractor engine standards’ projected stringency over the baseline increased from 4.2% to 5.1%. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase. We also strengthened the vocational engine standards after readjustment of the baseline values of the engines.

Organization: Truck & Engine Manufacturers Association (EMA)

Accounting for IRAFs

The Agencies are proposing to require the inclusion of the emissions from any infrequent regeneration events into the various Phase 2 test cycles. (See Proposed sections 1065.680, 1036.501(d) and 1036.530(a)). There is no basis for this change from Phase 1. The rates of infrequent regenerations have
been going down since the adoption of the Phase 1 standards, not up. Thus, there is no factual predicate for the proposed change from the Phase 1 program. [EPA-HQ-OAR-2014-0827-1269-A1 p.39]

In Phase 1, the Agencies excluded IRAF contributions based on their correct understanding that such contributions are minor, and that competitive pressures drive manufacturers to continue to seek ways to minimize the frequency of regeneration and its associated fuel efficiency penalty. The rationale for excluding IRAF in Phase 1 is equally valid for Phase 2. There are no reasonably anticipated circumstances under which manufacturers would seek to increase IRAF-associated fuel consumption penalties. In fact, the proposed fuel efficiency improvements are more than likely to pressure manufacturers towards developing engines at higher in-cylinder NOx levels, which are beneficial to passive regeneration of diesel particulate filters, and lower particulate emissions levels due to the natural tradeoff between NOx and particulates. Consequently, the need for active regenerations and the associated IRAF impact on fuel consumption can be expected to decrease. For these reasons, and in recognition of the vastly increased burden of the Phase 2 regulations, EPA should maintain the Phase 1 approach of excluding IRAF effects in the testing and data processing for Phase 2. [EPA-HQ-OAR-2014-0827-1269-A1 p.39]

Response:

We do not believe that the inclusion of CO$_2$ into IRAF will significantly impact the stringency of these standards because manufacturers have already made great progress in reducing the impact of regeneration emissions since 2007. Nevertheless, we believe it is prudent to begin accounting for regeneration emissions to discourage manufacturers from adopting compliance strategies that could reverse this trend. See Response 3.3.4.

Organization: Union of Concerned Scientists (UCS)

TRACTOR ENGINE STANDARDS

The largest single area of verifiable fuel consumption reduction over the lifetime of the vehicle comes from improvements to the engine. Therefore, it is critical that the regulations measure these improvements and push manufacturers to invest in technologies that will reduce fuel consumption from the engine without compromising further reductions in criteria pollution. [EPA-HQ-OAR-2014-0827-1329-A2 p.5]

Adjustment to the engine test cycle. Based on data from manufacturers, the agencies revised the SET engine test cycle. This revision for greenhouse gas emissions shifts much of the weighting of the highest test speed (C) to the lowest speed (A), reflecting the industry move towards downspeeding. We support the agencies’ revision and believe that this helps ensure that the standards reflect on-road behavior as much as possible and encourage investment in technologies that will provide real world benefits. [EPA-HQ-OAR-2014-0827-1329-A2 p.8]

Future regulation of criteria pollutants should correct the disparity the Phase 2 regulation has created between the SET test weightings for fuel consumption regulations and those for criteria pollutants. This correction is necessary both to better assess the real world pollution from these engines and to ensure that manufacturers cannot try to game the system by reducing NO$_x$ emissions more in the zone more heavily weighted in the criteria test while increasing NO$_x$ and reducing fuel consumption at the lower speeds where the vehicle is more likely to run. [EPA-HQ-OAR-2014-0827-1329-A2 p.8]

In assessing the impact of this procedural adjustment, however, the agencies did not seem to appropriately consider how this revision would affect the baseline for improvement. The agencies have presented two
engine maps that are compliant with 2017 model year standards: the 2017 map from Phase 1 and the 2018 baseline map for Phase 2. In the Draft RIA (p. 2-82), the agencies note that the 2018 baseline reflects two changes: 1) the “sweet spot” has been broadened, and 2) the engine is designed to be increasingly downsized. However, the resultant 2018 map shows an increase in fuel consumption at lower engine speeds, which is the exact opposite of what one would expect (Table 1). In fact, while the two engines would have similar scores under the Phase 1 SET weightings, our analysis shows that the agency’s revised engine results in a 0.6-percent increase in emissions from the 2018 engine on the Phase 2 weighting compared to the 2017 engine. This change effectively lowers the bar for manufacturers for Phase 2 without making any changes to their 2018 engines. [EPA-HQ-OAR-2014-0827-1329-A2 p.8]

[Table 1, ‘Comparison of Calculated Engine Performance and Regulatory Values’, can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

The fact that both engines showed a reduction in fuel usage on the SET(2) weighting compared to SET(1) the same value as the 2017 HHD tractor engine standard, which is based the SET(1). We thus further calculated the SET(1) and SET(2) results of all the engine maps that the agencies have used to set the stringency of the heavy duty engine regulations. Our analysis indicates that while the calculated values well-replicate the SET(1) values, the stringency in Phase 2 set according to the SET(2) weighting does not accurately reflect the engine maps provided. In fact, according to our analysis, the agencies’ engine maps significantly outperform the Phase 2 engine standard, by as much as 1.6 percent in 2027. It is difficult to assess the reason for this disparity—one possibility is that the agencies did not adjust the engine standard to reflect the new SET(2) weighting, since our calculated values for each engine’s performance on the SET(1) more closely mirror the standard. What is clear, however, is that the agency’s own engine maps achieve a 434 g CO2/bhp-hr level on the reweighted test cycle is an improvement of 5.7 percent over the agencies’ baseline value of 460 g CO2/bhp-hr, not 4.2 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.8-9]

The agencies' proposal must be 'technology-forcing' and achieve the 'maximum feasible' reductions in the timeframe of the rule. To do this, the agencies must strengthen Alternative 4 by: [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

- Increasing the stringency of the engine standard in 2024 to at least 9 percent from the current baseline to ensure real-world reductions over the lifetime of the vehicles; [EPA-HQ-OAR-2014-0827-1329-A2 p.27][This comment can also be found in section 1.5 and 1.7 of this comment summary]

Diesel engines. While most of the technologies assessed by SwRI on the diesel engine were considered by the agencies in setting the vocational engine standard, SwRI noted much greater potential in friction reduction than the agencies, achieving 1.9-percent improvement at 65-mph and 6.2 percent on the transient cycle compared to the baseline engine. After factoring in the improvements already captured by the agencies in Phase 1 and 2, this led to additional improvements to diesel-powered vocational vehicles of between 1.7 and 2.9 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.21]

Response:

We have made all necessary changes on the baseline tractor standards to reflect the new SET weighting factors. We also made a few key changes to the engine standards. See earlier responses and Chapters 2.3 and 2.7 of the RIA.
It should be pointed out that while the literature, specifically from the DOE SuperTurck program, demonstrates more reduction on the engine side, the technology demonstrations only focus on a single operating point. In contrast, we consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point.

Using the same principle as in the SwRI final report together with the agencies’ vehicle certification weights and certification cycle weighting factors over 55mph, 65mph, and ARB cycles; SwRI’s findings largely support the agencies’ final standards, including friction reduction.

**Organization:** Volvo Group

Fortunately, technologies aimed at reducing vehicle power demand, such as improving aerodynamics and reducing rolling resistance, result in less total work needed from the engine to complete the mission of moving cargo from point A to point B, and therefore proportionately less total NOx is emitted. This is not the case, however, when it comes to technologies focused on improving engine efficiency. Here, the NOx/efficiency trade-off typically results in precisely the opposite effect. The most logical thing EPA and NHTSA could do to avoid forcing this trade-off is to eliminate the separate engine standards in the proposal. At minimum, they should maintain the proposed engine stringency levels to mitigate undue risk of unintended consequences. This would permit manufacturers to focus their development efforts on efficiency technologies that capitalize on synergistic GHG-NOx reduction opportunities, rather than those engine technologies that complicate and frustrate future NOx reductions. [EPA-HQ-OAR-2014-0827-1290-A1 p.60]

While not referenced in the NODA, a paper had been submitted to the docket (EPA-HQ-OAR-2014-0827-1237) which presented arguments encouraging the Agencies to increase the stringency of the engine standards proposed in the NPRM. The Volvo Group joined with Daimler Trucks North America, Navistar, Inc., and PACCAR Inc. to prepare comments refuting many of the arguments posed in the paper. These joint comments, which stress the importance that the Agencies avoid unintended consequences by maintaining the standards as proposed, were submitted to the docket. [EPA-HQ-OAR-2014-0827-1928-A1 p.3]

**Response:**

We understand Volvo’s concerns on engine NOx trade-off with CO₂. We will work with Volvo closely on this matter of and when the time comes. We also appreciate Volvo’s comments submitted to the docket (EPA-HQ-OAR-2014-0827-1237).

**Organization:** Walsh, Michael and Charlton, Stephen

The literature related to control of GHGs from medium- and heavy-duty commercial vehicles is extensive. Every attempt has been made to include the most relevant, high quality and influential reports, presentations and reviews on the subject. [NHTSA-2014-0132-0102-A1 p.16]

5.1 **NAS GHG Phase 1, Final Report** [37]

Section 108 of EISA required that NHTSA contract with NAS to undertake a study and develop a report that evaluated medium- and heavy-duty truck fuel economy. This study was carried out between 2008 and 2010 and resulted in the publication of a 250 page report outlining possible regulatory structures, metrics, certification methods and available vehicle and engine technologies that could be applied to reduce GHG emissions and improve fuel efficiency. [NHTSA-2014-0132-0102-A1 p.16]
In addition to seeking input from a broad range of stakeholders, NAS contracted with TIAX [36] to carry out an in-depth analysis of available technologies and the related unit and capital costs. The TIAX study informed NAS significantly on the state of existing and emerging technologies across all vehicle classes from Class 2b through Class 8. [NHTSA-2014-0132-0102-A1 p.16]

Key findings included:

- The major enabling technologies necessary to achieve significant reductions in fuel consumption are hybridization, advanced diesel engines, and aerodynamics.
- Diesel engine advancements are helpful in all applications and will include continuing improvements to fuel injection systems, emissions control, and air handling systems, in addition to commercialization of waste heat recovery systems.
- Diesel engines have the potential for 15-21% reduction of fuel consumption in the 2015-2020 time frame, relative to a 2008 baseline. This was by far the most significant area of improvement for Class 8 tractor-trailers identified in the study. [NHTSA-2014-0132-0102-A1 p.16]

By this estimate, the NAS committee indicated a potential for diesel engine BTE to reach somewhere between 47.2% and 50.8%, (416 – 387 gCO2/HP-hr) given a 2008 baseline of 40.1%, which became the baseline for the Phase 1 regulation. [NHTSA-2014-0132-0102-A1 p.16]

A summary of the results from this study are included in Appendix D [see p.39] for reference. [NHTSA-2014-0132-0102-A1 p.16]

5.2 NAS GHG Phase 2, First Report, 2014 [38]

NAS published a further report to inform EPA and NHTSA as they prepared the proposed Phase 2 GHG rule [38]. This report is in effect an interim report, to be followed by a final report expected in 2016. The EISA anticipates that the NAS will update its report at 5-year intervals through 2025. The committee was formed in January 2013 and published their interim report in early 2014 by agreement with NHTSA. At the time of publishing the interim report the committee was unable to complete their assessment of available technologies to support the Phase 2 rule: [NHTSA-2014-0132-0102-A1 p.16]

“Owing to time constraints for preparation of this report, the committee has not been able to conduct a comprehensive analysis of new technologies that would supplement those identified in the National Research Council (NRC) Phase One Report.” [NHTSA-2014-0132-0102-A1 p.16]

The committee observed that the Phase I Rule was informed by off-the-shelf technologies included in the NAS Phase One Report, and that the Phase 2 regulations would be informed by the NAS Phase Two Report on future and advanced technologies. To this end, NHTSA contracted with the Southwest Research Institute (SwRI) to conduct a multiyear study of fuel-efficiency technologies for medium- and heavy-duty vehicles (Classes 2b-8) in the years before and during the Phase 2 regulations’ time frame. The SWRI reports are reviewed in this study [42, 43]. [NHTSA-2014-0132-0102-A1 p.16]

The focus here is on the stringency of GHG emission and fuel consumption standards for HD tractor engines used in line-haul and heavy-haul applications, since these trucks have the highest vehicle miles travelled, burn the most fuel and emit the most CO2. [NHTSA-2014-0132-0102-A1 p.5]

**Finding 1**

The most recent NAS report published September 11, 2015 [41], which followed an in-depth study carried out over several months with multiple on-site visits, for the DOE SuperTruck program found that:

“The engine systems Goal 1 of a 50% BTE for an emissions compliant engine has been achieved. Two of the four SuperTruck teams have successfully demonstrated BTE greater than 50% in on-road tests using commercial, ultra-low-sulfur diesel fuel” NAS [41].

This significant milestone should be compared with the proposed limit standard for HD tractor engines contained in the NPRM of 441 gCO2/HP-hr, which is equivalent to a BTE of only 44.6%. [NHTSA-2014-0132-0102-A1 p.6]

**Finding 2**

Having validated that the SuperTruck program had met Goal 1 (50% BTE in highway cruise operations) the NAS committee has shifted their focus to defining the pathways to a HD engine attaining 55% BTE. The NAS committee observed that all of the programs are pursuing improved friction and pumping, more effective air boosting systems, smaller auxiliary and accessory loads, and improvements in WHR, and that all teams are investigating advanced low-temperature combustion (LTC) approaches.

While industry has its sights set on delivering commercially viable HD tractor engines capable of 55% BTE, this should be compared with the proposed limit standard for HD tractor engines contained in the NPRM of 441 gCO2/HP-hr, which is equivalent to a BTE of only 44.6%. [NHTSA-2014-0132-0102-A1 p.6]

**Finding 3**
The proposed rule contains very modest standards for HD tractor engines equivalent to a 2.1% to 3.1% reduction in GHG emissions and fuel consumption for 2027 and beyond. [NHTSA-2014-0132-0102-A1 p.6]

2027 Standard 441 gCO2/HP-hr is a 4.13% reduction from the 2017 Phase 1 standard of 460 gCO2/HP-hr. Relaxation of 1-2% by re-weighting the SET test cycle.

**Net reduction of CO2 is only 2.13% to 3.13%**.

Given the 12 year lead time to 2027 and the weak engine standards contained in the NPRM; if this rule moves forward in its current form it will stall investment in the advanced engine technologies already demonstrated in the SuperTruck Program as providing a 15-20% reduction in GHG emissions and fuel consumption. R&D funds are a scarce resource that will be withdrawn or reallocated to other priorities. [NHTSA-2014-0132-0102-A1 p.6]

The agencies have recognized the emergence of downspeeding by their proposed changes to the SET engine test cycle, as discussed in section 3.2.1 of this paper. [NHTSA-2014-0132-0102-A1 p.7]

“One of the key technology trends is to down speed, moving the predominant engine speed from the range of 1300-1400 rpm to the range of 1150-1200 rpm at vehicle speed of 65mph.” Draft RIA section 2.7.3 [15]

“It can be argued that, if the current SET weighting factors were retained in Phase 2, the test would even more poorly reflect real-world driving operations.” Draft RIA section 2.7.3 [15]. [NHTSA-2014-0132-0102-A1 p.7]

While the agencies have acknowledged that engine downspeeding is a key technology trend and have modified the engine test cycle to reflect this trend, they have failed to include the CO2 and fuel consumption savings in the stringency of the engine limit standards. In fact quite the opposite – by changing the test cycle the agencies have relaxed the stringency by 1-2% (section 3.2.1). By not including downspeeding in setting limit standards for engines, they have in effect further relaxed the standards – by as much as 2-4% per SWRI report #1 [42]. The combined relaxation is 3%-6%, which exceeds the overall reduction proposed in the NPRM [14]. Even by the agencies estimate of 1.8% reduction due to downspeeding, the combined relaxation is 2.8%-3.8%. [NHTSA-2014-0132-0102-A1 p.7-8]

The agencies having wrongly included downspeeding as a vehicle technology and allocated the CO2 reduction to the vehicle via the GEM simulation. By so doing they have relaxed the stringency of the engine limit standards, which is a significant oversight by the agencies. This issue can be corrected by including downspeeding in the derivation of the proposed engine standards, Draft RIA section 2.7.4, Table 2-8 [15]. [NHTSA-2014-0132-0102-A1 p.8]

**Finding 7**

Even with effective exclusion of WHR, advanced combustion and downspeeding, the agencies failed to set aggressive technology forcing standards for the technologies it did include in its preferred package: [NHTSA-2014-0132-0102-A1 p.8]

- Combustion / fuel injection optimization
- Engine friction and other parasitic losses
- Exhaust aftertreatment (Lower DP)
- Engine breathing system
Turbocharging system • Engine downsizing

For example, Volvo demonstrated 48% BTE without WHR [34] compared with the proposed standard for HD tractor engines of 44.6% BTE (441 g/CO2/HP-hr). Cummins demonstrated 48.3% BTE without WHR [30]. [NHTSA-2014-0132-0102-A1 p.8]

The standards proposed assume only very minor incremental improvements to current engine designs, and fall short of being technology-advancing. [NHTSA-2014-0132-0102-A1 p.8]

Finding 9

It is evident that only scant attention was paid to the progress being made by the SuperTruck teams from Cummins / Peterbilt, Daimler, Navistar and Volvo to improve HD tractor engine GHG emissions and fuel consumption. There is little evidence in the published reports from SWRI and the agencies of seeking data from the SuperTruck program – beyond citing the annual merit reviews as references. SWRI chose instead to rely on a cycle simulation model based on a 2011 engine and an Excel spreadsheet model of WHR. [NHTSA-2014-0132-0102-A1 p.9]

SuperTruck achievements were largely dismissed by both SWRI and the agencies: [NHTSA-2014-0132-0102-A1 p.9]

“All of these results shown in this paragraph are demonstrated through the DOE SuperTruck program at single operating point on the engine map, and therefore the overall expected reduction of these technologies is less than the single point result.” [14] NPRM page 186.[NHTSA-2014-0132-0102-A1 p.9]

“Note that the SuperTruck program engine goal focuses on achieving 50% brake thermal efficiency (BTE) at a single operating point, and that many of the technologies used in this program may not be commercially viable in the 2015 timeframe.” [43] SWRI Report #2, June 2015 [NHTSA-2014-0132-0102-A1 p.9]

“This package borders on that of a SuperTruck, and it provides benefits approaching what are being reported in the SuperTruck program. This package would demand a large increase in cost and complexity. Fuel savings benefits for this package range from 16% on the GARB urban cycle at 100% payload, to 35% at 65 MPH.” [42] SWRI Report #1, June 2015 [NHTSA-2014-0132-0102-A1 p.9]

The SuperTruck program was specifically designed to integrate emerging advanced technologies into over-the-road line-haul trucks, in order to demonstrate significant reductions in GHG and fuel consumption in real-world freight operations [21,24,26]. The freight efficiency results obtained over mixed drive cycles are compelling: [NHTSA-2014-0132-0102-A1 p.10]

“One truck has achieved a freight efficiency of over 175 ton-miles per gallon, compared to a 2009 model baseline efficiency of 99 ton-miles per gallon. In terms of fuel economy, the truck achieved 10.7 miles per gallon (mpg), compared to the baseline truck at 6.45 mpg” [41] NAS 21CTP Report #3, September 11, 2015. [NHTSA-2014-0132-0102-A1 p.10]

“A second truck has doubled fuel economy from a 2009 baseline of 6.1 mpg to 12.2 mpg over one long-haul route, with a 120 percent increase in freight efficiency in ton-miles per gallon from a 2009 baseline

This performance was achieved through both vehicle power demand reductions and engine BTE improvements: [NHTSA-2014-0132-0102-A1 p.10]

“The SuperTruck projects incorporated a number of vehicle power demand technologies that accounted for about 56 to 74 percent of the total fuel consumption reductions, with 26 to 44 percent coming from engine efficiency improvements.” [41] NAS 21CTP Report #3, September 11, 2015. [NHTSA-2014-0132-0102-A1 p.10]

NAS [41] found that the engines developed for the SuperTruck program contributed significantly to the in-use real-world freight efficiency improvements demonstrated. These engines, which demonstrated 50% or greater BTE at a highway cruise condition, were operated over complete duty cycles in-vehicle, which included idle operation, and transient operations such as: acceleration, highway cruise and deceleration. [NHTSA-2014-0132-0102-A1 p.10]

No attempt is reported by SWRI or the agencies to seek data, present data, or evaluate in any other way, the true performance of a SuperTruck engine. This is a significant miss by the agencies. [NHTSA-2014-0132-0102-A1 p.10]

Finding 10

By modifying the HD engine SET test cycle for GHG emissions and fuel consumption certification, the direct linkage between criteria pollutants and GHGs has been broken, since NOx and PM would continue to be measured on the current cycle. This loss of linkage between criteria pollutants and GHG emissions could lead to unintended consequences, for example with regard to in-use emissions. [NHTSA-2014-0132-0102-A1 p.10]

Recommendations

Figure 2 shows both Phase 1 and proposed Phase 2 GHG emission and fuel consumption standards, expressed as HD tractor engine BTE%. Also shown for reference are the assessments of NAS, SWRI and the results of the SuperTruck program. The determination of BTE% from brake specific CO2 emission is described in Appendix B. [NHTSA-2014-0132-0102-A1 p.10]

[Figure 2 can be found on p.10 of docket number NHTSA-2014-0132-0102-A1]

1. The agencies should revise and strengthen the standards for HD tractor engines used in line-haul and heavy-haul applications. These engines have the highest annual mileage, consume the most fuel and emit the most CO2. The following limit standards and schedule were found to be feasible in the time scale under discussion, and are recommended for consideration:

MY 2027 and beyond HD Tractor Engines 390 gCO2/HP-hr (50.4% BTE) [NHTSA-2014-0132-0102-A1 p.10]

The proposed change of weighting factors illustrated in Figure 4, reduces the stringency of the HD tractor engine GHG and fuel consumption standards. Increasing the weighting of the A speed from 23% to 45%, and reducing the C speed weighting from 23% to 5% has more or less the same effect as downspeeding.
The fuel consumption of a HD tractor engine is typically lower at the A speed than the B or C speeds. If the same engine were tested on both cycles, the new proposed cycle would deliver approximately 1-2% lower CO2. The proposed weighting factors relax the stringency of the HD engine standards significantly and should be taken into account when setting limit standards for CO2. [NHTSA-2014-0132-0102-A1 p.12]

</tbody>
</table>

[Figure 4 can be found on p.12 of docket number NHTSA-2014-0132-0102-A1]

5.5.1 Derivation of the Proposed Engine Standards

As described in Section II.D(a) of the HD Phase 2 NPRM [15], the agencies derived the proposed engine standards based on their projections of the effectiveness of various technologies over the proposed engine test cycles (i.e., percent reduction) and the extent to which such technologies could be adopted by industry by 2021, 2024, and 2027. [NHTSA-2014-0132-0102-A1 p.20]

Figure 9 shows the agencies derivation of the 2027 GHG emission standard with 4.2% reduction versus the 2017 Phase 1 baseline. According to the agencies, the maximum available GHG reduction relative to the 2017 Phase 1 base line is 8.1%, or equivalent to a BTE of 46.4%. However, this reduction is discounted by the agencies assessment of technology effectiveness (Dis-Synergy Factor) and market penetration. [NHTSA-2014-0132-0102-A1 p.20]

[Figure 9 can be found on p.20 of docket number NHTSA-2014-0132-0102-A1]

The data supporting this determination of HD engine stringency is clouded by at least three factors:

- “The agencies would not be able to release the more detailed numbers along each mode of 13 SET modes to justify the stringency proposal due to the nature of CBI.” [15]
- No explanation is given for the Dis-Synergy Factors (75% and 85%) used to discount the SET weighted reductions.
- The market penetration percentages are the result of a confusion by the agencies between the forces of regulation and the forces of the free market. The market penetration should be limited only by the exclusion of vehicle applications for which the technology is not applicable – i.e. it would not produce the desired reductions or would prevent safe operation of the vehicle. [NHTSA-2014-0132-0102-A1 p.20]

Figure 16 tabulates the Phase 1 and proposed Phase 2 standards for HD tractor engines in terms of BTE%. Also shown in Figure 16 are the recommendations of NAS [37] and SWRI [42, 43] and the results of the SuperTruck Program [31-35]. Figure 2 shows the same data as Figure 16 in graphical form. [NHTSA-2014-0132-0102-A1 p.24]

The Phase 2 2027 limit standard for HD tractor engines is 441 gCO2/HP-hr, equivalent to a BTE of 44.6%, and a reduction from the Phase 1 2017 HD tractor engine standard of 460 gCO2/HP-hr, of only 4.13%. In fact, the relaxation of stringency of the SET test cycle for HD tractor engines proposed in the
Phase 2 rule, described earlier (section 3.2.1), reduces the stringency further by between 1% and 2%. [NHTSA-2014-0132-0102-A1 p.24]

The proposed rule is therefore equivalent to only a 2.1% to 3.1% reduction in GHG emissions and fuel consumption, commencing in 2027. [NHTSA-2014-0132-0102-A1 p.24]

When considering the lead time available through 2027, and the progress demonstrated by the SuperTruck projects in both engine testing and vehicle testing, there is a compelling case for more stringent HD tractor engine standards than contained in the NPRM. This study finds that the following standards are technologically and commercially feasible and meet the president’s expectation for utilizing advanced technology: [NHTSA-2014-0132-0102-A1 p.25]

MV 2027 and beyond HD Tractor Engines 390 gCO2/HP-hr (50.4% BTE) [NHTSA-2014-0132-0102-A1 p.25]

---

2 Based on analysis of fuel maps used in HD Phase 2 version of GEM to set 2021, 2024 and 2027MY Standards. Draft RIA – Figures 2-12, 2-13 and 2-14 [15].

5 The loss of alignment between criteria pollutant emissions with GHG emissions caused by proposed changes to the weighting factors for GHG emissions, should be remedied by either reverting back to the SET test cycle used for NOx and PM for GHG certification, or by adopting the new test cycle for NOx and PM certification. [NHTSA-2014-0132-0102-A1 p.11]

Response:

We appreciate the commenter’s constructive comments. In the final rule, we do readjust the baseline of the tractor engine standards to reflect the SET reweighting impact. Chapter 2.7.4 of the RIA and Response 3.3.3 detail the reasons for the change in the baseline. We respectfully disagree with many of the arguments that pertain to a more aggressive engine standard. See Response to EDF in this section above. We have reviewed the reports from four major vehicle OEMs (EPA-HQ-OAR-2014-0827-1894) as well as other comments made by individual vehicle OEMs (Daimler Truck North America and Navistar), which rebut the points made by the commenter. Specifically, we disagree with the approach taken by the commenter regarding the technology effectiveness from DOE’s Supertruck program and NAS’s report. It appears that the commenter took single values out of the literature, primarily reflecting peak values, such as their findings 1 and 2 related to 50% and 55% BTE. The values from the literature are single optimal operating points and not operation over the entire engine map. Further, those values were demonstrated in an R/D environment. In contrast, we consider stringency over the 13 modes of the SET, where the reduction over the composite is (necessarily) not as great as the reduction over the single, most efficient, operating point. The technology path for downspeeding proposed by the commenter is not practical, because while the peak torque of the engine moves down to an engine speed of around 800 rpm, the required high boost pressure cannot be maintained due to the engine’s low speed. While we disagree with many of the comments, we agree with some. We have made the standards more stringent than proposed. We increase the dis-synergy factor from 0.85 to 0.9, and increase the projected market penetration for WHR Rankine cycle technology from 15% to 25% in 2027, and included down speed benefits on engines. As a result of that, the tractor engine 2027 MY standards increased from 4.2% (proposal) to 5.1% in the final rule. Chapters 2.3 and 2.7 of the RIA detail the justification for this increase. For vocational engines, we have adjusted the vocational engine baseline CO₂ emission level based on the new certification data, strengthening the standards relative to the NPRM. Chapters 2.3 and 2.7 of the RIA detail the justification for this increase.

### 3.3.1 Diesel (Compression-Ignition) Engine Standards

**Organization:** American Automotive Policy Council

**§ 1065.680 Adjusting emission levels to Account for Infrequently Regenerating Aftertreatment Devices**

Proposed changes to 1065.680 require that manufacturers develop regeneration emission rate and frequency factors to account for GHGs emitted during a regeneration event. Furthermore, EPA opines that these changes would not significantly impact the stringency of the proposed standards without providing
supporting data. AAPC testing, the results of which are presented below, indicates that the proposed changes increase the stringency by 4 - 5 %. Additionally the technology and associated costs needed to recover the proposed IRAF application towards GHGs does not appear to be incorporated into the draft RIA nor any of the supporting cost benefit analysis. AAPC recommends that the Agencies withdraw the proposed IRAF requirement relative to GHG emissions. [EPA-HQ-OAR-2014-0827-1238-A1 p.29]

[Table of medium duty diesel emissions can be found on p.29 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

Response:

We do not believe inclusion of CO$_2$ into IRAF will significantly impact the stringency of these standards because manufacturers have already made great progress in reducing the impact of regeneration emissions since 2007. Nevertheless, we believe it is prudent to begin accounting for regeneration emissions to discourage manufacturers from adopting compliance strategies that could reverse this trend. See Response 3.3.4.

Specifically, the data given by AAPC in their comments is for one diesel engine model that appears to be poorly optimized. It does not represent all of the diesel engine makes and models manufactured, and more importantly does represent what can be achieved with proper design and calibration. IRAF is already required for criteria pollutants for engines that utilize aftertreatment that requires infrequent regeneration. Therefore there should be no cost associated with adding a requirement to measure CO$_2$ to the IRAF provisions, as most test cell typically have CO$_2$ measurement capability.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Standards for vocational vehicle engines

Diesel engines

The agencies’ Phase 2 technology package for diesel engines used in vocational applications is similar to that of diesel engines used in tractor trucks, except that the WHR technologies are not included. This is appropriate, considering that these technologies are suitable for steady-state operation, whereas vocational vehicles mostly operate in a transient duty cycle. However, the agencies’ estimates of effectiveness and penetration of other technologies are conservative in our estimation. SwRI estimates that friction reduction can provide almost 4% fuel savings while combustion improvements can provide at least 2% fuel savings, as we have discussed in the previous section. Model-based control is a promising technology, especially for the transient engine operation typical in vocational vehicles. Improvements in computing power and speed would make it possible to use much more sophisticated algorithms that are more predictive than today’s controls (p. 40195). We used the agencies’ penetration in our estimate, even though their estimate was very low. This technology has a cost of less than $100 but provides at least 2% fuel saving benefits, so its penetration would be expected to exceed the agencies’ estimate of 40% in 2027 timeframe. [EPA-HQ-OAR-2014-0827-1280-A1 p.13]

The agencies also appear to assume an overlapping of benefits for vocational engine technologies, without providing a justification. We did not include such a factor. In our calculation, diesel engines for vocational vehicles can attain 7% and 8% fuel savings beyond Phase 1 levels in 2024 and 2027, respectively. Table 3 outlines the agency package and our estimate for vocational vehicles in 2024 and 2027. [EPA-HQ-OAR-2014-0827-1280-A1 p.13]
The revised benefit from friction reduction in the final SwRI report ranges from 1% to 2.9% for highway cruising, dependent upon vehicle loading and speed. The SET-weighted average of these friction reduction estimates is 2.1%, which is 50 percent higher than the agencies’ estimate of friction reduction potential in the proposal (Appendix 1), indicating that friction reduction can contribute more efficiency benefit than the proposal indicates. [Appendix 1 can be found on p.8 of this docket][EPA-HQ-OAR-2014-0827-1896-A1 p.2]

Furthermore, the final SwRI report confirms the significant benefit of downspeeding on the engine side, even taking into account the accompanying loss in friction reduction potential. Downspeeding benefits are not reflected in the proposed engine standards, despite the fact that manufacturers have repeatedly acknowledged moving engine operation to even lower speeds. The agencies also have noted the benefits of downspeeding when combined with downsizing, which they did refer to in setting the standard: “engine downsizing could be more effective if it is combined with downspeeding” (NPRM p. 40217). The SwRI report estimates savings ranging from 3% to 8% after lowering the engine speed from 1368 to 1051 rpm. This estimate includes the 50 percent discounting of friction reduction potential for the downsped engine. An SET-weighted average of downspeeding combined with friction reduction results in 3.3 percent improvement in 2027. As noted in other comments to the docket, the agencies should consider downspeeding improvements on the tractor engine test because of how it affects engine design.[EPA-HQ-OAR-2014-0827-1896-A1 p.2]

The agencies also should further consider their assessment of the penetration of advanced technologies like waste heat recovery (WHR). The SwRI report clearly illustrates the benefits of WHR, and a consultant report recently uploaded to the docket outlines how it is making its way into the fleet ahead of the rate of penetration that underlies the agencies’ proposed targets. The report also makes clear that current research into even more efficient engines indicates the potential for a durable, reliable 50-percent brake thermal efficiency engine in the timeframe of this rule. Further evidence of the significant penetration possible for WHR can be found in a recent white paper that illustrates that the agencies have significantly overestimated the costs of WHR and therefore underestimated its cost-effectiveness and potential rate of penetration in the market.[EPA-HQ-OAR-2014-0827-1896-A1 p.2]

The finalized report from the Southwest Research Institute indicates that tractor engines are capable of achieving an 8 to 10 percent reduction in fuel consumption from the 2018 baseline when considering the agencies’ technology penetration rates; further analysis shows that a 15 percent reduction is possible (Appendix 1). [Appendix 1 can be found on p.8 of this docket][EPA-HQ-OAR-2014-0827-1896-A1 p.2]

Impact on proposal

The tractor truck engine stringency should be significantly strengthened in the final rule to reflect the most up-to-date data, which indicates that tractor engines can easily exceed the proposed 2027 target of 4.2 percent improvement. [EPA-HQ-OAR-2014-0827-1896-A1 p.2]

Southwest Research Institute Report

SET-weighted improvement

Improvements in efficiency measured on the drive cycles simulated in the SwRI report do not directly correspond to the improvements these technologies would achieve on the engine cycle. To estimate the improvements that would be achieved on the SET cycle, we have utilized specific drive cycles to represent the A, B, C, and idle points, weighting the improvements achieved on these cycles in accordance with the SET regulatory weighting (Table 1). [EPA-HQ-OAR-2014-0827-1896-A1 p.8] [Table 1 can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1896-A1]
The A speed and B speed are most similar to 55 mph and 65 mph, respectively. This can be confirmed with the drive ratio assumed in the SwRI report. However, the C speed represents an engine speed that is not easily represented by any of the drive cycles measured. Because we are primarily concerned with friction reduction, which we know will show diminished improvement at high speed, we have chosen to halve the improvement of the 65 mph cycle to represent a stand-in. The idle cycle is represented by the unloaded ARB transient cycle. Because the engine test is run at 25, 50, 75, and 100 percent loading, we have averaged the 0 and 50 percent loaded cycles to represent 25 percent loading, and the 50 and 100 percent loading to represent 75. [EPA-HQ-OAR-2014-0827-1896-A1 p.8]

Comparison of SwRI report and the NPRM: engine friction reduction

After assessing how to model the engine technologies in the SwRI report, we can compare these results to those of the NPRM (Table 2). Here, the fuel consumption reduction of each individual technology is shown as well as the agencies’ assumed penetration of this technology in 2027, yielding a weighted reduction. [EPA-HQ-OAR-2014-0827-1896-A1 p.8]

The revised effectiveness represents the SwRI SET-weighted value. In combining the technologies, the final value reflects some assumption about how the technologies interact, which we refer to as dis-synergy. Such interaction should be based on considerations specific to the technologies being combined—for example, the effectiveness of a waste heat recovery will be lower in combination with technologies that reduce the amount of waste heat available. However, we are unaware of other overlapping benefits among the particular technologies in the agency engine package. Therefore, while the agencies used a representative value of 15 percent for the dissynergy factor, we have reduced this value to 4 percent to reflect only the 25 percent of the fleet for which this the agencies applied this technology. [EPA-HQ-OAR-2014-0827-1896-A1 p.8]

Comparison of SwRI report and the NPRM: downspeeding

Downspeeding offers additional gains that are not included in Table 2. Higher brake mean effective pressure that results from downspeeding does interact with engine friction reduction; however, the SwRI report clearly showed that benefits from downspeeding were achieved beyond the levels outlined in Table 2. Table 3 outlines the additional benefits that are achievable when including downsizing on the engine standard, based upon the SwRI report. [EPA-HQ-OAR-2014-0827-1896-A1 p.9]

Feasibility Assessment of Future Efficiency Improvement for Class 8 Diesel Tractor Engines

In addition to the SwRI report, a presentation was uploaded to the docket from Dr. Stephen J. Charlton that outlines a path forward for the heavy-duty truck industry over the timeframe of the rule, taking into account ongoing research, product development cycles, and the breadth of technologies that could be available in the timeframe of this rule. [EPA-HQ-OAR-2014-0827-1896-A1 p.10]

Table 4 summarizes the findings of this report, illustrating a path to an engine standard in 2027 that would achieve a 15 percent reduction from the current 2018 baseline engine on the SET test. Notable differences between the agencies’ proposed targets are: 1) greater penetration of WHR; 2) recognition that downspeeding will lead to efficiency improvements on the SET cycle as well as on the vehicle; 3) greater potential improvements from model-based controls; and 4) increased stringency of the 2018 baseline itself to reflect the updated SET weighting. [EPA-HQ-OAR-2014-0827-1896-A1 p.10]

Table 4 can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1896-A1

Response:

The findings from SwRI’s report on friction are consistent with the agencies’ estimate if exactly the same certification cycle weighting factors for tractors and the certification vehicle weights are used. Using the same principle for overall technology effectiveness reported by SwRI, specifically from their revised report, their findings again support the agencies’ findings. We appreciated many of the constructive comments related to down speeding, and dis-synergy effect. Accordingly, we have made many changes on engine standards. On the vocational side, we changed the baseline engine to reflect the most recent certification data. The detailed vocational engine stringency and its baseline engine standards explanation can be found in Chapter 2.7 of the RIA. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the 2027 MY tractor engine standards’ projected stringency over the baseline increased from 4.2% (proposed) to 5.1%. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase.

Organization:  California Air Resources Board (CARB)

Oppose/Requested Change Comment

Comment – Stringency of the engine standards for heavy-duty tractors

The NPRM requests comment on the proposal to increase the stringency of the compression ignition tractor engine standards. CARB staff strongly supports U.S. EPA and NHTSA’s decision to increase the stringency of the compression ignition engine standards. The Phase 1 regulation established engine standards that were easily achieved using “off-the-shelf” technologies. With the Phase 2 regulation, U.S. EPA and NHTSA committed to establish more stringent engine standards that force the introduction of new and advanced cost-effective engine technologies. CARB staff supports that effort, and in fact believes the engine standards should be made more stringent than either the preferred Alternative 3 standards or the Alternative 4 standards. As discussed further below, CARB staff recommends that when fully implemented, the tractor engine standard stringency should be increased from 4.2 percent to 7.1 percent, and that full implementation should happen by MY 2024. [EPA-HQ-OAR-2014-0827-1265-A1 p.30-31]

As shown in Table II-6 of the NPRM (included below), U.S. EPA and NHTSA’s preferred Alternative 3 would result in standards for MY 2027 diesel engines that require a 4.2 percent reduction in CO2 emissions versus a 2017 baseline engine. Also proposed are interim standards for MY 2021 and MY 2024, requiring reductions in CO2 emissions of 1.5 to 3.7 percent better than a 2017 baseline. The proposed standards were determined by taking the SET weighted reduction for each technology, weighting it by the estimated market penetration, calculating a weighted average for the entire suite of technologies, and then applying a “dis-synergy factor” to the weighted average. Dis-synergy factors were used to make adjustments accounting for the potential that some combinations of technologies may result in CO2 reductions less than that indicated by the calculated weighted average. The dis-synergy factor applied to the 2021 weighted average was 0.75. The dis-synergy factor applied to the 2024 and 2027 weighted averages was 0.85. [EPA-HQ-OAR-2014-0827-1265-A1 p.31]

[The table, Table II-6 from the proposed rulemaking, can be found on p.31 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

CARB staff urges U.S. EPA and NHTSA to increase the stringency of the standards in consideration of the following concerns:
The estimated emission reductions used as the basis of Alternative 3 are overly conservative. A number of sources lead CARB to conclude that the SET weighted reductions that serve as the basis of the preferred Alternative 3 standards should be made more stringent, as listed below:[EPA-HQ-OAR-2014-0827-1265-A1 p.31]

- The estimated emission benefits of the Phase 2 engine standards from a 2010 baseline engine are significantly less than the potential cited in a number of published technical assessments. There are a number of published studies that estimated the potential reduction from the application of engine technologies on 2010 and pre-2010 engine technologies, and the estimated emission benefits of the Phase 2 engine standards from a 2010 baseline engine are significantly less than the potential cited in these assessments. The GHG emission rate of a 2010 baseline engine, 490 g/bhp-hr, was defined by U.S. EPA and NHTSA when developing the Phase 1 tractor engine standard. The proposed Phase 2 tractor engine standard for 2027 is 441 g/bhp-hr and represents a 10 percent reduction from a 2010 baseline engine, which is much less than what has been estimated as technically feasible in the following reports. [EPA-HQ-OAR-2014-0827-1265-A1 p.31-32]

- CARB’s recently released technology assessment for engine and vehicle efficiency estimates that tractor engines can achieve up to 34 percent reduction in fuel use/GHG emissions from a 2010 baseline through the application of fuel saving technologies within the Phase 2 timeframe.14 [EPA-HQ-OAR-2014-0827-1265-A1 p.32]

- U.S. Department of Energy’s Supertruck Program demonstrated engine efficiency improvements up to 22 percent from a 2009 baseline engine. Technologies demonstrated included waste heat recovery (WHR) systems using the Rankine cycle.15 [EPA-HQ-OAR-2014-0827-1265-A1 p.32]

- At the 2013 Society of Automotive Engineers (SAE) Commercial Vehicle Engineering Congress, Donald W. Stanton, Cummins Inc., presented a lecture entitled, “Systematic Development of Highly Efficient and Clean Engines to Meet Future Commercial Vehicle Greenhouse Gas Regulations.” Dr. Stanton estimated that over 20 percent reduction in GHG emissions is possible through the application of engine technologies in the Phase 2 timeframe.16 [EPA-HQ-OAR-2014-0827-1265-A1 p.32]

- The International Council on Clean Transportation (ICCT) research study on advanced tractor-trailer efficiency technologies estimated that up to 21.5 percent fuel consumption reduction from a 2010 baseline engine is possible in the 2020 to 2030 timeframe with the application of advanced engine technologies and WHR (Rankine).17 [EPA-HQ-OAR-2014-0827-1265-A1 p.32]

- The SET weighted reductions are overly conservative. Cummins and SwRI, have conducted independent technical analyses assessing the potential reductions resulting from the application of engine technologies. Both analyses assumed the baseline engine was a Phase 1 compliant engine. The Cummins analysis was over the SET certification cycle; the SwRI analysis was over the drive cycles used by GEM.
  o Cummins has indicated that tractor engines can achieve a 9 to 15 percent fuel savings from a 2017 baseline engine in the 2020 to 2030 timeframe.
  o Southwest Research Institute (SwRI) completed a study for NHTSA to inform the development of the Phase 2 standards that concluded that tractor engine fuel consumption
could be reduced 4 to 10 percent from a baseline 2019 engine compliant with the Phase 1 standards.\textsuperscript{18} [EPA-HQ-OAR-2014-0827-1265-A1 p.33]

Two of the above referenced sources, Cummins and SwRI, provided specific information relating the potential reductions from a Phase 1 compliant engine over either the SET certification cycle or the drive cycles used by GEM. The information they provided and how it compares to the proposed tractor engine standard is discussed in further detail below. [EPA-HQ-OAR-2014-0827-1265-A1 p.33]

\textit{Cummins}

At the April 22, 2015, CARB Symposium on Phase 2 GHG Emission Standards for Heavy-Duty Vehicles, Dr. Wayne Eckerle, Vice President of Corporate Research and Technology for Cummins Inc., presented Cummins’ perspective on the potential for reduction of CO\textsubscript{2} from tractor engines in the 2020 to 2030 timeframe. Dr. Eckerle stated that CO\textsubscript{2} emission reductions of 9 to 15 percent from a 2017 baseline engine are achievable through improvements in combustion and air handling, friction and parasitics, heat transfer management, and WHR (Rankine cycle). These reductions were estimated over the SET certification cycle using the current mode weightings. The SET weighted reductions from Table II-6 for a tractor engine that employs WHR in the 2020 to 2027 timeframe are presented in Table 1. The total reduction of CO\textsubscript{2} emissions from the application of the suite of technologies is 6.7 percent. This includes the application of a dis-synergy factor of 0.85. WHR (Rankine cycle) was included since the Cummins engine employs that technology. Turbo compounding was not included since it is unlikely that a manufacturer would install two WHR technologies on the same engine. [EPA-HQ-OAR-2014-0827-1265-A1 p.33-34]

[Table 1 can be found on p.34 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

The 6.7 percent reduction represents the projected emission reduction from a single tractor engine that uses WHR (Rankine cycle) and not turbo compounding. The 4.2 percent reduction for MY 2027 (Table II-6 in the NPRM) represents the percent emission reduction from a fleet of tractor engines taking into account the projected market penetration of each technology. CARB staff believes comparing the 6.7 percent reduction to the 9 to 15 percent reduction represents an “apples-to-apples” comparison of what U.S EPA and NHTSA, and Cummins believe is achievable in the 2020 to 2030 timeframe. So it is clear that U.S. EPA and NHTSA’s 6.7 percent is much lower than what Cummins has publicly stated is achievable in the Phase 2 timeframe. [EPA-HQ-OAR-2014-0827-1265-A1 p.22]

Outside of WHR (Rankine cycle), Cummins has not published any information regarding the percent reduction potential associated with the individual engine technologies that contribute to the total 9 to 15 percent reduction estimate. Regarding WHR (Rankine cycle), Cummins estimates that a 4 to 5 percent emission reduction is achievable in the 2020 timeframe. Cummins is currently in its fourth generation WHR (Rankine cycle) system design and plans to implement end-user testing by late 2015, and has stated that production of a WHR (Rankine cycle) is possible by 2020. [EPA-HQ-OAR-2014-0827-1265-A1 p.34]

Given the information provided by Cummins regarding the potential for CO\textsubscript{2} emission reductions, CARB staff strongly urges U.S. EPA and NHTSA to reevaluate the projected SET weighted reductions it used to determine the proposed tractor engine standards. Comparing the 3.6 percent reduction U.S. EPA and NHTSA projected for WHR (Rankine cycle) to the Cummins estimate of 4 to 5 percent, and U.S. EPA’s overall percent reduction of 6.7 percent to the Cummins estimate of 9 to 15 percent, suggests that the proposed SET weighted reductions in the 2020-2027 timeframe are overly conservative and should be made more stringent. [EPA-HQ-OAR-2014-0827-1265-A1 p.35]
SwRI Report

To inform the development of the Phase 2 standard, the SwRI conducted research assessing the effectiveness of potential GHG emission reducing technologies for the Phase 2 timeframe. Engine models were created and calibrated using available experimental data. Each engine model was exercised over five cycles that included the three Phase 1 GEM cycles, i.e., 55 miles per hour (mph) steady-state cruise, 65 mph steady-state cruise, and the CARB urban cycle. [EPA-HQ-OAR-2014-0827-1265-A1 p.35]

Based on the technologies studied, SwRI concluded that there is the potential to improve long-haul truck engine fuel consumption and GHG emissions by 8 to 10 percent over the Phase 1 baseline. This would require the use of WHR (Rankine cycle). The study also indicated that fuel savings and GHG emissions using friction reduction and down speeding could result in reductions in the 4 to 7 percent range. [EPA-HQ-OAR-2014-0827-1265-A1 p.35]

To more directly compare the results of the SwRI study to the proposed Phase 2 engine standards, staff compared the SET weighted reductions assumed by U.S. EPA and NHTSA in setting the engine standard (as shown in Table 1), to the SwRI simulation results from the drive cycles used in GEM. Staff believes directly comparing the percent reduction from the SET to the percent reduction from the weighted GEM cycles is appropriate since U.S. EPA and NHTSA concluded that tractor engine technologies will improve engines and tractors proportionally, even though the separate engine and vehicle certification test procedures have different duty cycles (page 40199 of the NPRM). Table 2 shows the simulation results for two technology packages modeled in the SwRI study. Technology package 1 (referred to as “DD15 Technology Package 2” in the SwRI report) includes aggressive friction reduction and downspeeding, but does not include WHR (Rankine cycle). Technology package 2 (referred to as DD15 Technology Package 3f in the SwRI report) includes technology package 1 with WHR (Rankine cycle). These simulation results were estimated using the same three test cycles used in GEM. Staff then weighted the results in accordance with the GEM drive cycle weightings for sleeper-cab tractor trailers and day-cab tractor-trailers, as shown in Table 3. The percent reductions represent the reductions from a Phase 1 compliant baseline engine at 100 percent payload (46,040 lbs). [EPA-HQ-OAR-2014-0827-1265-A1 p.35-36]

As shown in Table 3, based on the SwRI study, the percent reduction in GHG emissions is estimated to range from 10.0 to 10.7 percent with WHR (Rankine cycle) and 4.9 to 5.1 percent without it. Comparing this to U.S. EPA and NHTSA’s overall percent reduction of 6.7 percent with WHR (Rankine cycle) and 3.8 percent without WHR (Rankine cycle) suggests that the proposed SET weighted reductions in the 2020-2027 timeframe are overly conservative and should be made more stringent. [EPA-HQ-OAR-2014-0827-1265-A1 p.36]

The dis-synergy factors used to establish the final standards are unnecessary given the conservative nature of the proposed standards.

U.S. EPA and NHTSA applied dis-synergy factors of 0.75 for MY 2021 and 0.85 for MYs judgment and are meant to account for the potential dis-synergy of engine technologies. For example, friction reduction technologies reduce waste heat produced by the engine. This, in turn, could reduce the effectiveness of WHR (Rankine cycle) to some degree. The dis-synergy factor is intended account for this loss of effectiveness. CARB staff understands the rationale behind the application of dis-synergy factors, but believes they are unnecessary given 1) the conservativeness of the SET weighted reductions that serve as
the basis for preferred Alternative 3 standards and 2) the equation\textsuperscript{19} used to calculate the benefit of multiple combined technologies does not simply add the percent effectiveness of each technology, but accounts for the interaction between technologies and potential loss of effectiveness as technologies are combined. As noted previously, Cummins stated that CO2 emission reductions of 9 to 15 percent from a 2017 baseline engine are achievable. The 9 to 15 percent estimate incorporates the anticipated dis-synergy when combining engine technologies. Removing the application 0.85 dis-synergy factor from U.S. EPA and NHTSA’s calculation of the 2027 standard would raise the percent reduction of the standard from 4.2 percent to 4.8 percent. This is much less than what CARB believes is achievable, but would be a step in the right direction. [EPA-HQ-OAR-2014-0827-1265-A1 p.36-37]

Suggested Tractor Engine Stringency

In consideration of the information presented above and additional information as noted below, CARB recommends U.S. EPA and NHTSA reevaluate the stringency of the tractor engine standards for preferred Alternative 3. Specifically, CARB suggests U.S. EPA and NHTSA make the following changes to the assumptions used in setting the standards: [EPA-HQ-OAR-2014-0827-1265-A1 p.37]

- Increase the percent reduction associated with “Parasitic/friction, lubrication” from 1.4 percent to 3.3 percent. Parasitic/friction, lubrication improvements were included in the technology package discussed above. The SwRI study also evaluated the benefit of these improvements separately (referred to as DD15 Technology Package 1 in the SwRI report). The GEM drive cycle weighted average of the SwRI results ranged from 3.2 percent benefit for sleeper-cab tractor trailers to 3.4 for day-cab tractor-trailers. [EPA-HQ-OAR-2014-0827-1265-A1 p.37]
- Remove the dis-synergy factor from standard setting calculation. [EPA-HQ-OAR-2014-0827-1265-A1 p.37]
- Increase the 2024 penetration rate assumptions to those proposed in 2027. This more aggressive implementation schedule is consistent with our recommendation to adopt the Alternative 4 implementation schedule for all engine and vehicle categories. [EPA-HQ-OAR-2014-0827-1265-A1 p.37-38]

- Combine the WHR turbo compounding and Rankine cycle categories into one WHR category and increase the percent reduction associated with WHR to 4.5 percent. CARB staff is suggesting that for standard setting purposes the WHR SET reduction should reflect the percent reduction potential from the most effective technology, which would be 4.5 percent from WHR (Rankine cycle). The market penetration values used to set the standard would be the combined existing Alternative 3 percentages for turbo compounding and Rankine cycle technologies. Thus the market penetration for the engines that are projected to utilize WHR systems (either turbo compounding or Rankine cycle) remains unchanged from the original U.S. EPA proposal. But, the higher SET reduction associated with WHR would drive more to install WHR Rankine cycle systems. CARB is confident that manufacturers will have WHR Rankine cycle systems tested and production-ready to meet the MY 2024 standard. WHR Rankine cycle technology was developed and implemented as part of the Supertruck program. A fourth generation design of this technology is currently being developed for tractor applications by Cummins. End-user testing of this system is planned for late 2015. Production is possible as early as 2020. This should be sufficient leadtime to develop reliable and compliant engines for MY 2024. [EPA-HQ-OAR-2014-0827-1265-A1 p.38]
Table 4 below illustrates the impact the suggested changes would have on the stringency of the proposed tractor engine standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.38]

[Table 4 can be found on p. 38-39 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

To summarize, as shown in Table 4, CARB recommends that when fully implemented, the tractor engine standard stringency should be increased from 4.2 percent to 7.1 percent, and that full implementation should happen three years earlier than indicated in the preferred Alternative 3, moved from 2027 to 2024. This more aggressive implementation schedule is consistent with our recommendation to adopt the Alternative 4 implementation schedule for all engine and vehicle categories. [EPA-HQ-OAR-2014-0827-1265-A1 p.39]

Impact of More Stringent Tractor Engine Standards on Alternative 4 Tractor Vehicle Standards

If U.S. EPA and NHTSA adopt more stringent tractor engine standards, the corresponding tractor vehicle standards should also be made more stringent. Table 5 shows the fuel consumption reductions for the tractor engine and vehicle standards fully implemented by MY 2024. As discussed above we are suggesting that U.S. EPA and NHTSA adopt the Alternative 4 implementation schedule for tractor engine standards; the same holds true for tractor vehicle standards. Therefore, full implementation is shown as occurring by MY 2024 and not 2027 as prescribed by U.S. EPA and NHTSA’s preferred Alternative 3. [EPA-HQ-OAR-2014-0827-1265-A1 p.39]

[Table 5 can be found on p.39 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

As shown, CARB is suggesting that U.S. EPA and NHTSA adopt more stringent tractor engine standards that would result in an additional 3 percent reduction when fully implemented by MY 2024. This would result in a corresponding additional 3 percent reduction in the tractor vehicle standard. [EPA-HQ-OAR-2014-0827-1265-A1 p.40]

---

%GHG reduction\(_{\text{package}}\) = 100\(\left[1-(1-\frac{\%\text{GHG tech 1}}{100})(1-\frac{\%\text{GHG tech 2}}{100})\ldots(1-\frac{\%\text{GHG tech N}}{100})\right]\)

**Comment - Feasibility of vocational vehicle engine standards**

CARB staff strongly recommends strengthening the proposed vocational engine standard from the proposed 4.0 percent reduction in CO2 emissions beyond Phase 1 to 4.3 percent. For compression ignition engines fitted into vocational vehicles, the NPRM proposes an engine standard that achieves 4.0 percent reduction in CO2 emissions beyond the Phase 1 standard. This proposed engine standard was derived assuming certain SET weighted reductions for applicable technologies, along with a certain penetration for each technology. Table 6 shows the projected emission reductions from the SET weighted reductions for vocational engine technologies listed in the NPRM. Without accounting for penetration, the vocational engine reductions amount to a 6.0 percent improvement for MY 2027 (in other words, 6.0 percent reduction could be achieved if the described technologies had penetration of 100 percent; with the technology penetrations assumed, the technologies’ 6.0 percent potential improvement achieves an overall 4.0 percent reduction for vocational compression-ignition engines in total). Cummins, the largest manufacturer of heavy-duty truck engines, has publically stated a vocational engine emission improvement of 5 to 11 percent in the Phase 2 timeframe is feasible. U.S. EPA and NHTSA are currently proposing a vocational engine standard consistent with the lowest end of Cummins’ projections. [EPA-HQ-OAR-2014-0827-1265-A1 p.40]

In addition, in deriving the proposed standard, U.S. EPA and NHTSA applied a dis-synergy factor of 0.85. CARB staff does not believe that the dis-synergy factor adjustment is necessary for two reasons. One, manufacturers already account for dis-synergistic effects between various technologies when predicting future engine improvements. Therefore, U.S. EPA is, in essence, double discounting when applying in their own dis-synergy factor. Two, the proposed vocational engine standard for vocational engines is already conservative; therefore, CARB staff believes the application of a dis-synergy factor is unnecessary. CARB staff strongly urges U.S. EPA and NHTSA to improve the vocational engine standard. Overall, CARB staff believes that the proposed Phase 2 emission standard for vocational vehicles under both Alternative 3 and Alternative 4 is overly conservative and leaves emission benefits “on the table.” [EPA-HQ-OAR-2014-0827-1265-A1 p.40-41]

[Table 6 can be found on p.41 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

**Response:**

We appreciate many of constructive comments made by CARB. We recognized that CARB’s comments are largely based on the DOE SuperTruck programs, SwRI reports, and some of Cummins’s public reports. The values from the DOE SuperTruck program are single optimal operating points and not operation over the entire engine map. Further, those values were demonstrated in an R/D environment. In contrast, we consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point. The findings from SwRI’s report on friction is consistent with the agencies estimate if exactly the same certification cycle weighting factors for tractors and the certification vehicle weights are used. Using the same principle for overall technology effectiveness reported by SwRI, specifically from their revised report, their findings again support the agencies’ findings. We noticed that Cummins’s proposal on engine efficiency reduction is more aggressive than the agencies’. It should be clear that their proposed timing is out to 2030 and not 2027. Many technology adoption rates, such as WHR and other emerging technologies, would follow the S-shape curve as explained in Chapter 2.3.8 of the RIA, meaning that it will be adopted more slowly at the beginning, and then rapidly after a certain period of time. It can be expected that their reduction plan...
should potentially include a new engine platform, which can significantly increase the chance to meet more aggressive reduction goals. On the other hand, we don’t believe that developing a new engine platform is possible for all OEMs in the given timeframe. Consequently, we can’t develop more stringent standards predicated on all OEMs developing a new engine platform in the timeframe of Phase 2.

We disagree with CARB’s comments with respect to dis-synergy. The full justification regarding this matter can be found in Chapter 2.7.5 of the RIA. We also disagree with CARB’s recommendation on friction reduction, where their conclusion was mainly based on SwRI reports. The finding from SwRI’s report on friction is consistent with the agencies’ estimates if exactly the same certification cycle weighting factors for tractors and the certification vehicle weights are used. In addition, SwRI revised their finding due to errors found in the baseline modeling. The modified engine standards for the final rule are based on many comments received and our further investigation into emerging engine technologies. We do not believe that a WHR effectiveness of 4.5% is feasible. Furthermore, WHR with Rankine cycle and turbo-compound conflict with each other, and they would not be combined as a single technology package because they compete for the same energy source. Our WHR effectiveness is directly obtained from and consistent with data from one of the engine manufacturers.

After taking all constructive comments, including CARB’s, into consideration, we have made many changes to the proposed engine standards. These changes are described in previous responses.

**Organization:** Center for Biological Diversity

The Proposed Rule would require a 4.2 percent increase in diesel-engine efficiency between 2017 and 2027, yet efficiency gains of at least double this amount have been demonstrated. Furthermore, most diesel engines will improve efficiency at a much higher rate in the near future (about 6 percent between 2010 and 2017 alone).

It is unfathomable that a smaller total improvement in engine efficiency is proposed for decades from now than is currently required under Phase 1 standards. A variety of studies indicates that diesel engine improvements of at least 10 percent below 2017 emission levels – and often more – are achievable within the timeframe of the Proposed Rule. In this instance, there is no reasoned basis that the NHTSA and EPA could find that an efficiency standard set at less than half of what is technologically feasible fulfills the technology-forcing requirements of the EISA and the Clean Air Act, rendering the rulemaking subject to legal challenge. [EPA-HQ-OAR-2014-0827-1460-A1 p.7]

---

**Response:**

On the vocational side, we changed the baseline engine to reflect the most recent certification data. The detailed vocational engine stringency and its baseline engine standards can be found in Chapter 2.7 of the RIA. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the tractor engine standards’ projected stringency over the baseline increased from 4.2% to 5.1%. Chapters 2.3 and 2.7 of the RIA detail the justification of this
increase. It should be pointed out that while the literature, including the DOE SuperTruck program, demonstrate more reduction on the engine side, the technology demonstration only focused on a single operating point. In contrast, we consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point.

**Organization: Engine Research Center**

To be effective in achieving these benefits, however, the separate engine standard must not only be commercially acceptable and reasonable, but also meaningful. The new MDV and HDV standards are designed to 'spur innovation, encouraging the development of and deployment of existing and advanced cost-effective technologies for a new generation of cleaner, more fuel efficient commercial trucks ....' The standard are meant to be set 'not only on currently available technologies but also on utilization of technologies now under development or not yet widely deployed while providing significant lead time to assure adequate time to develop, test, and phase in these [technologies]. [EPA-HQ-OAR-2014-0827-1141-A1 p.2]

'The proposed Phase 2 standards only require a 4% reduction in fuel consumption and CO2 emissions of engines, compared to Phase 1, through 2027, a requirement that may well be met with already demonstrated technology. If the standard is set too low, it presents a risk that the agencies' goal of spurring development and deployment of advanced technology may not be met, and it may render the separate engine requirement largely meaningless. [EPA-HQ-OAR-2014-0827-1141-A1 p.2]

I respectfully suggest the Phase 2 engine standard can require a larger reduction in fuel consumption. Enough promising technologies and time exist to provide compliance at a cost increase that meets the payback scenarios outlined in the proposed standard. Based on my experience and judgment, I support a 10% fuel consumption reduction for Phase 2 heavy engine standards. [EPA-HQ-OAR-2014-0827-1141-A1 p.2]

**Response:**

We have made many changes on engine standards as detailed in previous responses and in RIA Chapters 2.3 and 2.7.

**Organization: Environmental Law and Policy Center**

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 217.]

Analysis from EPA, California, and manufacturers demonstrate that cost-effective technologies are currently available to achieve at least a 15 percent improvement in engine efficiency, more than three times greater than that which is reflected in EPA's current proposal. Similarly, the proposal -- the proposed regulation ignores fuel efficiencies that could be achieved through aerodynamic improvements to trailers.

**Response:**

We have made many changes on engine standards. See previous responses and RIA Chapters 2.3 and 2.7.

**Organization: International Council on Clean Transportation (ICCT)**
• **Diesel engines** – The engine standards are based on modest incremental improvements including engine friction, air handling, and combustion/controls, which are part of every engine/vehicle manufacturers existing technology portfolio and therefore allow for accelerated deployment before 2024. For context, the agencies proposed standards require less than half of the known technology potential for diesel tractor engines (e.g., see Eckerle, 2015; Thiruvengadam et al, 2014; Reinhart, 2015). The proposed standards (Phase 1 and 2 together from a 2010 baseline) also fall well short of SuperTrucks’ engine technologies (i.e., 10% versus SuperTrucks’ 15%, over the SET cycle) that have already been physically demonstrated in Peterbilt and Daimler tractors (Lutsey, 2015a). [EPA-HQ-OAR-2014-0827-1180-A4 p.4]

**Overall diesel tractor engine efficiency:** Based on the above data and rationale, including the more up-to-date data would result in technology potential for new diesel tractor engines that would achieve fuel use reductions of up to 8% in 2024, and 10% in 2027, from a 2017 baseline. This is based on penetration of just 15% WHR technology by model year 2027, as assumed by the agencies. Based on the above studies, we believe this is still a conservative interpretation of the data and is significantly short of the technologies being demonstrated in the SuperTruck program. [EPA-HQ-OAR-2014-0827-1180-A4 p.9]

**SET Reweighting.** We support the agencies proposed decision to re-weight the SET test points more toward lower speeds to better reflect real-world driving characteristics. However, we note that while the engine stringency was developed based on the new proposed re-weighting (new SET), the baseline used as a starting point to develop such stringency levels was based on the original SET weighing (old SET). We recommend that the agencies reflect the average shift that this re-weighting causes by re-setting the baseline Phase 2 (i.e., model year 2017) engine fuel consumption. Based on ICCT analysis of multiple engine maps (including GEM Phase 1 2010, GEM Phase 1 2017, GEM Phase 2 2017, a 2010 compliant engine tested by Thiruvengadam et al, 2014, and a projected 2017 engine by Thiruvengadam et al, 2014), it appears as though by not re-setting the baseline that the agencies give, on average, 1.5% (with a range of 0.4% up to 2.9%). Our analysis of the specific Phase 2 GEM engine maps shows that the Phase 2 baseline engine CO2 emission levels over the new SET is reduced by 1.5% when compared to the old SET. By providing a 1.5% fuel consumption benefit for the re-weighting, the agencies effectively “give away” more than one third of the proposed Phase 2 engine benefit for no new shift in technology. Stated another way, the actual stringency of the agencies proposed tractor engine standard is 2.5% rather than 4.0%. Moreover, the Phase 1 compliant engines in 2017 would be already compliant with the Phase 2 2021 engine standard. To appropriately adjust for this, the reference 2017 engine and the Phase 2 tractor engine standards would be reduced downward by approximately 1.5%. For example, the tractor engine standard for 2027, currently at 441 g/bhp-hr would be updated to 434 g/bhp-hr. An additional consideration is that this SET reweighting partially de-couples the GHG and criteria pollutant engine standards. The agencies should take steps to ensure that this action does not result in increased real world criteria pollutant emissions. [EPA-HQ-OAR-2014-0827-1180-A4 p.12-13]

**Response:**

We have made many changes on the tractor engine standards as described in previous responses.

We appreciate the commenter’s comments on SET reweighting (an error likewise pointed out by several other commenters) which indicate that there was an error in calculating reweighting impact on the engine standards in NPRM. Consequently, we adjusted reweighting impacts on the baseline values in the FRM. See Response 3.3.3.

**Organization:** Natural Resources Defense Council (NRDC)
Increase the stringency of the standards. NRDC believes standards that achieve fuel consumption and emissions reductions of at least 24 percent by 2024 and at least 31 percent by 2027 relative to Phase 1 would meet the agency obligations for setting standards that are maximum feasible (for NHTSA) and appropriate (for EPA). [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

- Important areas where the Phase 2 program stringency can be improved significantly include the standards for tractor diesel engines and for vocational vehicles. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

**Increase Stringency of the Tractor Engine Standards**

The stringency of the engine standard should be increased. As proposed, engines are projected to decrease fuel consumption and carbon dioxide emissions by 4.2 percent from 2017 to 2027. In reality, the standard is even weaker—and close to 3 percent—because the proposed re-weighting the Supplemental Emission Test (SET) toward lower engine speeds results in better performance on the test without any new technology addition. NRDC believes that the engine stringency should be strengthened to achieve reductions of at least 8 percent in 2024 and at least 10 percent in 2027 from 2017 levels. These stringency levels should be relative to a 2017 baseline that is adjusted to account for the reweighting of the SET. [EPA-HQ-OAR-2014-0827-1220-A1 p.4]

Analysis by the International Council on Clean Transportation (ICCT) of the U.S. SuperTruck program shows that demonstrated technology can achieve reductions of 12-17 percent. Additional research shows the technology potential of tractor engine reductions of 10 percent even without the application of more advanced technologies such as waste heat recovery. Using the agencies’ proposal assumption of a 15 percent penetration of waste heat recovery could justify a 2027 engine standard that achieves more than a 10 percent reduction. [EPA-HQ-OAR-2014-0827-1220-A1 p.4]

Engine advancements that contribute reductions beyond those of the proposal are found in technical analysis performed for NHTSA by the Southwest Research Institute (SwRI). For example, technologies that reduce friction and parasitic losses are found to reduce fuel consumption by 2 to 5 percent, compared to 1.4 percent assumed by the agencies. The SwRI assessment of reduced friction and parasitic losses are reinforced by the introduction of advanced lubricants that alone are projected to reduce fuel consumption by 1.5 to 2.0 percent and are projected to be available by the beginning of the Phase 2 regulatory period. [EPA-HQ-OAR-2014-0827-1220-A1 p.4-5]

Additional analysis demonstrates the potential to more than double the agency assessments of reduction potential from improvements in intake and exhaust air handling, turbocharging efficiency, and exhaust gas recirculation (assumed by agencies at 1.1 percent) and from combustion and controls optimization (assumed by agencies at 1.1 percent). [EPA-HQ-OAR-2014-0827-1220-A1 p.5]

---

Response:

We have made many changes to the proposed tractor engine standards. See earlier responses and RIA Chapters 2.3 and 2.7.

### 3.3.2 Spark-Ignited Engine Standard

The agencies received many comments suggesting that technologies be applied to increase the stringency of the SI engine standard, which technologies in fact are already presumed to be adopted at 100 percent to meet the MY 2016 engine standard. See RIA Chapter 2.6. The commenters did not identify any additional engine technologies that are not already fully considered by the agencies in setting the MY 2016 engine standard, that could be recognized over the HD SI Engine FTP test cycle. The agencies have identified certain improvements in friction reduction and increased use of cylinder deactivation which are reflected in the stringency of the vocational vehicle standard. See RIA Chapter 2.9.1.2.1.

**Organization:** American Automotive Policy Council

**Optional 621 g CO2/ hp-hr Phase 2 Standard**

The Agencies request comment (80 Federal Register 40160) on alternative Phase 1 standards for Heavy Duty Gasoline Engines of 621 g/hp-hr in 2027MY predicated in part on the use of advanced friction...
reduction technology and lubricants yielding benefits of about one percent on the GEM cycles. The Agencies also request comment on whether proposing more stringent standards for gasoline engines would create an incentive for purchasers who would have otherwise chosen a diesel vehicle to instead choose a gasoline vehicle. [EPA-HQ-OAR-2014-0827-1238-A1 p.30]

Given the 1/7 cold and 6/7 hot weight factors for the HDGE test cycle and that Phase 2 GEM fuel mapping will be conducted under hot conditions, AAPC contends it will be nearly impossible to measure the impact of these low friction lubricants over the proposed cycles. Furthermore the infrastructure to produce and distribute such low friction engine lubricants is currently not available in the U.S. If the Agencies wish to incentivize early introduction and adoption of such low friction lubricants in the U.S., AAPC recommends that low friction engine lubricant credits be included in Phase 2 GEM per the table below. [EPA-HQ-OAR-2014-0827-1238-A1 p.30]

![Table of low friction lubricant incentives can be found on p.31 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

AAPC further contends that the increase in stringency of the Phase 2 Heavy-Duty SI standard to 621 g CO2/hp-hr has not been thoroughly studied. Given the present stringency impacts of removing idle work for the HDGE calculation changing to low energy ethanol containing test fuel, additional standard reductions are not warranted. [EPA-HQ-OAR-2014-0827-1238-A1 p.31]

**Response:**

We recognize that most gasoline engines still have high brake-specific CO2 emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements.

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)

Gasoline engines

The gasoline engines used in vocational vehicles are developed for heavy-duty pickup trucks and vans primarily, but are also sold for use in vocational vehicles (p. 57180). For this reason, the agencies evaluated these engines in parallel with heavy-duty gasoline pickup engines in Phase 1 and based their estimate of improvement potential on technologies such as gasoline direct injection, friction reduction, and variable valve timing. Under the Phase 1 program, fuel consumption of the HD gasoline pickups and vans will decline by 10.8%, of which the agencies estimates almost half could come from engine technologies. Therefore, the 5% fuel consumption reduction required of vocational gasoline engines in Phase 1 was reasonable. [EPA-HQ-OAR-2014-0827-1280-A1 p.13]

In the Phase 2 proposal, fuel consumption of HD gasoline pickups and vans would decline by 16.2%, of which 6-7% would be contributed by engine technologies, including further friction reduction, variable valve lift/actuation, cylinder deactivation, and turbo downsizing. It is highly likely that these technologies will also be used in vocational engines, since they use the same design platform. Using these engine
technologies, vocational gasoline engines can achieve at least 6% reductions in Phase 2. [EPA-HQ-OAR-2014-0827-1280-A1 p.14]

10 p. 57171, Federal Register /Vol. 76, No. 179/September 15, 2011

**Gasoline engines**

Both boosted and naturally aspirated gasoline engines for vocational vehicles show considerable improvement potential in the revised SwRI report. Valve and EGR technologies were found to offer substantial benefit in gasoline engines, especially at high load. [EPA-HQ-OAR-2014-0827-1896-A1 p.6]

**Impact on proposal**
