The Phase 2 proposal did not call for improvement of the gasoline engines used in vocational vehicles. The benefits of valve and EGR technologies for these engines, especially at higher loads, as found in the revised SwRI report\(^2\), make a strong case for strengthening the standards for these engines. [EPA-HQ-OAR-2014-0827-1896-A1 p.7]

**Response:**

We recognize that most gasoline engines still have high brake-specific CO\(_2\) emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements.

**Organization:** California Air Resources Board (CARB)

**Oppose/Comment on Topic Where NPRM Requests Comment**

**Comment – Proposed GHG emission standards for spark-ignited engines**

Under these paragraphs in 40 CFR1036.108 a)(1)(i) and (ii), CO\(_2\) standards for 2016 and later spark-ignited engines remain at the Phase 1 levels of 627 grams per horsepower-hour (g/hp-hr), while compression ignition (and others deemed to be compression ignition in this section) have allowable CO\(_2\) limits that decline over time. U.S. EPA and NHTSA’s reasoning is that the volume of gasoline engines is relatively low in these vehicle classes, so reduction requirements will have few benefits to offset the research investment costs. CARB staff believes that some of the technology developed to reduce GHG emissions in the light-duty sector should be transferrable to the medium- and heavy-duty sectors and recommends that declining GHG standards for spark-ignited engines be set based on these technologies. CARB staff believes that such GHG reductions for Phase 2 spark-ignited engines are cost-effective. The NPRM does request comment on reducing the Phase 1 CO\(_2\) standard for spark-ignited gasoline engines by 1 percent to 621 g/hp-hr, based on the use of advanced friction reduction technology. CARB staff supports requiring more stringent standards for gasoline engines, and, at a minimum, supports the proposal in the NPRM to limit CO\(_2\) emissions for Phase 2 spark-ignited gasoline engines to no more than 621 g/hp-hr. [EPA-HQ-OAR-2014-0827-1265-A1 p.29-30]
The NPRM further requests comment on whether not requiring more stringent standards for gasoline engines would create an incentive for purchasers who would otherwise choose a diesel engine to instead choose a gasoline engine. CARB staff believes that, all other things being equal, such a switch could well occur. To avoid unintended incentives, CARB staff suggests that Phase 2 gasoline engines be required to meet reduced emission standards beyond the 621 g/hp-hr previously mentioned, the compliance with which would require similar investments and/or have a similar compliance cost as is anticipated for the compression ignition engines and vehicles. Because gasoline vehicles are currently cheaper than diesel, it is particularly important to avoid further incentives for buyers to choose less efficient, gasoline vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.30]

Response:

As noted in previous responses, there are persuasive reasons not to adopt more stringent SI engine standards, but rather to recognize SI engine improvements in the stringency of the vehicle standard. By doing so, the agencies believe that there will not be the inappropriate incentive to manufacture SI engines rather than diesel engines for vocational applications.

Organization: Center for Biological Diversity

The Proposed Rule also entirely exempts spark-ignition (gasoline) engines from any requirements to improve efficiency. Yet, as acknowledged in the Proposed Rule, there are feasible technologies that could result in fuel savings. There is a significantly wider range of technologies available for gasoline engines than was included in the Proposed Rule. An analysis by the ICCT indicates that up to a 23.5 percent improvement in gasoline engine efficiency is possible.27 Likewise, the American Council for an Energy-Efficient Economy (“ACEEE”) also found that gasoline engines for heavy-duty pickups and vans could improve by nearly 19 percent from 2010 levels.28 [EPA-HQ-OAR-2014-0827-1460-A1 p.7]

The decision to omit gasoline engines is related to the Agencies’ decision to avoid standards that would require use of every available technology. As discussed above, the very purpose of technology-forcing statutes is to require maximal reductions. The Agencies’ concern regarding hardship to manufacturers should some technologies not perform as expected is addressed through the existence of the averaging, banking and trading (“ABT”), early credits and banking/trading safety net. [EPA-HQ-OAR-2014-0827-1460-A1 p.7-8]

Response:

As noted in previous responses, certain improvements in SI engine performance are reflected in the stringency of the vocational vehicle standard. The agencies do not believe that any further increase in the
SI engine standard to be warranted. We recognize that most gasoline engines still have high brake-specific CO\textsubscript{2} emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, unfavorable cost proposition for investment in new engine platforms is not easily to be justified. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. See generally RIA Chapters 2.6 and 2.9.1.2.1.

Organization: Cummins, Inc.

Cummins opposes no increase in stringency of gasoline engine standards [EPA-HQ-OAR-2014-0827-1298-A1 p.20]

Fuel neutral standards are required to ensure this rulemaking achieves the goals set forth by the Agencies. Data (see Figure 10) from recent years has shown gasoline engines displacing diesel in class 3 thru 5. The current proposal keeps gasoline engine standards the same as Phase 1 (see Figure 11), which will encourage essentially no investment and therefore no CO\textsubscript{2} reduction. Conversely, there will be added technology required for diesels to comply, so low cost, low technology, low efficiency and high emitting gasoline engines are more attractive from an initial purchase price standpoint. [EPA-HQ-OAR-2014-0827-1298-A1 p.20]

[Figure 10 and 11 can be found on p.20 and 21 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

The Agencies request comment on reducing the gasoline standards by 1% in Phase 2. Even if the Agencies were to implement this reduction, the significant disparity between gasoline and other HD engines would still exist. Continued lack of improvement on gasoline engines could push a larger fraction of the market to move toward these less efficient engines, thereby emitting more CO\textsubscript{2} emissions than envisioned by the regulation. [EPA-HQ-OAR-2014-0827-1298-A1 p.20-21]

In studies conducted by SwRI's High Efficiency Durable Gasoline Engine (HEDGE)\textsuperscript{18} program, several production-available technologies have been used to demonstrate fuel consumption reductions well beyond what is being called for in this proposal. Similarly, through projects with the U.S. Department of Energy (DOE), manufacturers\textsuperscript{19,20,21} have demonstrated fuel economy improvements for gasoline engines beyond the Phase 2 standards. Technologies such as turbocharging, direct injection, variable valve timing and cooled EGR are all available in lighter duty products and have been the staples for improved fuel economy in light cars and truck for several years. These same technologies can be engineered for the higher loaded application in order to be durable while providing a fuel economy benefit. In Phase 1 of the rule, the regulation established an offset in gasoline and diesel efficiency that was explained as being needed due to the short timeframe versus the need for development and testing. Phase 2 has ample time for suppliers and manufacturers to develop the technologies in order to meet customer expectations for durability and reliability. By the end of Phase 2, diesel and gasoline engine CO\textsubscript{2} standards should be the same. In fact, the Agencies themselves indicate (80 FR 40519) that gaseous-fueled engines competing with diesel engines should be required to meet the same standards. A similar argument holds for gasoline-fueled engines competing with diesel engines. Cummins agrees with this principle of fuel neutral standards and urges the Agencies to implement such an approach throughout the Phase 2 program, including on gasoline engines. [EPA-HQ-OAR-2014-0827-1298-A1 p.21-22]

In the Phase 1 program, 40 CFR 1037.150(m) allows engines from spark-ignited (SI) chassis-certified vehicles to be sold separately for use in vocational vehicles, such as incomplete vehicles. For Phase 2, the Agencies indicated that engines intended for vocational vehicles should follow the primary certification path of separately certifying the engine on the FTP cycle and the vehicle using GEM (80 FR 40331). For this reason, the Agencies are proposing to eliminate the interim provision in 1037.150(m). Cummins supports this change as it ensures a fair and consistent evaluation of engines used in these HD vehicles. [EPA-HQ-OAR-2014-0827-1298-A1 p.30]

Response:

We recognize that most gasoline engines still have high brake-specific CO₂ emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sales volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. We recognized that significant progress has been made by SwRI HEDGE program as well as some of the DOE sponsored gasoline engine programs. However, one of the key issues that has not been addressed is the reliability. Since the operating zones are different between light-duty vehicles and the vehicles in Class 4-7, the heavier vehicles in latter would force the engine to run more frequently in the higher speed and higher load zones than the case with light-duty vehicles, and therefore the reliability would become more of an issue. As a result, the technologies developed under light-duty vehicles would not be straightforward to migrate to those used in Class 4-7 vehicles. All of these reports have not provided a clear path toward production in the timeframe of Phase 2. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements.

Organization: Daimler Trucks North America LLC

SI Engine Technologies Considered in Vehicle Standard-Setting - The agencies requested comment on the merits of setting a SI-based vocational vehicle standard predicated on adoption of SI engine technologies. 80 FR 40303. We are concerned that the lack of a forcing engine standard will leave the small volume gasoline engine suppliers, on which we depend for our small volume gasoline-powered vocational vehicles, without impetus to improve the engines. This could make it more difficult for those vehicles to meet the vehicle standards, even with credits. That said, the cost of upgrading small volume gasoline engines to advanced standards could be prohibitive. We think that [redacted]—assuming the
agencies fix the core problems with the vocational vehicle standards. [EPA-HQ-OAR-2014-0827-1164-A1 p.75]

Response:

We recognize that most gasoline engines still have high brake-specific CO\textsubscript{2} emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements. We agree that higher-emitting SI engines (that don’t meet the SI engine standard) if installed in vocational vehicles will require additional vehicle-level technology to meet the final SI vocational vehicle standards. See further information on this topic in the Preamble at Section V.C.1 b, and in the RIA Chapter 2.9.1.2.1.

Organization:  Environmental Defense Fund (EDF)

Gasoline vocational engine standard should be more robust

The Agencies decided not to propose new more stringent standards for gasoline engines used in vocational vehicles because of concerns that the manufacturers do not have capital to invest in this segment of the heavy-duty sector. Yet, Navistar and General Motors just announced a joint venture to develop more class 4 and 5 trucks, many powered with gasoline engines.\textsuperscript{157} The Agencies go on to conclude that some reduction will occur anyway because the engines used in this application are derived from engines used in pickups and vans. We do not support this rationale. [EPA-HQ-OAR-2014-0827-1312-A1 p.36]

The assertion that multi-billion dollar manufacturers can not make these investments is not supported by the rulemaking record. Furthermore, these gas engines compete – albeit in small numbers – with diesel engines. By allowing weaker standards for gasoline engines, the Agencies are giving them a competitive advantage and incentivizing a shift to gasoline. Indeed, recent data shows there has been a significant increase gasoline engines in medium-duty trucks.\textsuperscript{158} [EPA-HQ-OAR-2014-0827-1312-A1 p.36]

Historically, EPA has preferred setting fuel neutral standards to maintain a level playing field – and we believe the Agencies should do so here. We recommend that the Agencies set the most feasible, fuel neutral standard based on the capabilities of the technological leader – in this case the diesel engine. If the Agencies decide not to do this, they should at the very least set a standard based on the most advanced gasoline engine technologies deployable in the timeframe the standards take effect. It is reasonable to expect that efficiency improvements made to gasoline engines used in heavy-duty pickups and vans will migrate to those used in vocational vehicles, and that shift should be encouraged by robust standards. A recent SwRI study funded by NHTSA projects that gasoline engines could improve fuel efficiency by up to 8%.\textsuperscript{159} We urge the Agencies to set more rigorous standards for gasoline vocational engines based on this and other relevant analyses. [EPA-HQ-OAR-2014-0827-1312-A1 p.37]
Response:

We recognize that most gasoline engines still have high brake-specific CO\textsubscript{2} emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. We recognized the findings made by SwRI reports. However, one of the key issues that have not been addressed is the reliability of the technology. Since the operating zones are different between heavy duty pickups/vans in Class 2b-3 and the vehicles in Class 4-7, the heavier vehicles would force the engine to run more frequently in the higher speed and higher load zones than the case with Class 2b-3 vehicles, and therefore the reliability would become more of an issue. As a result, the technologies developed under pickups and vans would not be straightforward to migrate to those used in Class 4-7 vehicles. All of these behaviors would make it harder to stay fuel neutral. In order to provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements.

Organization: Honeywell Transportation System (HTS)

In addition to the fuel neutrality concerns on heavy duty pickup trucks and vans, HTS is also concerned that the current proposal excludes gasoline engines from the MD/HD Vocational portion of the Phase 2 regulation. While we appreciate that the proposed rule will apply vehicle-level fuel efficiency standards to gasoline powered vocational vehicles that are essentially the same as those applied to diesel vehicles, the lack of a gasoline engine-level standard is counter to the goals of the rule. The cost differential between diesel and gasoline engines has increased substantially over the past 10 years, as diesel engines have adopted technologies to comply with NOx and PM regulations. This has made diesel engines less competitive on initial cost, and the industry has seen a steady increase in the market share of gasoline engines in class 3-5 applications. We believe that the proposal as written will further increase the initial cost of diesel engines while allowing gasoline engines a “free pass” on CO2. This will likely result in a much larger share for gasoline in these markets and has the potential to create a double negative effect: higher operating cost for vehicle users and higher CO2 emissions for the fleet. [EPA-HQ-OAR-2014-0827-1230-A1 p.4] These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.259-260.}
Response:

We recognize that most gasoline engines still have high brake-specific CO₂ emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. Because of these reasons, we don’t believe that the rule would result in a much larger share for gasoline engines. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements. We disagree with the commenter that SI engine manufacturers are getting a “free pass.” We believe that many have reached a point in development where any cost-effective incremental changes may already be made, and platform redesigns may only be chosen for models with forecasted high production volumes. More particularly, as shown in RIA chapter 2.6, the improvements to SI engines suggested by many commenters are already shown to be adopted at 100 percent to meet the MY 2016 engine standard. See RIA Chapter 2.6.

Organization: International Council on Clean Transportation (ICCT)

- **Gasoline engines** – The proposed gasoline standards for Phase 2 indicate no new requirements. Gasoline efficiency technology tends to migrate upward from the heavy-duty pickup and van technologies that are manufactured at higher volume. In addition, a government-funded Southwest Research Institute study indicates that they can reduce fuel use by up to 8% (Reinhart, 2015b). Installing gasoline engine standards and advancing their technology penetration at the similar pace with diesel engine efficiency, as well as at a similar pace with the agencies’ assessment of pickup and van gasoline engine efficiency, would meet our assessment of technology availability and help to minimize unintended shifts in the market to higher fuel consumption gasoline products. [EPA-HQ-OAR-2014-0827-1180-A4 p.5]

**Overall gasoline engine efficiency:** Based on the above data, the agencies would include new increasingly stringent gasoline engine standards to reflect the existing technology potential and to ensure that the Phase 2 regulation does not perversely bias the market toward gasoline engines that have higher fuel consumption and higher CO₂ emissions for the same or lesser functionality. We recommend that the agencies require a reduction of fuel consumption for gasoline engines up to 8% in 2024 from baseline 2017 engines, based on Reinhart (2015b). In addition, it is widely recognized that gasoline efficiency technology migrates up from high-volume gasoline heavy light-duty trucks. As acknowledged directly by the agencies, vocational gasoline engines typically are the same engines as those in the pickups and vans. Ford/Ram/GM use much of the same engine technology in their high-workload light- and heavy-duty products, and these companies will likely be deploying 15%+ engine efficiency improvements in the 2020-2025 light-duty context (Lutsey, 2015a). Once these are being deployed at large volume in light-duty there is little reason that many of those same technologies could not be deployed in class 2b/3 pickup/vans, as well as in the vocational gasoline engines. As a result, implementing gasoline engine standards with similar stringency and timing with diesel engine efficiency, as well as at a similar pace with the agencies’ assessment of pickup and van gasoline engine efficiency, would match the availability of technology in the rulemaking timeframe. [EPA-HQ-OAR-2014-0827-1180-A4 p.9-10]
Response:

We recognize that most gasoline engines still have high brake-specific CO$_2$ emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. We recognized the findings made by SwRI reports. However, one of the key issues that have not been addressed is the reliability. Since the operating zones are different between heavy duty pickups/vans in Class 2b-3 and the vehicles in Class 4-7, the heavier vehicles in latter would force the engine to run more frequently in the higher speed and higher load zones than the case with Class 2b-3 vehicles, and therefore the reliability would become more of an issue. As a result, the technologies developed under pickups and vans would not be straightforward to migrate to those used in Class 4-7 vehicles. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements. See also introductory response to this RTC Section 3.3.2.

Organization: Motor & Equipment Manufacturers Association (MEMA)

Ensure Technology-Neutral, Performance-Based Standards [EPA-HQ-OAR-2014-0827-1274-A1 p.3]

As for the vocational vehicle category, MEMA is concerned with the agencies’ proposals and the potential market impact it may have. Specifically, MEMA objects to the proposal to leave the spark ignition engine standards unchanged in 40 CFR 1036.108(a)(1)(i) and 49 CFR 535.5(d)(3). Regulations that continue to increase the technical complexity of diesel engines relative to gasoline engines will “create an incentive for purchasers who would have otherwise chosen a diesel vehicle to instead choose a gasoline vehicle,” and thus may result in a much larger market share for gasoline in this particular space. MEMA urges the agencies to adopt more stringent standards for spark-ignition engines over the MY 2021-2027 timeframe, standards that are harmonized with those for light and medium heavy-duty diesel engines and thereby ensure technology neutrality. [EPA-HQ-OAR-2014-0827-1274-A1 p.4]

Response:

We recognize that most gasoline engines still have high brake-specific CO$_2$ emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. We thus do not accept the comment that a separate SI engine standard, or one not reflecting the commenter’s preferred level of stringency, will create a perverse incentive to replace CI engines with SI engines. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements.

Organization: Natural Resources Defense Council (NRDC)

Increase Stringency of Gasoline Engine Standards
NRDC recommends that the agencies set a gasoline engine standard that tightens over the period of the Phase 2 standards to reach the 8 percent technology potential found by SwRI. The agencies’ proposal requires no improvement to gasoline engine fuel consumption. SwRI shows improvements that can reduce fuel consumption by 8 percent in medium-duty and vocational gasoline engines. In the timeframe of the Phase 2 requirements, NRDC expects light-duty truck gasoline engine technologies to improve meet the 2017-2025 light-duty vehicle fuel economy and greenhouse gas emissions standards. It is reasonable to expect that many of these advancements will migrate to gasoline engines used in heavier vehicle classes. Additionally, the lack of tighter gasoline engine standards could encourage a market shift to gasoline engines that achieve no reductions in carbon pollution from diesel engines that must incur the cost of meeting tighter standards. The result would be more overall carbon pollution when cost-effective technologies are available to avoid those emissions. [EPA-HQ-OAR-2014-0827-1220-A1 p.5]

13 Reinhart, Report #2, op. cit.

Response:

See introductory response above. In addition, as noted in other responses, we recognize that most gasoline engines still have high brake-specific CO₂ emissions (g/hp-hr). Although low sales volume & low engine power (low hp), coupled with a number of low VMT vehicle applications (e.g., RVs), moderates the adverse inventory impacts from these engines, low sale volume with low market share eliminate ABT program flexibility. In addition, the cost for new SI engine platforms would be high and not cost effective, given the limited volumes of engines produced. At this time, only one manufacturer certified its gasoline engine, but it must rely on significantly de-rated speed and power for an RV application. We recognized the findings made by SwRI reports. However, one of the key issues that have not been addressed is the reliability. Since the operating zones are different between heavy duty pickups/vans in Class 2b-3 and the vehicles in Class 4-7, the heavier vehicles in latter would force the engine to run more frequently in the higher speed and higher load zones than the case with Class 2b-3 vehicles, and therefore the reliability would become more of an issue. As a result, the technologies developed under pickups and vans would not be straightforward to migrate to those used in Class 4-7 vehicles. To provide more flexibility but still recognize the possibility of feasible engine improvements, the final standards include increased stringency of the vocational vehicle standard to reflect feasible SI engine improvements.

Organization: Union of Concerned Scientists (UCS)

Gasoline engines. In Phase 2, the agencies have not set a separate gasoline engine standard for vocational engines due to market considerations surrounding the engines’ use in the pick-up and van market. However, they did note that engine improvements for vocational engines beyond Phase 1 would still be considered in setting the vocational vehicle stringency, and the agencies did apply additional friction reduction of 1 percent to the 60 percent of gasoline-powered vehicles that would not yet achieve this level as part of the MY2016 spark-ignited engine package. [EPA-HQ-OAR-2014-0827-1329-A2 p.21]

Engine friction reduction does not capture all of the potential for gasoline engines, however. SwRI noted a number of other technologies: improvements to variable valve lift and timing, stoichiometric exhaust gas recirculation (which could also be compounded with downspeeding on turbocharged engines), direct
injection (for naturally-aspirated vehicles) or turbocharger efficiency improvements (for turbocharged engines), and lean-burn operation. Due to timeline considerations and concerns raised in the first SwRI report (Reinhart 2015a), we did not include lean-burn GDI as part of the technology package for vocational vehicles. Similarly, because of concerns with the downsized EGR package raised around high idle duty cycles, we considered only the stoichiometric EGR package. Finally, we excluded cylinder deactivation as well for the V8 engine, focusing instead on engine friction reduction. [EPA-HQ-OAR-2014-0827-1329-A2 p.21-22]

Both diesel and gasoline engines have additional improvement opportunities beyond the NPRM based on analysis by the Southwest Research Institute (SwRI). These improvements are characterized by drive cycle. To translate those to duty cycle, they have been reduced by idle fraction (10 percent for regional vehicles, 15 percent for multipurpose, and 20 percent for urban). While some technologies like downsizing may increase idle fuel usage, generally this assumption should result in a conservative approach to assessing the certifiable stringency of these vehicles because most technologies that reduce fuel use under load will reduce it at idle as well. In all comparisons to SwRI data, we have taken the 100-percent payload value, which is most consistent with the agencies’ vehicle payload in GEM (8,860 pounds for the T-270, compared to the agencies’ value of 11,200 pounds for MHD vocational vehicles). This generally results in the most conservative application of the SwRI results, particularly on engine friction reduction. [EPA-HQ-OAR-2014-0827-1329-A2]

The SwRI analysis used two different baseline engines in its assessment of gasoline-powered vehicles, a turbocharged V6 and a naturally-aspirated V8 (Table 6). While the V6 is not currently in production for vocational vehicles, it is designed to be comparable to a 6L V8 and is extensively used in Class 2a pickup trucks. Furthermore, we have heard from some fleets who were disappointed when V6 gasoline engines went off the market due to a platform redesign because it forced them to move to V8 engines that were overpowered for their needs (and therefore wasted fuel relative to the V6). Therefore, we believe that there is opportunity for turbodownsizing in the gasoline market in the right application, and so we have additionally considered a V8>V6 package based on the relative difference in efficiency between the two SwRI engines. It should be noted that this would result in some differences in performance, and therefore we have only conservatively applied this technology, to just 10 percent of the gasoline-powered vocational fleet. [EPA-HQ-OAR-2014-0827-1329-A2 p.22]

In assessing the overall effectiveness for future gasoline engines, we turn to SwRI Package #16 for the 3.5L V6 (VVA+EGR) and SwRI Package #22 for the 6.2L V8 (GDI+EGR+EFR+dual cam phasers). Taken altogether, the gasoline package would achieve an average 7.4 percent improvement for spark-ignited vocational vehicles. [EPA-HQ-OAR-2014-0827-1329-A2 p.22]

[Table 6, ‘Effectiveness of vocational gasoline engine packages’, can be found on p.22 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

Response:

Because none of the technical data referenced by commenters who asked for more stringent SI engine standards provided information on how these technologies perform over the HD gasoline engine FTP test procedure, the agencies are considering these to be comments on the GEM-based vocational vehicle standards, not comments on the separate FTP-based SI engine standard.

The final SI vocational vehicle standards are calculated using an engine that meets the MY 2016 standard. In response to comments and with careful consideration of the SwRI data as well as information on
technologies for HD pickup and vans, the final vehicle-level standards for vocational vehicles powered by SI engines include additional reductions we believe can be achieved by additional engine technologies over the GEM vehicle cycles amounting to 0.8 percent beginning in MY 2021. See RIA Chapter 2.9.1.2.1. This is more stringent than the 0.6 percent of engine improvements on the vehicles proposed by the agencies that would have begun in MY 2027. We disagree with commenters asking for as much as 8 percent improvement. All of the referenced SwRI packages compare the future vehicle performance to a pre-Phase 1 baseline, thus counting all the improvements already presumed in the MY 2016 engine standard, so the delta between what the commenters seek and what the agencies proposed is considerably less than initially appears (and less than the commenter appeared to believe). We agree that higher-emitting SI engines (that do not meet the SI engine standard) if installed in vocational vehicles will require additional vehicle-level technology to meet the final SI vocational vehicle standards. See further information on this topic in the Preamble at Section V.C.1 b, and in the RIA Chapter 2.6 and Chapter 2.9.1.2.1.

3.3.3 Additional Discussion of Baseline Engines

Response:

Background

Phase 1 applied different test cycles depending on whether the engine is used for tractors, vocational vehicles, or both, and we are continuing this approach. Tractor engines are subject to standards over the SET (EPA’s steady-state heavy-duty test cycle), while vocational engines are subject to standards over the FTP (EPA’s transient heavy-duty test cycle).

The SET cycle was adopted by EPA in 2000 and modified in 2005 from a discrete-mode test to a ramped-modal cycle (RMC) to broadly cover the most significant part of the speed and torque map for heavy-duty engines, defined by three non-idle speeds and three relative torques. The low speed is called the “A speed,” the intermediate speed is called the “B speed,” and the high speed is called the “C speed.” As is shown in the below, the SET cumulatively weights these three speeds at 23 percent, 39 percent, and 23 percent.

The C speed is typically in the range of 1800 rpm for current heavy heavy-duty engine designs. However, it is becoming much less common for engines to operate at such a high speeds in real-world driving conditions, and especially not during cruise vehicle speeds in the 55 to 65 mph vehicle speed range. This trend has been corroborated by engine manufacturers’ in-use data that has been submitted to the agencies in comments and presented at technical conferences. Thus, although the current SET represents highway operation better than the FTP cycle, it could be improved by adjusting its weighting factors to better reflect modern trends in in-use engine operation. Furthermore, the most recent trends indicate that manufacturers are configuring drivetrains to operate engines at speeds down to a range of 1050-1200 rpm at a vehicle speed of 65mph.

To address this trend toward in-use engine down-speeding, the agencies are finalizing as proposed refined SET weighting factors for the Phase 2 CO\(_2\) emission and fuel consumption standards. The new SET mode weightings move most of the C weighting to “A” speed, as shown in the table below. To better align with in-use data, these changes also include a reduction of the idle speed weighting factor. These new mode weightings do not apply to criteria pollutants or to the Phase 1 CO\(_2\) emission and fuel consumption standards.

NPRM Baselines

In the Phase 2 proposal we assumed that the numeric values of the Phase 1 standards were the baselines for Phase 2. The Table below shows the Phase 1 standards for diesel engines.

<table>

We applied our technology assessments to these baselines to arrive at the Phase 2 standards for MY 2021, MY 2024 and MY 2027. In other words, for the Phase 2 proposal we projected that starting in MY 2017 engines would, on average, just meet the Phase 1 standards and not over-comply. However, based on comments we received on how to consistently apply our new SET weighting factors in our analysis and based on recent MY 2016 engine certification data, we realized the change in test procedures caused in a change in measured results that impacts the appropriate level of the standards. We also realized that the proposed FTP baseline misrepresented baseline performance for vocational engines. As described below, we are updating our Phase 2 baseline assumptions for both the SET and FTP.

Revision to the SET Baseline

With respect to the SET, in the proposal we compared our proposed Phase 2 standards, which are based on these new Phase 2 weighting factors, to the Phase 1 numeric standards, which are based on the current Phase 1 weighting factors. Because we continue to use the same 13-mode brake specific CO\textsubscript{2} and fuel consumption numeric values we used for the proposal to represent the performance of a MY 2017 baseline engine, we are not projecting a different technology level in the baseline. Rather, this is simply correcting an “apples-to-oranges” comparison from the proposal by applying the Phase 2 weighting factors to the MY 2017 baseline engine. While this did not impact our technology effectiveness or cost analyses, it did impact the numeric value of our baseline to which we reference the effectiveness of applying technologies to the 13 individual modes of the SET. Because the revised SET weighting factors result in somewhat lower brake specific CO\textsubscript{2} and fuel consumption numeric results for the composite baseline SET value, this correction, in turn, lowers the numerical values of the final Phase 2 SET standards. Making this particular update did not result in a change to the relative stringency of the final Phase 2 numeric engine standards (relative to MY 2017 baseline performance), but our updated feasibility analysis did; see Section II.D.(2)(a) of the FRM preamble.

This issue was raised by several commenters on the NPRM (in particular UCS, Cummins, ICCT and EDF in their public comments) who generally noted that the impact of not accounting for the different SET weightings would be to make the standards less stringent in actual effect. In other words, by over-estimating the emissions of MY 2017 engines when measured using the new SET weighting factors, we would enable manufacturers to comply with the standards using less technology than projected and, consequently, achieve less improvement in actual use. Several manufacturers addressed this issue in supplemental comments and in comments on the NODA.

Each of the tractor engine manufacturers provided supplemental information to us including 13-mode test results for their engines. All of this information was claimed as CBI. These data showed some variation,
but most showed the new weighting factors to reduce cycle-average emissions by slightly more than one percent.

The agencies have updated our analysis of SET baselines to be consistent with these data, and applied our projected per cent reductions to the revised SET baseline to obtain revised the numerical values of the standards. See Section 3.3.4 below (as well as certain responses in Section 3.3.1) for a discussion of how we considered the potential impacts of IRAFs on the baselines and the standards.

Revision to the FTP Baseline

The agencies also made adjustments to the FTP baselines, but these adjustments were not made because of test procedure changes. Rather, MY 2016 FTP certification data showed an unexpected step-change improvement in engine fuel consumption and CO₂ emissions. These data were not available at the time of proposal, so the agencies relied upon the MY 2017 Phase 1 standard as a baseline. EDF publicly commented in response to the NODA that the more recent certification data revealed this new step-change. MY 2016 certification data submitted to the agencies as well as to ARB show that many engines from many manufacturers already not only achieve the Phase 1 FTP standards, but some were also below the MY 2027 standards proposed for Phase 2. This was not the case for the SET, where most manufacturers are still not yet complying with the MY 2017 Phase 1 SET standards. In view of this situation for the FTP, the agencies are adjusting the Phase 2 FTP baseline to reflect this shift.

The underlying reasons for this shift are mostly related to manufacturers optimizing their SCR thermal management strategy over the FTP in ways that we (mistakenly) thought had already occurred in MY 2010 (i.e., the Phase 1 baseline). As background, the FTP includes a cold-start, a hot-start and significant time spent at engine idle. During these starting and idling portions of the FTP, the NOₓ SCR system can cool down and lose NOₓ reducing efficiency. One simplistic strategy to maintain SCR temperature is to inefficiently consume additional fuel, such that the fuel energy is lost to the exhaust system in the form of heat. There are more sophisticated strategies to maintain SCR temperature, however, but these apparently required additional time from MY 2010 for research, development and refinement. (As discussed in Section 3.3.4 below, in updating these baseline values, the agencies did consider the concerns raised by manufacturers about the potential baseline impacts of IRAFs, which can also be related to thermal management.)

At the time of Phase 1 we had not realized that these improvements were not already in the Phase 1 baseline. These include optimizing the use of an intake throttle to decrease excess intake air at idle and SCR catalyst reformulation to maintain SCR efficiency at lower temperatures. Based on this information, which was provided to the agencies by engine manufacturers, but only after the agencies’ specifically requested it, the agencies concluded that in Phase 1 we did not account for how much further these kinds of improvements could impact fuel consumption over the FTP. Conversely, only by reviewing the new MY 2016 certification data did we realize how little SCR thermal management optimization actually occurred for the engine model years that we used to establish the Phase 1 baseline – namely MY 2009 and MY 2010 engines.

Like the change to the SET baseline, this change to the FTP baseline does not impact the agencies’ projections of potential compliance pathway, cost, and stringency. This is because we never accounted for this kind of improvement in our Phase 2 proposal’s stringency analysis for meeting the Phase 2

39 https://www3.epa.gov/otaq/certdata.htm#oh.
proposed FTP standards. Therefore, we continue to apply the same improvements that we proposed, but we apply them to the updated FTP baseline.

**FRM Baseline SET and FTP Values**

The table below shows the Phase 2 diesel engine final CO₂ baseline emissions. The gasoline engine CO₂ baseline for Phase 2, which is not shown, is the same as the Phase 1 HD gasoline FTP standard, 627 g/bhp-hr. More detailed analyses on these Phase 2 baseline values of tractor and vocational vehicles can be found in Chapter 2.7.4 of RIA.

Some manufacturers argue that these changes represent increases in the “stringency” of the engine standards. As already noted, there are different ways in which the term “stringency” can be used. We recognize that the changes to the baselines and the test procedures being made for the FRM have resulted in numerically lower emission standards. However, the agencies do not consider these changes to be true changes in stringency because they are independent of the projected technology. Nevertheless, rather than engaging in the semantic debate of whether or not these changes represent a change in “stringency”, we note that the greatest significance of these changes is that they make the numerical standards consistent with the projected costs and in-use benefits of the proposed and FRM analyses. Thus, the final technological cost and feasibility analyses fully support the final engine standards.

**Baseline Maps**

In addition to estimating baseline SET and FTP values, the agencies also developed complete baseline maps to use as GEM inputs. For the NPRM, we started with the maps used in Phase 1 to represent engines compliant with the 2017 engine standards. Based the best available information, we modified these maps to better represent actual engine technology. In some ways these modified engine maps reflected more efficient engines than were used in Phase 1. However, based on comments, including confidential data from manufacturers we revised the NPRM maps to be more representative of MY 2017/2018 engines.

Navistar referred to these maps as hypothetical, but we find that term to be misleading. Although these maps do not reflect any single engine, they each are derived from real engine maps. The agencies developed these maps to represent the average performance of multiple real maps. Nevertheless, as already noted, we did agree that the NPRM maps could be improved and have done so for the FRM.

### 3.3.4 Additional Discussion of IRAFs

**Response:**

The current engine test procedures also require the development of regeneration emission rates and frequency factors to determine infrequent regeneration adjustment factors (IRAFs) that account for the emission changes for criteria pollutants during an exhaust emissions control system regeneration event.
In the 2011 Phase 1 final rule, the agencies adopted provisions to exclude CO\textsubscript{2} emissions and fuel consumption due to regeneration. In large part, this was because manufacturers had just begun using SCR on their engines and they had not yet optimized regeneration strategies.

However, for Phase 2, we are requiring the inclusion of CO\textsubscript{2} emissions and fuel consumption due to regeneration over the FTP and SET cycles, as determined using the IRAF provisions in 40 CFR 1065.680. While some commenters opposed this because of its potential impact on stringency, we do not believe this will significantly impact the stringency of these standards because manufacturers have already made great progress in reducing the frequency and impact of regeneration emissions since 2007. Rather, the agencies are including IRAF CO\textsubscript{2} emissions for Phase 2 to prevent these emissions from increasing in the future to the point where they would otherwise become significant. While some manufacturer comments on the NPRM opposed the inclusion of IRAFs, some qualitatively acknowledged the likely already small and decreasing magnitude of IRAF CO\textsubscript{2} emissions in their comments. For example, EMA stated, “the rates of infrequent regenerations have been going down since the adoption of the Phase 1 standards” and that IRAF “contributions are minor.” Nevertheless, we believe it is prudent to begin accounting for regeneration emissions to discourage manufacturers from adopting criteria emissions compliance strategies that could reverse this trend. Manufacturers expressed concern about the additional test burden, but the only additional requirement would be to measure and report CO\textsubscript{2} emissions for the same tests manufacturers are already performing to determine IRAFs for other pollutants.

At the time of the proposal, we did not specifically adjust baseline levels to include additional IRAF emissions because we believed them to be negligible and decreasing. Commenters opposing this proposed provision provided no data to dispute this belief in their comments on the NPRM (and, as just quoted, EMA’s comments corroborate the agencies’ approach at proposal). More recently, a few manufacturers have raised the possibility that IRAFs may be more significant than we believed – especially for the FTP. However, at least one manufacturer has provided CBI data to show that their IRAFs for CO\textsubscript{2} would be very small for both the SET and FTP. After considering this more recent information, we continue to believe that regeneration strategies can be engineered to maintain these negligible rates. Thus, we do not believe the regeneration emissions are of fundamental significance for our baselines in the FRM. Highway operation includes enough high temperature operation to make active regenerations unnecessary. Furthermore, recent improvements in exhaust after-treatment catalyst formulations and exhaust temperature thermal management strategies, such as intake air throttling, minimize CO\textsubscript{2} IRAF impacts during non-highway operation, where active regeneration might be required. Finally, as discussed in Section 3.3.3 above, recent significant efficiency improvements over the FTP cycle show that FTP emissions can be even lower than we have estimated in our updated FTP baselines, which would provide additional margin for manufacturers to manage any minor CO\textsubscript{2} IRAF impacts that may occur.

In summary, we believe that with proper design, regeneration event can be very infrequent and the emissions can be very low so that the impact of applying an IRAF should be less than 0.1 percent. We have considered this impact in our analysis of baseline emission rates, along with other marginal factors. Although manufacturers have recently given us some CBI data on their current engines that inform our estimated baseline values, this data set is still limited and leaves some uncertainty. To be prudent, we addressed this uncertainty by being somewhat conservative in the extent to which we adjusted the baselines downward.

For any manufacturers that currently have non-negligible IRAFs, we believe market forces would drive them to reduce fuel consumption during regenerations. Thus, we do not believe any costs to control fuel consumption during regenerations would be attributable to the Phase 2 program. Nevertheless, we note that the cost for such control would be limited to the cost of recalibration work, which should be low.
Even if that cost occurs and should have been attributed to Phase 2 (a premise with which we do not agree), including such costs would not have altered any decisions about the Phase 2 engine standards. Throughout the rulemaking, we did not find costs or cost-effectiveness to be a significantly limiting factor in determining the stringency of the standards.
3.4 Projected Engine Technologies, Effectiveness, and Cost

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Engine technology effectiveness

The Phase 2 engine package draws on research done by Southwest Research Institute (SwRI). However, the agencies sometimes use lower effectiveness values than SwRI finds, without offering a justification. First and foremost is the case of engine friction reduction. The SwRI study considered potential friction reduction from any component needed for engine operation, including engine piston, ring, liners, bearings, valve train, and gear train. It also considered reduced friction from variable speed oil and water pumps, from reduced-power fuel pumps, and by using low viscosity engine oil. While the SwRI study estimated more than 4% fuel consumption reduction from friction reduction, the agencies estimated 1.4% reduction from engine friction and parasitic reduction. [EPA-HQ-OAR-2014-0827-1280-A1 p.10]

Improvement in combustion and control is another area where the agencies underestimated effectiveness. The agencies estimated 1% improvement from combustion and control, while Cummins Inc. has estimated 4% thermal efficiency improvement, or almost 8% fuel efficiency improvement, beyond Phase 1 from combustion, air-handling, and after-treatment improvement. Similarly, industry sources have indicated 2% and 1% minimum fuel savings from combustion and engine controls, respectively. [EPA-HQ-OAR-2014-0827-1280-A1 p.10-11]

Additional fuel consumption reduction is possible from waste heat recovery (WHR) in the form of either turbo compounding or Rankine cycle. Volvo reported 2 to 4% fuel savings from turbo compounding in line haul applications (p. 40196), yet the agencies assumed only 1.8%. In Phase 1 the agencies reported 2.5% to 5% fuel savings from mechanical turbocompounding. Similarly, while the agencies assume 3.6% fuel savings for Rankine Cycle over the SET, the SwRI study estimated 4.4% fuel savings over a weighted average of transient, 55 mph and 65 mph cycles. The benefits of Rankine cycle would not accrue on the transient cycle, so one would not expect the fuel savings on the SET to be lower than the weighted SwRI results. Furthermore, Cummins Inc., in a recent presentation to the Air Resources Board, claimed 4.5% average fuel savings from Rankine cycle in their SuperTruck project. [EPA-HQ-OAR-2014-0827-1280-A1 p.11]

Engine technology penetration

The Phase 2 proposal estimates 100% penetration of all engine technologies in the 2027 timeframe except engine downsizing, turbo compounding and Rankine cycle. More than 40 percent of all energy loss in an engine is lost as heat to the exhaust and engine coolant (p. 40196). Therefore, manufacturers are actively pursuing WHR in at least one form. Hence we believe the agencies’ estimate of 15% penetration for Rankine cycle and 10% penetration for turbo compounding in Phase 2 are far too low. Both turbo compounding and Rankine cycle are suitable for the steady-speed operation that is typical in line haul operation. Furthermore, turbo compounding is part of the Phase 1 package for 2017 model year engines, so 10% penetration in next ten years is an overly conservative estimate. Two major manufacturers, Daimler Truck North America and Volvo, are likely to use this technology before 2020 (p. 40196). Cummins Inc., another major engine manufacturer, has invested in Rankine cycle and used it in their SuperTruck program. Therefore, we believe it is more appropriate to expect all line haul tractor trucks (62% of all tractor trucks) to take advantage of one of these two WHR technologies in the Phase 2 timeframe. [EPA-HQ-OAR-2014-0827-1280-A1 p.11]

Overlapping benefits
After calculating the combined benefits of engine technologies using a multiplicative approach, the agencies appear to have applied a further 15% discount to the benefits to account for overlapping benefits of the technologies. We agree that the percent fuel savings realized by a given technology may be lower when the technology is used with another technology, and this issue should be addressed in estimating combined benefits. However, no explanation is offered for how the 15% figure was arrived at, and this value does not appear to be justified in this case. [EPA-HQ-OAR-2014-0827-1280-A1 p.11]

Any attempt to quantify such overlaps in benefits should be based on considerations specific to the technologies to be combined. For example, the effectiveness of a waste heat recovery will be lower in combination with technologies that reduce the amount of waste heat available. However, we are unaware of other overlapping benefits among the particular technologies in the agency engine package. [EPA-HQ-OAR-2014-0827-1280-A1 p.12]

Using the above-mentioned effectiveness and penetration of these technologies, we estimate that the fuel consumption of tractor track engines can be reduced by 9% and 10% in 2024 and 2027, respectively. Table 2 summarizes the potential engine efficiency improvements for 2027 model year and compares with the proposed standards. Table A1 in the Appendix shows the corresponding comparison for model year 2024. [EPA-HQ-OAR-2014-0827-1280-A1 p.12]

[Table 2 can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1280-A1, and Table A1 can be found in Appendix A on p.12 of docket number EPA-HQ-OAR-2014-0827-1280-A1]

6 Test cycles may not be comparable.

7 p. 57205, Federal Register /Vol. 76, No. 179/September 15, 2011

8 http://www.arb.ca.gov/msprog/onroad/caphase2ghg/presentations/2 7 wayne e cummins.pdf

Response:

The finding from SwRI’s report on friction is consistent with agencies estimate if the exactly same certification cycle weighting factors on tractors and the certification vehicle weights are used. Using the same principle for overall technology effectiveness reported by SwRI, specifically from their revised report, their findings again support the agencies’ findings. We do not believe that 4% reduction on combustion is feasible for Phase 2 using an existing engine platform over 13 composite SET modes. Based on discussions with OEMs and consideration of CBI, the agencies believe that the type of reduction posited by the commenter could be achieved only by a new engine platform with significant capability of sustaining extremely high peak cylinder pressure. Most of the heavy duty engines currently marketed are relatively new; new engine platforms are not generally being contemplated. The cost of
designing a new engine platform outside the normal redesign cycle is enormous, and has not been considered by the commenter. Our effectiveness of WHR Rankine cycle technology is based on the credible information directly from one of the OEMs. Volvo’s finding on WHR turbo-compound benefits is from an on-highway operations. In contrast, we have to evaluate any technology benefits over the 13 modes of the SET cycle, where turbo-compound actually has negative benefits in the low loads and low speed regions. We are confident that the WHR effectiveness used represents the state-of-the-art values. Based on many constructive comments and the agencies’ further investigation on dis-synergy effect or overlapping effect, these values were adjusted for the final rule. An example if this is with the 2027 tractor engines, where we increased the dis-synergy factor from 0.85 to 0.9.

Organization: American Trucking Associations (ATA)

Specific technology MPRs under the Phase 2 Rule appear to be overly aggressive and must be adjusted downward for fleets to afford flexibility in spec’ing equipment, avoid excessive downtime due to unforeseen maintenance requirements, and maintain equipment affordability. The specific market penetration rates of concern are as follows: [EPA-HQ-OAR-2014-0827-1243-A1 p.6]

Waste Heat Recovery (15% in 2027)

Waste heat recovery (“WHR”) was explored as a potential fuel efficiency technology under the U.S. Department of Energy’s SuperTruck initiative – a program developed to advance the fuel efficiency of tractor-trailers by 50% over baseline models. The SuperTrucks equipped with WHR were developed and unveiled by heavy-duty manufacturers in project demonstration vehicles funded through federal and private sector sources. However, these prototype trucks are currently not production-ready and therefore have not been thoroughly tested across the challenging and widely varied duty-cycles that exist within our industry. ATA member fleets have clearly expressed their desire to only purchase technologies that are thoroughly tested, verified, affordable, and proven to be both durable and affordable. [EPA-HQ-OAR-2014-0827-1243-A1 p.6]

Waste Heat Recovery

The agencies assume Waste Heat Recovery (“WHR”) technology will cost $10,523 in 2021. Figures derived from the DOE SuperTruck program ranged from $7,200 - $15,000. Because WHR is not currently in the market, the actual costs remain unknown. Some OEMs state that the agencies’ costs are actually higher than this figure while another OEM says it is overinflated. This wide-ranging pricing uncertainty should raise a cautionary flag to the agencies. WHR is the highest cost menu item under the current heavy duty engine technology listings. The agencies must be more transparent in how they derived such cost figures given they are being so widely contested by all the OEMs. As you can imagine, these cost uncertainties have only escalated fleet concerns over the future pricing of equipment under Phase 2. [EPA-HQ-OAR-2014-0827-1243-A1 p.11]

Response:

We understand ATA’s concerns on the projected WHR market penetration. On the other hand, we received data and credible CBI information from one of the engine manufacturers as well as their public comments (EPA-HQ-OAR-2014-0827-1298) that their WHR system could be put into production in the 2021 timeframe. In addition to our response in RTC Section 3.4.1 below, Chapters 2.3 and 2.7 of the RIA detail the justification of WHR as one of the technologies used in our stringency development. We have reconsidered our WHR costs in the final rule and provide more detail for how it was derived. Please refer to RIA Chapter 2.11.2.15 for more detail on our final WHR cost estimates.

Page 577 of 2127
**Organization:** Caterpillar Inc, et al.

Waste Heat Recovery: 15% - Waste heat recovery technology is not currently in the market, has technical challenges for which production-viable solutions have not been identified, and is therefore not proven. Customers are concerned with the complexity of the system as well as likely maintenance and downtime increases, which will prevent uptake of this non-proven technology. EPA should not assume any penetration of waste heat recovery technology by 2027. [EPA-HQ-OAR-2014-0827-1215-A1 p.6]

**Response:**

We received data and credible CBI information as well as public comments (EPA-HQ-OAR-2014-0827-1298) from one the engine manufacturers that their WHR system could be put into production in the 2021 timeframe. With a technology effectiveness of 3.6% used in engine standards, it only translated to a total of reduction about 0.9% in 2027. Considering that the technology path proposed by the agencies is only one of many paths that can achieve the standards, this 0.9% reduction can be made up by many other means. In addition to our response in RTC Section 3.4.1 below, Chapter 2.3 and 2.7 of the RIA for detailed justification.

**Organization:** Clean Air Task Force et al.

We continue to find that achieving a 40% improvement in oil consumption in 2025 (over 2010 levels) is feasible and cost-effective. Further, there are some areas where the new data support our initial recommendations for strengthening. The report from Southwest Research Institute shows that heavy-duty engines for tractors, pick-ups, and vocational vehicles can all be much more efficient than the proposed targets. [EPA-HQ-OAR-2014-0827-1925-A1 p.1-2]

**Response:**

See earlier responses. Also, the commenter’s suggested improvement is over the 2010 baseline whereas the more germane comparison is over a 2017 MY baseline.

**Organization:** Clean Fuels Ohio (CFO)

Opportunities improving truck fuel efficiency are also great (and growing) based on already-existing technologies and others in the R&D pipeline that show future promise: [EPA-HQ-OAR-2014-0827-1192-A1 p.1]

**Response:**

See earlier responses.

**Organization:** Controlled Power Technologies, Inc.

I am writing to inform the EPA and the public about CO2 reduction-enabling technologies from Controlled Power Technologies (CPT). Simulink performance models are available and may be suitable for inclusion in GEM. [EPA-HQ-OAR-2014-0827-1307 p.1]

COBRA stands for COntrolled Boosting for Rapid response Applications. It is a fully integrated electric supercharger including all control and power electronics. [EPA-HQ-OAR-2014-0827-1307 p.1] By supplying instantaneous on demand air COBRA is an enabling technology which can support a number of
CO2 and emission reducing solutions. COBRA complements engine downsizing by supporting the low end torque gap allowing for the same drivability as a larger powertrain. [EPA-HQ-OAR-2014-0827-1307 p.1]

COBRA’s on demand over boost enables the use of down speeding, longer gearing and a simplified transmission to provide the same fuel cost benefits. The increased airflow delivered by COBRA not only improves acceleration and response times it also provides the ability to maintain the correct Air-Fuel ratio at key points to avoid transient smoke limit. [EPA-HQ-OAR-2014-0827-1307 p.1-2]

Additional information is contained in the attachment: CPT COBRA_4pp_APR2014_4print.pdf [See docket number EPA-HQ-OAR-2014-0827-1307-A1]

SpeedStart/SpeedTorq motor-generator from Controlled Power Technologies [EPA-HQ-OAR-2014-0827-1310 p.1]

The SpeedStart/SpeedTorq e-motor/generator is capable for providing idle-reduction (stop-start) functionality, additional torque assist to the engine. It can be used to drive auxiliary devices such as air conditioning compressors, while also providing a means of energy recuperation. [EPA-HQ-OAR-2014-0827-1310 p.1]

The key CPT SR e-Motor, aka SpeedStart and SpeedTorq, advantages are: No rare earth permanent magnets - price volatility and special recycling requirements are not a factor Design simplicity enables commonality of components across variants; 95% of the CPT SR e-Motor content is common across 12V, 24V and 48V variants. Provides the OEM with an option for multi-variants based on a common core motor design (e.g. P0, P4 hybrid in automotive applications) High efficiency (>80%) over a broad speed range Low inductance design and independent phase control allows quick response time to change in torque request. 0 - 100% Torque is possible in 1 electrical cycle Low rotating inertia reduces mechanical load on engine Zero generation capability, the ability to generate no electricity when the rotor is turning is a key safety characteristic which is important for ASIL C/D applications (e.g. electrified rear axle or transmission applications) High thermal efficiency - delivers peak performance over extended events independent of engine bay temperatures Advanced flexible control system enables the following programmable features Belt pre-tensioning for comfort stop-start Faster change-of-mind Electric driveTorque profiling 4 quadrant control for hybrid driveline applications. [EPA-HQ-OAR-2014-0827-1310 p.1-2]

additional information is contained in the attachment: Speedstart_05.15 [See docket number EPA-HQ-OAR-2014-0827-1310-A1]

WASTE EXHAUST ENERGY RECOVER TECHNOLOGY (AKA 'TIGERS') FROM CONTROLLED POWER TECHNOLOGIES [EPA-HQ-OAR-2014-0827-1313 p.1]

TIGERS

Waste to Watts - Powering the Planet with TIGERS TIGERS (Turbo-generator Integrated Gas Energy RecoverySystem) is a liquid cooled switched reluctance generator coupled to an exhaust driven turbine. [EPA-HQ-OAR-2014-0827-1313 p.1]

It is capable of operating in exhaust temperatures up to 750C, at speeds up to 45,000rpm, delivering a peak power of 2kW-4kW. The TIGERS system includes an electronically controlled full flow external by-pass that ensures the desired proportion of exhaust gas is delivered to the turbo-generator as

Applications and Benefits [EPA-HQ-OAR-2014-0827-1313 p.2]

* Waste exhaust heat energy is converted into useful electrical power

* More efficient electrical power generation compared with a conventional alternator at medium to high engine load

* Compact machine (240mm x210mm x 175mm) delivering high power (0.5 - 2kW @ 12v)

* Can be packaged any wherein the exhaust system* Integrated power & control electronics

* Internally controlled bypass valve system

* Able to control pressure limit, voltage limit and current limit commands over CAN

* Utilizes a be spoke low pressure turbine to extract power from exhaust flow with a minimal impact on back pressure [EPA-HQ-OAR-2014-0827-1313 p.2]

additional information is contained in the attachment: CPT TIGERS_8 13_4print.pdf [See docket number EPA-HQ-OAR-2014-0827-1313-A1]

Response:

We appreciate the commenter’s willingness to share their model with the agencies. However, GEM relies on the engine fuel map to represent all of the engine technologies that are quantified by the engine dynamometer tests. We will not model individual components that are part of the engine.

Organization: Cummins, Inc.

* Cummins expects market demand to drive performance that meets or exceeds the proposed engine standards, and the technologies will be available

The SuperTruck programs have demonstrated the capability of new engine technologies to increase efficiency and reduce fuel consumption and CO2 emissions. The Cummins-Peterbilt program demonstrated almost a 20% CO2 reduction from a 2009 baseline engine. [EPA-HQ-OAR-2014-0827-1298-A1 p.13]

Potential technologies for CO2 reduction on engines are found in Table 1. HHD tractor engine technologies are evaluated over the RMCSET certification cycle while MHD vocational engine technologies are evaluated over the FTP certification cycle. By using an engine system-level evaluation for the technologies in Table 1, the total cycle improvement numbers account for any inherent dis-synergies. [EPA-HQ-OAR-2014-0827-1298-A1 p.13]

[Table 1 can be found on p.14 of docket number EPA-HQ-OAR-2014-0827-1298-A1]
As noted in Cummins’ comments to NHTSA\(^3\), key areas of improved engine efficiency for tractor applications are combustion, air handling, friction and parasitic reduction, and WHR technology. Higher compression ratios, injection pressures and engine structural capability such as higher peak cylinder pressures are also showing benefits in engine efficiency. Organic Rankine Cycle (ORC) WHR technology has the capability to provide 4 to 5% improvement in fuel consumption on tractor drive cycles. [EPA-HQ-OAR-2014-0827-1298-A1 p.13]

Many of the technologies that can reduce tractor engine CO2 can also reduce vocational engine CO2. Combustion and air handling improvements will exist in the same form as for tractors; however, CO2 improvements differ between the two markets due to the lower average cycle power of the vocational market. [EPA-HQ-OAR-2014-0827-1298-A1 p.13]

Cummins expects market demand to drive performance that meets or exceeds the proposed engine standards. Given that the time span of this rule covers approximately three typical engine development cycles, we expect that the engine technologies listed will be reliably and cost effectively introduced to production engines within the Phase 2 timeframe. In fact, the engine standard changes of 0.5 to 0.6% in 2027 are within the CO2 measurement variability and compliance margin, so it can be expected that this final step will not drive meaningful additional technology adoption. [EPA-HQ-OAR-2014-0827-1298-A1 p.14]

**WHR will be a viable technology to comply with the Phase 2 GHG/FE standards for tractor engines** [EPA-HQ-OAR-2014-0827-1298-A1 p.15]

The Agencies have identified WHR as a potential Phase 2 technology for tractor engines, and Cummins agrees with this assessment. However, we believe the Agencies underestimate the commercial viability of the technology and overstate the development challenges and timing in the Draft RIA. Cummins expects WHR systems to be commercially viable and available in production as early as 2020 and will exceed the Agencies’ estimates for market penetration over the period of the rule. [EPA-HQ-OAR-2014-0827-1298-A1 p.15]

The Agencies have estimated 3.6% SET weighted CO2 reduction with WHR in tractor engines (Preamble, Table II-6). This is generally in line with Cummins experience of 4 to 5% improvement in fuel consumption on tractor drive cycles, as demonstrated in our SuperTruck program. [EPA-HQ-OAR-2014-0827-1298-A1 p.15]

The Agencies have stated that Waste Heat Recovery technology is “on the flat portion of the learning curve” (Draft RIA 2.12.2.15), particularly relating to cost reduction potential. This is incorrect. [EPA-HQ-OAR-2014-0827-1298-A1 p.15]

The WHR estimate in the NHTSA report referenced in the Draft RIA is based on references\(^6,7,8,9\) that are five or more years old. Table 3 shows the development progression of WHR technology at Cummins. With each generation, improvements have addressed system cost, packaging (weight and size) and reliability. Figure 7 shows the Generation 3 system integrated in the Cummins-Peterbilt SuperTruck, which includes significantly enhanced tractor aerodynamics with WHR compared to today’s truck designs. As we have continued WHR development, we have focused on a smaller system footprint, improved integration with the engine and vehicle and low-GWP working fluid, resulting in the much more compact and integrated Generation 4 system shown in Figure 8. This latest design will begin evaluation in extended customer testing by the end of 2015, and results of that experience will inform further technology development and product engineering leading to expected commercial product availability in the 2020 timeframe. Furthermore, given that the time period of the proposed rule...
encompasses multiple typical product development cycles, the opportunities for further development for reduced cost and improved performance and reliability during this time period are significant. [EPA-HQ-OAR-2014-0827-1298-A1 p.15-16]

[Table 3 can be found on p.16 of docket number EPA-HQ-OAR-2014-0827-1298-A1 and figure 7 and 8 can be found on p.17 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

The Agencies should also consider how duty cycles are evolving for regional haul as well as long haul applications. Increased focus on asset utilization by regional haul fleets is significantly increasing the vehicle miles traveled (VMT) of individual vehicles in those applications, which will extend the economic viability and market potential of WHR technology beyond typical long haul applications. [EPA-HQ-OAR-2014-0827-1298-A1 p.16]

Other manufacturers are investigating WHR systems as well. In 2015, three SuperTruck programs\textsuperscript{13,14,15} had WHR systems running on trucks. In 2012, Cummins Turbo Technologies\textsuperscript{16} announced the development of WHR turbine expanders (Figure 9) for the HD automotive market “for specific applications on behalf of a number of customers.” [EPA-HQ-OAR-2014-0827-1298-A1 p.18]

[Figure 9 can be found on p.18 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

WHR has significant potential for fuel saving and CO2 reduction to the benefit of truck operators and the environment. By not recognizing the evolution of design integration and component simplification at the engine and vehicle level subsequent to the cited studies, the Agencies have overestimated the cost of WHR technology in the timeframe of the Phase 2 rule compared to other available technologies and underestimated its market potential. We encourage the Agencies to apply a learning curve calculation that is more consistent with the continuing evolution of WHR system design and integration as they assess WHR relative to other technologies. [EPA-HQ-OAR-2014-0827-1298-A1 p.18]

(b) In setting the engine standards, the Agencies applied a dis-synergy factor (EPA-HQ-OAR-2014-0827-0712 Docket Memo) in their assessment of various technologies. However, the dis-synergy factor’s derivation is not described in any detail by the Agencies. Considering the importance of this factor to the engine standards, the Agencies should provide more reference data for the origin of the values used. [EPA-HQ-OAR-2014-0827-1298-A1 p.36]

Cummins uses an engine system-level modeling approach to evaluate the benefits of CO2-reduction technologies, such as those tabulated in Table 1. This inherently takes into account any synergies or dis-synergies across the individual technologies. Cummins urges the Agencies to take a similar system-level approach when evaluating engine technologies and setting engine standards to make standard-setting more explicit and to avoid the need for a separate dis-synergy discount factor. [EPA-HQ-OAR-2014-0827-1298-A1 p.36]

With respect to the proposed Phase 2 engine standards, Cummins is confident we have the engine technologies necessary to meet or exceed the required GHG/FE improvements. In fact, we expect our customers will demand even more improvement than the standards, and we are prepared to meet their demands with cost-effective and reliable products. Specifically with regard to WHR, based on recent progress we believe it can be available as a product as early as 2020. [EPA-HQ-OAR-2014-0827-1298-A1 p.42]
Response:

The final standards are largely consistent with this persuasive comment. In particular, the effectiveness, projected penetration rate, and estimated cost of WHR technology are informed by, and consistent with this comment. In addition, for tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the tractor engine standards' projected stringency over the baseline increased from 4.2% to 5.1% in 2027. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase. Largely based on the CBI information the commenter provided together with other sources, we made changes on the cost related to WHR as indicated by Chapter 2.11.2.15 of the RIA. We agree with Cummins that an engine system-level modeling approach would be the best approach to evaluate the benefits of CO₂-reduction technologies, which takes dis-synergy and synergy among all available energy into consideration. However, the agencies have added considerable detail to explain why we cannot take this approach while showing the reasonableness of our single dis-synergy factor approach. In addition to our response in RTC Section 3.4.3 below, see Chapter 2.7.5 of the RIA.

Organization: Daimler Trucks North America LLC

Thermodynamic Improvements - DTNA’s heavy duty diesel engine products have maintained a long standing status of industry leading fuel efficiency stemming from its expertise in developing engine designs utilizing leading edge combustion and controls designs. For example, today’s engine utilize
unique second generation advanced Amplified Pressure Common Rail fuel injection systems and proprietary asymmetric turbocharger / EGR control systems. Higher performing combustion systems than those currently in production have been explored in research programs supported by the Department of Energy. These programs aid in Daimler's understanding of the limitations and tradeoffs of stretch technologies between improved efficiency and both design constraints of today's materials and criteria pollutant emissions. [redacted] [EPA-HQ-OAR-2014-0827-1164-A1 p.21]

Alternative 4 is Too Stringent and Too Fast—Although the agencies premise their engine stringencies, including Alternative 4, on the idea of individual technologies being incorporated into engines, which is not the case. Rather, even individual changes like changing the piston bowl shape or larger changes like combustion improvements, friction reduction, or aftertreatment improvements require complete engine redesign. Unlike vehicle-side standards which may change simply because of increased penetration rates of technologies, engines require much more of a binary change—we cannot just adopt a few more new aftertreatment technologies or changes to meet the next set of standards. Rather, not until the whole engine family can change over can we radically change any one engine over. Further, any change can affect criteria pollutant emissions and must continue to deliver near zero NOx and PM emissions, plus meet the new N2O standards. Additionally, the significant time requirements to develop OBD diagnostics must be considered. On the development timeline, validation of stringent OBD diagnostics can only begin after final emissions calibrations are finalized. The consequence is that whereas prior to OBD implementation calibration changes could be refined and finalized near to production dates, now, with OBD time additional time is required after calibrations are finalized and final emissions control calibrations may have to be revisited depending on results of OBD testing. And the systems must often be tested for DFs. So, in short, we have individual changes requiring major engine redesign, drawing in the need for many other certifications and tests. Plus, we have the need to premise stringency steps on technologies that can be adopted across an entire engine family, not merely on a portion, so these constraints limit the pace at which engine standards can be tightened. [EPA-HQ-OAR-2014-0827-1164-A1 p.23]

g. Waste Heat Recovery (WHR)

WHR Is Not Yet Feasible For Production - DTNA in its Super Truck program has expended considerable development effort on its waste heat recovery technology and has identified a number of areas in need of significant additional development effort or invention to reach a production viable design. These developments needs have been explained in its updates to DOE program management and to the regulators. Additional design and development effort continues to be needed relative to reducing cost, improving packaging / space claim, reducing weight, developing controls, selecting an appropriate working fluid, developing working fluid seals of sufficient reliability and durability, implementing OBD diagnostics that can be expected to be required, and achieving the necessary reliability and durability goals of its customers. The available energy and therefor the utility of WHR systems may diminish in the future. Fuel efficiency improvements from WHR are a function of available heat for recovery. Available heat for recovery is in turn a function of the engine duty cycle in its actual application and the engine’s efficiency since combustion heat that is not converted to work is rejected in the form of heat to the cooling or exhaust systems. As engines are tuned for increased fuel efficiency, less heat is lost to exhaust gases, and the temperature of exhaust gas decreases. Consequently, both the heat flux to the WRH system decreases and the recoverability decreases due to the reduced exhaust gas temperature. Additionally, as aftertreatment performance is improves, EGR rates may be able to be reduced, once again reducing available heat for the WRH system. It is interesting to note that EPA proposes that benefit is available from both clutched turbocharging and from WHR. However, both technologies seek to recoup energy from the same exhaust heat source. Since these technologies compete for recovery of the same wasted heat they cannot be considered to be additive towards fuel efficiency improvement. Also countering the
efficacy of WRH technology is and will continue to be the trend towards improved vehicle efficiency. As tractor and trailer aerodynamics improve, rolling resistance of tires decreases and as drivelines become more efficient, the power demanded of the engines will also decrease. As power demand decreases so too will the available recoverable waste energy. For these reasons and others, DTNA estimates a potential of [redacted] fuel efficiency improvement in tractor applications from WHR technology. Packaging and heat rejection impacts on vehicle efficiency must be considered in assessment of WHR fuel efficiency gains from a vehicle perspective. Tractor cab under hood design must accommodate the space claim needed by additional heat exchangers integral to the WHR system and at the same time minimize the compromise to aerodynamic efficiency. EPA aggressively projects penetration of 1/5/15% in MY2021/2024/2027. DTNA at this time considers the development maturity of the technology to be inadequate to base market penetration projections with any level of confidence, and considers even a 5% penetration in MY2027 to be overly aggressive. [EPA-HQ-OAR-2014-0827-1164-A1 p.94-95]

· WHR’s Cost And Other Concerns Make the Technology Not Yet Feasible – In section 2.7.4 of the RIA, the agencies state several concerns about WHR, including high technology cost, a need for extensive field testing to ensure reliability before the product is ready for market, and a need to gain commercial acceptance for the technology. We agree that these are concerns with the technology that suggest it should not be the basis of stringency calculations. 2.7.4 of the RIA [EPA-HQ-OAR-2014-0827-1164-A1 p.95]

· WHR Creates Large Cooling Load That Must Be Overcome - The agencies discussed the ability of the WHR system decreasing the cooling load on the vehicle (80 FR 40197). We disagree with the agencies position on this matter. Through testing and running a WHR system in Super Truck we have concluded that there would be a net increase in cooling burden due to the WHR system of about 30 to 40% compared to a vehicle without WHR. This is essentially because the primary waste heat source to be recovered, with reasonable heat recovery efficiency, is that of exhaust and EGR. Exhaust energy simply escapes the tail pipe on today’s truck. However, with the WHR system a small portion of that exhaust energy is recovered as useful work, but at the same time a larger portion of that energy has to be rejected under hood at low temperatures through additional radiators and condensers. (See Figure 1). Our vehicles cooling packages are optimized to run with the fan off as it draws a large amount of energy. With the addition of the WHR the fan on time will increase in several drive cycle scenarios and compromise some of the recovered energy from WHR. The agencies on 80 FR 40197 also refer to recovering energy available in the coolant. This may be possible in principle, but extremely challenging and possibly impractical in reality. The low temperatures of the coolant make the heat recovery efficiency extremely low and will require impractically large heat exchangers. In summary, approaches to recover waste heat other than exhaust and EGR may prove to be very complex, impractical with low performance, and not cost effective for automotive and truck applications. The only reasonable waste heat recovery from exhaust and EGR will increase the vehicle cooling burden by 30 to 40% as describe above, has performance potential in the range of [redacted] FE improvement, and requires further R&D in several areas including reliability, durability, sealing, working fluid choice, cost effectiveness etc. [EPA-HQ-OAR-2014-0827-1164-A1 p.95]

Response:

Regarding the comments on WHR, we understand DTNA’s concerns. We appreciate DTNA’s detailed physics explanations on WHR through the law of thermodynamics and the impacts on packaging, cooling and potential high cost. We also understand that some WHR systems can have a negative impact on the cooling. On the other hand, we received data and CBI information from one engine manufacturer as well as public comments (EPA-HQ-OAR-2014-0827-1298) that shows that their WHR system could be put into production in 2021 timeframe. In addition, most of publicly available data is mainly from the DOE
SuperTruck program and indicates that WHR efficiency should be in the range of 4 to 5%, which is much higher than what we used, 3.6%. Thus, our 3.6% WHR effectiveness takes into consideration the negative impact on packaging and cooling. With the technology effectiveness of 3.6% used in the engine standards, this only translates to a total vehicle reduction of about 0.9% in 2027. Considering that the technology path proposed by the agencies is only one of many paths that can achieve the standards, this 0.9% reduction can be done by many other means. In addition to our response in RTC Section 3.4.1 below, Chapter 2.3 and 2.7 of the RIA details the justification.

**Organization:** Daimler Trucks North America, Navistar Inc., Paccar Inc., and the Volvo Group

**Engine Test Process Considerations**

The Charlton/Walsh Paper proposes two conflicting approaches. First that down-speeding (and down-sizing) should be considered as engine technologies (recommendation 4). Second that alignment between criteria emissions and GHG emissions must be maintained (recommendation 5). The former approach requires that engine test cycles be adjusted based on the installed driveline and power demand of the vehicle. The second approach requires fixed engine cycles not connected to the vehicle application, barring a complete new approach to criteria emissions testing. In fact, vehicle OEMs fully agree that down-speeding should be an important part of the GHG regulation, and both down-speeding and down-sizing are incorporated into the complete vehicle assessment, the only feasible way to do so. We note that down-speeding, in addition to extensive transmission design and control development, requires integrated engine-transmission controls, along with engine design and optimization for low-speed torque, efficiency, emissions, and vibration. The effectiveness of down-speeding is also linked to reductions in vehicle road load, facilitated by reduced aerodynamic drag, efficient tires, and other features such as predictive cruise control. [EPA-HQ-OAR-2014-0827-1894-A1 p.4]

The conflicting arguments in the subject paper demonstrate that overly stringent separate engine standards are inappropriate, unnecessary, and counterproductive. As we have argued, it is fundamental that the engine influence on the vehicle (size, weight, cooling demand, and cost) and the vehicle influence on the engine (power demand, gearing, and controls) must be considered. Furthermore, from a purely economic perspective, OEMs should be able to develop and choose the efficiency technologies that best fit with their capabilities and expertise to meet regulatory GHG objectives and customer requirements. This will increase competition and innovative approaches while providing optimized products with greater market acceptance. EPA should support this and acknowledge that the engine specific regulation is meant to ensure a level of improvement to be achieved with minimal potential tradeoffs on other vehicle efficiency features, and to ensure some continued link to criteria emissions testing. [EPA-HQ-OAR-2014-0827-1894-A1 p.4-5]

**Demonstration vs. Commercial Feasibility**

Most of the technologies discussed in the subject paper have only been demonstrated (or partially demonstrated) in the lab or in one-off vehicles. Such demonstrations over the years have frequently met major obstacles that prevent commercialization. These include operation under all necessary duty cycles and ambient conditions, full emissions control, real time dynamic control capability, durability and reliability limitations, and costs (including development, material, labor, amortization of development and tooling, operation, maintenance, and down time). In light duty, the most efficient production passenger cars have efficiencies from 58-88 mpg for PHEVs. The hybrid MY 2000 Honda Insight was rated at 53 mpg, Toyota Prius at 50 mpg, and the 1986 Chevrolet Sprint (1 liter, 3 cylinder, 5 speed manual) at 48 mpg. Yet the 2025 light duty standard was set at an average level of 54.5 mpg, clearly in consideration of
commercial feasibility and customer acceptance, not simply technical feasibility. [EPA-HQ-OAR-2014-0827-1894-A1 p.5]

**Funding and Resource Allocation**

The Charlton/Walsh paper states “if this rule moves forward in its current form it will stall investment in the advanced engine technologies already demonstrated in the SuperTruck Program as providing a 15-20% reduction in GHG emissions and fuel consumption. R&D funds are a scarce resource that will be withdrawn or reallocated to other priorities.” And later, “Given the 12 year lead time to product launch in 2027 and the relaxed engine standards proposed; if this rule moves forward in its current form it will make it impossible for truck and engine OEMs and tier 1 suppliers to continue to make investments in advanced engine technologies at the levels we have seen during the past 5-10 years.” The inherent assumption here is that engine efficiency development will occur only if forced by specific engine regulation. This flies in the face of many years of intense heavy duty engine efficiency development that had occurred despite the lack of fuel efficiency regulations. Additionally, and despite fuel efficiency being a lesser priority for light duty customers, the experience in that market has been that engine efficiency has played an important role in the vehicle efficiency portfolio, even without any engine efficiency regulations. OEMs and suppliers will allocate efficiency resources to the most productive and effective vehicle efficiency technologies (including the engine) in response to vehicle efficiency regulation and competitive pressures. Engine efficiencies with adequate payback will be developed and deployed as soon as possible, considering reliability, durability, and all the other aforementioned requirements. [EPA-HQ-OAR-2014-0827-1894-A1 p.5-6]

If OEMs and suppliers choose not to invest in engine efficiency, it can only be because such investment is judged as inadequate to meet customer and competitive expectations, or inferior to other efficiency investments to meet vehicle efficiency regulated targets. If technologies were proven and cost-effective, as the subject paper declares, these investment decisions would easily be supported. If not, then society is well ahead because better alternative investments were chosen to achieve target objectives. [EPA-HQ-OAR-2014-0827-1894-A1 p.6]

**Dis-synergies**

Slide 8 of the presentation related to the subject paper provides a breakdown of the supposed technology mix to support a recommended standard of 390 g CO2/hp-hr and claims this accounts for dis-synergies. Though recognizing a few minor dis-synergies, the paper fails to recognize the broad range of dis-synergies that exist within the engine alone, and within the vehicle-engine interaction. The “minor offsetting effect” from Waste Heat Recovery (WHR) is noted, when, in fact, the offset from aerodynamic impact of the cooling system (if designed for larger engines) can consume around half the efficiency benefit of the WHR system. Furthermore, since OEMs cannot afford multiple cab designs, the aerodynamic penalty is carried by all cabs, whether the installed engine is the larger available engine or not, and whether that engine is using WHR or not. This impact is not necessarily seen when packaging WHR into existing cabs, but becomes clear when comparing future optimized aero cabs with and without provision for WHR. Volvo has done this and finds about a 2% loss of fuel efficiency (4% drag increase) associated with cabs designed to accommodate a larger engine with WHR both due to the frontal area required and the impact on air flow through the cooling package and engine compartment. The negative aerodynamic impact is greatly increased for day cabs if packaging requires extension of the wheel base resulting in an increased trailer gap (already an issue due to packaging emissions equipment and for natural gas fuels systems). In the end, this means that for vehicles produced using a cab/hood designed to be WHR capable, the CO2 reductions achieved by those actually equipped with WHR are likely to be
negated by the population sold where WHR is not inappropriate for the application, yet the vehicle is bearing the efficiency penalty of being WHR capable. [EPA-HQ-OAR-2014-0827-1894-A1 p.6-7]

There are many other significant dis-synergies:

• Down-speeding or down-sizing greatly reduces friction and pumping losses, and therefore the potential benefits to be gained from additional friction and pumping reduction technologies. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Down-speeding below what is already applied in certain down-speeded production drivetrains provides minimal additional efficiency and compromises available exhaust backpressure required to drive EGR needed to control NOx. Correcting this will drive up pumping losses. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Continuous improvement in combustion efficiency, vehicle aerodynamic drag, driveline efficiency, tire rolling resistance, and more will diminish available exhaust energy for WHR. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Use of turbo-compounding reduces exhaust temperature for Rankine waste heat recovery and for effective NOx catalysis. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Improvements in combustion efficiency via increased cylinder pressure will increase bearing and piston ring loads which results in increased friction losses which counteract benefits. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Conventional combustion efficiency improvements drive up flame temperature and NOx formation. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Higher injection pressure for combustion improvement significantly increases pumping power losses to the injection system. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Low temperature combustion (homogenous, premixed, partially premixed) requires massive EGR to control ignition timing and to avoid excessive rates of heat release such that the combustion efficiency benefits are largely consumed by the pumping losses. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• Down-speeding and down-sizing cannot be measured on fixed engine test cycles, so must be considered in the vehicle simulation, not a separate engine test. In fact, down-sizing has a small negative impact on efficiency when measured on a cycle that is proportional to the engine’s power output (rather than vehicle power demand) due to well-established physics that heat transfer losses are proportionally reduced in larger engines. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

• It is incorrect to compare best point BTE (brake thermal efficiency) to cycle efficiency since the effectiveness of many technologies is significantly lower on the actual operating cycle than at the best operating point. [EPA-HQ-OAR-2014-0827-1894-A1 p.7]

SwRI Study and Proposed Engine Efficiency Target

Due to these dis-synergies, single technology engine efficiency gains cannot be added together, but must be considered as a system including the vehicle impacts, control of criteria emissions, and all other
requirements. The SwRI study referenced in the subject paper took this approach, although the authors could not fully account for the impacts of many requirements. Relative to this, the Charlton/Walsh paper notes first: “The study included a literature review to identify potential fuel saving technologies and to assess the state of the art. A large number of engine and vehicle technologies were selected for analysis, and their fuel saving performance was simulated to assess the fuel savings potential of each technology over a wide range of duty cycles.” But later the paper says: “The study is simply exploring the parametric design space, and makes little attempt to assess or extrapolate the state of the art between 2015 and 2027.” [EPA-HQ-OAR-2014-0827-1894-A1 p.7-8]

In fact, the charter given to SwRI includes “…assessing the effectiveness and cost of potential fuel efficiency/GHG improving technologies for the Phase 2 timeframe (post MY 2018 for vehicles and engines). When considering potential fuel efficiency/GHG-reducing technologies, NHTSA directed SwRI to include a range of factors: design, functionality, duty cycle, use (type of work done by the vehicle), and factors that can influence the effectiveness, feasibility, and cost. Vehicle safety, utility, and performance are also to be considered.”4 [EPA-HQ-OAR-2014-0827-1894-A1 p.8]

SwRI fully considered both the available literature on engine efficiency research as well as their own extensive internal research programs in developing their recommendations. However, these were tempered by the requirements to consider effectiveness, feasibility, cost, safety, utility, and performance, all areas that the Charlton/Walsh paper chooses to ignore. [EPA-HQ-OAR-2014-0827-1894-A1 p.8]

The SwRI study concludes that a reasonable goal of 44.6-45.9 cycle brake thermal efficiency (BTE) is achievable with known technology, but includes down-speeding to 1051 rpm at cruise speed. Although the reweighted RMC does provide some impact from down-speeding, it is nowhere near this aggressive. Hence the regulated limit for 2027 of 44.6 BTE (with a reweighted RMC that does not fully account for down-speeding to the extent considered by SwRI) is entirely justified. [EPA-HQ-OAR-2014-0827-1894-A1 p.8]

The revised version of the SwRI report5 notes that an error was made in the first report relative to the baseline version of the engine. Quoting from the revised report: [EPA-HQ-OAR-2014-0827-1894-A1 p.8]

“The results presented in this section have been revised since the original draft version of the report. Three errors were discovered during the independent peer review and public release of the draft report that have been corrected in this final version. The first error was the use of the wrong fuel map to represent the model year 2019 DD15 engine baseline. The fuel map inadvertently used was a model year 2011 baseline turbocompound engine with a 1% benefit from combustion duration, but otherwise unchanged. The analysis for this section should have used a fuel map representative of the more efficient 2013 DD15 engine as the baseline to allow exploration of improvements beyond the Phase 1 standards.” [EPA-HQ-OAR-2014-0827-1894-A1 p.8]

The revised report further notes:

“The revised results included in this version of the report show the following effects: [EPA-HQ-OAR-2014-0827-1894-A1 p.9]

- There is now a larger difference between the 2011 and 2019 DD15 baseline engine results, particularly on the CARB and WHVC cycles [EPA-HQ-OAR-2014-0827-1894-A1 p.9]

- The fuel savings benefits of all the DD15 technology combination packages are reduced by up to 3.3% depending on the technology packages and driving cycles compared to the original draft, primarily
because the post-Phase 1 2019 DD15 baseline now has lower fuel consumption [EPA-HQ-OAR-2014-0827-1894-A1 p.9]

• The relative benefit of waste heat recovery is essentially unchanged.” [EPA-HQ-OAR-2014-0827-1894-A1 p.9]

Although this revision does not affect the SwRI recommended engine BSFC capability, it does significantly reduce the relative benefit of further engine improvements beyond the 2019 baseline engine. This further supports our contention that efficiency expectations should be focused on the integrated vehicle, not the engine alone. [EPA-HQ-OAR-2014-0827-1894-A1 p.9]

History of Long-range, Technology Forcing Regulation

The Charlton/Walsh Paper points to the promulgation of the 2010 emissions standards in 2001: “This very successful program is an outstanding example of technology forcing standards combined with adequate lead time, and the commitment of industry. “The reality is that the industry was so concerned about the weakness of the technology feasibility demonstration EPA performed to support this rule that Cummins, the largest supplier of diesel engines to the US heavy-duty market at the time of that rulemaking, challenged that 2007/2010 rule in court, arguing according to court documents that “…no NOx control system will be capable of meeting the EPA's 2007 standards.” And later, Cummins argues “…the EPA acted arbitrarily and capriciously in concluding that engine manufacturers will be able to develop emissions-control systems satisfying the new rule.” We would argue that today’s level of development of waste heat recovery and stop-start technologies is no further advanced for the typical manufacturer of heavy-duty engines to the US highway vehicle market than EPA’s proposed Lean NOx Trap technology was at the time that it served as the basis of the 2007/2010 rule. [EPA-HQ-OAR-2014-0827-1894-A1 p.9]

In the end, this “very successful program” involved the deployment of completely different NOx control technology than the Final Rule envisioned (SCR rather than LNT). In the end, when coupled with the 2007 product cost increases, the full scope of the EPA “clean diesel” program drove up class 8 vehicle purchase and maintenance cost by as much as 40%, more than doubled engine system cost, increased lifetime operating cost (including downtime) around $20K, and resulted in customers purchasing a high volume of trucks prior to 2007 to avoid the new technologies and cost increases associated with the 2007 engines. This no-buy in 2007 resulted in large-scale layoffs of manufacturing workers. This is an example that should temper any viewpoint that we can accurately forecast long-range technology, costs, or market reaction. [EPA-HQ-OAR-2014-0827-1894-A1 p.9-10]

In Table 1, we can see the impact of the 2007 engine launch that introduced diesel particulate filters to meet a 90% reduction in the PM standard. Among the consequences was an almost 50% reduction in the heavy-duty OEM labor force, with corresponding impacts on suppliers, and a cascading effect on the overall economy. [EPA-HQ-OAR-2014-0827-1894-A1 p.10]

[Table 1 can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1894-A1]

Rankine Waste Heat Recovery

The Charlton/Walsh Paper states “WHR technology is an important component of the technology package that can deliver a 15% or greater reduction of GHG emissions and fuel consumption by 2027, as recognized by NAS 21CTP Report #3, September 11, 2015 [41].” Aside from the fact that the NAS report does not say WHR can deliver 15%, most reports on WHR systems that exploit all available heat sources
show between 3 and 6% efficiency gain on optimal vehicle duty cycles, not considering the negative impacts to vehicle weight, cooling and aerodynamics already discussed in the section above on dis-synergies. WHR efficiencies are highly dependent on operating conditions -- load, speed, terrain, and ambient temperature. [EPA-HQ-OAR-2014-0827-1894-A1 p.10-11]

The paper states: “…the only valid meaning of ‘adoption rate’ is in determining which real world applications should logically be included and excluded on the basis of effectiveness. In the case of WHR there is broad agreement that line-haul tractor trailer applications and heavy-haul applications (at least) will benefit from adoption of WHR. These applications form a high percentage of the Class 7-8 fleet (greater than 65%).” In fact EPA has correctly recognized that WHR effectiveness and therefore adoption rate depends on a large number of factors, including the installed engine size (impacting BMEP, exhaust temperature, and cooling demand), vehicle load factors, terrain (less effective in rolling hills), ambient temperature (avoid excessive radiator temperatures), and customer acceptance (if forced into the market, customers may delay purchases). [EPA-HQ-OAR-2014-0827-1894-A1 p.11]

The SwRI study notes that:

“Some of key technologies, such as waste heat recovery, would not be effective for a day cab engine, and therefore the overall benefits over the agencies’ certification categories would be further reduced.” [EPA-HQ-OAR-2014-0827-1894-A1 p.11]

“Because bottoming cycles have very slow transient response, there is a large drop-off in fuel savings between a steady-state test cell evaluation and real, on-road performance under transient conditions. The model does not include the effects of transient response, so the bottoming cycles were not run on the more transient drive cycles (CARB and WHVC). Real world performance of the bottoming cycles will be hurt by transient response issues, even at steady speed operation. Steady speed rarely involves steady load.” [EPA-HQ-OAR-2014-0827-1894-A1 p.11]

Furthermore, all indications are that long-haul trucking will be reduced as a fraction of total US road freight, as more marine shipments are delivered to ports on the Gulf of Mexico and Atlantic coast and more long-haul freight is delivered by rail. The growing regional road freight hauls are more constrained by traffic and rolling terrain, which is less conducive to effective deployment of WHR. Packaging of WHR systems in day cabs may also introduce further aerodynamic losses if extended wheelbases result in larger trailer gaps. These factors must be considered in establishing penetration expectations. [EPA-HQ-OAR-2014-0827-1894-A1 p.11]

Without firm designs, cost estimates for WHR systems are likely to be significantly under-estimated, as is typical for any early design estimate. Costs almost always inflate as the complexity of real world requirements drive up need for more robust designs, sensors, controls, control hardware, and complete vehicle integration. Development costs will be huge and must be amortized with limited volumes. Furthermore, the industry experience with such complex systems is that maintenance, repair, and downtime cost can be much greater than the initial purchase cost. [EPA-HQ-OAR-2014-0827-1894-A1 p.11]

**Combustion Efficiencies**

The subject paper quotes the RIA: “Alternative combustion processes such as homogeneous charge compression ignition (HCCI), premixed charge compression ignition (PCCI), low-temperature combustion (LTI), and reactivity controlled compression ignition (RCCI) technologies were not included in the feasibility analysis for Phase 2.” It then goes on to criticize: “Given the significant research efforts on advanced combustion (Appendix A, Figure 17) and the progress being demonstrated [27, 28, 31], it is
to be expected that some level of improvement in combustion technology will bleed through into product development programs over the next 12 years, providing reductions of GHG emissions and fuel consumption.” [EPA-HQ-OAR-2014-0827-1894-A1 p.11-12]

The reality is that, despite many years of heavy research within industry and academia, the promise of low temperature combustion (including HCCI, PCCI, LTC, and RCCI) has not materialized. The fundamental problem with these technologies is that ignition timing and rate of combustion are no longer managed by fuel injection timing and rate. Instead, combustion control must be managed by control of the intake charge mixture and temperature, typically by managing EGR rate, carefully timed multiple fuel injections, and/or mixtures of various fuels, all of which must react to rapid changes in load, varying ambient conditions, and varying fuel properties. There is no assurance that this will ever be effectively managed outside of controlled lab conditions, much less within some assumed time frame. Furthermore, as previously mentioned, the required high rate of EGR increases pumping losses, negating much of the claimed benefit, barring some new breakthrough in turbocharger efficiency. [EPA-HQ-OAR-2014-0827-1894-A1 p.12]

**SuperTruck and the National Academy Sciences Report on 21st Century Truck Program**

In comparing what SuperTruck has accomplished, it is necessary to separate what is accomplished by engine, tractor, and trailer technology from simply carefully controlling the vehicle’s operation. In fact, there are reports of production trucks in commercial operation today that achieve an average between 9 and 11 mpg with loads above 60,000 lbs. [EPA-HQ-OAR-2014-0827-1894-A1 p.12]

Furthermore, SuperTruck had no requirement for commercial feasibility or full regulatory compliance such as deterioration or OBD. Cost, maintenance, reliability, and durability were not considered, though they are key factors for market readiness and customer acceptance. SuperTruck vehicles were not developed to be driven in the same manner as a production vehicle and, indeed, these prototype designs are not representative of production-level components capable of full service life. SuperTruck sets the bar for future R&D toward potential commercialization of some technologies, but certainly does not demonstrate commercial feasibility to meet customer product longevity expectations. SuperTruck technologies were focused on specific long-haul duty cycles that showcased the best possible efficiency gains. Furthermore, the 50% BTE target was required only at a single operating point, not over the engine’s typical operating range or certification test cycles. In reality, the truck market has widely differing application requirements. SuperTruck should be viewed as creating a menu of potential technologies, not a formula for the majority of trucking applications. [EPA-HQ-OAR-2014-0827-1894-A1 p.12-13]

Figure 1 shows a typical tractor engine map. This is a representative 2018MY tractor map available in the EPA GEM simulation model that is used to set the baseline for the GHG Phase 2 regulations. The modes for the RMC are overlaid and show the weighting as proposed in the NPRM. From this figure it is clear that the authors have extrapolated the achievements of SuperTruck in their recommendation of 50% BTE in the RMC cycle. At the A-speed, which is the highest weighted speed, the BTE of a typical engine that meets 2017MY GHG will range from 39% at the lower torque to a maximum of 46% at the 75% load point. In order for such an engine to meet a composite number of 50% with the assumption of a flat map the part load points would need to improve over 11% efficiency points and this is without the appropriate engineering margins. Furthermore, the assumption of a flat map is counter to the physics and the optimization of the systems that support the function of the engine as is demonstrated by what EPA considers state-of-the-art today. Within the space of the RMC cycle, excluding the idle point, BTE ranges from 34% to the maximum already stated of 46%. Hence, in the event that a manufacturer had to design for the 50% BTE, the engine would have to significantly exceed the achievements of the SuperTruck.
program by having the cruise point be well above 55% BTE in order to achieve the composite number given the typical shape of the map. [EPA-HQ-OAR-2014-0827-1894-A1 p.13]

[Figure 1 can be found on p.13 of docket number EPA-HQ-OAR-2014-0827-1894-A1]

Stringency

The Charlton/Walsh paper recommends engine stringency stretching to 50.4% brake thermal efficiency (BTE) over the test cycle by 2027. As already discussed, the regulated GHG emissions and efficiency targets are based on the engine cycle average, not at a single operating point at or near the best BTE. Since the cycle average includes operation at light load and higher speeds, the best point BTE would likely need to be about 54-55% to achieve 50.4% cycle average BTE. Such a level has never been demonstrated by a multi-cylinder heavy-duty on-highway diesel engine, even in a controlled lab setting. [EPA-HQ-OAR-2014-0827-1894-A1 p.14]

According to the paper:

“To achieve these technology forcing standards it will be necessary for the following technologies to be developed:“ [EPA-HQ-OAR-2014-0827-1894-A1 p.14]

• Waste Heat Recovery / Organic Rankine Cycle

Comment: This technology is already included at appropriate penetration in the NPRM targets. Negative impacts on aero design and application limits must be considered. [EPA-HQ-OAR-2014-0827-1894-A1 p.14]

• Advanced Combustion

Comment: Presumably this refers to Low Temperature Combustion. See previous comments on this technology. [EPA-HQ-OAR-2014-0827-1894-A1 p.15]

• Reduced Frictional Losses

Comment: This will be part of the package to achieve standards. Note that down-speeding and down-sizing reduce effectiveness. Increased cylinder pressure and injection pressure increases frictional losses. [EPA-HQ-OAR-2014-0827-1894-A1 p.15]

• Reduced Accessory Losses

Comment: This is not part of the engine test cycle and should be considered at vehicle level. [EPA-HQ-OAR-2014-0827-1894-A1 p.15]

• Reduced Open Cycle Losses

Comment: There is no explanation of what this is. It seems to be another name for combustion improvement and reduced pumping. [EPA-HQ-OAR-2014-0827-1894-A1 p.15]

• Engine Design for Down-speeding
Comment: Down-speeding impact is already included within the vehicle GHG standard and cannot be measured on fixed engine cycles. Down-speeding efficiency impact, as shown on the plot, is approximately 2% when lowering cruise RPM from 1400 to 1100. Further down-speeding provide little additional efficiency based on known engine technology, but does drive up NOx due to operation below levels at which EGR can be pumped. [EPA-HQ-OAR-2014-0827-1894-A1 p.15]

[Figure 2 can be found on p.15 of docket number EPA-HQ-OAR-2014-0827-1894-A1]

Figure 3 shows the substantial increase in engine out NOx as engine speed is lowered and torque is increased. To operate at speeds below 1000 rpm requires significantly increased SCR efficiency and urea consumption that more than offsets any added fuel savings. [EPA-HQ-OAR-2014-0827-1894-A1 p.16]

[Figure 3 can be found on p.16 of docket number EPA-HQ-OAR-2014-0827-1894-A1]

Relative to down-speeding the subject paper states: “While the agencies have acknowledged that engine downsampling is a key technology trend and have modified the engine test cycle to reflect this trend, they have failed to include the CO2 and fuel consumption savings in the stringency of the engine limit standards. In fact quite the opposite – by changing the test cycle the agencies have relaxed the stringency by 1-2% (section 3.2.1). By not including downsampling in setting limit standards for engines, they have in effect further relaxed the standards – by as much as 2-4% per SWRI report #1 [42]. The combined relaxation is 3%-6%, which exceeds the overall reduction proposed in the NPRM [14]. Even by the agencies estimate of 1.8% reduction due to downsampling, the combined relaxation is 2.8%-3.8%.” [EPA-HQ-OAR-2014-0827-1894-A1 p.16]

It is illogical to say that the engine standard has somehow been relaxed because down-speeding is not included in the engine standard limits, especially since the engine test cycle cannot measure the impact of down-speeding. Down-speeding is correctly included in setting the vehicle standards, where it is measured within the Greenhouse Gas Emissions Model (GEM). [EPA-HQ-OAR-2014-0827-1894-A1 p.16-17]

The subject paper cites a master’s thesis from Chalmers University to support claims that down-speeding can provide up to 3.38% improvement in efficiency. There are serious problems with the methodology in this paper. [EPA-HQ-OAR-2014-0827-1894-A1 p.17]

First, this work is done only via simulation, and much of the efficiency improvement results from reduced in-cylinder heat transfer that supposedly results from reduced gas velocities at lower engine speed. What this fails to account for is the increased time for heat transfer or to effectively account for impacts of swirl. In-cylinder heat transfer is notoriously difficult to model, and improved models (proprietary within Volvo Group) since the Chalmers paper do not support the claim of reduced heat transfer. An engine efficiency expert within Volvo stated “this model response is seriously wrong when looking at rpm changes.” [EPA-HQ-OAR-2014-0827-1894-A1 p.17]

Much of the improved efficiency in the Chalmers paper comes from additional technologies, not just down-speeding. [EPA-HQ-OAR-2014-0827-1894-A1 p.17]

- Peak cylinder pressure is increased by 25%. This can improve combustion efficiency, but requires total redesign of the cylinder head, head gasket, piston, rings, rod bearing, main bearing, crankshaft, and block. In short, this requires a complete engine redesign that is problematic and unproven. Furthermore, without some breakthrough in bearing technology, the increased size of the bearings will increase friction. [EPA-HQ-OAR-2014-0827-1894-A1 p.17]
• Turbochargers (two stage turbos are used in this study) are re-matched to low speed operation. This would greatly reduce power and efficiency at higher speeds and loads that are still required when hauling heavy loads or on steep hills. Without this re-matching, it would not be feasible to drive the EGR necessary to control in-cylinder NOx at such low engine speeds. [EPA-HQ-OAR-2014-0827-1894-A1 p.17]

• Torque response is greatly compromised due to reduced mass flow. This will further exaggerate the drivability problem associated with lack of power at higher engine speeds. [EPA-HQ-OAR-2014-0827-1894-A1 p.17]

• Torque is increased to 3250 Nm at engine speed down to 850 rpm (compared to current engine at 2500 Nm at 1050 rpm). Aside from the problems with cylinder pressure already noted, this will create unresolved issues with engine and driveline vibration. [EPA-HQ-OAR-2014-0827-1894-A1 p.17]

In short, the design of this ultra-down-sped engine requires infeasible design trade-offs, unproven technologies, and double counts combustion improvements already accounted for. Even so, the model greatly overstates the benefits and is not backed up by any testing. In fact, the current level of down-speeding in US trucking is already near the optimum level with little more to be gained, barring new technology breakthroughs. [EPA-HQ-OAR-2014-0827-1894-A1 p.17-18]

• Advanced NOx and PM Aftertreatment

Comment: Expect any advances in this area to be consumed by future lower NOx expectations [EPA-HQ-OAR-2014-0827-1894-A1 p.18]

• Advanced Adaptive Controls

Comment: It is unclear how these might be factored into any test process, especially until it is clear what these might be. Adaptive control cannot be considered within fixed engine test cycles. [EPA-HQ-OAR-2014-0827-1894-A1 p.18]

• Advanced Sensors

Comment: Sensors contribute nothing to FE unless utilized for advanced combustion and control. Advanced sensors (and actuators) will be necessary, but lack of these is a barrier to commercialization. [EPA-HQ-OAR-2014-0827-1894-A1 p.18]

• Increased Turbocharger Efficiency

Comment: Although more efficient turbochargers can be built (at significant cost), it is unclear that they can maintain high levels of efficiency due to abrasion of blades and carbon build up. In order to be effective, high turbo efficiency must be coupled with turbo-compounding or new EGR systems. Otherwise, there is likely insufficient exhaust back pressure to drive EGR. [EPA-HQ-OAR-2014-0827-1894-A1 p.18]

Input from DOE Efficiency Symposium presented at DEER, Oct. 2011

Although there are countless publications on combustion engine efficiency, one study is particularly significant. On March 3-4, 2010, the US Department of Energy gathered top engine efficiency experts
from around the world with the express purpose of establishing the maximum potential efficiency that might ultimately be achieved.9 [EPA-HQ-OAR-2014-0827-1894-A1 p.18]

On page 11 the symposium presentation states: [EPA-HQ-OAR-2014-0827-1894-A1 p.18] 

“Increasing engine efficiency involves a Whack-a-mole (or Gopher) approach.” 

“Reduction of one loss term tends to result in an increase of another, for example,…Reducing in-cylinder heat loss tends to increase exhaust energy rather than piston work Lean operation increases piston work but increases combustion irreversibility and decreases exhaust energy” [EPA-HQ-OAR-2014-0827-1894-A1 p.18]

This is clearly stating that the dis-synergies are critical considerations in increasing efficiency. [EPA-HQ-OAR-2014-0827-1894-A1 p.18]

Although the consensus was that 60% best-point BTE might be the upper limit for a conventional crank-slider engine, it was fully acknowledged that this is a theoretical limit with many practical constraints. Each further incremental step toward this limit requires tremendous engineering effort and potentially complex systems with high cost and unreliability. Furthermore, it was acknowledged that larger engines are inherently more efficient, while power density and an engine optimally sized for vehicle power demand create constraints on engines for on-road operation. Also, NOx emissions were not considered in these discussions. [EPA-HQ-OAR-2014-0827-1894-A1 p.18-19]

Some key conclusions are noted on page 25 of the presentation, reproduced here: [EPA-HQ-OAR-2014-0827-1894-A1 p.19]

[Figure can be found on p.19 of docket number EPA-HQ-OAR-2014-0827-1894-A1]

Earlier in the presentation on slide 15 in a discussion about the irreversible nature of the internal combustion process, the presenter concludes: [EPA-HQ-OAR-2014-0827-1894-A1 p.19]

“Significant reductions (in fuel consumption) will require radical changes in how combustion occurs in engines: Thermochemical recuperation, staged reactions (chemical looping), etc.” [EPA-HQ-OAR-2014-0827-1894-A1 p.19]

These viewpoints from this group of global internal combustion engine experts highlight the level of complexity, dis-synergy, and unsolved technical challenges that stand in the way of achieving extreme levels of brake thermal efficiency. [EPA-HQ-OAR-2014-0827-1894-A1 p.19]

Conclusion:

Although there is tremendous speculation about the potential for heavy duty diesel engine efficiency improvement, this is accompanied by a huge number of unsolved issues, including whether any technology can reliably and effectively manage the full range of requirements while avoiding offsetting efficiency penalties in the vehicles. Impacts on reliability, cost, downtime, and maintenance must be considered. The ability of the engine to meet criteria emissions limits and related requirements, including certification, in-use requirements, OBD, and deterioration, must be taken into account. The effectiveness of each technology must be considered in setting target penetration levels. Many engine technologies are only possible when combined with the vehicle drivetrain and all should be evaluated against the steadily
reducing power demand dictated by the Phase 2 proposed rule. [EPA-HQ-OAR-2014-0827-1894-A1 p.20]

Response:

We appreciate the comments made by these four major vehicle OEMs. While we believe that the separate engine standard is necessary, we do agree significantly with most of the points that the four major vehicle OEMs have made. We agree with their assessment of the SwRI report. More importantly, the SwRI findings, specifically their revised report, supports the agencies’ stringency when taking the agencies’ certification procedure including vehicle weight, and cycle weighting factors, and WHR market penetration, into consideration. We also largely agree with this report’s statements on DOE’s SuperTruck program, which are solely used for technology demonstration in an R&D environment. We also appreciate their comments on many items, including the sections on demonstration vs. commercial feasibility, funding resource and allocation, and dis-synergy. We agree in principle with the commenter’s comments on down-speeding, specifically that the Walsh/Charlton report on down speed is impractical. We also found that many technical comments on various technologies, such as WHR, combustion with HCCI and PCCI concepts, friction, adaptive control, and advanced NOx and PM control are extremely helpful. These comments have further helped us to justify why we cannot use the Charlton/Walsh report as our base to increase the stringency to the level they recommend. See also response to EDF in Section 3.3.1 above.

Organization: Diesel Technology Forum
1. NEW CLEAN DIESEL TECHNOLOGY WILL CONTRIBUTE TO FURTHER EFFICIENCY GAINS AND CONTINUE TO BE THE PRIMARY POWERTRAIN FOR COMMERCIAL VEHICLES.

More than 95 percent of all heavy duty trucks on the road today are diesel-powered as are a majority of medium duty trucks. Advances in diesel engine technology will continue to contribute to the overall efficiency gains of vehicles under the proposed rule, and as a result we expect diesel technology to remain the primary power-plant for commercial trucks into the foreseeable future. Diesel will continue to be the technology of choice because it offers an unmatched combination of power, increasing energy efficiency, work capability, reliability and now near-zero emissions environmental performance, along with an ability to utilize a variety of low-carbon renewable diesel fuels. [EPA-HQ-OAR-2014-0827-1171-A2 p.1-2] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.120-121.]] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.108-109.]]

Since 2000, the leaders in clean diesel technology and the EPA worked together in establishing a regulatory pathway that brought about the introduction of an entire new generation of clean diesel engines for both on- and off-road applications. Manufacturers have met the challenge to virtually eliminate both NOx and particulate emissions from diesel engines, reducing emissions by as much as 98 percent from previous levels. [EPA-HQ-OAR-2014-0827-1171-A2 p.2] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p. 121.]] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.109.]]

In fact, last year the American Lung Association, in its annual State of the Air Report identified cleaner diesel fleets as one of the two main contributors to helping the nation achieve cleaner air and meet the national ambient air quality standards for ozone and particulate matter. [EPA-HQ-OAR-2014-0827-1171-A2 p.2] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p. 121.]]

[Image, 'Clean Diesel', can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-1171-A2]

These new technology clean diesel engines are being widely embraced by customers as evidenced by the increasing penetration into the vehicle population. According to state vehicle registration data for 2014, of the roughly 9.2 million Class 3-8 heavy-duty vehicles on the road nationwide, about 37 percent, or 3.4 million vehicles are deployed with a 2007 or newer model year engine. Of these, almost 21 percent or roughly 1.9 million vehicles on the road meet the 2010 emissions milestone that requires near zero levels of both particulate matter and nitrogen oxide emissions. [EPA-HQ-OAR-2014-0827-1171-A2 p.2-3] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p. 121.]] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.109-110.]]

Illinois is a leader in adoption of new clean diesel technology: 40 percent of class 3-8 trucks on the road are 2007 and newer making Illinois number 4 in the country for the largest population of heavy duty diesel trucks model year 2007 and newer (130,432). Twenty-one percent (58,157) are 2010 and newer making it 5th in the nation for registration of 2010 and newer commercial trucks. [EPA-HQ-OAR-2014-0827-1171-A2 p.3] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p. 121.]]

Last year (2014) was a very strong year for new truck sales across the industry, with over 186,000 new medium duty trucks sold (Class 4-7) along with over 230,000 heavy-duty (Class 8) trucks sold. The overwhelming majority of these vehicles are powered by clean diesel technology with just a few thousand units powered by other fuels. [EPA-HQ-OAR-2014-0827-1171-A2 p.3] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p. 122.]] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.109.]]
According to the Fuels Institute, as of 2013, diesel represents about 98 percent of the engines found in medium and heavy-duty vehicles including those that are covered by the proposed rule. By 2023, the Fuels Institute estimates that diesel engines will power between 95 and 97 percent of these vehicles despite the introduction of alternative fuels and powertrains including all-electric, fuel cell and continued introduction of natural gas powered vehicles. [EPA-HQ-OAR-2014-0827-1171-A2 p.3] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p. 122.]]

2. CLIMATE, FUEL SAVINGS AND CLEAN AIR BENEFITS FROM NEW TECHNOLOGY DIESEL ENGINES IN COMMERCIAL TRUCKS IN OPERATION TODAY ARE SIGNIFICANT AND GROWING

New diesel technology on the road today is delivering real world benefits in the form of fuel savings and reducing carbon emissions. According to research commissioned by the Diesel Technology Forum, in just the last four years—between 2010 and 2014-- technologies developed to meet strict emissions standards beginning for model year 2010 engines have generated substantial fuel savings and emission reductions. [EPA-HQ-OAR-2014-0827-1171-A2 p.3] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p. 122.]] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.110-111.]]

Now 18 months into the first ever fuel economy and greenhouse gas reduction rules for these medium and heavy-duty vehicles – the so called Phase 1 rules – are expected to save 530 million barrels of crude oil and eliminate 270 million tons of carbon emissions between 2014 and 2018 according to EPA and NHTSA. In this population of vehicles, diesel is the predominant powertrain found in about 98% of trucks. Industry estimates have diesel maintaining over 90 percent of this market over the lifetime of the rule. [EPA-HQ-OAR-2014-0827-1171-A2 p.3]

Response:

We appreciate Diesel Technology Forum’s comments.

Organization: Diesel Technology Forum

Advanced truck and engine designs that reduce emissions provide significant fuel savings for their owners and clean air benefits for everyone. [EPA-HQ-OAR-2014-0827-1171-A2 p.6]

Now achieving near zero emissions, clean diesel technology powers the overwhelming majority of medium and commercial trucks today and thanks to these improvements, is poised to continue as the prime powertrain technology for commercial vehicles in the future. [EPA-HQ-OAR-2014-0827-1171-A2 p.6]

The engine may look and perform somewhat differently, and may be burning different kinds of low carbon fuels. But in the end, it will still be a diesel engine and an integral component of meeting the needs of a growing economy and a cleaner and more sustainable future. [EPA-HQ-OAR-2014-0827-1171-A2 p.7]
Response:

We appreciate Diesel Technology Forum’s comments.

Organization:  Diesel Technology Forum

California Clean Diesel Adoption and Benefits

With one of the largest medium and heavy duty fleets in the country, California stands to benefit the most from these proposed Phase 2 rules. Already, model year 2010 and newer engines that are found in Class 3 – 8 vehicles in the state have eliminated 120,000 tons of NOx and 580,000 tons of carbon dioxide and saved 1.4 billion barrels of crude oil between 2010 and 2014, according to our most recent research. According to the Air Resources Board, the further adoption of new and newer diesel engines in heavy-duty applications in California is expected to reduce emissions of oxides of nitrogen by fifty percent between 2012 and 2020. [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

We believe these are also important considerations for EPA in developing a final Phase 2 rules, as follows: [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

- The program must consider the longstanding trade-off between NOx and CO2. The rule should avoid driving technologies that realize gains in fuel efficiency at the expense of NOx, reversing the huge achievements of clean diesel technology in recent years and limiting the potential for further reductions in the future. As we have stated previously, technologies developed to meet the current emission standard established for model year 2010 maximize reductions in NOx and CO2. The maximization of this trade-off may become jeopardized if pushed too far. [EPA-HQ-OAR-2014-0827-1171-A2 p.6]

Response:

We appreciate Diesel Technology Forum’s comments. We will work with all stakeholders to explore the trade-off between NOx and CO2. See also response in RTC Section 15.8.

Organization:  First Industries Corporation

The following EPA-proposed penetration rates are too aggressive and in our estimation must be adjusted downward: [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

Waste Heat Recovery: 15% - Waste heat recovery technology is not currently in the market, has technical challenges for which production-viable solutions have not been identified, and is therefore not proven. Customers are concerned with the complexity of the system as well as likely downtime, which will prevent uptake of this non-proven technology. This is the type of technology that is likely to cause a pre-buy/no-buy scenario. EPA should not assume any penetration of waste heat recovery technology by 2027. [EPA-HQ-OAR-2014-0827-1145-A2 p.2-3]

The estimated costs of the following technologies as presented in the proposed rule are too low: [EPA-HQ-OAR-2014-0827-1145-A2 p.4]

Waste Heat Recovery — EPA assumes this technology will cost up to $11,000. Because waste heat recovery is not currently in the market, the actual costs are unknown. However, step changes in
technology typically cost more. Moreover, the additional costs for maintenance and downtime need to be accounted for in the rule. With the phase-in implementation of new emission standards in 2007, fleets saw substantial extra costs in terms of missed loads, late loads, etc. Fleet owners also risk losing drivers if they are operating with new, unproven technology, and other fleets are operating with proven technology. This is a major reason fleets will pre-buy to avoid such technology. It is also a major cost that must be accounted for in the rule. EPA must also recognize that the potential benefits of waste heat recovery vary substantially depending on the duty cycle and powertrain. [EPA-HQ-OAR-2014-0827-1145-A2 p.4]

**Response:**

We recognize the WHR concerns of First Industries Corporation. Downtime and cost are two of the many key concerns, specifically for an emerging technology that has not been extensively tested on the market. We explain in RIA Chapter 2.3.9 how these challenges can be successfully met in the lead time provided by the Phase 2 rule. We received data and CBI information from one engine manufacturer as well as public comments (EPA-HQ-OAR-2014-0827-1298) that shows that their WHR system could be put into production in 2021 timeframe. Given their large market share in the class 8 engine sector, a 25% market share utilizing WHR by 2027 is certainly possible. In addition to our response in RTC Section 3.4.1 below, Chapter 2.3.9 and 2.7 of the RIA details the justification.

**Organization:** He, Leard, McConnell

**2 Sources of Improvements in Fuel Economy**

**2.1 Engine Efficiency and Vehicle Design**

Some technologies improve fuel economy through helping the engine operate more efficiently. For example, in a turbocharger, the radial exhaust-driven turbine drives the radial compressor to increase the air density going into the engine, therefore improving the efficiency of the compressor or turbine. Alternative combustion cycles are available to improve the efficiency, such as low-temperature combustion, homogeneous charge compression ignition, and premix charge compression ignition. Variable valve actuation is designed to facilitate the use of nonconventional combustion modes during the power stroke, allowing the valve actuation to be adjusted independently from the crankshaft angle. Another technology, low-temperature exhaust gas recirculation, increases engine efficiency by reducing peak combustion temperatures and thus cooling the exhaust gas before it returns to the engine intake manifold. Thermal insulation reduces heat rejection to the engine coolant (from exhaust ports) or to the ambient air (from manifolds), therefore reduces energy loss during operation. [NHTSA-2014-0132-0115-A1 p.2]

We do not directly measure the adoption of these technologies and vehicle design characteristics over time. Instead, the effects of these advances are absorbed by model year fixed effects in our estimation. Therefore, the time period fixed effects potentially reflect the adoption of a combination of these technologies. [NHTSA-2014-0132-0115-A1 p.3]

**2.2 Trade-off Factors**

Some truck attributes have a negative correlation with fuel economy, *ceteris paribus*. We examine closely two of these trade-off attributes, engine displacement and vehicle weight. [NHTSA-2014-0132-0115-A1 p.3]
While engine performance is usually measured by its horsepower and torque at the wheels, we argue that engine displacement serves as a good indicator of engine power. Engine displacement, by definition, measures the size of explosion inside the cylinders, which largely determines the power of the engine. The rotational force generated is torque at the engine. Horsepower is a man-made number, and it is defined as the product of torque at the engine and revolutions per minute (RPM), divided by 5,252. Torque at the wheels is the combination of torque at the engine with the torque magnification given by the transmission through gearing. [NHTSA-2014-0132-0115-A1 p.3]

3 Data and Graphical Evidence

The Vehicle Inventory and Use Survey was conducted by the Census Bureau from 1963 to 2002. We use data collected every five years from 1982 to 2002. Random samples are generated for every state, with surveys asking for detailed information about trucks’ physical and operational characteristics. [NHTSA-2014-0132-0115-A1 p.4]

The trade-off relationship between MPG and vehicle weight (including cargo), as well as between MPG and engine displacement, for combination trucks can be illustrated in the two graphs below. [NHTSA-2014-0132-0115-A1 p.4]

[Figure 2, ‘Trade-off between MPG and vehicle weight for class 7, 8 combination trucks’, and 3, ‘Trade-off between MPG and engine displacement for class 7, 8 combination trucks’, can be found on p.5 of docket number NHTSA-2014-0132-0115-A1]

Response:

We appreciate your comments, specifically on the trade-off between vehicle weight and engine displacement. The empirical correlation (equation 1) used in the report is also interesting.

Organization:  Honeywell Transportation System (HTS)

Additionally, HTS’ internal reviews, based on test results and on-engine simulation, show that air systems currently available for performance demonstration can reduce engine fuel consumption by nearly 2 percent relative to the current proposal’s 2017 baseline. Some of this technology, like ball bearing-equipped turbochargers, is available today and the rest can be in production by 2021, all with an end-user payback that is substantially less than the agencies’ proposed two-year threshold. An advanced turbocharger concept, including turbo-compounding, is under development, with series production planned before 2025. This advanced air system architecture is projected to reduce fuel consumption by nearly 3 percent over the 2017 baseline engine. Given that HTS can account for the majority of the regulated fuel economy reduction with only air systems changes, we believe that there is room for a stronger engine-level standard, given significant advancements in engine efficiency building blocks under development by engine OEM’s and other component suppliers. [EPA-HQ-OAR-2014-0827-1230-A1 p.3]

Beyond air systems, waste heat recovery technology like Organic Rankine Cycle (ORC) has shown the capability to improve engine fuel efficiency by 5 percent or more in laboratory and over-the-road trials. At the current time, being on the early end of the cost curve, ORC does not yet have a proven 2 year end-user payback. However, industry has repeatedly shown that technology costs can be reduced dramatically given sustained demand and market competitiveness. We are confident that if there is long-term regulatory certainty, industry will develop reliable technologies that can cost-effectively meet a more stringent standard. [EPA-HQ-OAR-2014-0827-1230-A1 p.3]
HTS appreciates the agencies’ continued recognition that turbochargers can contribute significantly to the reduction of GHG, NOx and PM emissions from the transportation sector. [EPA-HQ-OAR-2014-0827-1230-A1 p.5]

Response:

We appreciate HTS’s comments on the technologies related to air systems and WHR with ORC. All of these technologies are part of our technology road map and were taken into consideration by the agencies when developing the standard. We have made many changes to the engine standards to increase the stringency from that proposed. See responses in Section 3.3.1 above.

Organization: International Council on Clean Transportation (ICCT)

Technology potential

This section provides ICCT’s comments on the agencies’ determination of the stringency of the standards. It is emphasized, per our Section II comments above, that the agencies’ proposed 2027 standards can be moved forward by three years due to the maturity of the necessary technologies to achieve compliance with those proposed efficiency levels. Generally, the development of long-lead time regulations allow greater time to reduce technology investment risk, sustain long-term capital investments, and allow more widespread deployment of advanced technologies in the marketplace (See Lutsey, 2012). Based on the ICCT’s latest research, as well as the research literature, there are several areas where the agencies do not fully incorporate available technology that is applicable in the 2027 timeframe. [EPA-HQ-OAR-2014-0827-1180-A4 p.6]

Engine efficiency

One area where the proposed standards diverge from the available technology potential is in the engine area, where the agencies proposed to reduce the tractor diesel engine fuel use by 4% from 2017 to 2027. The engine standards would likely remain in effect for three additional years, so the standards would apply until 2029 or 2030. This would mean engine CO2 emissions would be reduced on average by 0.3% to 0.4% per year from 2017 through 2030. Moreover, our analysis of the specific Phase 2 GEM engine maps shows that the Phase 2 baseline engine CO2 emission levels over the re-weighted SET cycle is reduced by 1.5% when compared to the results over the originally weighted SET. By providing a 1.5% fuel consumption benefit for the re-weighting, the stringency of the agencies proposed tractor engine standard in 2027 is actually 2.5%, not 4.0%. [EPA-HQ-OAR-2014-0827-1180-A4 p.6] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.39.]]

Based on our own recent technical analysis and the research literature – much of which was not yet referenced or acknowledged in the rulemaking analysis – the agencies could include greater application of known technologies in their stringency determination for diesel tractor engines. With the exception of the Reinert (2015a, 2015b) studies, the referenced literature below [see p.19-22 for list of referenced literature] all appears to be new data to the agencies’ analysis. A recent engine audit and analysis indicates that tractor-trailer diesel engines can improve by over 10% from a 2017 baseline in the 2020-and-beyond timeframe (Thiruvengadam et al, 2014). The ICCT follow-on analysis that includes real-world synergies indicates that the same tractor engine technologies can achieve a 7% fuel consumption benefit without waste heat recovery (WHR) and 10-12% with more advanced WHR technologies – and also offer attractive payback periods that are comfortably less than 2 years (Delgado and Lutsey, 2015; Meszler et al, 2015). Work by the Southwest Research Institute for NHTSA indicates that diesel tractor engines can see reduced fuel consumption of 7%—and up to 10% with waste heat recovery—from a 2019
baseline within the Phase 2 timeframe (Reinhart, 2015). In addition, the highest-volume tractor engine
manufacturer, Cummins, indicates that engines can achieve a 9%–15% fuel use reduction from 2017,
within the 2020–2030 timeframe (Eckerle, 2015). With higher technology penetration rates for U.S. DOE
SuperTruck technologies, the standards could go further yet. Teams led by Cummins, Daimler, Navistar,
and Volvo have already physically demonstrated engine improvements of 12%–17% from a 2010
baseline (Delgado and Lutsey, 2014). The SuperTruck programs follow-on goal would go further, with a
brake thermal efficiency of 55% in peak conditions (Wall, 2014). [EPA-HQ-OAR-2014-0827-1180-A4
p.6]

Lutsey (2015a) assessed the above references and analyzed the prospects to increase the penetration of
the above technology levels and compare to the proposed stringency levels. Based on the latest research,
there is sufficient technology availability to reduce tractor engine fuel consumption by at least 7% from
incremental efficiency technology (i.e., from improvements from friction reduction, parasitics, air
handling, aftertreatment, combustion optimization, and advanced controls), about double what the
agencies included in the proposed rule for 2027. With greater penetration of the incremental technologies
and 15% penetration of organic Rankine cycle WHR system (as assumed by the agencies), a fleet-wide
CO2 improvement of up to 10% in 2027 is feasible. With greater penetration of WHR and U.S. DOE
SuperTruck technologies, the technology potential is higher still. The particular underlying data
assumptions that appear to drive the agencies’ unduly conservative engine stringency analysis would
ideally be modified to reflect the recent state-of-the art technical work in the following areas: [EPA-HQ-
OAR-2014-0827-1180-A4 p.6-7] [These comments can also be found in Docket Number EPA-HQ-
OAR-2014-0827-1420, pp. 39-40.]

*Engine friction reduction*: To reflect the most recent data, we recommend the agencies increase
technology effectiveness in this area from 1.4% to 3%. The recent data on this from Reinhart (2014a)
indicates that a 24% improvement is feasible in this area. In addition, engine friction reduction from
technologies including electrified variable-speed oil and water pumps delivered an absolute improvement
of about +1% brake thermal efficiency (BTE) for at least a 2% fuel consumption reduction in the Navistar
depicts a 3% improvement. [EPA-HQ-OAR-2014-0827-1180-A4 p.7]

*Aftertreatment*. We recommend the agencies increase technology effectiveness in this area from 0.6% to
1%. Advances in substrates to reduce back pressure and SCR system improvements to better optimize
gear controls are already being commercialized. Stanton (2013) indicates that aftertreatment
improvements could deliver a 2% fuel consumption benefit. Similarly, the Cummins/Peterbilt SuperTruck
project delivered a +0.5% BTE gain or at least a 1% fuel consumption benefit (Delgado and Lutsey,
2014). Sisken and Rotz (2012) indicated a 2% improvement. In addition, expert stakeholder workshop
findings pointed to the potential for 2-4% improvements in efficiency that are enabled from improved
aftertreatment systems in the Phase 2 timeframe (Lutsey et al, 2014). [EPA-HQ-OAR-2014-0827-1180-
A4 p.7]

*Intake and exhaust air handling, turbocharging, and EGR improvements*. We recommend the agencies
increase technology effectiveness in this area from 1.1% to 3%. Reinhart (2014a) indicates that 1.6% fuel
consumption reduction is feasible from a more advanced turbocharger. Stanton (2013) found that 3% fuel
consumption reduction is feasible from EGR, ports, and turbomachinery efficiency enhancements. In
addition, another study indicates a 4% improvement just from an advanced asymmetric turbocharger
system (Chebli, et al, 2014). Advanced piston design and injector geometry contribute to a peak
improvement of 5% and overall improvements of about 3% (Roberts et al, 2011; Thiruvengadam et al,
2014). Jadin (2012) indicates about a 4% improvement from air handling technologies. [EPA-HQ-OAR-
2014-0827-1180-A4 p.7]
**Combustion, control optimization:** We recommend the agencies increase technology effectiveness in this area from 1.1% to 3%. The Navistar SuperTruck program demonstrated a 3% BTE improvement from increased compression ratio pressure and in-cylinder pressure (Delgado and Lutsey, 2015), equivalent to an approximate 6% fuel consumption improvement. Stanton (2013) indicates that 2.5% fuel consumption improvement is feasible from improved heat transfer and compression ratio-related improvements. A stakeholder workshop of industry experts indicated that up to 4% improvement is available from combustion optimization and up to 4% from model-based engine controls (Lutsey et al, 2014). The National Research Council (NRC) (2014) indicates that increased fuel injection pressures with piezoelectric nozzle use could make 6% fuel consumption reduction realizable in real operating conditions. Finally, real-time combustion control, advanced fuel injection concepts, and alternative combustion strategies can contribute to an additional 1 to 4 percent reduction in fuel consumption (NRC, 2014) [EPA-HQ-OAR-2014-0827-1180-A4 p.7]

**Turbocompounding:** We recommend that the agencies increase tractor turbo compounding penetration to at least 15% in 2024, and to over 25% in 2027, and also increase the technology’s fuel consumption effectiveness from 1.8% to 3%. Navistar’s SuperTruck project achieved a 1.5% brake thermal efficiency improvement (Delgado and Lutsey, 2014), which in turn offers a 3-4% fuel consumption improvement, from its electric turbo compounding system. Thiruvengadam et al (2014) indicates that a 3.5% benefit is achievable from turbo compounding. This could be an alternative for companies that do not find waste heat recovery as attractive for their particular operations or technology preferences. [EPA-HQ-OAR-2014-0827-1180-A4 p.7]

**Waste heat recovery:** We recommend that the agencies increase the waste heat recovery effectiveness from 3.6% to 5% fuel consumption reduction to better match the available research on the technology. Salemme (2013) indicates the technology could result in 5-7% fuel use reduction. Similarly, Stanton (2013) found a 5% benefit. The recent SwRI study indicated the technology could deliver a 3-6% benefit (Reinhart, 2015a), and we believe that over the long timeframe of this rule the upper bounds of this technology are likely to be most appropriate, especially if the technology is only limited to 15% of the tractor market, which presumably would be the tractors for which the duty cycles are matched to where the technologies’ benefit is greatest. [EPA-HQ-OAR-2014-0827-1180-A4 p.7-8]

**Dis-synergy factors:** We recommend the agencies increase their synergy adjustment factor from 0.85 to 0.9 in 2024, and 0.85 to 0.95 in 2027. The agencies appear to be incorporating an engineering assumption that is not validated and cuts across all the technologies above, thus greatly reducing the stringency determination for tractor engines. The multiplicative accounting between the various engine efficiency factors is already intended to account for the interaction effects whereby the multiple technologies together results in less benefit than the simple sum of the technologies’ effectiveness. Reinhart (2015a, b) results appear to indicate greater overall engine improvements than the agencies determined, and the agencies’ dis-synergy factors appear to substantially diverge from the government-contracted work. Model-based control is an enabling technology that reduces such losses from interactions between the technologies. In addition, the extensive co-development of engines and engine components among suppliers and vehicle manufacturers – as a general practice, and demonstrated in the SuperTruck projects (Delgado and Lutsey, 2014) – all go directly toward minimizing such losses. In addition, the long lead-time of the standards, through model year 2027, provides the appropriate timeframe for minimizing undesirable negative synergies and maximizing positive synergies. The dis-synergy factors should ideally be based on supported data. Engine simulation tools can prove useful to account for such interactions (e.g., the Reinhart 2015a, b analysis). If such adjustment factors are continued, we recommend their impact be reduced over time, to 0.9 in 2024 and 0.95 in 2027 (from 0.85 as proposed). [EPA-HQ-OAR-2014-0827-1180-A4 p.8]
Table 1 summarizes the technology effectiveness values assumed in the Phase 2 proposal, along with comparable technology values in the research literature. Whether looked at from the perspective of overall engine improvements on studies that incorporated multiple technologies or from the perspective of each of the individual technology areas, the agencies were conservative across the board based on best available data on directly applicable tractor efficiency technologies. [EPA-HQ-OAR-2014-0827-1180-A4 p.8]

[Table 1 can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1180-A4]

Response:

We have received many constructive comments on the engine standards with many differing views. We have made many changes to the engine standards which increased the stringency of the standard from that proposed. See responses in Section 3.3.1 above.

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

The report is consistent with our views that waste heat recovery technology at this high cost and level of complexity is not ready for the road. At various points, waste heat recovery is described as: [EPA-HQ-OAR-2014-0827-1895-A1 p.3]

- Complex and expensive technologies that are not fully developed
- High cost and uncertainty of reliability and warranty
- Exotic and untried

The UAW recognizes and supports the high level of communication and collaboration between regulators, the industry, and other stakeholders in crafting a very complex standard. We urge all parties to continue working together to solve outstanding issues before regulations are finalized. To take one example, the proposed standard’s prohibition of the conversion of on-road motor vehicles to dedicated racing vehicles is problematic and the final regulations must arrive at a workable solution. [EPA-HQ-OAR-2014-0827-1895-A1 p.3]

Response:

Many commenters share the same concerns on WHR with UAW. Downtime and cost are two of the key concerns, specifically for an emerging technology that has not been extensively tested in the market. These concerns are addressed in Chapter 2.3.9 of the RIA where the agencies indicate how current challenges can be successfully addressed in the lead time provided by the rule. We received data and CBI information from one engine manufacturer as well as public comments (EPA-HQ-OAR-2014-0827-1298) that shows that their WHR system could be put into production in 2021 timeframe. Given their large market share in the class 8 engine sector, a 25% market penetration of WHR by 2027 is certainly possible. In addition to our response in RTC Section 3.4.1 below, Chapter 2.3 and 2.7.5 of the RIA details the justification.

Organization: Lubrizol Corporation

The Phase 2 Proposal estimates that shifting to today’s higher-performing engine lubricants will result in increased fuel economy and CO2 benefits of 2.4-3.4 percent in 2027, compared with 2010 engines. Low-viscosity axle lubricants are estimated to add another 0.5 percent improvement. According to Shell, every 1 percent increase in fuel economy will reduce CO2 emissions by 4,000 tons per year and will reduce fuel consumption by one million gallons per day, which is roughly comparable to removing 23,000 trucks
from the road and saving fleets and owner-operators roughly $3 million per day.\textsuperscript{7} [EPA-HQ-OAR-2014-0827-1325-A1 p.3-4]

The benefits in 2027 should be even higher. Starting in 2017, the lubricants in the market will be far superior from the perspectives of fuel economy, emissions reduction, engine performance, and engine durability than the CJ-4 lubricants that are the basis for the estimates in the Phase 2 Proposal. These benefits will only increase in later years, as even better formulations enter the market. [EPA-HQ-OAR-2014-0827-1325-A1 p.4]

To meet the objectives of the Phase 2 Rule without compromising engine performance and durability, the American Petroleum Institute (API), at the request of the Engine Manufacturers Association (EMA), is developing a new industry standard for HPLs that will be used in the trucks covered by the Phase 2 Rule.\textsuperscript{8} This specification, currently designated as PC-11, will bring a new generation of HPLs to the market by 2017. [EPA-HQ-OAR-2014-0827-1325-A1 p.4]

As will be discussed further below, the benefits of the new specification will be significant. Today’s lubricants, which meet API’s CJ-4 specification, will be replaced by PC-11 lubricants that will combine lower viscosity for improved fuel economy and lower emissions with advanced additives for improved durability and engine performance. [EPA-HQ-OAR-2014-0827-1325-A1 p.4]

For the first time, consumers of lubricants will have a choice of two different specifications. PC-11A lubricants will replace today’s CJ-4 lubricants, and will be compatible with all trucks on the road. They will be suitable for use in today’s existing trucks and in future trucks. PC-11B lubricants will be designed for new engines. Both will enter the market by 2017. PC-11B lubricants will be specially designed to contribute to greater fuel economy and CO2 emissions benefits while maintaining engine protection and durability. The two categories will largely be distinguished by their High Temperature High Shear (HTHS) viscosity rates. (Simply put, HTHS provides a better way to measure the impacts of a lubricant on fuel economy). [EPA-HQ-OAR-2014-0827-1325-A1 p.4]

The benefits of PC-11B lubricants are expected to be comparable to, or greater than, the benefits of using low rolling resistance tires. As with low rolling resistance tires, however, it will be important to take steps to help ensure that they penetrate the truck market, and that they are used throughout the useful life of the trucks that are initially certified with them. To reap the full, real-world environmental benefits of the Phase 2 Rule, EPA should consider provisions in the final Phase 2 Rule to help ensure that PC-11B lubricants are used throughout the useful life of future trucks and engines. [EPA-HQ-OAR-2014-0827-1325-A1 p.4]

Engine Oils and Lubricants

A Primer on Engine Lubricants

The choice of lubricants impacts nearly every part of the energy conversion process that occurs in a commercial vehicle. Until recently, high viscosity lubricants were typically used to lubricate and protect automotive engines.\textsuperscript{11} However, their high viscosity required more energy to pump the lubricant throughout the inner walls of the engine, which resulted in reduced engine efficiency. In order to achieve higher engine efficiency, better fuel economy, and lower emissions, OEMs increasingly desire lower viscosity synthetic and semi-synthetic lubricants for their engines, as well as for their transmission and drivetrain lubricants. [EPA-HQ-OAR-2014-0827-1325-A1 p.6]
Shifting to low viscosity engine lubricants reduces pumping losses associated with moving the lubricant around the engine to maintain sufficient lubrication. While low viscosity increases efficiency because less pumping work is required, the low viscosity lubricant must still provide sufficient wear protection. Not only must they provide wear protection that is comparable with the protection provided by higher viscosity lubricants, but they must be able to achieve this performance at the higher temperatures and pressures experienced by today’s advanced engine technologies. [EPA-HQ-OAR-2014-0827-1325-A1 p.6]

Higher temperatures further complicate the switch to low viscosity lubricants. As temperature increases, viscosity decreases. Because today’s engines experience a wide range of operating temperatures, lubricants are required to maintain ideal viscosity across these conditions. Balancing the lowest viscosity lubricant capable of providing sufficient film thickness across a wide range of operating conditions is the key to improving efficiency while also ensuring engine components are adequately protected. [EPA-HQ-OAR-2014-0827-1325-A1 p.6]

As OEMs push efficiency to new heights in the coming decade, ensuring robustness and durability will become increasingly important. Improved lubricants will be required to protect engine integrity under increasingly harsh environments, and they will have to deliver this performance at lower viscosities in order to provide additional efficiency improvements. In order to provide improved performance under more demanding conditions, new higher-performing lubricants that are tailored to specific operating conditions, engine strategies, and advanced technologies will need to be developed and commercialized. [EPA-HQ-OAR-2014-0827-1325-A1 p.6]

In sum, HPLs provide OEMs with two opportunities:

As an enabler of advanced engine strategies and technologies: HPLs will provide the viscosity, frictional, and durability characteristics that allow advanced engine strategies and technologies to be used without concerns over premature product failures, engine and driving performance, and durability over the oil drain interval or throughout the engine’s useful life. [EPA-HQ-OAR-2014-0827-1325-A1 p.6]

As a strategy that delivers improved fuel economy: HPLs have been demonstrated to increase fuel economy by 1-3 percent. Because OEMs will need to consider every available tool to meet their 2027 requirements in the most cost-effective manner, HPLs should play an increasingly important role in OEM’s compliance strategies. [EPA-HQ-OAR-2014-0827-1325-A1 p.7]

To address this challenge, additive packages are being formulated that can be blended into low viscosity base oils to maintain their performance characteristics across a range of operating conditions, while improving efficiency and reducing emissions. Some of the most common additives that will be blended with base oils will include:[EPA-HQ-OAR-2014-0827-1325-A1 p.7]

- Viscosity modifiers: polymers that help control the viscosity of a lubricant over a specified temperature range;\textsuperscript{13} [EPA-HQ-OAR-2014-0827-1325-A1 p.7]
- Friction modifiers: organic (carbon, hydrogen, and oxygen) and metal-containing friction modifiers that reduce sliding and rolling friction between metal components;\textsuperscript{14} [EPA-HQ-OAR-2014-0827-1325-A1 p.7]
- Antioxidants and detergents: blended with base oils to reduce sludge formation, reduce deposit formation on pistons, and prevent against the effects of poor fuel quality;\textsuperscript{15} [EPA-HQ-OAR-2014-0827-1325-A1 p.7]
Dispersants: solubilizes sludge that can otherwise form blockages in an engine’s inner walls;\textsuperscript{16} and [EPA-HQ-OAR-2014-0827-1325-A1 p.7]

- Anti-wear additives: protect key engine parts from excessive wear which can degrade engine performance.\textsuperscript{17} [EPA-HQ-OAR-2014-0827-1325-A1 p.7]

In sum, HPLs can play an important role in each manufacturer’s compliance strategy, whether by enabling other strategies, by directly improving fuel economy, or both. [EPA-HQ-OAR-2014-0827-1325-A1 p.7]

A New Generation of PC-11 Engine Oils Are Being Developed to Meet the CO2, Fuel Consumption, and Performance Needs of the Phase 2 Rule’s Engines

Truck engine design and combustion technology are already undergoing a period of significant change, driven by the need to meet the requirements of the Phase 1 Rule and other EPA emission standards, as well as industry demands for better driving performance, durability, and reliability. [EPA-HQ-OAR-2014-0827-1325-A1 p.7]

These changes include, without limitation: [EPA-HQ-OAR-2014-0827-1325-A1 p.7]

- Engine downsizing;
- Downspeeding;
- Active oil temperature control;
- Advanced combustion design;
- Higher oil temperatures;
- Start/Stop technology; and

Each of these changes require improved engine lubricants that will enable the new technologies and hardware designs to work properly. [EPA-HQ-OAR-2014-0827-1325-A1 p.8]

As noted above, today’s truck lubricants are designed to meet API’s CJ-4 specification. While CJ-4 is not a “fuel economy” specification \textit{per se}, EPA SmartWay data shows that current, low-viscosity CJ-4 lubricants provide fuel consumption and CO2 benefits that are comparable to low rolling resistant tires. According to SmartWay and as shown in Figure 2 below, the typical combination truck will reduce its fuel consumption by roughly 500 gallons per year by using low rolling resistance tires, while typical combination trucks that use low-viscosity lubricants will reduce their fuel consumption by an average of 485 gallons per year. In other words, SmartWay estimates that both strategies will cut fuel savings by roughly 3 percent. Similarly, the typical combination truck will reduce CO2 emissions by 4.93 metric tons in a typical year, while using low-viscosity lubricants will reduce CO2 emissions by 5.08 metric tons.\textsuperscript{18} [EPA-HQ-OAR-2014-0827-1325-A1 p.8]

[Figure 2 can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1325-A1]

Going forward, API will soon finalize a new set of lubricant specifications that will provide even greater fuel economy and CO2 benefits. These specifications are the result of a consensus-based process that involves the oil and additives industries and the engine manufacturers, as well as millions of dollars of research and development and millions of miles of field testing over a period of years. [EPA-HQ-OAR-2014-0827-1325-A1 p.9]
To develop the new specifications, currently designated as PC-11, at least five different categories of work are involved, including: [EPA-HQ-OAR-2014-0827-1325-A1 p.9]

- Test development, which is typically conducted by OEMs working in conjunction with oil and/or additive companies; [EPA-HQ-OAR-2014-0827-1325-A1 p.9]
- Test validation, which is typically done on an industry-wide, collective basis; [EPA-HQ-OAR-2014-0827-1325-A1 p.9]
- Formulation development, which is the process by which additive companies conduct tests to determine the impact of formulation changes; [EPA-HQ-OAR-2014-0827-1325-A1 p.9]
- Customer programs, which includes conducting specific tests for oil companies and on the specific products that they are considering selling; and [EPA-HQ-OAR-2014-0827-1325-A1 p.9]
- Field testing, which includes tests of the various formulations being considered [EPA-HQ-OAR-2014-0827-1325-A1 p.9]

Lubrizol’s own PC-11 field testing demonstrates the rigor and seriousness of the investments to create the new PC-11 lubricants. Since 2010, in anticipation of PC-11 lubricants being introduced, Lubrizol has accumulated in excess of 35 million miles of field testing on prototype PC-11 lubricants. This testing has been conducted across more than 140 vehicles representing a cross section of OEMs products. This investment alone will amount to in excess of $2 million, which will be dwarfed by the full extent of testing required to prove out products to meet the PC-11 specification. [EPA-HQ-OAR-2014-0827-1325-A1 p.10]

PC-11 lubricants are being designed to address the following needs: [EPA-HQ-OAR-2014-0827-1325-A1 p.10]

- Increased fuel economy and reduced CO2 emissions;
- Improved oxidative stability;
- Increased resistance to aeration;
- Increased wear protection;
- Increased shear stability; and
- Full compatibility with all existing and new vehicles. [EPA-HQ-OAR-2014-0827-1325-A1 p.10]

First licensing of PC-11 lubricants is expected by the end of 2016. The new PC-11 specifications will, for the first time, divide the market into two categories that are distinguished by their High Temperature High Shear (HTHS) viscosity. Most pertinent to the Phase 2 Rule, distinguishing lubricants by their HTHS performance and viscosities will allow truck users to improve their fuel economy by using the right oils. PC-11A oils will be higher viscosity HTHS fluids, and will replace the current CJ-4 oils with new formulations that offer higher levels of protection and performance. These oils will be backwards compatible, and will be suitable for all engines. PC-11B oils will be designed for new engines only—engines that are designed for thinner lubricants with better HTHS performance (i.e., lower HTHS viscosity rates) to maximize engine performance, durability, fuel economy, and emissions reduction. [EPA-HQ-OAR-2014-0827-1325-A1 p.10]

Table 1 summarizes some basic distinctions between PC-11-A and PC-11B: [EPA-HQ-OAR-2014-0827-1325-A1 p.10]

[Table 1 can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1325-A1]
It is worth noting that the PC-11 process is part of a broader move towards low HTHS lubricants that is occurring in both the U.S. and Europe. In both cases, OEMs are demanding cleaner and thinner lubricants that enable engines to deliver higher efficiency and lower emissions while maintaining or improving engine performance and durability. In the U.S., EMA initiated the drive to create PC-11 with its initial request to API in 2011. In Europe, the European Automobile Manufacturers Association (ACEA) is planning to update its current ACEA E6/E9 specifications in 2018 with F6-18 specifications to meet the demand for engines that deliver high efficiencies. It is reasonable to assume that these specifications may be updated again by 2027, providing the potential for even greater benefits in years to come.

It is worth noting that EPA and EU Euro emissions standards have been the catalyst for lubricant reformulations for many years. EPA’s 1998 heavy-duty engine standards and Euro II led to turbocharged engines that introduced higher temperatures and pressures that required improved thermal and oxidative stability. Euro III, Euro IV, and the EPA 2004 standards introduced retarded injection and exhaust gas recirculation, which created a demand for lubricants that delivered improved acid and corrosion control, as well as improved soot handling. Euro V and the EPA 2007/2010 standards led to the widespread use of selective catalytic reduction and diesel particulate filters, which set the stage for the current CJ-4 specification and its restrictions on sulfur, sulfated ash, and phosphorus. Today, API and its members are working together to develop PC-11 to help the OEMs meet the expected requirements of the Phase 2 program.

Summary of Comments Related to Engine Oils and Lubricants

As currently drafted, the Phase 2 Proposal does not mention the development of PC-11 for post-2017 engine oils and does not appear to anticipate its implementation and benefits. This has two ramifications:

- Assumptions of fuel economy and CO2 emissions reductions from the use of HPLs are based on CJ-4 lubricants in the market today, rather than PC-11 oils that will be in the market in 2017 and thereafter; and
- The Proposal does not include provisions to help encourage the use of PC-11B lubricants beyond the first use (the so-called “factory fill”).

As noted above, we expect that the proper use of PC-11B lubricants will improve fuel economy and reduce CO2 emissions by 1.5-2.0 percent in real world applications, compared to the baseline CJ-4 lubricants available today. As EPA and NHTSA consider the feasibility of the various alternatives proposed for the Phase 2 program, correctly assessing the benefits of the lubricants that will actually be in the market in 2017 and thereafter will be critical.

In addition, while it is to be hoped that OEMs will use PC-11B lubricants in their certification testing and factory fills, the Phase 2 Proposal does not take any steps to help ensure or encourage that these lubricants are used in certification testing, factory fills, or so-called “service fills” that happen throughout an engine’s useful life. It may be reasonable to assume that OEMs are adequately incentivized to use PC-11B lubricants in their certification testing and factory fills by the performance advantages of doing so. Because using PC-11B lubricants in service fills will maximize lubricant-related fuel economy and CO2 benefits, and will help ensure that no emissions degradation will occur over the oil drain interval and throughout the engine’s useful life, EPA and NHTSA should consider strategies to help ensure or encourage that PC-11B HPLs are properly used throughout an engine’s useful life.
There are many strategies that can be taken to help ensure or encourage that PC-11B HPLs are properly used throughout an engine’s useful life. Indeed, prior EPA emissions rules and other programs have used an array of strategies to help ensure the widespread use of emissions-cutting components in other contexts, including credits and other incentives, labeling, warranty requirements, sensors, onboard diagnostics (OBD) approaches, and even engine derating (e.g., when urea is not present in SCR systems). [EPA-HQ-OAR-2014-0827-1325-A1 p.12]

As EPA and NHTSA consider these comments and develop the final Phase 2 Rule, we would be very interested in discussing the range of possible strategies that might be appropriate to encourage or ensure that PC-11B lubricants are used throughout the useful life of Phase 2 engines. Selecting the right strategies will help ensure that the public reaps the full environment and health benefits of the Phase 2 program, and that truck fleets and users maximize the durability and performance of their engines. [EPA-HQ-OAR-2014-0827-1325-A1 p.12]

7 Shell, “PC-11: What is it all about,” June 10, 2015, slides 4 and 5.

11 A lubricant’s viscosity is defined as the fluid’s internal resistance to flow at a given temperature.

16 Howard, K. (2013)

17 Howard, K. (2013)

Along with new performance criteria, new tests will be introduced, including for oil oxidation, shear stability, and aeration.

"Beyond CJ-4: Introducing PC-11, the New HDDEO Performance Category.” HDDEO, Lubrizol. 

Response:

We appreciate Lubrizol’s comprehensive comments on lubricants. Although PC-11 has not been specifically mentioned in our rulemaking, any new technologies that can be measured and recognized during an engine dynamometer test will be accounted for in the engine’s GHG emission result. The reason is that the Phase 2 GHG rule allows OEMs to provide their own engine fuel maps that are measured by testing the engine on an engine dynamometer, which means that any technology, such as advanced lubricant, that can be accounted for by the engine fuel map test procedure would be accounted for while conducting vehicle certification using GEM. We also are finalizing the use of an axle test procedure to quantify the power loss; thus, the actual efficiency of the axle can be used to replace the default power loss specified by the agencies. Thus, the overall benefits to the vehicle will be recognized by the certification using GEM.

Organization: Manufacturers of Emission Controls Association (MECA)

Our industry and the regulatory agencies have invested significant resources to insure that the current structure delivers cost-effective and durable emission reductions. Manufacturers have made significant investments in developing engine-based technologies under the first phase of heavy-duty GHG standards that will continue to deliver environmental benefits under this second set of GHG regulations. Engine and powertrain CO2 reductions are verifiable and future OBD systems can be used to insure reductions over the life of the vehicle. The proposal includes a number of engine and vehicle technologies that demonstrate significant reductions but may not remain on the vehicle over its lifetime. These include, low friction lubricants, aerodynamic fairings, low rolling resistance tires among others. To achieve the goals of this regulation, we urge EPA to develop methodologies and policies that insure that the real emission reduction benefits from all technologies remain through the end of life and multiple owners of the vehicle.

There is a large set of technologies that can significantly reduce, either directly or indirectly, mobile source emissions of CO2, N2O (as well as other NOx emissions), CH4, and black carbon. A range of powertrain technologies can be applied to both heavy-duty gasoline and diesel powertrains to help improve overall vehicle efficiencies, reduce fuel consumption, both of which can result in lower CO2 exhaust emissions. In many cases, the application and optimization of advanced emission control technologies on advanced heavy-duty powertrains can be achieved in a manner that lowers overall fuel consumption while reducing criteria emissions. Our comments focus on available engine efficiency and exhaust emission control technologies and the impacts these technologies can have on greenhouse gas and criteria emissions.

Control of Black Carbon with Particulate Filters

Black carbon is a major component of particulate matter emissions from mobile sources and is believed to have a significant net atmospheric warming effect by enhancing the absorption of sunlight. Black carbon is a mix of elemental and organic carbon, in the form of soot, emitted by fossil fuel combustion, bio-mass burning, and bio-fuel cooking. Black carbon is a dominant absorber of visible solar radiation in the atmosphere. Anthropogenic sources of black carbon are transported over long distances and are most
concentrated in the tropics where solar irradiance is highest. Because of the combination of high absorption, a regional distribution roughly aligned with solar irradiance, and the capacity to form widespread atmospheric brown clouds in a mixture with other aerosols, emissions of black carbon are thought to be the second strongest contribution to current climate change, after CO2 emissions. The glacier retreat has accelerated since the 1970s and several scientists have speculated that solar heating by soot in atmospheric brown clouds and deposition of dark soot over bright snow surfaces may be an important contributing factor for the acceleration of glacier retreat. A study published in a 2009 issue of Nature Geoscience (vol. 2, 2009) by researchers from the NASA Goddard Institute and Columbia University found that black carbon is responsible for 50% of the total Arctic warming observed from 1890 to 2007 (most of the observed Arctic warming over this timeframe occurred from 1976 to 2007). [EPA-HQ-OAR-2014-0827-1210-A3 p.10]

It is estimated that 70% of the black carbon emissions from mobile sources are from diesel-fueled vehicles, with the assumption that 40% of gasoline PM is black carbon and 60% of diesel PM is black carbon. The black carbon concentration and its global heating will decrease almost immediately after reduction of its emission. Black carbon from diesel vehicles can be significantly reduced through emission control technology that has been required on every U.S. heavy-duty diesel truck manufactured since 2007. The basis for the design of wall-flow particulate filters is a ceramic honeycomb structure with alternate channels plugged at opposite ends. As the gases pass into the open end of a channel, the plug at the opposite end forces the gases through the porous wall of the honeycomb channel and out through the neighboring channel. The porous wall and the filter cake of particulate matter that forms within and on the surface of the wall serve as the filter media for particulates. Since the filter can fill up over time by developing a layer of retained particles on the inside surface of the porous wall, the accumulated particles must be burned off or removed to regenerate the filter. This regeneration process can be accomplished with a variety of methods including both active strategies that rely on generating external sources of heat (e.g., fuel burners, fuel dosing strategies that utilize fuel combustion over a catalyst, electrical elements, intake air throttling) and passive strategies that utilize catalysts that are displayed directly on the filter element or upstream of the filter. During the regeneration of DPFs, captured carbon is oxidized to CO2 but this filter regeneration still results in a net climate change benefit since the global warming potential of black carbon has been estimated to be as high as 2,200 times higher than that of CO2 on a per gram of emission basis. It is estimated that the installation of DPFs has reduced PM emissions from U.S. heavy-duty diesel vehicles by 110,000 tons per year. The ACES Phase 2 study that evaluated the PM emissions from 2010 technology heavy-duty engines showed that DPF equipped engines emit PM at one to two orders of magnitude below the current standard of 0.01 g/bhp-hr and deliver over 99% PM capture efficiency over their lifetime. MECA encourages EPA to develop policies and/or incentives that reward vehicle and engine manufacturers for employing technologies such as particulate filters that provide significant reductions in mobile source black carbon emissions. [EPA-HQ-OAR-2014-0827-1210-A3 p.10-11]

Looking ahead, transportation greenhouse gas emissions are forecast to continue increasing rapidly, reflecting the anticipated impact of factors such as economic growth, increased movement of freight by trucks, ships, and rail, and continued growth in personal travel. The transportation sector is the largest source of domestic CO2 emissions, representing 33% of the nation’s total in 2006. There are significant opportunities to reduce greenhouse gas emissions from the transportation sector through the design of fuel efficient powertrains that include advanced exhaust emission controls for meeting even the most stringent criteria pollutant standards being discussed today in California. These emission control technologies allow all high efficiency powertrains to compete in the marketplace by enabling these powertrains to meet current and future criteria pollutant standards. [EPA-HQ-OAR-2014-0827-1210-A3 p.14]
Response:

We appreciate MECA’s comments on control of black carbon with a DPF. We will work with MECA in the future to evaluate technologies such as particulate filters that provide significant reductions in mobile source black carbon emissions.

Organization: NAFA Fleet Management Association

Fleets are concerned about the incremental investment and operating costs of complex new engine technology. Putting excessive emphasis on the engine as a stand-alone component can result in costly engine technology that would bring little or no benefit in many real world applications. Fleets have already seen significant increases in vehicle costs and more expensive maintenance associated with increasingly complex engine and after treatment systems. Engines are best evaluated based on how they operate in the vehicle, considering the engine size and power output, the vehicle power demand, and the driveline characteristics – that is, by the full vehicle approach [NHTSA-2014-0132-0111-A1 p.1-2]

Response:

We understand that the NAFA comment is more or less related to a separate engine standard that could result in costly engine technology that would bring little or no benefit in many real world applications. We have extensively evaluated the benefits of all certification options, including with and without separate engine standards. We also received a large number of comments on certification options, specifically on whether a separate engine standard should be adopted. As one can imagine, opinions and recommendations are split. After taking all factors into consideration, we believe that a separate engine standard would be the best option. Section II of Preamble details our justification on why we are moving forward with a separate engine standard.

Organization: National Automobile Dealers Association (NADA)

Waste Heat Recovery

The Phase 2 proposal assumes that 15 percent of MY 2027 tractors will utilize waste heat recovery. This is a very aggressive assumption given that the technology is very costly, has only been used in demonstration projects, and is nowhere near production-ready. Given the cost, reliability, and design constraints associated with this technology, ATD suggests that the proposal’s MY 2027 tractor MPR for be revised downward to 2 percent. [EPA-HQ-OAR-2014-0827-1309-A1 p.7]

These technology uptake concerns should be taken seriously since, as mentioned above, real or perceived reductions in vehicle choice or increases in vehicle costs associated with questionable compliance technologies will cause commercial customers to avoid new tractors to the detriment of OEMs, suppliers, dealerships, and the Phase 2 public policy objectives. [EPA-HQ-OAR-2014-0827-1309-A1 p.7]

Response:

Downtime and cost are two of the many key concerns, specifically for an emerging technology that has not been extensively tested in the market. At the same time, others are pushing for a lot more aggressive market penetration. We received data and CBI information from one engine manufacturer as well as public comments (EPA-HQ-OAR-2014-0827-1298) that shows that their WHR system could be put into production in 2021 timeframe. Given their large market share in the class 8 engine sector, a 25% market
share utilizing WHR by 2027 is certainly possible. In addition to our response in RTC Section 3.4.1 below, Chapter 2.3 and 2.7.5 of the RIA details the justification.

**Organization:** Navistar, Inc.

- Lubricants, though efficient, have long lead times for development and adoption; usage of certain lubricants can bring lifetime cost impacts and can require changes to hardware to support newer lubricants

**Response:**

We recognize the issue associated with lubricant, specifically on its reliability and cost that can result in a long lead time. Because of this reason, we carefully lump this technology together with friction and parasitic loss reduction into one technology package, where the effectiveness is only 1.4%. See also response to Lubrizol in this section.

**Organization:** Navistar, Inc.

Walsh and Charlton’s claims and recommendations were summarized as 11 major findings and are focused on tractor engines. In the proposed Phase 2 regulations, these engines are certified in the ramp modal cycle (RMC) for CO2 and the FTP for the other GHG constituents. The NPRM also proposed a reweighing of the modes in this cycle that departs from that used for criteria pollutants, but that aim to align the engine standard to the real world or in-vehicle usage of these engines. In the following, Navistar highlights the major concerns with the authors’ findings. [EPA-HQ-OAR-2014-0827-1919-A2 p.9]

**Finding 4:** In as much as the rule is intended to be technology-forcing, it cannot also be technology-selecting. The premise of SuperTruck, for example, was to result in a wide breadth of technologies that would then be evaluated for production and commercial feasibility in order to achieve engine and vehicle efficiency improvements. The authors specifically challenge the EPA’s adoption rates for waste heat recovery (“WHR”). In WHR systems efficiency is tied to sourcing the highest \( \Delta T \) or \( \Delta P \) from the engine systems. With the expected increases in the engines’ base BTE over the lifetime of this rule, there will be a resulting reduction in available “waste” pressure and temperature or potential for waste heat recovery. The rule itself becomes a dis-synergy to this technology. This is further compounded by the proposed reweighting of the RMC, which reduces the weighting in the rated speeds and loads where the WHR has the highest potential, but reflects the integration of the engine with the vehicle drive cycle. Furthermore, the agencies have found it is critical to include adoption rate, based on experience from previous rulemaking and the need to truly have an environmental impact. [EPA-HQ-OAR-2014-0827-1919-A2 p.12]

Beyond the benefit being significantly less than originally proposed, the cost is still prohibitively high. Additional concerns for the vehicle manufacturers include the following: [EPA-HQ-OAR-2014-0827-1919-A2 p.12]

- WHR working fluids have a significant GHG impact based on their high GWP
- Packaging and weight penalty will negatively impact the aggregate freight efficiency

Unlike SCR technology, which was deployed in Europe prior to adoption in the US, there are no commercially available systems of this technology in production at this time in mobile source application.
Given the size and complexity of the system, its application in a mobile platform is not ideal. The agencies’ assumed penetration rates acknowledge that there are still major developments needed to make this a commercially viable solution, but are encouraging the continued investigation for a longer term objective. [EPA-HQ-OAR-2014-0827-1919-A2 p.12]

Finding 5: The technology path proposed to achieve the GHG Phase 2 NPRM targets for engine already includes technology improvements in combustion. However, the advanced combustion processes such as HCCI, PCCI, low-temperature combustion and RCCI (reaction controlled compression ignition) were excluded as these are not commercially feasible now or in the Phase 2 timeframe. Though these processes have been demonstrated in laboratory environments, in the case of HCCI for over 20 years, production feasibility has yet to be demonstrated due to the breath of conditions and variability in the real world. Moving these technologies from the laboratory to the production environment requires advances in control strategies, sensor sets and manufacturing processes in order to ensure robustness and reliability. [EPA-HQ-OAR-2014-0827-1919-A2 p.13]

In addition, although some of the different combustion regimes show strength in certain areas of an engine operating map they are not applicable to the entire map. This will translate into limited improvement with no payback. In Navistar’s experience, some of these processes (e.g., PCCI and low-temperature combustion) have been demonstrated to be effective in criteria pollutant control, but have been demonstrated to increase the CO2 emissions in key areas of the operating regions of the engine map. [EPA-HQ-OAR-2014-0827-1919-A2 p.13]

Finding 6: The authors argue that this downspeeding technology should be accounted for in the engine standard rather than on the vehicle standard. Downspeeding is when the vehicle powertrain matched in such a way that the engine operates at a lower engine speed, but higher torque. This results in a net improvement in fuel consumption due to lower parasitic losses and higher BMEP operation for the engine. Without the adequate powertrain match, the gains cannot be achieved. Thus, it is appropriate to have downspeeding as currently included in the proposed Phase 2 NPRM in the vehicle standards, as it is a technology that requires the integration with vehicle and is not possible with just an engine. Demonstration of the benefits of downspeeding requires the definition of entire drivetrain and how it operates over the prescribed vehicle drive cycles. [EPA-HQ-OAR-2014-0827-1919-A2 p.13]

Finding 8: Costs included in Phase 2 RIA from the agencies are underestimated for the technology selection, deployment and validation of a fully US compliant 1 Million-mile vehicle. The DOE sponsored SuperTruck program has definitely been instrumental to OEMs in understanding the possibilities in bridging the gap between today’s products and the product needs of the future as driven by the GHG regulations. However, the majority of the technologies are in their infancy and have not been assessed to the full extent that is needed for commercialization and real world operation. The technologies demonstrated in the SuperTruck program need to be vetted for full tailpipe compliance, OBD compliance, real world robustness, customer acceptance/satisfaction, and reliability/warranty impact. [EPA-HQ-OAR-2014-0827-1919-A2 p.13]

With any technology-forcing standard, selection of the enabling technology for commercialization has many facets including: customer acceptance, cost/affordability, technology maturity, packing and weight, manufacturability, reliability and supporting infrastructure. Supporting infrastructure for the technologies is one of the first hurdles. For example, it was clear that to enable PM control to the regulatory-required level, the Sulphur content of diesel fuel needed to be reduced. Beyond being a significant cost to the petrochemical companies to change the production of fuel, there were unintended and unaccounted consequences to this change. Sealing technologies that were tried-and-true in engines had to be
redeveloped for the new fuel. These costs are difficult to estimate. [EPA-HQ-OAR-2014-0827-1919-A2 p.13-14]

Also, as technologies are developed toward production, the commercial aspects start to weigh more and can change the course of technology adoption. For example, as the 2007/2010 tailpipe rules were being finalized, the NOx control technologies were less understood and Lean NOx Trap (LNT) was envisioned as the primary technology. SCR, which was the prevalent, in-production NOx control strategy in Europe, was not the envisioned technology. This was primarily because catalyst durability along with perceived issues with DEF (cost, availability or infrastructure, freezing/thawing issues, additional need for on-board fluid, etc.). In the end, PGM (platinum group metal) costs associated with the technology and its complexity and durability of the LNT for the HD market quickly let to reconsideration of SCR. However, the deployment of SCR into the US market still had its own significant challenges given the extent of US regulations, which have lower NOx standard, wider ambient condition NTE requirements and the EPA’s concerns with the substrate technology in Europe. Hence, this case shows that even a technology already in production in another market still poses unknown or unaccounted risks in the commercialization. Cost estimates in the rulemaking stage are typically under predicted. [EPA-HQ-OAR-2014-0827-1919-A2 p.14]

Finding 11. Charlton and Walsh argue that the agency arbitrarily assigned a dis-synergy factor to the composite benefit of the technologies identified in the roadmap. They almost seem to argue that dis-synergies do not exist. The dis-synergies do exist and it is unrealistic to definitively assign values without prescribing the design and system functions of all individual engines. The implementation of 2014 compliant engines is extremely varied across all OEM’s. Although the technologies are all the same – combustion improvement, EGR and SCR – the implementations are highly varied from fuel systems with different characteristics, fixed to variable geometry turbo chargers and even the displacement selections of the engines. In such a case, it is difficult to precisely estimate the dis-synergies of a set of technologies without detailed understanding of a given engine’s system design. [EPA-HQ-OAR-2014-0827-1919-A2 p.15]

A strong example of dis-synergy is the implementation of WHR as discussed earlier. As the engine becomes more efficient to meet the proposed rule, there will, by definition, be less waste heat available to extract from these systems. Increased cylinder pressure and fuel injection pressures are also counter to friction reduction assumptions and again very specific to the particular design and architecture of a given engine. The dis-synergy factor is an appropriate acknowledgement by the agencies that the technologies are not simply additive. [EPA-HQ-OAR-2014-0827-1919-A2 p.15]

Response:

We appreciate Navistar’s comments together with other reports, such as the one from four major vehicle OEMs - Daimler Trucks North America, Navistar Inc., Paccar Inc., and the Volvo Group. We largely agree with the assessment on DOE’s SuperTruck program. We also appreciate Navistar’s comments on many items, including WHR, HCCI, PCCI related combustion, downspeeding, and dis-synergy. This report has helped us to justify why we cannot use the Charlton/Walsh report as the basis to increase the stringency of the standard to the level they recommended. See the response to EDF in Section 3.3.1 above.

Organization: Owner-Operator Independent Drivers Association (OOIDA)

Among the technologies listed under Alternative 3, where the agencies believe CO2 emissions and fuel consumption could be improved, were: [EPA-HQ-OAR-2014-0827-1244-A1 p.11]
Waste Heat Recovery

The agencies proposed phase-in standards from 2021 through 2027 for OEMs to gradually introduce various technologies, one of which is waste heat recovery (WHR). EPA assumes that WHR will cost up to $11,000, but because this technology is not currently available in any production form, the actual costs are unknown and more than likely much higher than EPA has estimated. Though the technology has some promise, its potential benefits are dependent upon many confounding variables. According to the researchers at the Southwest Research Institute, no all duty cycles can expect to benefit from WHR. Again, this speaks to the diversity of the trucking industry, while also demonstrating the unsuitability of forcing technology. It is important for the agencies to remember that while OEMs may utilize WHR to receive credits, the customers will more than likely never actually benefit from this technology. This is especially likely with Alternatives 3, 4, and 5. [EPA-HQ-OAR-2014-0827-1244-A1 p.30]

Ultimately, with multiple fluid pumps, additional hoses, and heat exchangers, the WHR system has a great potential for failure. Until more is known and understood about WHR and until more real-world data is collected, OOIDA suggests that WHR not even be considered as part of Phase II. With an estimated 200 parts, this technology is certain to be expensive to purchase and maintain, and will add a notable amount of weight to the vehicle, thus WHR would be counter-productive to the agencies proposal to reduce weight. This as-yet-developed technology is so far from even being tested to determine if it actually will work in a class 8 truck environment those who are testing it continue to drastically alter the very method in which they propose to capture the waste heat. It is doubtful that any owner-operator would risk purchasing a truck with such a technology, which will once again prime the market for a pre-buy or no-buy situation. [EPA-HQ-OAR-2014-0827-1244-A1 p.30-31]

Response:

Downtime and cost are two of the key concerns, specifically for an emerging technology that has not been extensively tested in the market. As explained in RIA Chapter 2.3.9, the agencies have outlined a path forward to resolve technical issues within the lead time provided by the final rule. In addition please see our response in RTC Section 3.4.1 below. With respect to issues related to cost of the technology, see RIA Chapter 2.11.2.15.
Meeting Alternative 3 Engine Stringency will Require Use of New Technologies

EPA and NHTSA set stringency levels for vocational and tractor engines at 4% and 4.2%, respectively. These standards, when viewed against PACCAR’s current engine performance and the available existing technologies that can improve the engine’s performance, will require the development and implementation of new technologies. Some of the technologies envisioned by the Agencies for meeting the stringency, such as waste heat recovery, turbo compounding, low delta pressure aftertreatment system, and model-based controls, are not at the prototype level for PACCAR and other OEMs. Technologies like waste heat recovery are technically sophisticated and will require a longer lead time for development, OEM testing, field reliability growth to ensure a robust product for the customer. PACCAR anticipates that meeting these standards will be possible, but doing so will be challenging and will require all of the lead-time provided in Alternative 3. As discussed below, meeting the same standards within the more accelerated timeframe of Alternative 4 would be infeasible. [EPA-HQ-OAR-2014-0827-1204-A1 p.3-4]

As a result of this assessment, PACCAR recommends that the Agencies finalize the Alternative 3 engine standards as they are proposed in the NPRM. [EPA-HQ-OAR-2014-0827-1204-A1 p.4]

Response:

We have received a large number of comments from the public as well as CBI from individual companies in response to the NPRM. As one can imagine, opinions and recommendations are split in terms of the stringency of engine standards. Taking all factors into consideration, we have made many changes to the engine standards that were proposed. On the vocational side, we changed the baseline engine to reflect the most recent certification data. The detailed vocational engine stringency and its baseline engine standards can be found in Chapter 2.7 of the RIA; see also RTC Section 3.3.3. For tractor engines, new information allowed us to increase the dis-synergy factor from 0.85 to 0.9 in 2027, and increase the market projected penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and included down speed benefits for engines. As a result of this, the 2027 MY tractor engine standards’ projected stringency over the baseline increased from 4.2% (proposal) to 5.1% in 2027. We have also identified ways in which greater reductions would be feasible in 2024. Chapters 2.3 and 2.7 of the RIA detail the justification of these increases. Thus, we do not agree with Paccar that meeting the 4.2% standard within the more accelerated timeframe of Alternative 4 would be infeasible, and are adopting 2024 standards that are equivalent to the Alternative 4 engine standards for MY 2024.

TRACTOR ENGINE STRINGENCY

There are four key issues in the agencies’ analysis that lead to an engine standard that is far more conservative than can be achieved in the timeframe of this rule: the use of a dis-synergy factor, an underestimate of the effectiveness of technologies applied, discounting the benefit of a revised test cycle, and the exclusion of downspeeding. Accounting for these four factors would raise the effective engine standard in the preferred alternative from 3.7 percent in 2024 up to 9.0 percent compared to the baseline performance given in the NPRM. Using the agencies’ assumed technology penetration rates, these factors would raise the engine standard up to 10.3 percent relative to the assumed baseline in 2027; however, the agencies are likely underestimating the potential uptake for waste heat recovery in this timeframe. [EPA-HQ-OAR-2014-0827-1329-A2 p.6]
Dissynergy. Because the agencies cannot model every possible engine configuration for every manufacturer, they have utilized a generic baseline engine map and then applied, via multiplication, the effectiveness of different technologies on this map: \( \%\text{FE}_{\text{Total}} = 1 - (1 - d) \times f \times \%\text{FE} \), where \( f_i \) represents the fraction of engines with technology \( i \) and \( d \) is the dissynergy factor. The agencies’ dissynergy factor is equal to 25 percent in the earliest years and 15 percent in the later years. [EPA-HQ-OAR-2014-0827-1329-A2 p.6]

The dissynergy factor is meant to discount the effects of combining different separate technologies, since some technologies may be trying to reduce the same type of energy losses and therefore will not simply add. However, it is rarely applied in the technology-independent manner that the agencies have used in assessing the potential for engine reductions, since many technologies may be unaffected by the application of an additional technology—for example, the effectiveness of improving the efficiency of the turbocharger is unlikely to be affected by the effectiveness of reducing engine friction. In fact, in some cases the application of two technologies can even have a synergistic effect, where the complementary fuel reductions result in an overall effectiveness beyond the individual technologies—this is often the case when considering technologies applied to both the engine and vehicle, like cylinder deactivation and load reduction. [EPA-HQ-OAR-2014-0827-1329-A2 p.6]

Because synergy/dissynergy is dependent upon specific technology interactions, it is preferable to consider modeling the technology packages separately. Recent research by the Southwest Research Institute (SwRI), commissioned by NHTSA for the express purpose of informing these regulations, helps shed light on whether the agencies’ use of a dissynergy factor is appropriate. In the first report issued by SwRI, the effectiveness of 20 different tractor engine technologies was examined (Reinhart 2015a). In the second report, these different technologies were combined into 11 different engine packages (Reinhart 2015b). By comparing the multiplicative model noted in the formula above and the modeled package results, we can assess what dissynergy is present, if any, in these technologies. [EPA-HQ-OAR-2014-0827-1329-A2 p.6]

It should be noted that not all technologies applied in the packages were analyzed separately in the first report, so we have trimmed the selection to six specific packages: 2019 Baseline DD15, Package #1 (2019 DD15 + friction reduction), Package #2 (2019 DD15 + Downsampling B + 50% friction reduction), Package #3 (Package #2 + H2O bottoming cycle), Package #3a (Package #2 + R-245 bottoming cycle), Package #4 (2019 DD15 – EGR, – turbo compounding, with fixed geometry high-efficiency turbocharger), and Package #5 (2011 DD15 + optimized turbo compounding + Downsampling B + 50% friction reduction + optimized combustion + air handling). In the case of the 50% friction reduction, we have modeled the effectiveness of this as \( 1 - (1 - \%\text{FEFR})^{1/2} \), which when applied twice would thus equal \( \%\text{FEFR} \). We have modeled the 1% combustion improvement of the 2019 DD15 engine and Package #5 as a simple 1-percent improvement in fuel consumption. [EPA-HQ-OAR-2014-0827-1329-A2 p.6-7]

[Figure 1, ‘Comparison of Package Effectiveness’, can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

The results of the multiplicative method compared to the fully simulated packages are shown in Figure 1. Here we have used the results on all five drive cycles modeled (CARB Transient, 55 MPH steady state, 65 MPH steady state, World Harmonized Vehicle Cycle, and the Northeast States Center for a Clean Air Future cycle) under three different load conditions (0-, 50-, and 100-percent load) to assess fifteen different datapoints for each of the six packages. As is evident from the data, the majority of the data falls below the x=y line—this actually means that, on average, we find evidence for a net synergy, in stark contrast to the agencies’ assessment. Fitting to the data, we find that the simplified multiplicative
approach underestimated the fully simulated package model results by 6 percent, on average—this is in direct contrast with the agencies’ use of a blanket dissynergy factor. Furthermore, the few datapoints that show some dissynergy are almost exclusively either the 2019 DD15 baseline or Package #5, run over either the CARB Transient or NESCCAF cycles—this suggests that rather than a dissynergy, it is much more likely that our simplistic assessment of the 1% combustion improvement is invalid under heavy transient operation. [EPA-HQ-OAR-2014-0827-1329-A2 p.7]

Based on the data in Figure 1, we find no supporting evidence for the agencies’ use of a dissynergy factor in combining engine technologies. Removing the broad application of the dissynergy factor would raise the value of the proposed engine stringency in 2027 to 4.9 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.7]

Technology effectiveness. In addition to the synergy between technologies, the agencies have not appropriately considered the effectiveness of the technologies themselves. Despite the thorough work by Southwest Research Institute commissioned by NHTSA, the agencies have assumed levels below this work in nearly every technology examined.1 In many cases, this effectiveness is also inconsistent with public data from the industry. [EPA-HQ-OAR-2014-0827-1329-A2 p.7]

Friction reduction was noted as an exceptionally effective technology in the SwRI analysis initially (Reinhart 2015a), and the conventional engine package in the follow-on study yielded an improvement of 3.3 percent over the 2018 baseline engine. This is significantly beyond the agencies’ 1.4-percent improvement. [EPA-HQ-OAR-2014-0827-1329-A2 p.7]

Combustion controls are expected to advance considerably over the timeframe of the rule, with industry estimating possible improvements of between 1 and 4 percent, with an industry average of 2.5 percent (Lutsey et al. 2014). The agency’s assessment of 1.1 percent is obviously again at the low end of this scale. [EPA-HQ-OAR-2014-0827-1329-A2 p.7]

The effectiveness of turbo compounding varies widely by engine manufacturer, as some companies may be implementing this already in engines today, while others may not see this as part of their product plan; estimates range from 0.5 to 5 percent, with an average of about 2.3 percent. SwRI analysis finds that an optimized turbo compounding engine package could achieve a 5.8 percent improvement over the 2018 baseline, 2.6 percent better than improvements to combustion and friction reduction alone and higher than the agencies’ assumption of 1.8 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.7]

Organic waste heat recovery is challenging to assess because only one manufacturer is currently planning on deploying these engines ahead of the 2021 rule, while others are still at the demonstration stage. However, the SuperTruck program has shown great promise, and industry assessment estimates that it holds the potential for between 2- and 8-percent improvement, with an average of 5-percent improvement (Lutsey et al. 2014). The package that is furthest along in development involves a recuperator and uses a refrigerant as the working fluid— SwRI modeling of this package yields a total improvement of 9.2 percent for the engine package, or 4.4 percent from the waste heat recovery system alone. This again exceeds the 3.6-percent improvement estimated by the agencies. [EPA-HQ-OAR-2014-0827-1329-A2 p.7-8]

Even while maintaining the agencies’ dissynergy factor and penetration rates, these adjusted technology effectiveness values would raise the engine standard from 4.2 percent to 6.1 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.8]
Downspeeding. Downspeeding is a strategy used by manufacturers to reduce fuel usage from the engine by operating at a lower speed, which reduces parasitic and friction related losses. This recent trend has been enabled by a move by the industry towards more automated manual transmissions, which can help keep a narrower gear spread at the highest gears without having to worry about issues like driver fatigue. It also requires axles designed to handle a greater torque at low speed. [EPA-HQ-OAR-2014-0827-1329-A2 p.9]

While the agencies acknowledge the benefits of downspeeding on the vehicle side, they have not considered the benefits of downspeeding at the engine level. This is at odds with the actual design process—engines are designed to operate within a specific range of speeds, especially at high load. Downspeeding typically results in an engine that operates with higher torque at low speeds to generate the same power, often operating in a narrower range of speeds at peak power (Figure 2). This changes the torque curve, resulting from the manufacturer’s desire to maintain the level of performance for its users while shifting the cruise speeds lower. Shifting the torque curve would also shift the A, B, and C speeds of the SET cycle, which is used for both greenhouse gas and criteria emissions testing. [EPA-HQ-OAR-2014-0827-1329-A2 p.9]

[Figure 2, 'Comparison of Downspeed Engines', can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

The agencies’ engine maps for 2018, 2021, 2024, and 2027 all maintain the same torque curve and therefore the same SET A, B, and C speeds. Despite assuming the engine will be run at lower speeds over time, the agencies have not chosen to adjust the torque curve accordingly—this may be allowable because the power demands of the regulatory cycle are not particularly severe, but it is not reflective of real world engine design. This is problematic because on the vehicle side, they alter the drive axle ratio to shift the cruise speed by 16 percent, down from 1500 rpm to 1300 rpm at 65 mph. For reference, we calculate the SET cycle speeds for the EPA engine to be A = 1233 rpm, B = 1515 rpm, and C = 1797 rpm, with the “not-to-exceed” (NTE) zone thus starting at 1120 rpm. With the 2027 axle ratio and default transmission gearing, the 55mph cruise speed is at 1100 rpm in overdrive—at this speed, the vehicle would actually be operating outside the NTE zone used for criteria emissions. This is true only because of the way in which the agencies have treated downspeeding. [EPA-HQ-OAR-2014-0827-1329-A2 p.9-10]

It should also be noted that the agencies’ 2018 cruise speed of 1500 rpm is exceptionally high compared to the performance of even today’s powertrains (Table 2). The agencies’ torque curve for 2018-2027 matches that of the Detroit Diesel DD15 engine, yet the 2014 model of that engine already is meant to operate today at speeds lower than the agency is targeting in assessing stringency. This is even more drastic when compared to other popular Class 8 engines. [EPA-HQ-OAR-2014-0827-1329-A2 p.10]

[Table 2, 'Comparison of Tractor Engine Speed', can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

Downspeeding ultimately is linked to engine design and must be reflected in engine stringency to ensure that there is no gaming occurring between criteria emissions and greenhouse gas emissions testing. The SwRI modeling identified an additional 1.8-percent improvement in efficiency for the downspeed engine package compared to friction and combustion improvements alone (Reinhart 2015b). This would revise the engine standard up to 6.0 percent from 4.2 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.10]

Advanced technology penetration. The agencies have estimated a 15-percent penetration rate for Rankine cycle waste heat recovery and a 10-percent adoption rate for turbo compounding (NPRM p. 40197)—higher adoption rates are feasible by 2027. Both turbo compounding and Rankine cycle waste heat
recovery are designed to capture energy from the exhaust and are most effective in highway operation. However, Cummins has presented data indicating nearly the same levels of performance for a regional-haul cycle as line-haul operation (Salemme 2014), which means this technology could see application beyond the long-haul sleeper cabs assumed in the agencies’ analysis. Furthermore, a 25-percent application represents just half of all line-haul trucks, assuming no application in regional haul, yet a significant number of vehicles are already on the road with mechanical turbo compounding offered by both Detroit Diesel and Volvo, and Cummins is expected to roll out small numbers of Rankine cycle-powered vehicles before the rule even begins (Lockwood 2015). Therefore, the agencies’ assumed penetration rates do not correspond to a “technology-forcing” standard, and adjusting these to reflect what the market is already primed to do on its own would result in a much more stringent standard, by as much as 3 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.10]

1 While the SwRI modeling study did not directly model the effects on the SET cycle, we are considering technology effectiveness as represented by a 50/50 split of the regulatory cycles for day and sleeper cabs, since the ARB transient and 55-mpg and 65-mpg cruise cycles were all modeled by SwRI.

Response:

We appreciated the commenter’s constructive comments, specifically on down speeding. However, we do not believe that 10.3% increase in 2027 per commenter’s recommendation is feasible. Also, we do not believe that the commenter properly used SwRI’s data to deduce the dis-synergy factor, because SwRI made a correction to the 2019 baseline engine results, which changes all of the conclusions the commenter made. First of all, the data quote from the commenter mainly relies on the literature, including DOE SuperTruck programs. The values from the literature are single optimal operating points and not operation over the entire engine map. Further, those values were demonstrated in an R/D environment. In contrast, we consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point. Technology effectiveness is also not additive. Chapter 2.7.5 of the RIA details justifications of dis-synergy used in the rule. These justifications were also supported by many industry comments, such as the reports made by four major vehicle OEMs (EPA-HQ-OAR-2014-0827-1894) as well as other comments made by individual vehicle OEMs (Daimler Truck North America and Navistar). See response to EDF in Section 3.3.1 above. The technology effectiveness of WHR in Rankine cycle used by the agencies, which is less effective than what commenters (including this commenter) recommended, were directly obtained from credible, but CBI information, based on the recommendation from a leading engine manufacturer. It is critical to derive the standards based on the agencies’ weighting factors over 13 modes, vehicle weight,
and three vehicle certification cycles. Thus, the adjusted values for stringency are typically much smaller than the values seen in the literature. Having said that, we have made changes to make the standards more stringent than those proposed. In the final rule, we readjusted the baseline of the engine standards to reflect the reweighting impact. Chapter 2.7.4 of the RIA details the change in the baseline. We made a few key changes on engine standards. For tractor engines, we increased the dis-synergy factor from 0.85 to 0.9 in 2027, and increased the market penetration rate for WHR Rankine cycle technology from 15% to 25% in 2027, and include down speed benefits for engines. As a result of this, the 2027 MY tractor engine standards’ projected stringency over the baseline increased from 4.2% to 5.1%. Chapters 2.3 and 2.7 of the RIA detail the justification of this increase. We also increased the stringency of the vocational vehicle standards from those proposed.

**Organization:** United Parcel Service (UPS)

The specific market penetration rates that concern UPS, given our particular fleet, are listed below and UPS strongly recommends reduction of these MPRs: [EPA-HQ-OAR-2014-0827-1262-A1 p.4]  

**Waste Heat Recovery (projected 15% in 2027)**

UPS agrees generally with the comments of the American Trucking Association on this issue. Specifically, UPS favors a successful rulemaking for Phase II, but urges that the technologies offered in compliant trucks are fully tested, verified, and affordable before adoption. UPS keeps its class 8 tractors for 10-12 years, unlike many in our industry, and so durability is a major factor for us. So is maintenance. Our engineers' review of the current state of WHR technology gives us little basis for confidence in the WHR approach at this point, especially given the magnitude of the improvement in efficiency that the proposed rule hopes to achieve relative to other technologies. Note that UPS is very familiar with the SuperTruck program and its prototype usage of WHR. Reliance on WHR in the final rule will necessitate compliance margins that the proposed rule does not contain now. [EPA-HQ-OAR-2014-0827-1262-A1 p.4]

**Waste Heat Recovery**

UPS agrees with the ATA on their following comments: [EPA-HQ-OAR-2014-0827-1262-A1 p.7]

The agencies assume that Waste Heat Recovery ('WHR') technology will cost $10,523 in 2021. The only WHR system of which we are aware is a prototype in the SuperTruck. Because waste heat recovery is not currently in the market, the actual costs remain unknown. Some OEMs state the cost is actually higher than this figure, while another OEM says it is over-inflated. Perhaps these differences reflect varying perceptions as to prospective business opportunities. This wide-ranging pricing uncertainty should raise a cautionary flag to the agencies. WHR is the highest cost menu item under the current heavy-heavy duty engine technology listings. The agencies must be more transparent in how they derived such cost figures given how some OEMs are contesting these projections. As you can imagine, these cost uncertainties have only escalated fleet concerns over future pricing of equipment under Phase 2. [EPA-HQ-OAR-2014-0827-1262-A1 p.7]

UPS is also concerned about the heavy reliance the agencies place on the penetration of this technology in the market. [EPA-HQ-OAR-2014-0827-1262-A1 p.7]
Response:

As already acknowledged, downtime and cost are two important concerns, specifically for an emerging technology that has not been extensively tested in the market. In addition to our response in RTC Section 3.4.1 below, see RIA Chapter 2.3.9 (and especially RIA at p. 2-17) indicating how WHR can be brought to market reliably within the lead time provided by the final rule.

Organization:  Volvo Group

Future Technology

If we consider the example of waste heat recovery, full scale development is estimated at $130 Million from proof of concept to market launch, with an expected development project period of 6 years. Volumes can be determined from Volvo Group’s expected Sleeper Tractor production and taking the expected penetration rates of from Table II-6 and fitting a curve to interpolate volume growth between stringency steps and extrapolate to MY2030. Assuming the project costs are spread evenly over the project period and series production starts in engine MY 2021, Volvo Group would need to charge nearly $21,700 per unit over the ten year regulatory period just to recover the R&D investment and cost of capital. [EPA-HQ-OAR-2014-0827-1290-A1 p.36]

The Agencies’ estimate that WHR will provide a 3.6% SET weighted improvement (Table II-6 of the Preamble). In a typical line haul application of 125,000 miles per year and a $3.98 fuel cost a 3.6% improvement is worth ~$2,520 per year with a customer expected payback period of no more than 18 months, thus the market price for the 3.6% fuel economy improvement would be no more than $3,780. Given the estimated $21,700 per unit cost, Volvo Group would lose $17,920 per unit on R&D alone, without regard to material costs, sales and administrative expense, production costs, or even considering Volvo Group expects payback and profit within 5 years. [EPA-HQ-OAR-2014-0827-1290-A1 p.36]

The Agencies, however, determined a cost for WHR of $10,500 in 2012 dollars in MY2021 (Preamble Table II-8), which is inclusive of all direct and indirect costs and markup. [EPA-HQ-OAR-2014-0827-1290-A1 p.36]

Response:

Given our adoption rates for WHR and our estimated costs along with projected sales, we estimate total costs of WHR ranging from $10.3 million in MY2021 up through $188 million in MY2027 and then $166 million in MY2030 (the slight reduction in costs being attributable to learning). The cumulative total costs would be roughly $850 million. Using our ICMs, and the RPEs upon which they are based as a guide, then the cumulative total R&D would be $30 million to $40 million. This amount is below the $130 million suggested by the commenter. This could mean one or more of the following: we have underestimated costs; we have underestimated adoption rates; Volvo should not enter the market with a WHR system. We believe that our WHR cost estimate is sound, and would have preferred that the commenter provide an estimated technology cost for WHR rather than a development estimate since that development estimate, presumably, would pay dividends in other areas not fully attributable to WHR and/or this final rule. If development costs are truly that high, then perhaps other technologies will be chosen to meet the demands of the new standards. Importantly, we have put forward what we believe to be a reasonable path to compliance but do not mean to suggest that it is the only path or that Volvo must choose that path. In 2015, Volvo reported R&D of roughly 15 billion Swedish Krona (SEK, or $1.8 billion). (15 billion SEK from “The Volvo Group Annual And Sustainability Report 2015, page 80; conversion to USD using factor of 0.12 USD to 1 SEK via google.com on 6/23/2016) If we simply use
that value, we could estimate Volvo’s R&D at roughly $17 billion over the years 2021 through 2030. For WHR, $130 million would represent less than 1 percent of R&D.

**Organization:** Walsh, Michael and Charlton, Stephen

The standards set for HD tractor engines fall well short of being “technology advancing” – the original stated goals of the rulemaking: [NHTSA-2014-0132-0102-A1 p.6]

“This technology-advancing program would phase in over the long-term, beginning in the 2018 model year and culminating in standards for model year 2027, responding to the President’s directive on February 18, 2014, to develop new standards that will take us well into the next decade.” [NHTSA-2014-0132-0102-A1 p.6]

The agencies have underestimated the potential of key technologies when setting the GHG emission and fuel consumption standard for HD tractor engines, in particular: waste heat recovery (WHR), advanced combustion and engine downspeeding. [NHTSA-2014-0132-0102-A1 p.6]

**Finding 4**

WHR technology is an important component of the technology package that can deliver a 15% or greater reduction of GHG emissions and fuel consumption by 2027, as recognized by NAS 21CTP Report #3, September 11, 2015 [41]: [NHTSA-2014-0132-0102-A1 p.6]

“The 21CTP has successfully met Goal 1, to develop and demonstrate an emissions compliant diesel engine system for Class 7 and 8 highway trucks that achieves 50 percent brake thermal efficiency in an over-the-road cruise condition. The engine uses a waste heat recovery system.” [NHTSA-2014-0132-0102-A1 p.7]

In the Draft RIA WHR was effectively eliminated by the agencies because of assumed adoption rates and outdated and illogical cost assumptions: [NHTSA-2014-0132-0102-A1 p.6]

“We consider this technology to be on the flat portion of the learning curve (curve 12) because although waste heat recovery is a new technology and in the 2015 to 2017 timeframe remains, perhaps, on the steeper portion of the learning curve, applying such rapid learning effects to the cost estimate we have would result in costs too low in the MY2024 to 2027 timeframe.” Draft RIA section 2.12.2.15 [15] [NHTSA-2014-0132-0102-A1 p.7]

The agencies used cost data from 2009 developed by TIAX [36] and reported by Tetra Tech. Inc. [44], thereby penalizing the technology with unrealistically high costs. WHR was then effectively eliminated from consideration when the assumed adoption rate was set at only 15% in 2027. [NHTSA-2014-0132-0102-A1 p.7]

The role of ‘adoption rate’ in this rulemaking should be questioned. Since the regulation is intended to drive the introduction of technology beyond that which normal market forces would achieve, the only valid meaning of ‘adoption rate’ is in determining which real world applications should logically be included and excluded on the basis of effectiveness. In the case of WHR there is broad agreement that line-haul tractor trailer applications and heavy-haul applications (at least) will benefit from adoption of
WHR. These applications form a high percentage of the Class 7-8 fleet (greater than 65%). [NHTSA-2014-0132-0102-A1 p.7]

**Finding 5**

Advanced combustion was eliminated from consideration – “since the agencies do not anticipate these technologies will be commercially available by 2027” [15] Draft RIA section 2.3.2. Given the significant research effort on advanced combustion (Appendix A) and the progress being demonstrated [27,28,31], the agencies should at the very least allow for incremental improvements being transferred from this work into products released in 2021, 2024 and 2027. [NHTSA-2014-0132-0102-A1 p.7]

**Finding 6**

Downspeeding results from SWRI report #1 [42] shown in section 5.3, Figure 6 of this paper, present results from a GT-Power cycle simulation of a HD tractor. Through overall gearing, the highway cruise speed of the engine was reduced from 1368 rpm to 1209 rpm at 65 mph (Downspeed A) and reduced further to 1051 rpm (Downspeed B). Figure 6 shows that downsizing can reduce fuel consumption by 2%-4% with engine speeds as low as 1051 r/min at 65 mph. [NHTSA-2014-0132-0102-A1 p.7]

Downspeeding should be seen *primarily* as an engine technology, since the engine has to be significantly redesigned to allow downsizing to 1000-1050 rpm to deliver fuel savings, while continuing to meet road load demands. The redesign involves increased peak cylinder pressure to allow higher BMEP at low engine speeds, increased wrist pin, journal and main bearing performance to protect oil film thickness, increased air handling performance at low engine speeds and re-optimized combustion. [NHTSA-2014-0132-0102-A1 p.7]

Vehicle design changes include changing the overall gear ratio between engine (rpm) and tires (rev/mile) by selecting an appropriate rear axle ratio and transmission top gear ratio, and adopting either an AMT or DCT transmission integrated with the engine controller. [NHTSA-2014-0132-0102-A1 p.7]

**Finding 8**

The cost and retail price data used by the agencies in the development of this rule [44] for key engine technologies are outdated, being taken from sources published in 2009. The cost and retail price data took no account of the advances made by the SuperTruck Program which ran from 2010 through 2015 at a cost to the U.S. government and industry of $375M [30-35]. [NHTSA-2014-0132-0102-A1 p.8]

The agencies should consider developing more accurate and current cost and retail price estimates based on a dialog with the SuperTruck OEMs and tier 1 supply base. Progress has been made between 2010 and 2015 both in simplifying designs for cost and reliability, and in better understanding manufacturing processes. [NHTSA-2014-0132-0102-A1 p.8]

**Finding 11**

A *synergy* or *dis-synergy* factor is intended to account for the fact that some technologies may positively or negatively impact the performance of other technologies. For some technologies, such as combustion optimization, friction reduction and turbocharger efficiency improvements, one would expect only a positive effect. For some other technologies there can be a minor offsetting effect – for example by adding weight or increasing heat rejection – WHR and EGR are examples of this. Yet in 2021 the
agencies applied a 25% dis-synergy factor with only a 1% adoption of WHR, and knowing that the 2017 baseline engines already contained EGR. [NHTSA-2014-0132-0102-A1 p.9]

Synergistic and dis-synergistic effects need to be accounted for with the specific combinations of technology in mind. The agencies did not do this. Instead, they crudely applied a 25% discount in 2021 and a 15% discount in 2024 and 2027 across all technologies. Furthermore, there is no explanation for the agencies' derivation or justification of its use in the rulemaking record. The agencies' use of a dis-synergy factor is inappropriate and many of the technologies in EPA’s preferred package may not have any dis-synergistic effects. This step in the agencies’ analysis further contributes to setting weak engine standards. [NHTSA-2014-0132-0102-A1 p.9]

4. The agencies having wrongly included downspeeding as a vehicle technology and allocated the CO2 reduction to the vehicle via the GEM simulation. By so doing they have relaxed the stringency of the engine limit standards, which is a significant oversight by the agencies. This issue can be corrected by including downspeeding in the derivation of the proposed engine standards, Draft RIA section 2.7.4, Table 2-8 [15]. [NHTSA-2014-0132-0102-A1 p.10-11]

3.3 Technology Roadmaps

The most accessible and relevant Technology Roadmaps, related to improvements in HD diesel engine efficiency and emissions are the government funded, industry cost-shared initiatives which fall under the 21st Century Truck Partnership (21CTP). These initiatives, which culminated in the SuperTruck Program, have been significant in the development of clean and efficient HD diesel engines which meet both the EPA/NHTSA Phase 1 GHG standards and the near-zero EPA on-highway criteria pollutant standards. [NHTSA-2014-0132-0102-A1 p.14]

3.3.1 21st Century Truck Partnership [22]

The 21st Century Truck Partnership was formally launched on April 21, 2000. The 21CTP is a cooperative research and development (R&D) partnership including four federal agencies—the U.S. Department of Energy (DOE), U.S. Department of Transportation (DOT), U.S. Department of Defense (DOD), and the U.S. Environmental Protection Agency (EPA)—and 15 industrial partners. The management of specific projects under the 21CTP umbrella rests with the individual federal agencies that have funded the work. These agencies use the 21CTP information-sharing infrastructure to coordinate efforts and ensure that valuable research results are communicated and that any overlap of activities is reduced. [NHTSA-2014-0132-0102-A1 p.14]

The purpose of this partnership is to reduce fuel consumption and emissions, increase heavy-duty vehicle safety, and support research, development and demonstration to initiate commercially viable products and systems. DOE released 21CTP Roadmap and Technical White Papers in 2006 [23] and in 2013 [24] which outline the goals and objectives of the partnership. [NHTSA-2014-0132-0102-A1 p.14]

3.3.2 U.S. DOE Programs in Support of HD Diesel Engine Technology Development

In addition to being a member of the 21CTP partnership, DOE has initiated programs in Advanced Combustion R&D, Materials and Vehicle Systems for example, which have engaged the National Laboratories and industry in collaborative cost-shared projects. A listing of these projects from NAS 21CTP Report Phase 3 [41] is provided in Appendix A [see p.36 of docket number NHTSA-2014-0132-0102-A1], Figure 17. These projects have provided enabling technologies and knowledge which has been
integrated into programs such as SuperTruck, a program launched under the 21CTP umbrella with the intention of demonstrating complete truck systems. [NHTSA-2014-0132-0102-A1 p.14]

3.3.3 U.S. DOE SuperTruck program [21,26]

The SuperTruck Program was launched on January 11, 2010 when the Department of Energy (DOE) announced the selection of nine projects, totaling more than $187 million, to improve the fuel efficiency of heavy-duty trucks. The funding included more than $100 million from the American Recovery and Reinvestment Act of 2009 (ARRA). The projects required that private industry contribute at least 50% of the project cost, and so a total of more than $375 million was provided for research, development, and demonstration projects. [NHTSA-2014-0132-0102-A1 p.15]

The goal of SuperTruck is to develop and demonstrate by 2015, a 50% improvement in freight efficiency (ton-miles per gallon) for Class 8 long-haul trucks compared with a 2010 base line. At least 20% is expected to be achieved through heavy-duty engine improvements, and the remainder from reductions in aerodynamic losses, rolling resistance, vehicle weight and auxiliary loads, and other approaches such as hybridization. [NHTSA-2014-0132-0102-A1 p.15]

3.4 Criteria Pollutant Regulation – Progress through Technology Forcing Standards

The 2010 standards for control of NOx and PM from HD engines was published as a final rule in January, 2001 [19]. These standards were introduced over a phase-in period 2007 through 2010, and required the availability of ultra-low sulfur diesel fuel as an enabler for PM and NOx aftertreatment. This very successful program is an outstanding example of technology forcing standards combined with adequate lead time, and the commitment of industry. The aggressive limit standards for NOx (0.2 g/HP-hr) and PM (0.01 g/HP-hr) were considered to be at the limits, if not beyond the limits of technology understood in 2001. The candidate technologies (DPF, NAC, AMOX and SCR) had existed in research labs for several years prior to the rule. However, component and system level refinement and demonstration had not taken place. Given the research foundation, industry was able to step up to the challenge and develop products that met or exceeded the near-zero standards [58, 59]. Additionally, the DEF infrastructure was also developed to support the launch of SCR systems across the fleet by 2010. [NHTSA-2014-0132-0102-A1 p.15]

By contrast, most of the engine technologies needed for the Phase 2 program, are known and the development is evolutionary in nature. Even in the case of WHR, its development is advanced when compared to some of the criteria pollutant technologies when EPA set the 2007/2010 standards – such as Urea SCR or NOx adsorber catalysts. [NHTSA-2014-0132-0102-A1 p.15]

5.4 SWRI Report #2 Commissioned by NHTSA, June 2015 [43]

This SWRI report is the second of two reports commissioned by NHTSA. The report evaluates the effectiveness of packages (“Combo Packages”) of the individual technologies studied in Report #1 [42]. [NHTSA-2014-0132-0102-A1 p.18]

The conclusions reached regarding HD tractor engine fuel savings are shown in Figure 8. [NHTSA-2014-0132-0102-A1 p.19]

[Figure 8 can be found on p.19 of docket number NHTSA-2014-0132-0102-A1]
Waste heat recovery was modeled separately as a stand-alone Rankine cycle – with water, R245fa, ethanol and methanol working fluid options. The R245 WHR system was claimed to provide benefits of 3 to 3.5% over Combo Package 2, described in Figure 8. Adding a recuperator to the R245 system increased the fuel savings to well over 4%. Comparing the Combo Package 3 systems to the 2019 baseline, the overall benefits at 55 and 65 mph and on the NESCCAF cycle reach and sometimes exceed 10%. The results for all technology combinations included in the study are shown in Appendix G [see p.42]. [NHTSA-2014-0132-0102-A1 p.19]

Given the nature of this second study, where technology packages are created from semi-arbitrary parametric value ranges, it would be difficult if not impossible to make a forecast for the future performance of these technologies. However, the report attempted to draw quantitative conclusions nonetheless: [NHTSA-2014-0132-0102-A1 p.19]

“One surprise that came out of this project is the relatively large benefit from engine friction reduction in long haul applications”

“Assuming a reduction in FMEP ranging from 10% at high speed and load, to 35% at low speed and light load, significant benefits were found”

“An aggressive reduction in Cd (25%) and Crr (30%) provides nearly a 20% fuel consumption reduction on the long haul NESCCAF cycle” [NHTSA-2014-0132-0102-A1 p.19]

The SuperTruck projects [30-35] were nearing completion as this report [43] and its partner report [42] were being written, yet no attempt to obtain data for comparative purposes is reported, and no comparisons are made in order give a point of reference for the conclusions. [NHTSA-2014-0132-0102-A1 p.19]

5.5 Draft RIA [15]

The draft RIA reviews available technologies for HD diesel engines in Section 2-3: [NHTSA-2014-0132-0102-A1 p.19]

- Low Temperature Exhaust Gas Recirculation Reduction
- Model Based Control System
- Combustion System Optimization
- Turbocharging System
- Engine Breathing System

- Engine Parasitic and Friction Reduction
- Integrated Aftertreatment
- Engine Downsizing
- Waste Heat Recovery

Relative to WHR, the Draft RIA states that: [NHTSA-2014-0132-0102-A1 p.19]

“... at a single optimal engine operating point, Cummins reports potential efficiency gains from WHR on the order of 2.8 percent points from the engine without WHR.”

Important qualifiers are necessary: [NHTSA-2014-0132-0102-A1 p.19]
This data is over 2 years out of date, having been presented at the 2013 DOE Annual Merit Review [30];

The 2.8% efficiency gain in question is Brake Thermal Efficiency – which when converted to CO2 or fuel savings is a 4-5% reduction; and

More recent data from Cummins showed potential for a 3.6% BTE improvement [31], which is a 5-6.5% reduction of CO2 and fuel consumption.

The agencies expressed their concern with WHR technology readiness, citing complexity, reliability, durability, weight, heat rejection and other concerns. However, while the agencies’ recognized the challenges that would need to be overcome, they also stated that they – “believe with enough time and development effort, this can be done” [15]. [NHTSA-2014-0132-0102-A1 p.19-20]

The agencies took a similarly conservative view of potential combustion system improvements to reduce CO2 and fuel consumption, Page 2-8 Draft RIA [15]: [NHTSA-2014-0132-0102-A1 p.20]

“Alternative combustion processes such as homogeneous charge compression ignition (HCCI), premixed charge compression ignition (PCCI), low-temperature combustion (LTI), and reactivity controlled compression ignition (RCCI) technologies were not included in the feasibility analysis for Phase 2” [NHTSA-2014-0132-0102-A1 p.20]

Given the significant research efforts on advanced combustion (Appendix A, Figure 17) and the progress being demonstrated [27, 28, 31], it is to be expected that some level of improvement in combustion technology will bleed through into product development programs over the next 12 years, providing reductions of GHG emissions and fuel consumption. [NHTSA-2014-0132-0102-A1 p.20]

5.6 Cummins SuperTruck Program [31]

Key engine technologies used by each of the four projects are listed in Appendix H [see p.43], for reference. [NHTSA-2014-0132-0102-A1 p.21]

The Cummins SuperTruck project is a consortium of industry partners, with Peterbilt providing vehicle integration expertise. Other partners include Modine, Oakridge National Lab and Purdue University. Cummins closed out the project in Q2 2015 having met all of the objectives. [NHTSA-2014-0132-0102-A1 p.21]

5.7 Daimler SuperTruck Program [32, 33]

The Daimler SuperTruck program is a consortium of industry partners including: Detroit Diesel, Schneider National, Walmart, National Renewable Energy Lab, Oregon State University, Strick Trailer and Michelin. This project was completed successfully and closed March 2015. [NHTSA-2014-0132-0102-A1 p.21]

[Figure 10 and 11 can be found on p.21 and figure 12 and 13 can be found on p.22 of docket number NHTSA-2014-0132-0102-A1]

5.8 Volvo SuperTruck Program [34]

The Volvo SuperTruck consortium members are: Penn State, Grote, Freight Wing and Ridge Corporation. This project continues and is expected to complete by June 2016. [NHTSA-2014-0132-0102-A1 p.22]
5.9 **Navistar SuperTruck Program** [35]

The Navistar SuperTruck consortium consists of: Bosch, Wabash, ANL and LLNL. This project is expected to close September 2016. [NHTSA-2014-0132-0102-A1 p.22]

5.10 **NAS Review of the 21CTP: Third Report – September 11, 2015** [41]

This report is the third review of 21CTP by NAS. They found a number of important accomplishments, most notably by the projects that form the DOE SuperTruck Program: [NHTSA-2014-0132-0102-A1 p.22]

- “The engine systems Goal 1 of a 50% BTE for an emissions compliant engine has been achieved. Two of the four SuperTruck teams have successfully demonstrated BTE greater than 50% in on-road tests using commercial, ultra-low-sulfur diesel fuel” NAS [41].
- “It is anticipated that by the end of each of the respective SuperTruck programs, the teams will have developed a technology pathway for achieving 55% BTE” NAS [41].
- “The SuperTruck projects incorporated a number of vehicle power demand technologies that accounted for about 56 to 74 percent of the total fuel consumption reductions, with 26% to 44% coming from engine efficiency improvements” NAS [41]. [NHTSA-2014-0132-0102-A1 p.22]

The NAS committee has moved their focus from attaining HD engine technology for 50% BTE to defining the pathways to a HD engine attaining 55% BTE. While the NAS committee see 55% BTE as extremely challenging, they observed that all of the programs are pursuing improved friction and pumping, more effective air boosting systems, smaller auxiliary and accessory loads, and improvements in WHR, and that all teams are investigating advanced low-temperature combustion (LTC) approaches. [NHTSA-2014-0132-0102-A1 p.22]

5.11 **Technology Cost Estimates**

Tetra Tech, Inc. (TTI) was retained by NHTSA to work in conjunction with SWRI [42, 43] to study the cost of implementation of the key technologies for reducing GHG emissions and fuel consumption [44]. Due to the limited timeframe and funding available for the study, this analysis relied on existing MD/HD literature for price inputs. [NHTSA-2014-0132-0102-A1 p.22]

The TTI study [44] assessed the incremental retail prices for the implementation of the key technologies in constant 2011 U.S. dollars. The list of technologies and configurations identified by SwRI and included in the TTI study are shown in Figure 14. [NHTSA-2014-0132-0102-A1 p.22]

[Figure 14 can be found on p.23 of docket number NHTSA-2014-0132-0102-A1]

5.11.1 **WHR Cost / Retail Price Assessment** [44]

TTI obtained their cost data from the open literature, and for WHR they relied upon two main sources – the NESCCAF/ICCT 2009 study [48] and TIAX 2009 report [36]. While these studies were the primary sources of the data, they also referenced secondary sources – NAS [37] and NHTSA [18], which in fact had relied upon the primary NESCCAF/ICCT and TIAX sources. Therefore all of the data used to project costs for the Phase 2 rulemaking process, for WHR, have their origins in two studies published in 2009, pre-dating the SuperTruck program. [NHTSA-2014-0132-0102-A1 p.23]

Page 633 of 2127
The NESCAF/ICCT study, supported by TIAX and SWRI, based their WHR cost assessment on a steam cycle, with a multiple-stage turbine expander driving an electric generator with associated battery storage. The study found up to 8% fuel consumption and GHG reduction, at a cost of $15,100 ($30,200 retail price equivalent) and payback of 5.2 years. In this study, the WHR was sized for the full rated power of the engine. Later analysis by TIAX [36] found that most of the benefits could be realized using a smaller, lower cost system with fuel consumption savings and retail price equivalents of: [NHTSA-2014-0132-0102-A1 p.23]

- 32 kW system – 8 percent reduction in fuel use, $15,100
- 12 kW system – 6 percent reduction in fuel use, $8,400

According to TIAX [36], manufacturers could not provide firm costing information on these systems, as they were still in the development stage. However, they expected to be able to achieve payback in 18 to 24 months if development proceeds as projected. For a line-haul truck, this would suggest a low-end system cost of $7,200 to $8,400 for a system that gives 6 percent reduction of GHG emissions and fuel consumption [36]. [NHTSA-2014-0132-0102-A1 p.23]

The agencies used the TTI analysis as the basis for the cost / price assessments included in the Draft RIA [15]. In the case of WHR, the source data was created in 2009 for a system that has little in common with the state of the art demonstrated by the SuperTruck Program between 2010 and 2015 [30, 35]. [NHTSA-2014-0132-0102-A1 p.23]

The agencies estimated the cost of WHR at $12,000 (retail, 2013S) [15], based on the estimate from TTI [44]. From this data the agencies were able to use their models to estimate a Direct Material Cost of $8,692. The agencies also attempted to place technologies on a ‘learning curve’ to project costs as experience is gained. This leads to the odd conclusion below, which seems to say that the agencies don’t want to consider a learning curve for WHR, because that would result in the projected costs being “too low.” [NHTSA-2014-0132-0102-A1 p.23]

“We consider this technology to be on the flat portion of the learning curve (curve 12) because although waste heat recovery is a new technology and in the 2015 to 2017 timeframe remains, perhaps, on the steeper portion of the learning curve, applying such rapid learning effects to the cost estimate we have would result in costs too low in the MY2024 to 2027 timeframe.” Draft RIA section 2.12.2.15 [15]. [NHTSA-2014-0132-0102-A1 p.23]

Other engine technology costs and retail price equivalents used by the agencies as input to the determination of HD tractor engine stringency were also largely based on data that pre-dated the 2010 to 2015 SuperTruck Program – mainly the NESCAF/ICCT 2009 study [48] and TIAX 2009 report [36]. [NHTSA-2014-0132-0102-A1 p.24]

To achieve these technology forcing standards it will be necessary for the following technologies to be developed: [NHTSA-2014-0132-0102-A1 p.25]

- Waste Heat Recovery / Organic Rankine Cycle
- Advanced Combustion
- Reduced Frictional Losses
- Reduced Accessory Losses
- Reduced Open Cycle Losses
- Engine Design for Downspeeding
- Advanced NOx and PM Aftertreatment
- Advanced Adaptive Controls
- Advanced Sensors
- Increased Turbocharger Efficiency
Although the agencies have expressed concern that WHR is costly and complex – they also recognize that industry is capable of resolving these concerns given adequate lead time: [NHTSA-2014-0132-0102-A1 p.25]

“The agencies believe manufacturers will improve these systems [WHR] over time just as they have for other advanced technologies that initially had high cost and complexity at a comparable stage of development” Draft RIA 2.3.9 [15],[NHTSA-2014-0132-0102-A1 p.25]

It is important that the agencies elevate their support for WHR, advanced combustion and downspeeding, since these are key enablers for the technology forcing standards proposed above. Furthermore, this study finds that there is a high probability of successfully implementing these technologies by the time the standards are phased in. [NHTSA-2014-0132-0102-A1 p.25]

Given the 12 year lead time to product launch in 2027 and the relaxed engine standards proposed; if this rule moves forward in its current form it will make it impossible for truck and engine OEMs and tier 1 suppliers to continue to make investments in advanced engine technologies at the levels we have seen during the past 5-10 years. R&D funds are a scarce resource that will be withdrawn or reallocated to other priorities. [NHTSA-2014-0132-0102-A1 p.25]

37 “Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles – Phase 1,” Committee to Assess Fuel Economy Technologies for Medium- and Heavy-Duty Vehicles; National Research Council; Transportation Research Board, March 31, 2010

Response:

We respectfully disagree with many of arguments that pertain to a more aggressive engine standard stringency. We have reviewed the reports from four major vehicle OEMs (EPA-HQ-OAR-2014-0827-1894) as well as other comments made by individual vehicle OEMs (Daimler Truck North America and Navistar), which rebut the points made by the commenter. Specifically, we disagree with the approach taken by the commenter regarding the technology effectiveness from DOE’s SuperTruck program and NAS’s report. It appears that the commenter took single value out of these literatures, primarily based on peak values, such as their findings 1 and 2 related to 50% and 55% BTE. The values from the literature are single optimal operating points and not operation over the entire engine map. Further, those values were demonstrated in an R&D environment. In contrast, we consider stringency over the 13 modes of the SET, where the reduction over the composite is not as great as the reduction over the single, most efficient, operating point. The technology path for downspeeding proposed by the commenter is not practical, because while the peak torque of the engine moves down to an engine speed of around 800 rpm, the required high boost pressure cannot be maintained due to the engine’s low speed. We disagree with the commenter statements that we did not consider combustion technology. We do consider advanced combustion as one of the technologies as indicated in Chapter 2.7.5 of the RIA. We also disagree with the commenter’s comments on dis-synergy and synergy. We have updated our justification on the dis-synergy we used for our rulemaking, which can be found in Chapter 2.7.5 of the RIA and discussed below in RTC Section 3.4.3. While we disagree with many of the comments, we have responded to some in a positive manner. We have updated the cost tables associated with technologies, such as WHR, as shown in Chapter 2.11.2.15 of the RIA. We have made the standards more stringent. We increase the dis-synergy factor from 0.85 to 0.9, and increase the market penetration for WHR Rankine cycle technology from 15% to 25% in 2027, and included down speed benefits on engines. As a result of that, the tractor engine standards increase from 4.2% to 5.1% in 2027. Chapters 2.3 and 2.7 of the RIA detail the justification for this increase. For vocational engines, we have adjusted the vocational engine baseline CO₂ emission level based on the new certification data, strengthening the standards relative to the NPRM. Chapters 2.3 and 2.7 of the RIA detail the justification for this increase.

3.4.1 Additional Discussion of Rankine Cycle Waste Heat Recovery
Response:

As noted above, the agencies received numerous comments on the proposed engine stringencies and the agencies’ assumed application rates of WHR.

More than 40 percent of all energy loss in an engine is lost as heat to the exhaust and engine coolant. For many years, manufacturers have been using turbochargers to convert some of this waste heat in the exhaust into usable mechanical power that is then used to compress the intake air. Manufacturers have also been developing a Rankine cycle-based system to extract additional heat energy from the engine. Such systems are often called waste heat recovery (WHR) systems. The possible sources of waste heat energy include the exhaust, recirculated exhaust gases, compressed charge air, and engine coolant. The basic approach with WHR is to use waste heat from one or more of these sources to evaporate a working fluid, which is then passed through a turbine or equivalent expander to create mechanical or electrical power, then re-condensed.

For the proposal, the agencies projected that by 2027, 15 percent of tractor engines would employ WHR systems with an effectiveness of better than three percent. Some of the comments included confidential data related to systems not yet on the market. (As CBI, these comments are not fully addressed above).

After carefully considering all of these comments, we have revised our projections to increase the effectiveness, decrease costs, and project higher adoption rates than we proposed.

Prior to the Phase 1 Final Rule, the NAS estimated the potential for WHR to reduce fuel consumption by up to 10 percent. However, the agencies do not believe such levels will be achievable within the Phase 2 time frame. There currently are no commercially available WHR systems for diesel engines, although research prototype systems are being tested by some manufacturers. American Trucking Association, Navistar, DTNA, OOIDA, Volvo, and UPS commented that because WHR is still in the prototype stage, it should not be assumed for setting the stringency of the tractor engine standards. Many of these commenters pointed to the additional design and development efforts that will be needed to reduce cost, improve packaging, reduce weight, develop controls, select an appropriate working fluid, implement expected OBD diagnostics, and achieve the necessary reliability and durability. Some stated that the technology has not been thoroughly tested or asked that more real-world data be collected before setting standards based on WHR. Some of these commenters provided confidential business information pertaining to their analysis of WHR system component costs, failure modes, and projected warranty cost information.

Alternatively, a number of commenters including Cummins, ICCT, CARB, ACEEE, EDF, Honeywell, ARB and others stated that the agencies should increase the assumed application rate of WHR in the final rule and the overall stringency of the engine standards. They argued the agencies’ WHR technology assessment was outdated and too conservative, the fuel savings and GHG reduction estimation for WHR were too low, and the agencies’ cost estimates were based on older WHR systems where costs were confounded with hybrid component costs and that these have since been improved upon. In addition, the agencies received CBI information supporting the arguments of some of these commenters.

Cummins stated the agencies underestimated the commercial viability of WHR and that we overstated the development challenges and timing in the NPRM. They said WHR can provide a 4 to 5 percent improvement in fuel consumption on tractor drive cycles and that WHR would be commercially viable and available in production as early as 2020 and will exceed the agencies’ estimates for market penetration over the period of the rule. According to Cummins, the reliability of their WHR system has

---

41 See 2010 NAS Report, page 57.
improved with each generation of the technology and they have developed a smaller system footprint, improved integration with the engine and vehicle and a low-GWP working fluid, resulting in a much more compact and integrated system. They added that their system would be evaluated in extended customer testing by the end of 2015, and that results of that experience will inform further technology development and product engineering leading to expected commercial product availability in the 2020 timeframe. Furthermore, they said multiple product development cycles over the implementation timeframe of the rule would provide opportunities for further development for reduced cost and improved performance and reliability.

Some commenters, including EDF, said the agencies’ assumed design had little in common with the latest designs planned for production. They cited several publications, including the NAS 21st Century Truck Program report #3 and stated WHR effectiveness is much higher than the agencies estimated. Gentherm cited an ICCT study saying that up to a 12 percent fuel consumption reduction from a 2010 baseline engine is possible with the application of advanced engine technologies and WHR.

The agencies recognize that much work remains to be done, but we are providing significant lead time to bring WHR to market. Based on our assessment of each manufacturer’s work to date, we are confident that a commercially-viable WHR capable of reducing fuel consumption by over three percent will be available in the 2021 to 2024 time frame. Concerns about the system’s cost and complexity may remain high enough to limit the use of such systems in this time frame. Moreover, packaging constraints and lower effectiveness under transient conditions will likely limit the application of WHR systems to line-haul tractors. See RIA Chapter 2.3.9 for a detailed description of these systems and their applicability.

For our analysis of the engine standards, the agencies project that WHR with the Rankine technology could be used on 1 percent of tractor engines by 2021, on 5 percent by 2024, and 25 percent by 2027, with nearly all being used on sleeper cabs. We project this sharper increase in market adoption in the 2027 timeframe because we have noted that most technology adoption rate curves follow an S-shape: slow initial adoption, then more rapid adoption, and then a leveling off as the market saturates (not always at 100 percent). We assumed an S-shape curve for WHR adoption, where we project a steeper rise in market adoption in and around the 2027 timeframe. Given our averaging, banking and trading program flexibilities and that manufacturers may choose from a range of other technologies, we believe that manufacturers will be able to meet the 2027 standards, which we based on a 25 percent WHR adoption in tractor engines. Although we project these as steps, it is more likely that manufacturers will try to gradually increase the WHR adoption in MY 2025 and MY 2026 from the 5 percent in 2024 to generate emission credits to smooth the transition to the 2027 standards. As shown in the figure below manufacturers that gradually increase the adoption rate after 2021 could achieve the standards with 17 percent adoption of WHR in 2025, and would not need to reach 25 percent adoption until 2029.
Commenters opposing the agencies’ WHR projections argued that the real-world GHG and fuel consumption savings will be less than in prototype systems. DTNA said a heat rejection increase of 30 percent to 40 percent with WHR systems will require larger radiators, resulting in more aerodynamic drag and lower fuel savings from WHR systems. DTNA cited a Volvo study showing a 2 percent loss of efficiency with the larger frontal areas needed to accommodate heat rejection from WHR systems. Daimler stated effectiveness may be lower than expected since there is large drop off in fuel savings when the tractor is not operating on a steady state cycle and the real world performance of WHR systems will be hurt by transient response issues. Daimler and ACEEE said the energy available from exhaust and other waste heat sources could diminish as tractor aerodynamics improve, thus lowering the expected fuel savings from WHR. Daimler said because of this, WHR estimated fuel savings was overestimated by the agencies. Navistar said WHR working fluids will have a significant GHG impact based on their high global warming potential. They commented that fuel and GHG reductions will be lower in the real world with the re-weighting of the RMC which results in lower engine load, and thus lower available waste heat. However, none of these commenters have access to the full range of data available to the agencies, which includes CBI.

Daimler said that with increased freight movement by ship, barge, and rail, some steady-state long haul truck VMT would be replaced with more regional truck VMT over time. This Daimler said, would further reduce the effectiveness of WHR as an approach to lower GHG emissions and fuel consumption. However, this is very speculative.

It is important to note that the net cost and effectiveness of future WHR systems depends on the sources of waste heat. Systems that extract heat from EGR gases may provide the side benefit of reducing the size of EGR coolers or eliminating them altogether. To the extent that WHR systems use exhaust heat, they increase the overall cooling system heat rejection requirement and likely require larger radiators. This could have negative impacts on cooling fan power needs and vehicle aerodynamics. Limited engine compartment space under the hood could leave insufficient room for additional radiator size increasing.
Many of these issues disappear if exhaust waste heat is not recovered from the tailpipe and brought under the hood for conversion to mechanical work. In fact, it is projected that if a WHR system only utilizes heat that was originally within the engine compartment (e.g., EGR cooler heat, coolant heat, oil heat, etc.), then any conversion of that heat to mechanical heat actually reduces the heat rejection demand under the hood; potentially leading to smaller radiators and lower frontal area, which would actually lead toward improved aerodynamic performance. Refer to RIA Chapter 2.3.9 for more discussion, and in particular RIA at 2-17 describing how these engineering challenges can be successfully addressed.

Several commenters stated that costs are highly uncertain for WHR technology, both for manufacturers and for fleets. OOIDA, Volvo, ATA and UPS stated costs for WHR systems are uncertain yet somehow argued that the agencies’ assumption of a $10,523 cost in 2027 are likely significantly lower than reality. Volvo estimated a cost of $21,700 for WHR systems. Volvo said that in addition to hardware cost being underestimated, the agencies had not properly accounted for other costs such as the R&D needed to bring the technology into production within a vehicle. Volvo said they would lose $17,920 per unit R&D alone, excluding other costs such as materials and administrative expenses. Daimler said that costs almost always inflate as the complexity of real world requirements drive up need for more robust designs, sensors, controls, control hardware, and complete vehicle integration. They added that development costs will be large and must be amortized over limited volumes. Furthermore, OOIDA said the industry experience with such complex systems is that maintenance, repair, and down-time cost can be much greater than the initial purchase cost. ATA and OOIDA said that potential downtime associated with an unproven technology is a significant concern for the industry. They said if a truck goes out of service, the fleet must dispatch a tow truck to recover it and this could result in penalties for missed delivery times, added costs for the use of an additional truck, repair parts, and other related expenses. We agree that in-service failures can be costly, but the commenters overstate the risks of such failures. We are providing many years of lead time before WHR system would be widely needed to meet the standards (and potential alternative compliance pathways exist as well). This extended lead time includes the time needed for extensive field testing. See RIA Chapter 2.3.9 at 2-16 and 2-17 and Figure 2-1. Our conversations with manufacturers since they began implementing the 2007/2010 standards indicate that they learned important lessons about how to implement new technologies and have all developed internal processes to ensure that reliability problems are fully addressed before new technologies are widely introduced into the market.

On the other hand, some commenters argued that the agencies had actually overestimated WHR costs in the proposal. These commenters generally argued that engineering improvements to the WHR systems that will go into production in the Phase 2 time frame would lower costs, in particular by reducing components. For example, they cited the possibility of low-GWP working fluids that could result in much more compact and integrated systems. They added such a system would be evaluated in extended customer testing by the end of 2015, and results of that experience will inform further technology development and product engineering leading to expected commercial product availability in the 2020 timeframe.

EDF cited several publications such as Walsh/Charlton and John Wall stating the agencies’ effectiveness assessment for WHR was overly conservative and based on outdated assumptions. Wall, EDF, and Walsh/Carlton said the agencies’ assumed design had little in common with the latest designs planned for production. Wall, CARB, and others also stated the agencies underestimated the effectiveness of WHR systems.

The costs developed by the agencies were challenged by Cummins, Wall, ACEEE, EDF, and others. Cummins said costs developed in a report from Tetra Tech for NHTSA and referenced in the Draft RIA is based on references that pre-date the SuperTruck program. They added that improvements have
significantly lowered system cost since that study was published. John Wall commented that the agencies’ assumption of cost was based in part on the 2009 NESCCAF study which used an electrical system with full hybridization. Wall said the WHR system included a 30 kW system and a full hybrid whereas a 10 kW system is used in more current designs. He added that current systems do not need an exhaust heat exchanger and other components assumed in the TIAx report and that a retail price equivalent of a 10 kW system would be $4,760, less than half the agencies’ cost estimate.

Wall said this substantially lower cost estimate should allow the agencies to consider a more significant penetration of WHR technology with acceptable cost effectiveness and a higher overall engine stringency. Similarly, Walsh/Charlton said the agencies’ costs were based in part on a steam system with multiple expanders which is very different from today’s designs.

The agencies largely agree with these commenters’ estimates of costs (in particular, that the system evaluated at proposal contained certain elements which are unnecessary for the type of system and effectiveness projected for the final rule) and we have revised our analysis to reflect these lower costs. See RIA Chapter 2.11.2.15 for additional discussion.

A number of commenters took issue with the assumption made by the agencies that WHR is on the flat portion of the learning curve with regard to cost reduction potential, saying this overstates the costs of the technology over the long term. Cummins encouraged the agencies to apply a learning curve calculation that is more consistent with the continuing evolution of WHR system design and integration. In the final rule, we estimate that WHR is on the steep portion of the learning curve. See RIA Chapter 2.11.2.15.

The agencies have carefully evaluated comments submitted on the NPRM and information submitted on cost, technology effectiveness, and system design since the publication of the NPRM. As stated above, some of this information was submitted publicly in comments or attachments to comments and other information was provided as confidential business information. Taken together, these comments provide significant technical, cost, and manufacturing information, as well as other information that leads us to believe a higher application rate of WHR is possible in the 2027 timeframe. The agencies are not assuming any changes in the 2021 or 2024 introduction rates for WHR to allow manufacturers adequate research and development and testing time to bring the technology into production. Assuming low application rates of WHR in the early years of the Phase 2 program will allow manufacturers to integrate the technology over normal product development cycles. The agencies are, however, assuming a WHR adoption rate of 25 percent in 2027. As we have explained in RIA Chapter 2.3.9, some technological challenges remain, but we have outlined means of resolving these challenges successfully and provided manufacturers sufficient lead time to do so. We believe the significant information provided to the agencies in the public comments and CBI information after the publication of the NPRM further supports this approach for the 2027 timeframe.

In summary, while we understand the concerns raised by commenters opposing the agencies’ assessment of WHR, we believe these concerns arise primarily form a lack of information. None of these commenters have access to the full range of data available to the agencies. In large part, this is because much of the most compelling information supporting the agencies’ projection is considered to be CBI, and thus is not widely available. While the projections can be justified based on the public information, the CBI gives the agencies even greater confidence that these projections are reasonable. In addition, by projecting a maximum adoption rate of only 25 percent (with an effectiveness of about 4 percent), we limit the overall impact of this analysis to an average reduction of about one percent. While we project WHR to be an important engine technology, we do not base the standards completely on this one technology. Given the ten years of lead time before manufacturers must meet the 2027 engine standards, it is possible that some other engine technology may arise that would provide this one percent reduction without WHR. For example, manufacturers choosing to not invest in WHR, could potentially invest
instead in expanded use of other technologies such as model-based controls, turbo-compound, and downspeeding.

3.4.2 Additional Discussion of Confidential Business Information

Response:

Given the competitive nature of the heavy-duty industry, manufacturers of components, engines, and vehicles very often consider information on technologies they are developing to be confidential business information (CBI). It is also true that manufacturer CBI is often the best information available when evaluating technological feasibility. In the interest of transparency and public participation, the agencies have tried to rely as much as possible on publicly available information, including our own research. Nevertheless, in establishing standards that are appropriate and achieve the maximum feasible reductions, we cannot avoid some reliance on CBI.

When using CBI, the agencies have applied the same standards of analysis as we have the publicly available information. We have given more weight to more detailed information that was fully documented; and less weight to less rigorous information. In general, the CBI supported the more public statements of these manufacturers. However, in some rare cases, we found the public statements to be more optimistic and/or more pessimistic than the data truly supported.

Overall, CBI played a limited but significant role in our feasibility analysis. The agencies were generally able to find public information to support our conclusions. For these technologies, the CBI was more corroborative than determinative. For example, as discussed in Section 3.4.1 above, CBI was very helpful to corroborate our analysis of WHR. However, even there, the impact on overall program was small. We project WHR to provide a roughly one-percent reduction for the tractor and tractor engine standards, which represents a small part of the overall program.
3.4.3 **Additional Discussion of Dis-Synergy**

While many effective technologies are considered for this rulemaking, it is important to point out that the benefits of these technologies are not additive. For example, when multiple technologies are applied to an engine, it is incorrect to simply sum the individual technologies’ effectiveness to arrive at an overall combined effectiveness of the technologies. We have received a number of public comments regarding this non-additive effect. Most of them focus on the agencies’ projections of our so-called “dis-synergy” effect and our use of a dis-synergy factor to account for this effect. This effect could also be called a negative synergy because it is a decrease in technology effectiveness as a result of multiple technologies being applied to an engine. As used here, a factor less than one indicates a net dis-synergy, and a smaller factor indicates more dis-synergy and lower overall effectiveness.

As discussed in RIA Chapter 2.7.4, the agencies applied dis-synergy factors to our effectiveness estimates to reflect the degree to which combining multiple technologies reduces slightly the effectiveness of each individual technology. First, the weighted reductions of individual technologies were combined using the “Π-formula,” which was then augmented to account for technology dis-synergies that occur when combining multiple technologies. RIA Chapter 2.7.4 provides details on the “Π-formula” and an explanation for how the dis-synergy factors were determined. Some commenters recommended that we adopt lower numeric values of our dis-synergy factors, but a few commenters recommended higher dis-synergy factors than what we proposed (i.e., less dis-synergy).

We also note that the degree of dis-synergy is sufficiently small to make the impact of any errors on the resulting standards negligible. For example, even a 0.05 difference in the dis-synergy factor would change the percent reduction of the 2027 engine standard only by about one-quarter of a percent.

**Causes of Dis-Synergy**

As background, it is helpful to first review how engine fuel efficiency technologies interact with one another. One example is the interaction between WHR and other technologies, such as combustion, friction reduction, and fuel injection system improvements. WHR effectiveness is directly proportional to the amount of thermodynamic available energy (i.e., energy available for conversion into mechanical work) provided from an engine’s sources of waste heat. In a modern internal combustion engine, these sources include exhaust gas energy available from the EGR cooler and tailpipe, and from the coolant and lubricating oil systems. Therefore, decreasing the amount of available energy from these sources reduces the effectiveness of WHR. Some of the fuel efficiency technologies we identify in our stringency analysis decrease the amount of available energy from these sources. For example, advancing fuel injection timing will improve efficiency to a certain point, but it will also decrease available exhaust energy by lowering exhaust temperature, and thus exhaust WHR effectiveness would decrease. To a lesser extent, reducing bearing friction or piston ring-wall friction improves fuel efficiency, but this also leads to less heat transfer to the coolant; and hence lower available energy for WHR. As another example, increasing compression ratio can improve combustion thermal efficiency (until the peak cylinder pressure rises past a given mechanical limit), but this in turn increases friction losses at piston rings and bearings. As another example increasing fuel injection pressure provides more opportunity for fuel injection optimization (e.g., enabling more multiple injection events), which can improve fuel efficiency, but this will in turn increase fuel pump parasitic energy losses. In another example, increasing turbocharger efficiency can improve fuel efficiency, but this will also reduce EGR flow due to lower back pressure, thus potentially increasing NOx, and also reducing the exhaust gas energy that can be utilized by waste heat recovery devices, such as turbo-compound and Rankine cycle systems. Increasing NOx would also put more demand on the after-treatment system or force less fuel efficient fuel injection timing. There are more examples, but in conclusion, there are numerous complex interactions between fuel efficiency technologies.
Use of a Single Dis-Synergy Factor

Fully evaluating all of the potential engine technology fuel efficiency dis-synergies would likely require a multi-million dollar multi-year effort. Such an analysis was not available to the agencies. However, it would not be appropriate to ignore such dis-synergies. Therefore, the agencies developed a single set of empirical constants to account for these known dis-synergies, based on the best information available.

The agencies’ experience dealing with engine technologies strongly supports the likelihood that these interactions between technologies will have a net dis-synergy, and we thus we expect the factor to be less than one. And practically speaking, it is highly unlikely that adding a technology to an engine that leads to a dis-synergy factor on the order of 0.5 would even be considered a fuel efficiency improving technology. Therefore, the agencies focused on determining where within the range of 0.5-1.0 we should project this dis-synergy factor to be. We sought the most probable single dis-synergy factor that matches the diverse set of data that we collected. We determined a range of dis-synergy factors and the value of the factor depended in part on the selection of technology packages. We found that this constant varies in the range of 0.75 - 0.90. Some commenters recommended using a dis-synergy factor of 0.95, however, our analysis shows this would be inappropriately high and likely not achievable.

Based on our analysis, we have reduced our projection of dis-synergy compared to the NPRM analysis, but are still applying a dis-synergy factor that is less than one. More specifically, we applied dis-synergy factors of 0.85 for MY 2021 and 0.90 for MY 2024 and MY 2027. We project these improvements to result from manufacturers increasing their research and development efforts to optimize engine technologies together as a package, in order to comply with the HD Phase 2 engine standards. The agencies have accounted for our projected increased investment in research and design by including respective incremental vehicle cost increases in our cost analysis. In other words, by increasing the dis-synergy factor from 0.85 to 0.90, our MY 2024 and MY 2027 engine standards reflect projections of increased technology package optimization.

3.5 Proposed EPA Engine Standards for N₂O

Organization: Advanced Engine System Institute (AESI)

AESI supports the Agency’s efforts to tighten the nitrous oxide (N₂O) cap to ensure that efficiency enhancements made by engine manufacturers to reduce carbon dioxide pollution do not lead to unintended increases of this other potent greenhouse gas. The changes in engine technology to meet Phase 2 overall, particularly the great likelihood that the new more efficient engines will produce a higher volume of nitrogen oxides, will make meeting that new N₂O cap challenging. Our members are working now on the cutting edge materials necessary to limit N₂O formation. [EPA-HQ-OAR-2014-0827-1152-A1 p.3] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.292.]

Organization: American Gas Association (AGA) et al.

We Strongly Support Preserving the Compliance Pathway Flexibility

In the HD Phase 1 Rule,² the agencies adopted provisions that allowed original equipment manufacturers (OEMs) to offset any nitrous oxide (N₂O) and methane emissions above the standard with carbon dioxide (CO₂) emissions below the standard. Under this approach, an OEM would convert measured N₂O and methane emissions levels generated on the engine certification test cycle into a CO₂-equivalent credit.³ [EPA-HQ-OAR-2014-0827-1223-A1 p.2]
We strongly support the maintenance of this provision in the Phase 2 Proposal. Doing so preserves the valuable compliance pathway flexibility for cross-pollutant trading of methane, N2O, and CO2. We further note that this flexibility is not only beneficial to the OEMs in the natural gas sector that use it to offset methane emissions with CO2-equivalent credits, but it is also a necessity for some diesel engine OEMs who use the provision to offset high N2O emissions with CO2-equivalent credits. [EPA-HQ-OAR-2014-0827-1223-A1 p.2]

**We Support the Proposed Deterioration Factors for Natural Gas Tailpipe Emissions**

Westport and Cummins Westport Inc. (CWI) have reviewed the proposed deterioration factors (DFs) for natural gas tailpipe emissions and do not have sufficient data or a strong rationale to propose alternate DFs at this time. Accordingly, we support the agencies’ proposed DFs of 0.0 g/hp-hr for CO2, 0.020 g/hp-hr for N2O (0.010 g/hp-hr for model year 2021 engines and later), and 0.020 g/hp-hr for methane. ²⁹ [EPA-HQ-OAR-2014-0827-1223-A1 p.8]

---

³ Phase 2 Proposal, page 40341.

²⁹ Phase 2 Proposal, page 40587.

**Organization:** American Automotive Policy Council

**Deterioration Factors (DFs)** – AAPC suggests that DFs for CH4, N2O, and CO2 can be both positive and negative. Testing at 4,000 miles is sometimes worst case and future rules need to allow for negative DFs. [EPA-HQ-OAR-2014-0827-1238-A1 p.12]

**Organization:** American Automotive Policy Council

**2021 MY N2O stringency increase on dyno-tested engines**

AAPC is concerned that the long term costs and benefits attributed to lowering the heavy-duty N2O standard to 0.05 g / hp-hr may not be properly reflected in the RIA. We note that EPA included a simple graph of reported N2O vs the Phase 1 requirement of 0.100 g / bhp-hr as supporting rationale to lower the standard to 0.05 g/hp-hr. However, the data appears to be incomplete. Furthermore, EPA only recently finalized N2O measurement equipment requirements, and AAPC is concerned that the reported data in EPA’s database may be underestimating actual N2O emissions. Quantum Cascade Laser (QCL) equipment is more sensitive to N2O than the historical data which was most likely collected using Fourier Transfer Infrared Spectroscopy (FTIR) type equipment. Merely switching to more sensitive measurement equipment may cause a large fraction of N2O measurements to increase beyond the 50 mg/bhp-hr threshold and thus incur an effective increase in stringency of 3 – 6 g/bhp-hr not properly reflected in the RIA. See data on the next page comparing N2O results using FTIR and new QCL equipment. [EPA-HQ-OAR-2014-0827-1238-A1 p.27]

[Chart, comparison of N2O emissions, can be found on p.28 of docket number EPA-HQ-OAR-2014-0827-1238-A1]
Adjusting for changes in measurement from FTIR to QCL suggest that the standard would be more appropriately set at a value of 0.06 g/hp-hr N2O in lieu of the proposed 0.05 g/hp-hr. [EPA-HQ-OAR-2014-0827-1238-A1 p.28]

**Organization:** American Power Group Inc (APG)

As the Proposed Phase II regulations allow CO2 reported results to be taken from the FTP-HDT HHDD test for vocational vehicle engines and from the RMC13 HHDD test for line haul vehicle engines, but all HHDD vehicle engine CH4 and N2O reported emissions come from the FTP-HDT HHDD tests, would the EPA consider allowing the CH4 and N2O emission reported results for come from the RMC13 HHDD test for line haul vehicle engines? The RMC13 test results are more representative of the line haul vehicle duty cycle.[EPA-HQ-OAR-2014-0827-1197 p.2]

The current GHG regulations have HHDE reportable CO2 results from the FTP-Heavy Duty Transient test cycle for vocational HHDE vehicles and Ramped Modal Cycle 13 test for line-haul HHDE vehicles. All N2O and CH4 reportable HHDE values come only for the FTP-HDT test results. As the APG Mixed-Fuel system is utilized by line haul HHDE vehicles we would respectfully request that EPA allow all GHG emission values for HHDE vehicle line haul applications be taken from the RMC 13 test results as the RMC 13 test more represents our customers duty-cycle. Is there some reason the CH4 and N2O reportable results are only used from the FTP-HDT cycle test? [EPA-HQ-OAR-2014-0827-1197-A1 p.4]

**Organization:** Cummins, Inc.

*Cummins supports use of assigned deterioration factors (DFs) for GHG emissions* [EPA-HQ-OAR-2014-0827-1298-A1 p.28]

For reasons outlined in EMA’s comments, Cummins supports the use of assigned DFs for CO2 emissions. Furthermore, it is also appropriate to apply assigned DFs for CH4 and N2O emissions. In the Preamble, the Agencies indicated the same assigned DFs used for diesel engines are appropriate for natural gas engines. Cummins agrees with this assessment. [EPA-HQ-OAR-2014-0827-1298-A1 p.28]

*Cummins opposes reducing the N2O standard to 0.05 g/hp-hr* [EPA-HQ-OAR-2014-0827-1298-A1 p.19]

For reasons outlined in EMA’s comments, Cummins opposes reducing the N2O standard to 0.05 g/hp-hr. [EPA-HQ-OAR-2014-0827-1298-A1 p.19]

Additionally, the Agencies are requesting comment on changing the GWP for CH4 and N2O for Phase 2. Changes should only be made if they are Agency-wide, consistent across all GHG programs (for example, light-duty, GHG inventories, reporting rules, etc.). Also, to the extent that Phase 1 credits are carrying over and can be used for CH4 and N2O compliance in Phase 2, maintaining the same Phase 1 GWP values is appropriate. [EPA-HQ-OAR-2014-0827-1298-A1 p.31]

**Organization:** Daimler Trucks North America LLC

The agencies must revise the N2O proposal, as the agencies improperly analyzed N2O data and failed to take account for the fact the increased stringency of the currently-proposed CO2 standards will result in greater difficulty to meet even existing N2O standards. [EPA-HQ-OAR-2014-0827-1164-A1 p.6]
6. **N2O**

EPA proposes to set an N2O standard of 0.05 g/bhp-hr which based on their assessment of model year 2015 engines. (80 FR 40203). EPA’s certification data base shows that the N2O emissions standard of 0.10 g/bhp-hr is stringent for the majority current diesel fueled heavy-heavy duty engine- ATS technologies (Figures 1 -3). Due to fundamental tradeoffs of SCR and engine technology, the increased stringency of proposed CO2 standards will result in greater difficulty to meet the existing 0.10 g/bhp-hr N2O standards, thereby the standard will maintain its intended purpose of being anti-backsliding at this level. [EPA-HQ-OAR-2014-0827-1164-A1 p.24] We agree with the N2O formation and the reduction mechanism (80 FR 40204) as discussed in EPA’s literature review of research studies. However, it is also important to note, that there is a tradeoff to consider when lowering the CO2 standards concurrently with lowering the N2O standards. This trade-off does not go hand-in-hand with each other. CO2 emissions standards that are proposed for Phase 2 demand the most fuel efficient in-cylinder technologies, while keeping the extremely low tailpipe NOx emissions. The demand for increasingly efficient in-cylinder combustion technologies will by driven by the proposed decrease in CO2 emissions standards and will drive manufacturers to develop engines with higher engine-out NOx levels. On a given SCR based technology, N2O formation over the SCR based catalyst increases proportionally with increased engine out NOx levels as has been discussed in the N2O formation section by EPA in the literature review. This is true even for the most advanced SCR catalyst technologies in the market today. Consequently engine manufacturers will be extremely challenged to maintain current N2O limits while pursuing combustion based fuel efficiency improvements at the same time as maintaining compliant NOx levels. CO2 emissions and tail pipe N2O emissions trends for a SCR based catalyst technology are shown in Figures 4,5. As depicted in Figure 5, maximum N2O formation occurs in the mid-temperature range. Although in theory, N2O formation could be reduced by elevating temperatures above this range, it is not possible to push temperatures upwards by using the engine thermal management without greatly sacrificing fuel economy and CO2 emissions. [EPA-HQ-OAR-2014-0827- 1164-A1 p.24-25]

We disagree with EPA comment that “We are proposing this change at no additional cost and no additional benefit because manufacturers are generally meeting the proposed standard today.” EPA’s data base upon which it determined its proposed N2O formation level (Figures 1-3) of 0.05 g/bhp-hr shows that the anti-backsliding standards are not being met by most of the manufacturers today. In fact, only two of fifteen heavy-heavy duty engine families were certified at levels that would suggest the possibility of complying with a 0.05 g/bhp-hr standard for engines that are certified to 2014 model year N2O formation levels. As discussed above, pressures to develop to 2017 model year’s lower CO2 levels can be expected to further increase N2O emissions, as will any additional increases in Phase 2 CO2 stringency. [EPA-HQ-OAR-2014-0827-1164-A1 p.25]

Due to increased engine efficiencies demanded of in-cylinder technologies for GHG Phase 2 and the increased upcoming demands from ATS for commensurately increased NOx conversion efficiencies, the tailpipe N2O emissions must be kept at the current 0.10 g/bhp-hr with the current default deterioration factor of 0.02 g/bhp-hr. DTNA recommends that to meet EPA’s intent of setting a standard that allows adequate compliance margin, the N2O standard be set no lower than 0.10 g/bhp-hr. [EPA- HQ-OAR-2014-0827-1164-A1 p.25]

Although EPA has stated that it proposes no changes to criteria pollutant emission standards within the Phase 2 regulation, DTNA is aware that the California Air Resources Board has strong interest in lowering heavy duty diesel NOx standards to mitigate ambient Ozone concerns in certain regions of their state. As was described above, there is an adverse relationship between improving in cylinder efficiency and the SCR systems ability in reducing engine out NOx to meet tailpipe emissions standards while at the same time controlling N2O emissions. Any reduction in tailpipe NOx standards will commensurately
increase the difficulty of meeting N2O standards especially while under simultaneous pressure to meet more stringent CO2 standards. DTNA therefore recommends that in order to maintain a reasonable balance between these various tradeoffs, and in order to ensure that N2O targets remain feasible, the EPA should not tighten the current NOx limits. [EPA-HQ-OAR-2014-0827-1164-A1 p.25]

[Figures 1-3, which show that the N2O emissions standard of 0.10 g/hp-hr is stringent for the majority of current diesel field heavy-duty engine ATS technologies, and Figures 4 and 5, which show CO2 emissions and tail pipe N2O emissions trends for a SCR based catalyst technology, can be found on p. 26-27 and p.27-28 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

Organization: Manufacturers of Emission Controls Association (MECA)

Nitrous Oxide (N2O)

While total N2O emissions are much lower than CO2 emissions, N2O is approximately 298 times more powerful than CO2 at trapping heat in the atmosphere. One of the anthropogenic activities producing N2O in the U.S. is fuel combustion in motor vehicles. In 2006, N2O emissions from mobile source combustion were approximately 9% of total U.S. N2O emissions. N2O is emitted directly from motor vehicles and its formation is highly dependent on temperature, NO2 to NOx ratio entering the SCR catalyst, ammonia to NOx ratio, the SCR catalyst formulation and the temperature of the catalyst over the test cycle. Temperatures favorable for N2O formation (approximately 250o C) are achieved inside catalytic converter systems, especially during cold-start conditions when engine exhaust temperatures are lower. [EPA-HQ-OAR-2014-0827-1210-A3 p.8]

EPA is proposing to tighten the N2O cap and deterioration factor by 50% from 100 mg/bhp-hr to 50 mg/bhp-hr and 20 mg/bhp-hr to 10 mg/bhp-hr, respectively. This is to ensure that climate change impacts of this potent greenhouse gas are minimized on future medium- and heavy-duty vehicles. Furthermore because 75% of engine families certified in 2014 already meet a 50 mg/bhp-hr N2O level, the agency is concerned that engine manufacturers may emit higher levels in the future as they optimize the overall CO2 emissions of engines. EPA estimates that a 40 mg/bhp-hr N2O emission reduction has the CO2 equivalent climate impact of a 2.6% improvement in engine efficiency. Although MECA members believe that meeting the proposed N2O levels will be achievable, it will be challenging given the types of engine developments that we expect to see in the future. In particular we expect that future engines will have higher engine-out NOx levels in the exhaust as a way of achieving lower CO2 levels. Furthermore, overall cooler exhaust temperatures may be expected as a result of efficiency technologies such as turbo-compounding being deployed upstream of the exhaust emission control system. Furthermore, it is important to consider N2O emissions in-light of future regulations such as the 0.02 g/bhp-hr heavy-duty NOx standard under consideration by California. Below, we discuss the primary formation mechanisms for N2O and some approaches that may be used in the future to achieve lower levels of N2O emissions on future diesel engines. [EPA-HQ-OAR-2014-0827-1210-A3 p.8-9] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.211-212.]]

At low temperatures, around 250o C, the predominant mechanism for N2O formation is by the decomposition of ammonium nitrate, whereas at high temperatures, above 5000 C, the primary mechanism is ammonia oxidation. Nitrous oxide can form at intermediate temperatures (300-3500 C) if the NO2 to NOx ratio exceeds 50%. Excess ammonia injection across the SCR catalyst can also lead to an increase in N2O formation if the ammonia to NOx ratio exceeds 1.0. A recent study published by the Society of Automotive Engineers (SAE Technical Paper 201301-2463) concluded that the test cycle, cycle exhaust temperature, system design and urea injection calibration all play a role in the formation of
N2O on the SCR catalyst. The authors observed that the inlet conditions of the SCR catalyst had the greatest effect on the formation of nitrous oxide. [EPA-HQ-OAR-2014-0827-1210-A3 p.9]

Another SAE technical paper (2015-01-0997) studied the effect of SCR catalyst type on the formation of N2O. The authors observed that the lowest N2O emissions were observed from a vanadia/titania SCR and Cu-zeolite SCR systems. Furthermore the Cu-zeolite SCR exhibited little deactivation after aging. The authors found that the system design, linear versus muffler, can impact the overall NOx performance and N2O emissions as a result of the average temperature of the SCR catalyst in each configuration relative to the optimal temperature for N2O formation. Upstream components such as the DOC and DPF can also impact the N2O levels based on their relative activity to form higher NO2/NOx ratio feedgas to the SCR. The authors of this paper discuss ways to formulate the precious metal composition and loading on the DOC and DPF to minimize their contribution to N2O formation while still maintaining high NOx conversion efficiency. For all SCR systems, the N2O emissions could be reduced by tighter urea dosing control to limit excess ammonia, by targeting an optimal amount of ammonia storage in the SCR catalyst and reducing engine-out NOx. [EPA-HQ-OAR-2014-0827-1210-A3 p.9]

In another recent paper published at the 2015 SAE Congress (SAE paper Number 201501-1030), the authors looked at ways to design the SCR catalyst architecture to target lower N2O emissions from the system. Because the front part of the SCR catalyst is more prone to form N2O, the authors looked at coating the front of the SCR substrate with a vanadia-SCR formulation and the rear of the substrate with a standard Cu-zeolite SCR. Further optimization may be possible through the use of modeling tools to identify the SCR formulation and coating volume combinations that minimize N2O emissions and maximize NOx conversion. [EPA-HQ-OAR-2014-0827-1210-A3 p.9]

Advanced gasoline and diesel powertrains for medium- and heavy-duty vehicles in conjunction with advanced emission control technologies can be optimized to minimize N2O emissions. Catalyst manufacturers can utilize a number of approaches to reduce N2O emissions from the exhaust emission control components and therefore MECA believes that the proposed N2O emission cap is achievable with the use of appropriately designed emission controls on today’s medium- and heavy-duty powertrain options. The proposal further provides manufacturers with the flexibility of meeting emission caps or factoring in emissions of N2O or CH4 into the CO2-equivalent emissions calculation of the overall vehicle. MECA supports continuing this proposed flexibility introduced under Phase 1 of this regulation. [EPA-HQ-OAR-2014-0827-1210-A3 p.9-10]

Organization: Navistar, Inc.

In order to meet the proposed N2O standard, manufacturers would have to introduce technologies that will not be available prior to 2020. The alternative would be to trade CO2 for reduced engine out NOx in order to control N2O for current aftertreatment technologies, effectively reducing the emission standard. In addition, the expected margin that is to be built into fuel maps actually will result in an additional estimated 3% of stringency to the engine standard, now requiring a 4.5% improvement between 2017 and the first step of Phase 2, which is again a technology forcing step in stringency. On the other hand, with this added margin the final phase will represent a greater than 10% improvement over the engines currently on the road today with less than 10 years for technology development and implementation. [EPA-HQ-OAR-2014-0827-1199-A1 p.21]

The major concerns with the technology projections and penetrations for both vocational and tractor engine standards include: [EPA-HQ-OAR-2014-0827-1199-A1 p.21]
• Insufficient technologies have been identified, particularly considering the proposed changes in N2O [EPA-HQ-OAR-2014-0827-1199-A1 p.22]

Changes to engine breathing systems, such as improved EGR systems, may run counter to the N2O requirement and impact the reliability of the system [EPA-HQ-OAR-2014-0827-1199-A1 p.22]

Navistar has substantial concerns regarding the proposed 50% reduction in the N2O standard. The NPRM and RIA both assume no technology changes are necessary to meet the standard. On the contrary, Navistar believes that some technology will be necessary, likely a redesigned catalyst or catalyst with new materials. [EPA-HQ-OAR-2014-0827-1199-A1 p.23]

The NPRM requested comments based on the assumption that there would be no costs associated with a reduction of the engine N2O standard from 0.10 g/bhp-hr with an assigned DF of 0.02 g/bhp-hr to a proposed standard of 0.05 g/bhp-hr with a DF of 0.01 g/bhp-hr. We believe this is incorrect and that there will be costs associated with this change. [EPA-HQ-OAR-2014-0827-1199-A1 p.23]

As part of the EPA evaluation for the proposed standard EPA presented an evaluation of the Model Year 2014 EPA certification database. Based on a review of the data presented and the current EPA database, here are several observations: [EPA-HQ-OAR-2014-0827-1199-A1 p.23]

• The DF is not included in the data presented by the EPA. Figure 1 (Attachment A) shows the sample of engines used in the NPRM shown with and without the manufacturer declared DF (unless the family has a zero DF in the database). [EPA-HQ-OAR-2014-0827-1199-A1 p.23]

• Two of the 24 families EPA included in their discussion of N2O test data are non-2SCR equipped engine families (blue-green bars in Figure 1). It is not anticipated that any non-SCR diesel engines will be used in the HD on-highway segment by the time the Proposed Regulations are to take effect. Therefore, these families are not relevant to the proposed N2O standard. [EPA-HQ-OAR-2014-0827-1199-A1 p.23]

• Two of the 24 data points EPA included in their analysis are natural gas fueled engines and another is a gasoline engine. These engines are also not SCR equipped engines and therefore are not relevant to the proposed N2O standard. [EPA-HQ-OAR-2014-0827-1199-A1 p.23]

• An evaluation of the remaining 19 engine families shows the following, assuming a 0.01 g/bhp-hr DF (Figure 1): [EPA-HQ-OAR-2014-0827-1199-A1 p.24]
  o 6 families have test data below the 0.05 g/bhp-hr
  o 5 families have test data approximately at 0.05 g/bhp-hr
  o 9 families have test data above 0.05 g/bhp-hr.

• The evaluation of the 2014 engines also shows that these EPA tested engines are not all at the CO2 standard. The range of engines spans both Vocational and Tractor applications and are shown in Figure 2 and 3, respectively, against the Medium Vocational and the Tractor standard. The same engines are separated between Vocational Medium, Vocational Heavy and Tractor based on displacement and shown in a N2O vs CO2 trade-off in Figures 4-6. All tractor engines fall outside the Phase II N2O-CO2 box. Similarly, a large population of heavy and medium vocational vehicles does not fall within the box. A trade-off trend is observed across the population of engines. [EPA-HQ-OAR-2014-0827-1199-A1 p.24]
Based on the certification data at least half of the currently certified engine families would need to make significant reductions in N2O emissions in order to meet the proposed standard. Furthermore, bringing these engines into CO2 compliance could drive increases in N2O if not mitigated by system improvements. [EPA-HQ-OAR-2014-0827-1199-A1 p.24]

Some of the projected technologies (see attached Table 2) do not have an impact on N2O such as friction reductions, WHR and turbo compound. The other technologies can actually have an adverse effect, for example, reductions in EGR and higher compression ratio combustion systems. Therefore, to meet the proposed N2O standard most of the certified engines would require technology development in aftertreatment, such as SCRF (SCR combined with DPF in one unit). Hence, an assumption of no additional cost is not accurate. [EPA-HQ-OAR-2014-0827-1199-A1 p.24]

[Table 2 can be found on p.44 of the docket]

As far as the interaction between N2O and NOx emissions, it is not appropriate or justified to assume any unknown, future new regulations in the analysis of this proposed regulation. The costs and technical feasibility of the proposed regulation is based on existing engines and regulations. Any future rulemaking must account for the technological limitations and regulations in existence at the time of the proposed regulation. [EPA-HQ-OAR-2014-0827-1199-A1 p.24]

Organization: Truck & Engine Manufacturers Association (EMA)

Similarly, the Agency should not lower the Phase 1 N2O standard. In the NPRM, the Agencies have proposed reducing the N2O standard for heavy-duty engines from 0.10 g/hp-hr (with an assigned DF of 0.02 g/hp-hr) to 0.05 g/hp-hr (with a DF of 0.01 g/hp-hr). The Agencies claim that they “are proposing this change at no additional cost and no additional benefit because manufacturers are generally meeting the proposed standard today.” (See 80 FR at 40203). As part of the underlying rationale for the proposed standard, the Agencies have presented an evaluation of the Model Year 2014 EPA certification database. (See 80 FR at 40205). EMA has the following comments based on its review of the data that the Agencies have presented: [EPA-HQ-OAR-2014-0827-1269-A1 p.64]

a. The proposed DF is not included in the N2O emissions data that the Agencies have cited in the NPRM. Figure 1 (below) shows the sample of engines referenced in the NPRM with and without the proposed DF of 0.01 (unless the family had a zero DF in the database). [EPA-HQ-OAR-2014-0827-1269-A1 p.65]

b. Two of the 24 engine families that the Agencies included in their discussion of the N2O test data are non-SCR equipped engine families (the blue-green bars in Figure 1 below). However, it is not anticipated that any non-SCR diesel engines will be used in the heavy-duty on-highway segment by the start of the proposed Phase 2 program. Therefore, those engine families are not relevant to the proposed N2O standard. [EPA-HQ-OAR-2014-0827-1269-A1 p.65]

c. Two of the 24 data points that the Agencies have included in their supporting analysis are natural gas-fueled engines and another is a gasoline engine. Those engines also are not SCR-equipped engines and therefore are not relevant to the proposed N2O standard. [EPA-HQ-OAR-2014-0827-1269-A1 p.65]

d. An evaluation of the remaining 19 engine families, assuming the proposed DF of 0.01 g/hp-hr, shows the following (see Figure 1 below): [EPA-HQ-OAR-2014-0827-1269-A1 p.65]

i. 6 engine families have test data below the proposed 0.05 g/hp-hr standard;
ii. 4 engine families have test data approximating the proposed 0.05 g/hp-hr standard; and

iii. 9 engine families (almost half) have test data above the proposed 0.05 g/hp-hr standard.

e. EMA’s evaluation of the 2014 engine data shows that not all of those engines meet the applicable CO2 standards. Some engines are credit-users. The CO2 emission from the range of engines that the Agencies referenced in the NPRM, which span both Vocational and Tractor applications, are shown in Figure 2 and 3 below, respectively, as compared against the applicable Medium Vocational and the Tractor CO2 standards. The referenced engines are separated between Vocational Medium, Vocational Heavy, and Tractor, based on displacement, and are shown in N2O versus CO2 trade-off charts in Figures 4 through 6 below. All of the tractor engines fall outside the Phase 2 N2O-CO2 box. Similarly, a large population of heavy and medium vocational vehicles fall outside the box as well. A trade-off trend can be clearly observed across the entire population of engines. [EPA-HQ-OAR-2014-0827-1269-A1 p.65]

Accordingly, based on the Agencies’ referenced certification data, roughly half of the currently certified engine families would need to make significant reductions in N2O emissions to meet the proposed standard. Furthermore, bringing those engines into CO2 compliance could drive increases in N2O if not mitigated by system improvements. [EPA-HQ-OAR-2014-0827-1269-A1 p.65]

While some of the projected Phase 2 engine technologies (see Figure 7 below) do not have an impact on N2O, such as friction reduction, Rankine cycle operation and turbo compounding, other technologies can have an adverse effect, for example, reductions in EGR and higher compression-ratio combustion systems. Therefore, most of the referenced certified engines would need to incorporate technology development in aftertreatment solutions, which to this point have not been identified, in order to meet the proposed N2O standard. Consequently, the Agencies’ assumption of “no additional cost” is simply not accurate. [EPA-HQ-OAR-2014-0827-1269-A1 p.65-66]

With respect to the Agencies’ discussion of the interaction between N2O and NOx emissions (see 80 FR at 40205), it is not appropriate for the Agencies to assume any future low-NOx regulations in the analysis of this proposed regulation. The costs and technical feasibility of the proposed regulation is based on existing engines and regulations. Any future rulemaking must account for the technological limitations and regulations in existence at the time of the proposed regulation. [EPA-HQ-OAR-2014-0827-1269-A1 p.66]

In sum, EMA objects to the Agencies’ proposal to reduce N2O emissions as a component of the pending rulemaking. The Agencies are simply incorrect in their assumption that the proposed lower N2O standard could be implemented “with no additional cost or lead time.” [EPA-HQ-OAR-2014-0827-1269-A1 p.66]

[Figures 1-7 can be found on p.66-69 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

3. The Proposed N2O Standards

The NODA does not provide any supplemental data regarding N2O emissions, and so falls well short of justifying the Agencies’ proposed new N2O standard of 0.05 g/bhp-hr. To the contrary, the most current relevant emissions data, including those being developed by the Southwest Research Institute (“SwRI”) under its pending low-NOx research program, establish that prevailing N2O emission rates from HDOH engines are higher than the Agencies’ assumptions and are likely to trend up as lower NOx emissions requirements are phased-in. Thus, the premise for this aspect of the Agencies’ proposal – that the proposed reduced N2O standard can be met without the need for any additional engine improvements, design changes, or costs – is simply incorrect. [EPA-HQ-OAR-2014-0827-1891-A1 p.3-4]
**Organization:**  Volvo Group

**N2O Emissions Reduction**

Volvo Group supports the comments made by EMA that N2O emissions cannot be lowered with existing technology. In addition we note that N2O is generated on the diesel oxidation catalyst (DOC) and the diesel particulate filter (DPF) during warm-up and on the selective catalytic reduction catalyst (SCR) and ammonia slip catalyst (ASC). One method to reduce N2O is to reduce precious group metal (PGM) loading on the DOC in order to reduce N2O production. EPA states that N2O should be reduced simply by recalibration, but this is not the case. Although it may be barely possible, at the current NOX standard, to meet the proposed 0.04 g/bhp-hr N2O standard (plus .01 DF), if NOX standards are lowered it will drive higher diesel exhaust fluid (DEF) dosing rates and more than likely require increased DOC PGM loading. Both of these will increase N2O production (beyond the proposed standard). In addition, some N2O reduction strategies may make some of the OBD monitors difficult (or impossible) to achieve. [EPA-HQ-OAR-2014-0827-1290-A1 p.16]

**Response:**

EPA has evaluated the deterioration factors for CO₂, CH₄, and N₂O. These deterioration factors will not change from the Phase 1 values. We have no intention of allowing negative DFs as that is counter to the purpose of DFs, which is to account for deterioration of the emission control systems over the full useful life of the vehicle. Historically, DFs reflected the trend of increasing emissions, so some manufacturers have come to think of them as a way to predict end-of-life emissions. However, they are actually intended to represent the highest emissions during the useful life, relative to the low-hour test data. That is why EPA has never allowed additive DFs less than zero or multiplicative DFs less than one.

In the NPRM, we proposed reducing both the standard and deterioration factor for N₂O to 0.05 and 0.01 g/bhp-hr respectively because engines certified in model year 2014 were generally meeting the proposed standard. We also explained the process behind N₂O formation in urea-SCR aftertreatment systems and how that process could be optimized to elicit additional N₂O reductions. 80 FR 40203. While we have seen some reductions and a few increases in engine family certified N₂O levels across the 2014, 2015, and 2016 model years, the majority have remained unchanged.

While we still believe that further optimization of SCR systems is possible to reduce N₂O emissions, as demonstrated for some engine families, we do not know to what extent further optimization can be achieved given the tradeoffs required to meet the Phase 2 CO₂ standards. These tradeoffs potentially include advancing fuel injection timing to reduce CO₂ emissions resulting in an increase in NOₓ emissions at the engine outlet before the aftertreatment, increasing the needed NOₓ reduction efficiency of the SCR system. We will continue to assess N₂O emissions as SCR technology evolves and CO₂ emission reductions phase in, and we will revisit the standard at a later date to further control N₂O emission. This would likely be included in any upcoming rule to consider more stringent NOₓ standards.

Finally, with respect to test cycles, we note that these standards were adopted as anti-backsliding or cap standards. Thus, we believe a simple broad test method is appropriate. The FTP covers a broader range of test conditions than the RMC, including engine starting and low temperature operation, which makes it an appropriate test cycle.

**3.6 EPA Engine Standards for Methane**

**Organization:**  American Power Group Inc (APG)
We believe the proposed CH4 exhaust emission standard, while not a challenge for gasoline and diesel fueled engines/vehicles, will present a significant challenge for converted HHDD Mixed-Fuel engines even with the option to trade off CO2 GWP ratio’d ‘credits’. These concerns are further explained within the attached document [EPA-HQ-OAR-2014-0827-1197 p.1]

APG also would like to understand how the EPA will credit CO2 reductions enabled by vehicle efficiency improvements (tires, Aero, drive-train friction reduction, etc) as the reported CO2 results only come from the FTP or RMC13 engine dynamometer tests. [EPA-HQ-OAR-2014-0827-1197 p.1]

As the Proposed Phase II regulations allow CO2 reported results to be taken from the FTP-HDT HHDD test for vocational vehicle engines and from the RMC13 HHDD test for line haul vehicle engines, but all HHDD vehicle engine CH4 and N2O reported emissions come from the FTP-HDT HHDD tests, would the EPA consider allowing the CH4 and N2O emission reported results for come from the RMC13 HHDD test for line haul vehicle engines? The RMC13 test results are more representative of the line haul vehicle duty cycle.[EPA-HQ-OAR-2014-0827-1197 p.2]

Challenges to meet the proposed CH4 exhaust emission standard of 0.1 g/bhp-hr for a Dual Fuel (EPA - Mixed-Fuel, ARB - Bi-Fuel, simultaneous diesel and NG fuel) Small Volume Manufacturer: The HHDD diesel engine system configuration should have little to no challenge meeting the proposed Phase II GHG CH4 standard of 0.1 g/bhp-h as there is no CH4 being induced or injected during diesel fueled engine operation. In a Mixed-Fuel conversion, the OEM HHDD engine, engine control systems and after-treatment systems (2010 and newer) are typically unchanged. This can present significant challenges to the Mixed-Fuel system to meet the proposed GHG CH4 0.1 g/bhp-h emission standard. The reasons are two-fold: [EPA-HQ-OAR-2014-0827-1197-A1 p.1]

2) After-treatment oxidation temperatures during the FTP Heavy Duty Transient Cycle
EPA/CARB certification test: In researching possible after-treatment alternatives to help oxidize the ‘quench volume’ induced CH4 exhaust emissions, after-treatment/Diesel Oxidation Catalyst suppliers have investigated significantly higher precious metal loading (Pt) of current DOC configurations, but the exhaust gas temperatures needed to oxidized 80%+ of the exhaust CH4 (585oC) are not realized during the EPA test used to determine CH4 emissions, the FTP—Heavy Duty Transient cycle emission tests, (Please see Figures 1-2). [EPA-HQ-OAR-2014-0827-1197-A1 p.1]

Conversely, conventional DOC’s have a NMHC oxidation effectiveness of 80%+ at 300oC exhaust gas temperature. [EPA-HQ-OAR-2014-0827-1197-A1 p.1]

The cost increase associated with the increased Pt loading would more than double the DOC cost, but would not provide for CH4 oxidation at a high enough effectiveness to significantly reduce CH4 emissions during the FTP Heavy Duty Transient cycle test. Furthermore changing the DOC within the OEM DOC/DPF after-treatment system would void the OEM after-treatment system warranty. [EPA-HQ-OAR-2014-0827-1197-A1 p.1]

[Figure 1 can be found on p.2 and figure 2 can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1197-A1]

The current GHG regulations have HHDDE reportable CO2 results from the FTP-Heavy Duty Transient test cycle for vocational HHDDE vehicles and Ramped Modal Cycle 13 test for line-haul HHDDE vehicles. All N2O and CH4 reportable HHDDE values come only for the FTP-HDT test results. As the APG Mixed-Fuel system is utilized by line haul HHDDE vehicles we would respectfully request that EPA allow all GHG emission values for HHDDE vehicle line haul applications be taken from the RMC
13 test results as the RMC 13 test more represents our customers duty-cycle. Is there some reason the CH4 and N2O reportable results are only used from the FTP-HDT cycle test? [EPA-HQ-OAR-2014-0827-1197-A1 p.4]

**Organization:** Cummins, Inc.

*Cummins supports maintaining the Phase 1 CH4 standard of 0.10 g/hp-hr* [EPA-HQ-OAR-2014-0827-1298-A1 p.19]

Cummins agrees with maintaining the Phase 1 CH4 standard. It is set at an appropriate, fuel neutral level that constrains CH4 emissions while allowing natural gas engines to comply though the use of CO2-equivalent credits if necessary. [EPA-HQ-OAR-2014-0827-1298-A1 p.19]

Additionally, the Agencies are requesting comment on changing the GWP for CH4 and N2O for Phase 2. Changes should only be made if they are Agency-wide, consistent across all GHG programs (for example, light-duty, GHG inventories, reporting rules, etc.). Also, to the extent that Phase 1 credits are carrying over and can be used for CH4 and N2O compliance in Phase 2, maintaining the same Phase 1 GWP values is appropriate. [EPA-HQ-OAR-2014-0827-1298-A1 p.31]

**Organization:** Daimler Trucks North America LLC

*CH4 Standards* - EPA proposed to keep the methane standard at 0.10 g/bhp-hr with a 0.02 DF. We agree that this is [redacted]. Therefore we agree with retaining the Phase 1 CH4 standard. 80 FR 40205. [EPA-HQ-OAR-2014-0827-1164-A1 p.30]

**Organization:** NGVAmerica

The phase 1 heavy-duty vehicle rulemaking, establishing greenhouse gas emission standards, included a compliance alternative allowing heavy-duty manufacturers and conversion companies to comply with the respective methane or nitrous oxide standards by means of over-complying with CO2 standards. For Phase 2, EPA proposes to extend this compliance flexibility. NGVAmerica commends EPA for again extending this compliance option. Given that the ability to offset methane (and also nitrous oxide) emissions with CO2 credits is critical for new natural gas engines and vehicles, we strongly support this provision. With respect to aftermarket conversions, we respectfully request that EPA consider the comments in the previous section. [EPA-HQ-OAR-2014-0827-1270-A1 p.8]

**Response:**

EPA will continue to apply the Phase 1 methane engine standards to the Phase 2 program. EPA adopted the cap standards for CH4 (along with N2O standards) as engine-based standards because the agency believes that emissions of this GHG are technologically related solely to the engine, fuel, and emissions after-treatment systems, and the agency is not aware of any influence of vehicle-based technologies on these emissions. We are applying these cap standards against the FTP duty-cycle because the FTP cycle is the most stringent with respect to emissions of these pollutants and we do not believe that a reduction is stringency from the current Phase 1 standards is warranted. We also note that these standards were adopted as anti-backsliding standards. Thus, we believe a simple broad test method is appropriate. The FTP covers a broader range of test conditions than the RMC, including engine starting and low temperature operation, which makes it an appropriate test cycle.
EPA continues to believe that manufacturers of most engine technologies will be able to comply with the Phase 1 CH₄ standard with no technological improvements. We note that we are not aware of any new cost-effective technologies that would have allowed us to adopt more stringent standards at this time. Nevertheless, EPA will continue to monitor both emissions and the development of emission controls, and may revisit these standards in a future action.

3.7 Compliance Provisions and Flexibilities for Engine Standards

Organization:  Allison Transmission, Inc.

EPA and NHTSA Should Adopt and Improve Alternative Certification Approach

The agencies have requested comment on an alternative certification approach that would allow both vehicles and engines to use the same drive cycles for certification. Allison supports this concept. One benefit of adopting the alternative certification approach would be to alleviate the concerns of engine manufacturers in providing detailed fuel consumption maps (containing proprietary information) for use in GEM. In addition, it is reasonable to protect that the alternate approach will reduce testing burdens, result in more meaningful and realistic fuel maps, result in transient fuel maps and better protect engine and transmission intellectual property. Finally, the alternative certification approach would allow for and realistically result in additional engine and transmission integration efforts. [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

There are several caveats, however, that are important to consider for adoption of the alternative approach in the final rule: [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

(1) Further testing will be required to determine the accuracy of this approach. [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

(2) The approach will not address several real world fuel-economy improvement features that do not receive credit in the proposed GEM – or in powertrain testing. Specifically, EPA and NHTSA should improve the alternative certification approach to give credits to: [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

(a) Transmission elements that adjust shift points based on mass and grade. [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

(b) Transmission elements that manage vehicle acceleration. [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

(3) EPA has included a preliminary comparison between the primary and alternative approaches, but this comparison lacks cost estimates. While raising several key questions in terms of the credibility and accuracy of the approach, another consideration must be the economic impact of adopting the alternative approach and what entities would likely bear this cost. [EPA-HQ-OAR-2014-0827-1284-A1 p.39]

Transmission elements and features such as those outlined above can make a substantial difference in GHG emissions and fuel efficiency, resulting in a 5 to 15% reduction in GHG emissions and improvement in fuel efficiency. EPA and NHTSA should therefore make efforts prior to finalization of this rule to expand the alternative approach and incorporate additional currently “non-creditable” features. [EPA-HQ-OAR-2014-0827-1284-A1 p.39]
62 See additional comments in Section IV.

63 RIA at 3-101.

64 Depending on the scope of this effort, additional regulatory process may be required.

**Organization:** American Automotive Policy Council

**In-Use Compliance and Useful Life** - AAPC agrees with continuing the 3 percent adjustment factor applied to the full useful-life certification standards for the purpose of determining in-use emissions and fuel consumption standards. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

**Loose engine provision** - AAPC recommends the continued allowance for “loose engine” sales to be counted in the sales of the manufacturer’s complete pickup and van products for greenhouse gases. Our primary market continues to be complete heavy-duty vehicles in the 2b/3 classes with a relatively small number of engines being sold to outside vehicle manufacturers. To continue to support this business model, the AAPC members request the continued use of this provision to allow continuity in our business practice. This continued flexibility will allow the individual manufacturers to accurately report compliance of the “loose engine” sales. AAPC considers the Phase 1 final rule statement of reason to be valid and required to comply with the complex Phase 2 greenhouse gas regulations – “...we are adopting a related special provision involving chassis certification aimed at simplifying compliance for manufacturers of complete heavy-duty pickups and vans that also sell a relatively small number of engines...” (76 Federal Register 57260) [EPA-HQ-OAR-2014-0827-1238-A1 p.11-12]

The Agencies requested comment (80 Federal Register 40206) on the appropriateness of continuing the 3 percent adjustment factor applied to the full useful-life certification standards for the purpose of determining in-use emissions and fuel consumption standards. This adjustment factor was applied in Phase 1 based on the Agencies’ assessment of testing variability inherent in comparing results among different laboratories and different engines. AAPC supports the continuance of this allowance for in-use testing. No material advances have occurred that would result in the variability factors relevant in Phase 2 being significantly different than they were in Phase 1. Furthermore, the appropriateness of the 3% allowance has not yet been assessed against actual in-use data on 2014 MY or later vehicles and engines near their full useful lives. Absent such data, a thorough assessment of the appropriateness of this allowance cannot be made. AAPC further notes that in-use verification program limits in Light-Duty are 10% to account for in-use variations. [EPA-HQ-OAR-2014-0827-1238-A1 p.16]

§ 1036.535 Determining engine fuel maps and fuel consumption at idle. Section 1036.535 requires the OEM measure and record fuel flow and NOx emission rates at ~143 points during the GEM fuel mapping process. The NOx (g/s) measurement proposed standards potentially implicate and imply new criteria pollutants requirements that where not discussed or evaluated in the RIA. Additionally, the provisions of CAA section 202(a)(3)(C) seem to apply, notably the requirement of four years lead time and three years stability. Given these considerations AAPC recommend removing the NOx (g/s) reporting requirement from 1036.535 or making it voluntary until a subsequent heavy-duty on-road emission rule making. [EPA-HQ-OAR-2014-0827-1238-A1 p.33]

**Organization:** California Air Resources Board (CARB)

**Oppose/Requested Change Comment**
Comment – Appropriateness of useful life adjustment factor

The NPRM requests comment on the useful life adjustment factor allowance. [EPA-HQ-OAR-2014-0827-1265-A1 p.158]

Consistent with Section 202(a)(1) and 202(d) of the CAA, for Phase 1, U.S. EPA established in-use standards for heavy-duty engines. Based on their assessment of testing variability and other relevant factors, U.S. EPA established in-use standards by adding a 3 percent adjustment factor to the full useful life emissions and fuel consumption results measured in U.S. EPA certification process to address measurement variability inherent in comparing results among different laboratories and different engines. See 40 CFR part 1036. U.S. EPA and NHTSA are not proposing to change this for Phase 2, but request comment on whether this allowance is still necessary. [EPA-HQ-OAR-2014-0827-1265-A1 p.158]

CARB staff believes that the current 3 percent adjustment factor should be removed. An emission standard inherently already accounts for measurement variability due to different laboratories and engines being tested. While the 3 percent in-use factor was allowed for Phase 1 vehicles since the Phase 1 standards were new, this in-use factor should not be necessary for Phase 2 vehicles. Historically, CARB typically does allow an in-use factor when phasing in new standards that force new technology. Many manufacturers have already implemented the technologies that will be required to meet the proposed Phase 2 standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.159]

In conclusion, CARB staff encourages U.S. EPA and NHTSA to not apply the proposed 3 percent adjustment factor to the in-use emission standard. [EPA-HQ-OAR-2014-0827-1265-A1 p.159]

Neutral/Provide Additional Info Comment

Comment – Not-to-Exceed (NTE) Standards

There may be opportunities to fold in-use compliance testing for CO2 and N2O into the NTE protocol currently in place for criteria pollutants. This could provide greater assurance of in-use compliance, and provide manufacturers an efficient way to demonstrate in-use compliance for greenhouse gas and criteria pollutants simultaneously. When U.S. EPA and NHTSA next consider changes to the NOx standards and NTE requirements, CARB staff recommends considering adding in-use testing of CO2 and N2O. A manufacturer could conduct NTE testing and determine in-use compliance for the entire suite of pollutants (GHG as well as other criteria pollutants). [EPA-HQ-OAR-2014-0827-1265-A1 p.159]

CARB staff also suggests that tracking of vehicle weight and speed with engine CO2/N2O emissions could be used as a tool to determine overall vehicle performance. This information could be used as a GEM correction/correlation tool going forward. [EPA-HQ-OAR-2014-0827-1265-A1 p.159]

Organization: Clean Energy

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 249.]

And, for the record, we are strongly supportive of closed crank systems for spark-ignited engines in our space as they have successfully implemented this strategy in Europe.

Organization: Cummins, Inc.
Cummins opposes the exclusion of curb idle torque from the engine certification cycle work calculation [EPA-HQ-OAR-2014-0827-1298-A1 p.19]

In 40 CFR 1036.501(g)(1), the Agencies are proposing to exclude work generated during “any portion of the duty cycle that has a zero reference value for normalized torque.” This modification can increase the brake specific CO2 calculated on the certification cycle by up to 8% for engines being used with automatic transmissions. The Agencies’ belief that this change is insignificant is incorrect. The addition of curb idle torque to a cycle does not always reduce the cycle’s brake specific CO2 emissions. More fuel is burned to achieve that higher cycle work, so the impact of that extra work on the total cycle performance depends on how efficiently that extra fuel is burned. Engine certification based on the engine work performed is the appropriate measure. How efficiently that engine work is used to propel the vehicle is accounted for in the vehicle regulation and does not need to be considered in the engine regulation. Furthermore, exclusion of curb idle torque work for CO2 certification yields an inconsistency between criteria emissions and CO2 evaluation, undermining regulatory integrity. Criteria emission and GHG emission results must be consistently measured and calculated over the same test protocols. For these reasons, 40 CFR 1036.501(g)(1) should not be finalized. [EPA-HQ-OAR-2014-0827-1298-A1 p.19]

Cummins supports continuation of a 3% compliance margin for engine CO2 emissions [EPA-HQ-OAR-2014-0827-1298-A1 p.22]

In Phase 1, a 3% compliance margin was provided for engine CO2 emissions to be applied during selective enforcement audit (SEA) and in-use testing. This margin accounts for measurement variations between facilities and engines. The Agencies are proposing to maintain the 3% compliance margin for engine standards in Phase 2, and Cummins supports this proposal. A similar 3% compliance margin should be applied to GEM results from the engine fuel map used for the vehicle program for SEA testing, as suggested in EMA’s comments. [EPA-HQ-OAR-2014-0827-1298-A1 p.22]

Organization: Daimler Trucks North America LLC

The FCL to FEL allowance is still necessary – In Phase 1, the agencies created a 3 percent adjustment factor to the FEL results measured in the certification process thereby accounting for lab to lab and engine to engine variability (i.e., by applying a 1.03 multiplier to the CO2 FCL to establish the FEL for CO2 levels established during the engine certification process). The agencies request comment from manufacturers regarding continuation of the Phase 1 approach. 80 FR 40206. DTNA supports the agencies’ proposal to continue to utilize this adjustment factor since one can expect that testing variability and other factors considered by the agencies in establishing this approach will not change significantly in the timeframe of Phase 2. DTNA also believes that a variability allowance is also applicable to a manufacturers certified fuel map to account for the same sources of variability and strongly recommends that EPA address the issue in Phase 2 in a similar manner as in Phase 1, for the same reasons (as discussed in our comments above). [EPA-HQ-OAR-2014-0827-1164-A1 p.12-13]

DF For Criteria Pollutants, CO2, and N2O – The agencies discuss DF test procedures and request comment, particularly for how to apply DFs on low level pollutant emissions for which test-to-test variability may be larger than the actual deterioration rates being measured (e.g., N2O). 80 FR 40206. The current dynamometer medium-heavy and heavy-heavy duty diesel DF methodology is overly burdensome and costly while yielding DF results that are driven as much by test-to-test variation as the actual deterioration in emissions that the DF testing is designed to characterize. The cost to the manufacture for a 50% unaccelerated useful life DF test, EPA’s preferred method, is in excess of $1 M and takes a minimum of 40 weeks to complete. Since DF’s must be complete prior to the finalizing the emissions calibration, DF testing must start, at the latest, 20 months prior to start of production. Since this
leaves no time to start a new DF engine, in the event of a catastrophic failure of engine or aftertreatment system, manufactures typically run multiple DF’s in an effort to generate a DF that is driven by measurement capability as much or more than the actual deterioration in emissions characteristics. As an example, a measurement noise level of 0.02 g/hphr extrapolated within the calculation can result in a 20-40% non-aging effect that is enough to influence the final result to be potentially non-representative. Additionally, due to time, resource, and cost constraints, most manufacturers only conduct emissions at 3 points, beginning, middle, and end, and extrapolate the DF to full useful life via a straight line linear regression, as required by EPA. This linear “curve fit” and extrapolation does not necessarily yield a DF that is representative of an actual aged to full useful system. NOx standards below today’s level, if adopted, will only serve to exacerbate the influence of test to test variation as well as measurement error on the actual emissions DF. DDC recommends EPA adopt an optional assigned DF for dynamometer certified medium-heavy and heavy-heavy duty diesel engines. [EPA-HQ-OAR-2014-0827-1164-A1 p.17-18]

**DF for Hybrids or Cases with High Measurement Variability** – The agencies request comment on DF procedures where deterioration is nonlinear, for example a saw-tooth as might happen with hybrids if the batteries are replaced during a test. 80 FR 40206. We think that it is unlikely the duration of hybrid testing that a battery would be replaced for normal maintenance reasons, so a saw-tooth is unlikely. But if it were, the DF paradigm would be incorrect. The Clean Air Act requires regulating emission standards over the useful life, but it does not require the use of a DF. CAA § 202(a)(1). Where the tip of the saw-tooth represents the worst-case emissions over the useful life, that is the emission level that must be lower than the emission standard—not an extrapolation through that point. For this reason, we think that the agencies’ focus on saw-tooth patterns and extrapolation is improper. Similarly, the agencies pose questions about busing the DF on the highest value measured. 80 FR 40206. The idea of taking the highest point tested and extrapolating through that point is improper, as the highest point in any test—especially as we get to low emission levels—could be confounded by measurement noise. Rather, the agencies should stick with extrapolation unconstrained by the erroneous requirement to pass through the highest point. [EPA-HQ-OAR-2014-0827-1164-A1 p.18]

**Potential Alternative Certification (Cycle Average Mapping) Approach** - The agencies request comment on an approach that could mitigate certain engine manufacturer concerns by allowing both vehicle and engine to use the same driving cycle for certification. 80 FR 40193. In this proposal, GEM generates engine torque and speed profiles for a subsequent engine dyno test of the engine family parent rating, the results of which are then input back into GEM for vehicle compliance purposes for any engine rating. This is a very complicated procedure, and we have not had time to evaluate it. But we have concerns that testing the parent of a family on a drive cycle that involves gear shifts and high torque operation will not characterize the results of the child ratings to the level of accuracy needed for this regulation, and may in fact provide an easy pass for certain ratings. Further, we are concerned that to resolve the inaccuracy the process will force manufacturers to test most or all child ratings, thereby exacerbating the already increased burden of this process, rather than easing the burden as the agencies suggest will happen. More accurately, we see little benefit in terms of accuracy and no benefit in terms of protecting CBI (as we have stated elsewhere in our comments, the fuel map does not convey CBI), yet we see much increased test burden. We recommend against adopting this alternative certification approach or, at least, we recommend delaying making regulations on this procedure until there has been adequate time to resolve the many outstanding issues. [EPA-HQ-OAR-2014-0827-1164-A1 p.43]

**Dual rating engines, remote changes to fuel map, etc** - The EPA proposes that, for vehicles that have multi-torque ratings or vehicles whose engine ratings might be reflashed, the vehicle manufacturer certifies the vehicle using in GEM the worst-case rating that the vehicle might see in its lifetime. (This was based on oral discussions with the agency and is not written in the NPRM. Nonetheless, we feel it
important to respond). As a preface to our comments, it is important to explain certain aspects of our industry just to make sure the agencies are aware. Heavy-duty vehicle manufacturers and their dealers need the ability to reflash engine ratings, e.g., because many vehicles are sold as stock vehicles with a generic rating that will be reflash when the vehicle is configured to its particular customer and job application, and because many vehicles change jobs during their lifetime such that they need power curve changes to perform the new task. However, we do not know a priori which vehicles will need to be reflash. If the EPA required that we take a penalty—using the worst-case rating is a penalty—for a practice inherent in the industry, then the EPA would need to factor such penalty into its standard setting process and in turn loosen the emission standards. If the EPA is unwilling to do so, then the agency needs to provide flexibility so as to avoid stifling an important industry practice. We propose that the EPA allow us to reflash an engine’s rating to another rating selected from the ratings certified within the subject certified engine family and whose emissions control and fuel consumption characteristics are of common design. We understand the EPA’s concern that manufacturers might sell a vehicle with a “best-case” rating (meaning the rating that gives the lowest fuel consumption in GEM) but, immediately upon sale of the vehicle, reflash the rating to a higher emission one. We would not do that, however, because it is prohibited tampering, prohibited under the CAA. But to give the EPA even more certainty that we are not trying to game the system, we would agree to track the vehicles and report their actual rating at the end of the 270 day reporting period after the close of the model year. (Note that we are using the 270 day number because, as we mention elsewhere in our comments, the 90 day number is too short for the EPA to get valuable information). Similarly, if in the future we have software that reflash a rating on the fly, then we propose that the EPA accept that the heavy-duty industry does so to facilitate vehicle operators’ business and thus treats this not as prohibited tampering but as an allowable act. This would be similar to the allowance to change vehicle configurations currently in 1037.655, except that we should not be hamstrung by the limitation on doing this before the regulatory useful life expires; optimizing fuel efficiency should not wait until the end of the useful life. And this would not limit us to modifications that only result in a decrease of fuel consumption, as it may be necessary for a vehicle to have higher torque and higher fuel consumption than when it was built so that it can complete a task. In short, we recommend that the EPA exercise its regulatory discretion to allow multi-torque ratings or reflash without penalizing manufacturers. (Concurrent with this change, the EPA should amend 1037.655 to reflect the agency’s intent to allow modifications that are necessary for vehicle owners to complete their jobs). [EPA-HQ-OAR-2014-0827-1164-A1 p.47-48]

Organization: International Council on Clean Transportation (ICCT)

Engine mapping procedure

Regarding the agencies’ consideration of an alternative mapping procedure, we offer several comments. In principle, we support the agencies seeking to better estimate real-world transient effect of engines in full-vehicle operational settings. We believe this alternative mapping approach does offer the potential for improved fidelity regarding transient effects, to better promote transient operation efficiency and better reflect real-world effects. However, such a dramatic change engine certification and the GEM process -- without substantial data, and without a public understanding of the data comparing the methods for multiple high volume engines by various companies, and without detailed assessment of the pros and cons of the alternative approach -- would be premature. We do not believe that the agencies have put forward sufficient information to validate a shift to the alternative mapping method at this time. We also believe that it is critical that the agencies’ require engine manufacturers to submit all engine maps that will be utilized in real-world driving to ensure the regulators can understand how the regulation connects to the real world operation of the engines and vehicles. Especially for a regulation such as this that is based fundamentally on the simulation of engines and based on limited data from a select few parent engines, for regulators to not have detailed maps (e.g., 100 engine torque and speed points) would
essentially provide no ability to monitor and ensure compliance and troubleshoot on any potential in-use issues. [EPA-HQ-OAR-2014-0827-1180-A4 p.14]

**Organization:** Isuzu Motors Limited

Isuzu also would like to have the agencies extend the loose engine provision from the Phase I Rule. Currently the loose engine provision is scheduled to end in 2020MY. Isuzu would like to see the rule extended to at least through 2024MY. This provision allows us to continue to provide Class 3, 4 and above Spark Ignited products in limited quantities and also still allows us to produce alternative gaseous fueled vehicles. [EPA-HQ-OAR-2014-0827-1263-A1 p.3]

**Organization:** Motor & Equipment Manufacturers Association (MEMA)

*Ensure Technology-Neutral, Performance-Based Standards* [EPA-HQ-OAR-2014-0827-1274-A1 p.3]

Beginning with regulations for Class 7 and 8 engines and vehicles, we agree with classification of vehicle technologies based on end-user expectations for useful life and emissions warranty. Although certain criteria outlined in Table II-17 do not logically apply to Heavy Duty SI engines, we agree with classification of vehicle technologies based on end-user expectations for useful life and emissions warranty. If left as proposed, it does not provide sufficient clarity for criteria emission requirements. The agencies should take a technology-neutral, performance-based approach in order to provide a predictable, consistent and level playing field for technologies and energy sources. [EPA-HQ-OAR-2014-0827-1274-A1 p.3-4]

**Organization:** National Propane Gas Association (NPGA)

*Classification of Alternative Fuel Engines*

We disagree with the agencies’ classification of spark-ignited alternative fuel engines under the same emissions standards as diesel fuel engines for vehicles at and above 19,500 lbs GVWR. We find the classification adverse to the overall objectives of the NPRM as well as an inaccurate assessment of alternative fuel engines for heavier vehicles. The agencies determine that similar treatment of spark-ignited alternative fuel engines to diesel for this weight range is logical because, in part, the likely competition to alternative fuels in this weight range are diesel engines. Firstly, it is inaccurate to assume that diesel fuel engines are the principle vehicle type at and above 19,500 lbs GVWR. There are many vehicles at that weight that are fueled by gasoline. Moreover, autogas is an increasingly popular alternative fuel for school buses, among other medium- and heavy-duty vehicles. Therefore, the existence of alternative and gasoline fueled vehicles above 19,500 lbs GVWR renders application of the standards for diesel engines incongruous with the actual demographics of such weight range. [EPA-HQ-OAR-2014-0827-1272-A1 p.3]

Secondly, the agencies’ decision to apply the standards for diesel engines to alternative fuel engines creates a disincentive for the expansion of alternative fuel. Over the years, diesel engines have been subject to increasingly technical, discerning regulations implemented over a timeframe that facilitates research, development and disbursement throughout the marketplace for gradual improvement. Unlike the tactful, timely evolution of standards for diesel engines, the analogous approach in the NPRM proposes immediate application of such evolved standards to alternative fuels that are in various stages of development; to some degree, less advanced than diesel engines. If required to meet the same standards as diesel engines, it is our concern that dissemination of alternative fuels, like autogas, to the public would be delayed or precluded due to additional time in research and development, higher cost, etc. Therefore,
the result of the proposed analogous treatment of diesel fuel engines and alternative fuel engines for vehicles at and above 19,500 lbs GVWR may be a general disincentive for autogas, among other alternative fuels. [EPA-HQ-OAR-2014-0827-1272-A1 p.4]

Organization: PACCAR, Inc.

Engine Family/Subfamily Certification

Manufacturers need flexibility for engine GHG subfamilies within NO\textsubscript{x} certification families. A requirement to certify with a new NO\textsubscript{x} family when differences in technologies only affect GHG/fuel efficiency of the engine will add to certification burdens, costs, OBD demonstrations, certification fees, etc. PACCAR requests the Agencies work with manufacturers to develop a reasonable resolution of this issue. The subfamily approach used for vehicles may be a viable concept. [EPA-HQ-OAR-2014-0827-1204-A1 p.30]

Organization: Truck & Engine Manufacturers Association (EMA)

Parent-Child Engine Ratings

One open question that the Agencies have raised is whether they should set additional Phase 2 CO2 and fuel consumption standards for the other engine ratings (often called the “child ratings”) within an engine family. EPA has requested comment from manufacturers regarding the continuation of the Phase 1 approach to GHG certification of an engine family, pursuant to which the certification of the parent and child ratings is based on emissions results from testing the parent rating. (See 80 FR at 40206). EMA supports the continuation of this Phase 1 approach for the certification of parent and child ratings, and also supports the Phase 1 requirement that parent rating sales volumes achieve a minimum level. EMA further agrees that by including the actual fuel map and rating-specific full load curve in the GEM simulation, the range of engine ratings are appropriately represented in the vehicle certification. [EPA-HQ-OAR-2014-0827-1269-A1 p.32]

Powertrain Compliance Responsibility

Proposed 1036.630 allows an engine manufacturer to choose to include engines used in powertrain families in their engine families. However, under proposed section 1036.630(b), even if an engine manufacturer chooses not to certify any engines in the family over the powertrain test cycles, EPA may still require the engine manufacturer to participate in recalls associated with a powertrain-associated GHG emissions exceedance when the powertrain has presumably been certified by some other manufacturer. [EPA-HQ-OAR-2014-0827-1269-A1 p.43]

An engine manufacturer should not be held responsible for powertrain test results certified by a different manufacturer, since the engine manufacturer may not have knowledge of the engine test cycles or the
compliance margin used by the manufacturer certifying the powertrain test. In such a case, the engine manufacturer should only be liable for the FTP/SET-based and the engine fuel map-based GHG emissions for which the engine is certified. In that regard, EPA already has other means of ensuring engine compliance, such as through engine SEAs and in-use testing of the engine family. [EPA-HQ-OAR-2014-0827-1269-A1 p.43]

Alternative-Fuel Engines

As in Phase 1, alternative-fuel engines are included within the scope of the Phase 2 GHG/FE program. EMA has no objection to that aspect of the Phase 2 program, nor to the Agencies’ proposal for how alternative-fuel engines are to be classified as either compression-ignition (“CI”) or spark-ignited (“SI”) engines in the context of the proposed GHG emission standards. (See Proposed section 1036.140). However, the Agencies should clarify that the proposal also applies to the manner in which engine manufacturers categorize their alternative-fuel engines with respect to compliance with the emission standards for criteria pollutants, as well as with respect to the categorization of vocational vehicles for GHG/F E purposes. (See, e.g., Proposed §1037.105 (Table 3).) [EPA-HQ-OAR-2014-0827-1269-A1 p.45]

Measuring NOx During Fuel-Mapping

EMA objects to the Agencies’ proposed requirement that manufacturers also measure NOx emissions during the proposed engine and powertrain fuel-mapping processes. There is no need or reasonable justification for that added testing burden on top of processes that already require the development of a 143-point engine map (plus 4 idle test points) and a 24-to-27 point powertrain map. Moreover, since manufacturers still remain subject to NTE and SEA requirements, other regulatory mechanisms are already in place to guard against any discernible backsliding with respect to the control of NOx emissions. In sum, there is no basis for imposing an additional NOx-testing burden. [EPA-HQ-OAR-2014-0827-1269-A1 p.48]

Deterioration Factor for CO2 Emissions

EMA agrees with the Agencies that the Phase 2 deterioration factor for CO2 emissions should remain at 0.0 g/hp-hr. Engine manufacturers do not foresee utilizing engine technologies that would increase CO2 emissions as the engines age. [EPA-HQ-OAR-2014-0827-1269-A1 p.63]

In the NPRM, the Agencies request comment on how to apply DFs to low-level emission measurements where test-to-test variability may be larger than the actual deterioration rates measured. (See 80 FR at 40206). That challenging question arises when regulated emissions levels are approaching zero, as they are now. EMA believes that the best way to address the Agencies’ question is to analyze the emissions data from the EMA DF Test Program that industry is currently conducting with oversight from both EPA and CARB. Under the DF Test Program, a number of engines are being operated for thousands of hours and are generating emissions data throughout that extensive testing. At the conclusion of that test program, EMA will be in a much better position to address the Agencies’ question regarding how best to apply a DF to low-level emissions measurements. When the DF Test Program concludes next year, EMA will analyze the available data together with EPA and CARB, and at that time will be able to provide more informed input. Additionally, at that time, EMA, EPA and CARB can assess whether any potential changes to the application of DFs to low-level emissions should be carried over to criteria pollutant emissions to maintain consistency. [EPA-HQ-OAR-2014-0827-1269-A1 p.63-64]

Organization: Volvo Group
**Engine Families**

Volvo Group also notes that there is an opportunity to simplify the certification burden by making modifications to the definition of the engine family. As has been discussed in the past, there is a marked difference in the engine family definition for On-Highway engines versus Non-Road engines. The method utilized for On-Highway is based more on traditional convention where the defining parameters were centered on the base engine (e.g. bore center-to-center dimensions). However, the Non-Road regulations are more flexible and allow engines of the same architecture, but differing displacements to be grouped into the same engine families. [EPA-HQ-OAR-2014-0827-1290-A1 p.41]

The intention of the definition is to group engines of similar emissions characteristics. The current definition has not been updated since the advent of modern aftertreatment systems and unduly segregates engines of like nature based on parameters that no longer have a bearing on emissions. [EPA-HQ-OAR-2014-0827-1290-A1 p.41]

Volvo Group recommends a revision of the Engine Family definition, which would better align it with modern emissions related families (e.g. Engine Families, Powertrain Families) that an OEM (and the EPA) have to manage. [EPA-HQ-OAR-2014-0827-1290-A1 p.41]

**Organization:** Cummins, Inc.

(a) Cummins agrees the reweighted Ramped-Modal Cycle Supplemental Emissions Test (RMCSET) reflects the engine downspeeding trend of HD engines. However, the current criteria emissions protocol has a different NO\textsubscript{x} weighting than the proposed CO\textsubscript{2} RMCSET. Different weighting factors may allow CO\textsubscript{2} improvement at the expense of increased NO\textsubscript{x} emissions. Any future rulemaking on criteria emissions should reestablish the link between NO\textsubscript{x} and CO\textsubscript{2} emission test cycles. [EPA-HQ-OAR-2014-0827-1298-A1 p.7]

(b) Separate credit for engine downspeeding at the vehicle level conveys CO\textsubscript{2} benefit in the vehicle program which is not reflected in the engine standard and may be accomplished at the expense of in-use NO\textsubscript{x} emissions, especially when downspeeding leads to operation outside the NO\textsubscript{x} NTE zone. Figure 1 shows a copy of Figure 2-14 from the Draft Regulatory Impact Analysis (RIA). Overlayed on this figure is the NTE zone for the criteria emissions regulation and the engine operating speeds for the vehicle on the 55 and 65 MPH GEM cycles. [EPA-HQ-OAR-2014-0827-1298-A1 p.8]

**Cummins opposes engine manufacturers being held liable for powertrain results submitted by another manufacturer** [EPA-HQ-OAR-2014-0827-1298-A1 p.40]

In 40 CFR 1036.630(b), the Agencies are proposing to require that engine manufacturers participate in recalls associated with a powertrain GHG exceedance, even if the engine manufacturer did not generate the powertrain results. For reasons outlined in EMA’s comments, Cummins opposes engine manufacturers being liable for powertrain results submitted by other manufacturers. [EPA-HQ-OAR-2014-0827-1298-A1 p.40]

**Organization:** Navistar, Inc.

The requirement for NO\textsubscript{x} measurement during the 143 point fuel mapping exercise is unnecessary, burdensome and redundant to the existing certification (FTP and RMC, AECD qualification) and compliance testing (confirmatory, SEA and NTE). We believe there is no development, certification or compliance value in collecting this data. Furthermore, for the purposes of modeling, manufacturers have
sufficient second--by--second emissions data that can be designated as CBI and provided to the EPA upon request. We agree with EMA comments on this topic as well. [EPA-HQ-OAR-2014-0827-1199-A1 p.23]

10 42 U.S.C. §7521(a)(3)(C). Navistar believes this provision applies to this rulemaking since this rule addresses heavy duty vehicles and engines. Even if it didn’t, however, as the NPRM notes, EPA acknowledges that four years of lead time is necessary and the four year lead time of EISA does apply. NPRM at 40150.

Organization: Eaton Vehicle Group Eaton

Data acquired with powertrain testing

We do question the implications of the proposed retaining of NOx measured data. While we do understand the concern that the engine and transmission controller might adversely impact the NOx emissions, we believe that is an issue of all advanced powertrains certified through the powertrain test or just through GEM simulation. Therefore, we do not see the added value of recording emission data on select powertrains (not those certified under GEM only). Additionally, such data collection is an added burden to the testing entity and it raises questions on the accuracy and cell calibration requirements. Indeed, if the data is recorded for archival purposes only, the testing entity would have to maintain full criteria emissions capabilities similar to an engine emissions certification test cell. [EPA-HQ-OAR-2014-0827-1194-A1 p.10]

Recommendation: the EPA should not require certification-grade NOx data, as there is no standard to compare it to and it puts the burden on non-engine manufacturers to implement advanced engine measurements. [EPA-HQ-OAR-2014-0827-1194-A1 p.10]

We expect the data provided from the powertrain test be treated as business confidential and competitive intellectual property. We believe the amount of data should be limited to the minimum necessary for certification, especially as powertrain manufacturers are both suppliers and competitors of the OEMs. [EPA-HQ-OAR-2014-0827-1194-A1 p.10]

Response:

Engine Classification

EPA emission standards have always applied differently for gasoline-fueled and diesel-fueled engines. The regulations in 40 CFR part 86 implement these distinctions by dividing engines into Otto-cycle and Diesel-cycle technologies. This approach led EPA to categorize highway natural gas engines according to their design history. A diesel engine converted to run on natural gas was classified as a diesel-cycle engine; a gasoline engine converted to run on natural gas was classified as an Otto-cycle engine.

Under the existing EPA regulatory definitions of “compression-ignition” and “spark-ignition,” a natural gas engine would generally be considered compression-ignition if it operates with lean air-fuel mixtures and uses a pilot injection of diesel fuel to initiate combustion, and would generally be considered spark-ignition if it operates with stoichiometric air-fuel mixtures and uses a spark plug to initiate combustion. As described in Section II.D.(5)(e), EPA proposed a change because we now believe this approach does not fully reflect the reality that engines used in Class 8 vehicles compete directly with diesel engines.
EPA’s basic premise for the proposed change is that natural gas engines performing similar in-use functions as diesel engines should be subject to similar regulatory requirements. The compression-ignition emission standards and testing requirements reflect the operating characteristics for the full range of heavy-duty vehicles, including substantial operation in long-haul service characteristic of tractors. The spark-ignition emission standards and testing requirements do not include some of those provisions related to use in long-haul service or other applications where diesel engines predominate, such as steady-state testing, Not-to-Exceed standards, and extended useful life. We believe it would be inappropriate to apply the spark-ignition standards and requirements to natural gas engines that are being used in applications mostly served by diesel engines today. We therefore proposed to adopt a differentiated approach to certification of natural gas engines across all of the EPA standards – for both GHGs and criteria pollutants. 80 FR 40207.

We are finalizing this provision with modifications. We will require manufacturers to divide all their natural gas engines into primary intended service classes, as we already require for compression-ignition engines, whether or not the engine has features that otherwise could (in theory) result in classification as SI under the current rules. We proposed that any natural gas engine qualifying as a medium heavy-duty engine (19,500 to 33,000 lbs. GVWR) or a heavy heavy-duty engine (over 33,000 lbs. GVWR) would be subject to all the emission standards and other requirements that apply to compression-ignition engines. However, based on these comments, we are finalizing this change only for heavy heavy-duty engines.

Commenters identified medium heavy-duty applications in which SI alternative fuel engines compete significantly with gasoline engines, which is not consistent with the premise of the proposal. Thus, we are not finalizing the proposed change for medium heavy-duty engines.

We are not aware of any currently certified engines that will change from compression-ignition to spark-ignition under this approach. Nonetheless, because these proposed changes could result in a change in standards for engines currently under development, we believe it is appropriate to provide additional lead time. We will therefore continue to apply the existing interim provision through model year 2020.42 Starting in model year 2021, all the provisions will apply as described above for heavy heavy-duty engines. Manufacturers will not be permitted to certify any engine families using carryover emission data if a particular engine model switched from compression-ignition to spark-ignition, or vice versa. However, as noted above, in practice these vehicles are already being certified as CI engines, so we view these changes as clarifications ratifying the current status quo.

These provisions will apply equally to engines fueled by any fuel other than gasoline or ethanol, should such engines be produced in the future. Given the current and historic market for vehicles above 33,000 lbs. GVWR, the agencies believe any alternative-fueled vehicles in this weight range will be competing primarily with diesel vehicles and should be subject to the same requirements as them.

Finally, beginning in 2021, we will limit the ability of these medium heavy-duty engines operating on alternate fuels to generate credits relative to the SI standards. However, should we identify a more precise way to differentiate between SI engines that compete primarily with gasoline engines from those that compete significantly with diesel engines, we may reconsider this restriction.

42 Section 202 (a)(2), applicable to emissions of greenhouse gases, does not mandate a specific period of lead time, but EPA sees no reason for a different compliance date here for GHGs and criteria pollutants. This is also true with respect to the closed crankcase emissions discussed in the following subsection. Also, as explained in section I.E.i.e, EPA interprets the phrase “classes or categories of heavy duty vehicles or engines” in CAA 202(a)(3)(C) to refer to categories of vehicles established according to features such as their engine cycle (spark-ignition or compression-ignition).
In-Use FEL Adjustment

In Phase 1, the agencies adopted a compliance structure using two related compliance levels: the “family certification level” (FCL); and the “family emission limit” (FEL), which is specified in the regulations to be equal to 1.03 times the FCL. This structure, which was adopted to address several areas of uncertainty, applied the FCL for certification testing and the FEL for production-line and in-use testing. The agencies proposed to continue this approach for Phase 2.

Manufacturers supported continuation of this approach while CARB opposed it, arguing that it is inconsistent with past practices for other standards. The agencies understand CARB’s goal of eliminating the 3% in-use adjustment, but do not have enough information to do so at this time. Thus we will continue to evaluate the need for this adjustment as we gather data from production-line and in-use engines.

It is important to emphasize that, although we are including this in the final Phase 2 regulations, we do not expect manufacturers to design their engines to have higher fuel consumption in-use than they have during certification. Rather, we expect most engine families to meet their FCLs in actual use. Thus, if we collect sufficient data in the future that allows us to determine the 3% is too large or even unnecessary, we could revise or eliminate it without impacting the intended stringency of the standards.

Manufacturers argued that we should extend this approach to fuel maps. We did not propose this because we believe the broader nature of the fuel maps further reduces the need for any in-use adjustments. This is even more appropriate under the final regulations, which has revised the SEA test provisions to further reduce variability.

In a related matter, CARB supported applying the not-to-exceed (NTE) approach to GHG emissions. However, we have not determined how this could be applied, or if it would be appropriate to do so. Nevertheless, we will continue to evaluate this and may reconsider such action in the future.

CITT

In an attempt to simplify the test procedures, the agencies proposed to exclude work generated during any portion of the duty cycle that has a zero reference value for normalized torque. However, manufacturers objected noting that the change would make the engine standards more stringent. Because this was not our intent, we are not finalizing this change.

Deterioration Factors

The agencies are finalizing the deterioration factor provisions essentially as proposed, which manufacturers generally supported. However, DDC objected to what it appears to believe to be the agencies proposed approach for engines and vehicles with nonlinear deterioration patterns. DDC appears to believe the agencies proposed or were considering an approach where deterioration would be extrapolated in a way to overestimate emissions. This is not correct. The proposed deterioration factor approach (which is being finalized) requires only that the final deteriorated emission level reflect the highest level projected to occur within the useful life – whether it occurs at the beginning, the end, or somewhere in between.

EPA also requested comment on how to apply DFs on low level pollutant emissions for which test-to-test variability may be larger than the actual deterioration rates being measured. EPA generally agrees with the type of approach suggested in EMA’s comments. EMA believes that the best way to address the
Agencies’ question is to analyze the emissions data from the EMA DF Test Program that industry is currently conducting with oversight from both EPA and CARB.

Refloashing Engine Controls

DDC objected to requirements/prohibitions related to reflashing engine controls in-use. Viewed from the perspective of certification, this is a requirement for manufacturers to certify based on the worst case ratings. Viewed from an in-use perspective, it is a prohibition against configuring the engine in a manner that is inconsistent with the certificate. It is unclear to what aspect of this approach DDC is objecting because it acknowledges and accepts the prohibition of tampering. Therefore, the agencies will continue to work with manufacturers to clarify what is and is not permissible.

Alternative Cycle-Average Fuel Mapping

The agencies requested comment on an alternative mapping procedure based on engine testing over the GEM duty cycles over a range of simulated vehicle configurations. This approach would use GEM to generate engine duty cycles by simulating a range of transmissions and other vehicle variations. See 80 FR 40179. Comments received on this issue during the formal comment period that ended on September 11, 2015 were mixed. However, since then the agencies have met with manufacturers and other interested stakeholders to improve this approach, which have led some who initially opposed this approach to become more supportive. For additional discussion on the development of the cycle average mapping procedure see RIA Chapter 3.1.2.6.

Engine Manufacturer Liability

EMA commented that engine manufacturers “should not be held responsible for powertrain test results certified by a different manufacturer, since the engine manufacturer may not have knowledge of the engine test cycles or the compliance margin used by the manufacturer certifying the powertrain test.” It added that “the engine manufacturer should only be liable for the FTP/SET-based and the engine fuel map-based GHG emissions for which the engine is certified.” We largely agree with these statements, with an important clarification. Should we determine from powertrain testing that the engines are causing vehicle noncompliance because the engines do not conform to their certificates of conformity, we may require the engine manufacturer to participate in a recall to remedy the noncompliance.

Engine Families

The agencies did not propose to significantly change the engine family provisions. However, PACCAR commented on engine families, apparently in reference to the provision in §1036.230 (d), which states:

> Engine configurations within an engine family must use equivalent greenhouse gas emission controls. Unless we approve it, you may not produce nontested configurations without the same emission control hardware included on the tested configuration. We will only approve it if you demonstrate that the exclusion of the hardware does not increase greenhouse gas emissions.

PACCAR suggested the agencies work with manufacturers to consider flexibility in applying this provision, which is allowed under the existing language.

---

43 Memos to Docket, “Test Procedure Review with Cummins, Volvo, Navistar, Paccar, Daimler Eaton and Allison.”
Volvo suggested more fundamental changes. Given the broad nature of their suggestion, we believe it would be more appropriate to consider it in a separate rulemaking with additional notice and comment.

**Loose Engines**

The agencies proposed to not continue beyond Phase 1 the interim "loose engine" allowance for engines equivalent to engines in chassis-certified HD pickups and vans. AAPC and Isuzu both commented in support of extending it into Phase 2. However, this provision was originally intended only as a transitional provision as the agencies began regulating GHGs and fuel consumption for heavy-duty engines. Thus, we do not believe it would be appropriate to continue it indefinitely. Nevertheless, we see some value in extending it for an additional three years (through MY 2023), subject to a lower production of 10,000 engines per engine manufacturer, per model year.

**Measuring NOx Emissions**

AAPC commented that NOx measurement could “imply new criteria pollutants requirements that [were] not discussed or evaluated in the RIA.” This is not the case. Rather, the NOx information would be evaluated for compliance only in the context of existing requirements. EMA objects to the requirement to measure NOx emissions during the engine fuel-mapping processes, based on their concerns about test burden. EMA argues that “there is no basis for imposing an additional NOx-testing burden.” However, this ignores EPA’s previously stated interest in ensuring NOx and CO2 emissions are controlled simultaneously. Nevertheless, we are finalizing some provisions to address the concerns about test burden. In particular, we note that we will allow manufacturers to use field-grade NOx instruments, which can be less expensive and easier to use. We also will not require manufacturers to invalidate fuel maps if the NOx measurement fails during the mapping.

In addition, we believe requiring NOx measurements will address concerns such as those raised by Cummins.

**Crankcase Emissions**

Spark-ignition engines are already required to have closed crankcases. See Section 12.7 of this RTC for a discussion of crankcase emissions from natural gas-fueled engines and vehicles.

### 3.8 Engine Test Procedures

**Organization:** American Automotive Policy Council

**Vocational Engines** - AAPC details multiple concerns associated with idle work, infrequent regeneration adjustment factors (IRAF), and test fuel changes and recommends approaches for addressing these concerns. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

**Heavy Duty Diesel Urea Decomposition Adjustment**

AAPC believes it is inappropriate to downward adjust Heavy-Duty diesel CO2 requirements by 2 g CO2 / bhp-hr to reflect urea decomposition without supporting data. To perform an accurate analysis, AAPC recommends that the Agencies collect, analyze and report on feedgas NOx emission rates, urea dosing rates, and resulting tailpipe NOx levels for a wide variety of diesel engines, power ratings, and aftertreatment system configurations used today and in future years. The test program should collect data
on the cold and hot Heavy-Duty FTP and RMC test cycles. [EPA-HQ-OAR-2014-0827-1238-A1 p.29-30]

§ 1036.530 fuel adjustment impacts on CO2

The planned change from Tier 2 to Tier 3 gasoline certification fuel by the end of 2022MY significantly changes baseline 2017MY HDGE and GEM starting assumptions. Furthermore, the impact of test fuel change was not discussed, documented, or analyzed in the draft RIA and or proposed rule. [EPA-HQ-OAR-2014-0827-1238-A1 p.28]

AAPC members conducted heavy-duty gasoline engine transient testing with four different fuels. The results indicated that a change to Tier 3 E10 regular grade test fuel amounts to an additional 3% increase in stringency relative to baseline assumptions for over 14,000lb GVWR gasoline products. AAPC recommends that the specific Tier 3 E10 regular gasoline factor (BTU/lbm C) be developed for Tier 3 E10 certification fuels. [EPA-HQ-OAR-2014-0827-1238-A1 p.28-29]

[Table of fuel type testing results can be found on p.29 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

Changes to Engine Test Calculation Methods

Proposed changes in 1036.501(g)(1) would require manufacturers to exclude work during any portion of the duty cycle with a zero reference value for normalized torque (i.e. idle work) from the total engine work calculation. While not discussed in the initial RIA, subsequent materials submitted to the docket indicate that the rationale for this change was to eliminate the effect of procedural differences between engines intended to be equipped with manual and automatic transmissions. AAPC is not aware of any heavy-duty spark ignition engines equipped with manual transmissions in the US market. [EPA-HQ-OAR-2014-0827-1238-A1 p.26]

AAPC estimates that this calculation method change results in an effective stringency increase of 3-4% for spark ignition engines and 5-8% for compression ignition engines intended to be equipped with automatic transmissions (See table below and graph on next page for details). The technology needed to make up for this difference is not incorporated into the existing RIA. [EPA-HQ-OAR-2014-0827-1238-A1 p.26]

[Table of engine and gasoline/diesel types can be found on p.26 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

Curb idle torque varies widely by application consistent with good engineering judgment which dictates that applications requiring high curb idle torque will be worst case for emissions. [EPA-HQ-OAR-2014-0827-1238-A1 p.26]

[Chart, curb idle torque vs torque converter K-factor, can be found on p.27 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

AAPC recommends that the Agencies withdraw this proposed change to the total work calculation method, keeping the existing method unchanged and harmonized between CO2 and criteria emissions calculations. Idle emission reductions are already being driven by GEM model idle inputs. [EPA-HQ-OAR-2014-0827-1238-A1 p.27]
Proposed changes in 1036.501(g)(3) require that manufacturers use continuous sampling and prohibit batch sampling to measure CO2 emissions over the ramped modal cycle. To avoid potential facility impacts to engine manufacturers, AAPC requests that manufactures be allowed to propose alternative methods to collect emissions via batch sampling that are equivalent or more conservative compared to the mode-weighted continuous sampling methodology. [EPA-HQ-OAR-2014-0827-1238-A1 p.27]

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)

Reweighting operating points for tractor truck engine certification to reflect today’s lower real-world operating speeds is another positive step. [EPA-HQ-OAR-2014-0827-1280-A1 p.5] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.55-56.]]

**Cycle-average approach to engine performance**

For purposes of representing the engine in GEM, i.e. for certifying tractor and vocational vehicle fuel consumption levels, manufacturers must provide a 140-point steady-state engine map showing fueling rates. However, the agencies request comment on an alternative procedure for representing engine performance, both for input to GEM and for engine certification, using “cycle average maps” (RIA p.3-80). The agencies note that this alternative could be the procedure finalized in the Phase 2 rule. [EPA-HQ-OAR-2014-0827-1280-A1 p.8]

The rationale for this alternative is two-fold. First, some engine manufacturers believe that the engine fueling map constitutes confidential business information and would prefer not to divulge it to the OEMs, as the proposal would require. Second, the alternative procedure can capture transient performance of the engine, which is an important factor in engine fuel consumption. [EPA-HQ-OAR-2014-0827-1280-A1 p.8]

Given that some OEMs have indicated their willingness to provide engine maps, we are not sympathetic to the concern regarding engine CBI. However, we strongly support the agencies’ efforts to capture engines’ transient performance in testing, which will both improve the agreement between certified and real-world performance and enable the standard to promote technologies that reduce fuel consumption in transient operation. [EPA-HQ-OAR-2014-0827-1280-A1 p.8]

Agency test data indicates that, when tested over a cycle that includes transient operation, engines consume from 3 to 7% more fuel than would be calculated from modeling the engine based on a steady-state fuel map. Cycle–based engine testing would create an incentive for the adoption of transient controls that minimize this fuel consumption, especially if the standards were tightened to reflect this opportunity for additional fuel consumption reduction. [EPA-HQ-OAR-2014-0827-1280-A1 p.8]

**Recommendation:** Cycle-average approach to engine performance [EPA-HQ-OAR-2014-0827-1280-A1 p.8]

- Continue to develop and refine the proposed cycle-average approach to engine testing. Should this approach be adopted, greater efficiency should be required of engines to drive the adoption of transient controls. [EPA-HQ-OAR-2014-0827-1280-A1 p.8]
Comment on Topic Where NPRM Requests Comment

Comment - Proposed reweighting of SET modes

The NPRM requests comment on the reweighting of SET modes. CARB staff agrees with U.S. EPA and NHTSA that the current 23 percent weighting of “C Speed” in the SET Cycle will not adequately represent typically real world driving conditions seen in future heavy-duty applications. Therefore, CARB staff supports the reweighting of the SET cycle as proposed to increase the importance of the A Speed engine applications, while decreasing the application of C Speed engine modes. [EPA-HQ-OAR-2014-0827-1265-A1 p.41]

Neutral/Provide Additional Information Comment

Comment – Engine-only testing over the GEM duty cycle approach

CARB staff generally supports the NPRM’s proposal for vehicle simulation and engine testing and is interested in the extent to which engine-only testing can help capture the transient behavior that is lost in a steady state fueling map simulation approach. This capture of transient behavior could yield more robust results for vocational applications that are characterized by hard acceleration and by stop-and-go driving patterns. [EPA-HQ-OAR-2014-0827-1265-A1 p.114]

As has been noted, the simulation burden for correctly capturing transmission behavior is non-trivial even with access to the proprietary control algorithms. CARB staff anticipates that engine/transmission interactions will continue to develop in both sophistication and prevalence as powertrain development groups seek to maximize efficiency and minimize GHG emissions. This increased complexity is likely to make high fidelity transmission modelling increasingly difficult over time. The advantages of engine-only testing to augment the GEM model inputs could be viewed as a partial step toward eventual use of powertrain and powerpack testing inputs in the GEM model. [EPA-HQ-OAR-2014-0827-1265-A1 p.114]

Organization: Daimler Trucks North America, Navistar Inc., Paccar Inc., and the Volvo Group

EPA has recognized that fixed engine test cycles are not as reflective of real world operation as vehicle-based duty cycles. There is nothing new about optimization of engines and vehicles for on-road performance while optimizing for criteria emissions on fixed test cycles. This has always occurred since the dawn of emissions control. EPA has added significant and onerous in-use test and OBD requirements that, in fact, largely dictate emissions control design more so than the fixed engine tests. The advent of GHG emissions control has changed this only to the extent that it forces recognition that vehicle-engine interactions must be recognized to optimize efficiency. EPA should propose to bring the criteria and GHG control process into alignment, not by forcing an ineffective engine regulatory scheme, but by looking to develop criteria emissions controls that account for the vehicle-engine interactions as a long-term objective. Clearly this is not easy and will take quite some, but acknowledging this goal as a key objective for future rulemakings could diffuse some of the pressure to adopt ineffective engine regulations just to align with old criteria emissions processes. In fact, EPA has intimated that “cycle average” engine testing as discussed as an alternative in the Phase 2 Regulatory Impact Analysis is attractive because it may have potential to better align efficiency and criteria regulations. [EPA-HQ-OAR-2014-0827-1894-A1 p.5]

Organization: Environmental Defense Fund (EDF)

C. Agencies should restore the linkage between the GHG and criteria pollutant test cycles
The Supplemental Engine Test (SET) steady-state cycle is one of two test cycles that EPA uses to
determine compliance with existing criteria pollutant emission standards. The SET was also adopted as
the sole test cycle for GHG compliance determinations in EPA’s medium- and heavy-duty Phase 1 GHG
rule finalized in September 2011. By using the same SET cycle for both programs, manufacturers are
prevented from trading off criteria pollutant control for CO2 control. [EPA-HQ-OAR-2014-0827-1312-A1 p.35]

As explained above, however, the Agencies are proposing to revise the cycle weighting for CO2
compliance testing purposes only, based on the belief that the revised weighting would make the SET
more representative. But by proposing the SET re-weighting for CO2 only, EPA breaks the linkage
between criteria pollutants and CO2, because PM and NOx would continue to be measured on the
existing SET cycle. Setting aside the merits of the revisions, this de-linkage is of serious concern because
it creates a loophole in the regulations that could lead to increases in criteria pollutants. We strongly
recommend that EPA maintain the same test cycle for CO2 and criteria pollutants in order to prevent
these unintended consequences. One possible way to do this, if EPA decides to finalize the CO2 cycle re-
weighting, is to apply the same revisions to the criteria pollutant program. [EPA-HQ-OAR-2014-0827-
1312-A1 p.35]

Organization:  Navistar, Inc.

The proposed reweighting of the RMC appears to be appropriate and Navistar believes that it will
improve the functioning of that test. The re-weighting allows for technology developments to be aligned
with the usage of tractor applied engines. [EPA-HQ-OAR-2014-0827-1199-A1 p.22]

Organization:  Walsh, Michael and Charlton, Stephen

There is a large amount of information available in the published literature related to HD tractor engine
fuel consumption and BTE measurement. The metrics used vary widely – with the common goal of
representing the real-world fuel consumption of HD tractor-trailers in tests or in simulations. In the Phase
1 rule [17], EPA and NHTSA adopted the SET steady-state cycle with the weighting factors used in the
original European ESC cycle. These same weighting factors are used by EPA in the SET test for criteria
pollutants (NOx and PM) for HD on-highway engines. In the proposed Phase 2 rule [14], the agencies
have adjusted the weighting factors to favor lower engine operating speeds. The current and proposed
SET cycles with weighting factors are shown in Figure 4. [NHTSA-2014-0132-0102-A1 p.11]

[Figure 4 can be found on p.12 of docket number NHTSA-2014-0132-0102-A1]

In addition, by proposing a new cycle for GHG regulation, the linkage between criteria pollutants and
GHGs has been broken, since NOx and PM would continue to be measured on the current cycle. The loss
of direct linkage between NOx, PM and GHG emissions could lead to unintended consequences, for
example with regard to in-use emissions. This misalignment should be remedied by either reverting back
to the SET test cycle used for NOx and PM for GHG certification, or by adopting the new test cycle for
NOx and PM certification. [NHTSA-2014-0132-0102-A1 p.12]

A further engine test of importance here is the SuperTruck 65mph cruise test cell test point. This test
point will vary between SuperTruck projects depending on the engine speed at 65 mph cruise (i.e. overall
gearing and tires assumed), and on the vehicle road load at 65mph. With reasonable assumptions, the test
point will likely fall between the A and B speeds at 50% to 75% load, see Figure 5. [NHTSA-2014-0132-
0102-A1 p.12]
Response:

The agencies are not finalizing an allowance to adjust CO₂ emissions for FTP or SET testing to eliminate CO₂ from urea (although we are finalizing a similar allowance for fuel maps). Thus, we will not adjust heavy-duty FTP or SET CO₂ emission standards downward to account for CO₂ derived from urea decomposition. As noted in the NPRM, we estimate that current engines produce about 2 g/hp-hr of CO₂ from urea. However, this is based on very limited data.

Regarding gasoline test fuels containing ethanol, the agencies have performed heavy-duty engine testing at Southwest Research Institute utilizing both Tier 2 and Tier 3 certification test fuels. These results in g CO₂/bhp-hr show that with post-test correction of the eCO₂ results back to the reference fuel as required in 40 CFR 1036.530, there does not appear to be a statistically significant difference between the Tier 2 and Tier 3 fuel results. In other words, the specified correction adequately accounts for test fuel effects. In addition, the agencies disagree with the commenter’s conclusion based on their test data that the change to Tier 3 cert fuel increases stringency. The change to Tier 3 certification fuel should not include an engine’s change in behavior due to octane. The correct comparison for regular-octane fueled engines is low octane Tier 2 fuel to low octane Tier 3. The results of this comparison from the manufacturers’ test data show that there is not an increase in stringency due to the certification fuel change. Thus there is no effect on the stringency of the heavy-duty SI engine standards and the agencies will not be developing a Tier 3 E10 gasoline factor for Tier 3 certification fuels for heavy-duty engines.

The agencies have removed the proposed requirement to exclude work with zero reference value normalized torque from the total engine work calculation, keeping the existing method unchanged.

The agencies have provided an optional alternate RMC cycle with different weightings for CO₂ measurement in 40 CFR 1036.505. This alternate cycle affords the use of bag CO₂ measurement in place of the continuous measurement that would be required if using the current RMC in 40 CFR part 86.1362. We believe this will provide equivalent results to the continuous measurement technique.

The agencies are finalizing the use of cycle average fuel mapping for transient operation and making it optional for highway cruise cycles. Steady-state fuel mapping remains the default/reference method for cruise and idle cycles. The agencies will further consider the use of cycle average fuel mapping in the future when it undertakes further criteria pollutant reductions.

The agencies appreciate the support for the reweighting of the SET cycle, and we agree that it should largely reflect operation at 65 mph. At this time we are not in a position to align GHG and criteria pollutants with respect to the use of this reweighted duty-cycle due to the effect of the reweighting on criteria pollutant emission results. However, we do not agree that this causes a misalignment with NOx because CO₂ and NOx will be measured at the same test points.
4 Class 7 and 8 Combination Tractors

4.1 General Comments

All of the tractor comments are included in subsections 4.2 through 4.6.

4.2 Proposed Tractor Standards for CO\textsubscript{2} and Fuel Consumption

**Organization:** California Air Resources Board (CARB)

**Comment – Approved low-GWP refrigerants for heavy-duty vehicles**

The NPRM states that currently, there are no low-GWP refrigerants approved for the heavy-duty vehicle sector. This appears to be a misstatement. Two low-GWP refrigerants, R-744 (CO\textsubscript{2}) and HFC-152a have been approved for motor vehicle air conditioning systems, including those for heavy-duty vehicles. (In addition, HFO-1234yf is SNAP approved for light-duty use and Chemours is applying for SNAP approval for this low-GWP refrigerant for heavy-duty use). [EPA-HQ-OAR-2014-0827-1265-A1 p.141]

**Response:**

Section III of the FRM Preamble has been corrected. Additional discussion regarding alternative refrigerants is included in Section I.F of the FRM Preamble.

**Organization:** Climate 911

Several independent analyses by transportation energy experts concur that diesel consumption by heavy duty trucks could be reduced to 40% of 2010 levels as early as 2025 using technology which is, for the most part, commercially available. Economic analysis showed this could be accomplished at a reasonable cost (payback from fuel savings within 12-24 months) with substantial long term savings. (NRC, 2010. ACEEE, 2013). [EPA-HQ-OAR-2014-0827-1179-A1 p.1]

The proposed Phase 2 standards fall far short of what is possible, increasing the fuel economy of tractor trailers from the current 5-6 mpg to 8-9 mpg in 2027. The Department of Energy's Super Truck Program has already surmounted this low bar with a Cummins-Peterbuilt Class 8 tractor trailer which gets 10.7 mpg and another built by Daimler which gets 12.2 mpg. (USOEEREE, 2015) [EPA-HQ-OAR-2014-0827-1179-A1 p.1]

National Research Council; Transportation Research Board Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles. Committee to Assess Fuel Economy Technologies for Medium- and Heavy-Duty Vehicles; National Academies Press 2010

Response:

The agencies considered all of the general comments associated with the 40 percent reduction and the SuperTruck program. We believe there is merit in many of the detailed technology comments received and these are discussed in detail in Section III of the FRM Preamble. DOE has partnered with the heavy-duty industry to demonstrate high roof sleeper cab tractor and box trailer combinations that achieve a 50 percent improvement in freight efficiency evaluated as a 65,000 pound vehicle operating on the highway. This type of tractor represents only one of the ten subcategories of tractors where the agencies have set new stringencies for Phase 2. In addition, these SuperTrucks are not necessarily designed to handle the rigors of daily use over actual in-use roads. For example, they generally have very limited ground clearance that would likely preclude operation in snow, and would be very susceptible to damage from potholes or other road hazards. Thus, simply applying SuperTruck efficiencies would lead to infeasible standards, since the SuperTruck program does not account for the range of operating conditions likely to be experienced in use. Nor does the SuperTruck program account for cost of technology, or lead time needed to reliably deploy the technology. Nevertheless, the SuperTruck program has led to significant advancements in the efficiency of combination tractor-trailers. While the agencies cannot simply apply the SuperTruck program achievements directly into the Phase 2 program because of the significant differences in the purpose of SuperTruck and the plenary applicability of regulations with the force of law, it is helpful (although not determinative) to assess the achievements and evaluate how the technologies could be applied into mass production into a variety of real world applications and maintaining performance throughout the full useful life of the vehicle.

Organization: Edison Solar Inc.

Finally, we know that improving truck fuel efficiency can is achievable and can be done affordably:

• Through partnerships with the Department of Energy, major manufacturers have proven fuel economy ratings of over 12 mpg are achievable for combination tractors through advanced technologies. [EPA-HQ-OAR-2014-0827-1176-A1 p.2]
technologies could be applied into mass production into a variety of real world applications and maintaining performance throughout the full useful life of the vehicle.

**Organization:** International Council on Clean Transportation (ICCT)

*Tractor-trailers* – Overall for tractors, the technologies included in the stringency determination are far short of the full technology potential. Applying the available incremental technologies for engines, transmissions, and aerodynamics can achieve technology potential far greater than agencies’ proposed 8 miles-per-gallon tractor-trailer standards before 2025 (See Delgado and Lutsey, 2015). SuperTruck teams are achieving 10.7 mpg (Peterbilt) and 12.2 mpg (Daimler/Freightliner) in real-world testing (Buchholz, 2014; Daimler, 2015) with combinations of engine, tractor, and trailer technologies that greatly surpass the proposed 2027 standard analysis. After correcting for test cycle differences, the SuperTruck technologies demonstrated by manufacturers would achieve up to 10 miles per gallon (Lutsey, 2015b); because the proposed 2027 stringency levels do not approach these stringency levels, the standards can be advanced by at least several years. [EPA-HQ-OAR-2014-0827-1180-A4 p.5]

**Response:**

The agencies considered all of the general comments associated with the 40 percent reduction and the SuperTruck program. We believe there is merit in many of the detailed technology comments received and these are discussed in detail in Section III.D of the FRM Preamble. For example, the agencies included the technology assessments in the ICCT tractor-trailer technology reports that were cited in the ICCT comments.

DOE has partnered with the heavy-duty industry to demonstrate high roof sleeper cab tractor and box trailer combinations that achieve a 50 percent improvement in freight efficiency evaluated as a 65,000 pound vehicle operating on the highway. This type of tractor represents only one of the ten subcategories of tractors where the agencies have set new stringencies for Phase 2. In addition, these SuperTrucks are not necessarily designed to handle the rigors of daily use over actual in-use roads. For example, they generally have very limited ground clearance that would likely preclude operation in snow, and would be very susceptible to damage from potholes or other road hazards. Organization: Union of Concerned Scientists (UCS)

The agencies' proposal must be 'technology-forcing' and achieve the 'maximum feasible' reductions in the timeframe of the rule. To do this, the agencies must strengthen Alternative 4 by: [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

- Increasing the stringency for tractors by 6 percent in 2024 to reflect the full range of improvements to the powertrain; [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

Response:

First, UCS is mistaken that section 202 (a)(2) of the Clean Air Act mandates technology-forcing standards, although it allows them. See generally 74 FR 49464-465 (Sept. 28, 2009). Second, the agencies acknowledge UCS’s comment about increasing the stringency of the tractor program due to the opportunity to further improve powertrain optimization through powertrain testing. For the Phase 2 final rule, we have made several changes since proposal that capture much of the improvement potential highlighted by UCS. First, the agencies have used additional engine technologies in the technology package used to determine the tractor standards for the final rule, as described in Section III.D.1 of the Preamble. In addition, the final rule requires the use of a cycle average fuel map in lieu of a steady state fuel map for evaluating the transient cycle in GEM will recognize improvements to transient fuel control of the engine. The agencies are including the impact of improved transient fuel control in the engine fuel maps used to derive the final standards. Second, the optional transmission efficiency test will recognize the benefits of improved gear efficiencies. Therefore, the agencies have built some improvements in transmission gear efficiency into the technology package used to derive the final standards. This leaves only the optimization of the transmission shift strategy, which would need to be captured on a powertrain test. The agencies believe that the opportunity of shift strategy optimization is less for tractors than for other types of vocational vehicles because a significant portion of the tractor drive cycles are at highway speeds with limited transmission shifting. Therefore, we have not included the powertrain optimization portion only recognized through powertrain testing into the standard setting for the final rule.
4.3 Projected Tractor Technologies, Effectiveness, and Cost

**Organization:** A de F Limited

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 167-168, 171.]

And I want to applaud EPA on incentivizing small, incremental, innovative technologies that ultimately add value in the big picture.

A lot of times, we underestimate the incremental. And when that incremental is scalable, we may very well miss meaningful opportunities that move us to our ultimate goal, in this case CO2 mitigation.

The market opportunities of aerodynamic wheel covers have gained momentum with many new entrants salivating at the commercial prospects. An aerodynamic wheel cover is the only aerodynamic component that is functional on both tractor and trailer. And, yet, because of this regulatory process that splits tractor from trailer in testing, it is lost in the noise.

The addition of a single sentence to this regulation that would embrace testing of tractor-trailer combinations for aerodynamic components found on both would be helpful to permit aerodynamic wheel covers to scale in a marketplace that is worldwide.

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 169, 171.]

We applaud EPA’s focus on vigilantly bumping efficiency of long-haul tractor-trailer combinations through this new phase 2 as it will bring further fuel savings through trailer efficiency.

When measuring the increases in efficiency of wheel covers on trailers and tractors independent of each other, the fuel savings get lost in the margin of error of the test methodology. With no enmity suggested, it is our belief that a hugely scalable opportunity is being missed. We suggest a remedy that would permit testing of both tractor and trailer in combination for the purposes of aerodynamic components that can be fitted to both.

We believe current testing methodology is sufficient, albeit misapplied to either tractor or trailer and not the combination.

**Response:**

The agencies considered technologies, including wheel covers, in establishing the more aerodynamic bins, such as Bin V, in Phase 2.

**Organization:** Alliance of Idle Mitigation Technologies

The Alliance of Idle Mitigation Technologies was formed out of concern that Phase 2 will drastically and unintentionally limit the options available for idle reduction. [EPA-HQ-OAR-2014-0827-1311-A1 p.1]

The Alliance consists of best in class companies, including Idle Smart, IdleAir, and Shorepower Technologies, who offer high impact solutions to extended main engine idling of class 8 trucks. Common
among member companies is the threat that a radical increase in adoption of Automatic Engine Shutdown (AES) will have on member companies’ viability. The threat varies from complete incompatibility, as in the case of adjustable automatic shutdown, to frustration of relevance, as in the case of electrified parking space providers. [EPA-HQ-OAR-2014-0827-1311-A1 p.1]

Unlike the transition away from tire pressure monitoring systems towards a system that both monitors and inflates the tires, the transition to AES is not a straightforward progression to greater efficiency. AES will necessarily result in APU adoption. The costs and environmental effects of APU’s are not fully considered within the proposed rule. [EPA-HQ-OAR-2014-0827-1311-A1 p.1]

The Alliance recognizes that the AES scoring scheme is not new. However, in light of the ambitious increase in the efficiency threshold, even after accounting for the inclusion of technologies that are arguably not commercially feasible today, the effect of this scoring scheme is as different between Phase 1 and Phase 2 as the meaning of the word “lightening” after appending the word “bug.” [EPA-HQ-OAR-2014-0827-1311-A1 p.1]

Response:

The agencies received a number of comments regarding “mandating APU” or “mandating AES.” There is a misconception of the proposed Phase 2 program where stakeholders thought that the agencies were mandating APUs (or mandating any technology for tractors, for that matter). This is incorrect. The tractor standards are performance standards to be met by any means an OEM chooses. The agencies merely projected an adoption rate of up to 90 percent for tamper-proof AES in our analysis as one part of one technology package for determining the stringency of the proposed standard. We did not propose to differentiate between the various idle reduction technologies in terms of effectiveness and only used the diesel powered APU in terms of estimating the cost and effectiveness of the proposed, or final standard. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths and combinations of technologies. They will not be required to apply all technologies to every tractor; nor will they be required to apply any specific technology to any tractor.

The agencies have assessed the environmental impact of APUs in the NPRM and FRM. As noted in Section III.C of the Preamble, EPA is adopting a new PM standard of 0.02 g/kW-hr that applies exclusively to APUs installed in MY 2024 and later new tractors. EPA is also amending the Phase 1 GHG standards to provide that as of January 1, 2018 and through MY 2020, a tractor can receive credit for use of an AES with an APU installed only if the APU engine is certified under 40 CFR part 1039 with a deteriorated emission level for PM that is at or below 0.15 g/kW-hr.

Organization: Allison Transmission, Inc.

Several key projections with regard to technology penetration rates and cost estimates in the Proposed Rule are flawed. The agencies are too optimistic with regard to the ability to incorporate hybrids into the MD/HD sector; cost estimates with respect to different transmission architectures are understated; cost estimates for Neutral-Idle and Stop-Start technology are below costs that have been reported. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]

EPA and NHTSA lack a rational basis to provide more credits to automated manual (“AMT”) and dual clutch transmissions (“DCTs”) than fully automatic transmissions. Allison’s real world studies indicate that automatic transmissions (“ATs”) are as good as or better than AMT or DCTs in terms of greenhouse
EPA and NHTSA’s 2 Percent Credit for Advanced Transmissions is Reasonable

EPA and NHTSA have requested comment on “all aspects” of the feasibility analysis that underlies the regulatory alternatives presented in the Proposed Rule. With respect to the projections of the relative emission impact of various transmission technologies, the agencies are proposing a 2% technology input for ATs, AMTs and DCTs for Class 7 and 8 vehicles. While Allison ATs can exceed this level (versus the baseline contained in the Proposed Rule) we believe it is a reasonable level to apply based on the record for this rulemaking for ATs and AMTs. Moreover, we do not believe that EPA and NHTSA have articulated any basis in the Proposed Rule to differentiate between the technology inputs that should be available to ATs and AMTs.

DCTs in Tractors

Mesilla Valley Transportation (“MVT”) operates a fleet of 1345 trucks and over 5000 trailers and is known as one of the largest locally owned, full service truck load carrier companies in the southwest. In October 2014, EPA recognized MVT with the SmartWay® Excellence Award for their progress on environmental performance and energy efficiency. As part of their on-going efforts to find more energy efficient vehicles, MVT has done extensive evaluation of transmissions during 2015. 50 production-built fully automatic TC10TM equipped trucks have been operating in normal fleet operations as a comparison to the Eaton Fuller Advantage® Automated Transmission. The latest data from August 2015 shows the TC10 having 4.6% higher MPG than the fleet average with the AMT. Based on this significant level of improvement, MVT plans to have over 400 AT’s in their fleet of sleeper cab tractors by the end of 2016. It is also notable that when combined with all of the other vehicle efficiency improvements, the TC10 equipped vehicles demonstrated 9.25 MPG in August 2015.

With respect to the Phase 2 proposal, the MVT experience is evidence of the following:

- AT’s can be more fuel efficient than AMTs in real-world tractor duty cycles
- ATs penetration into tractors is feasible per EPA’s assumptions
- ATs are viable in sleeper cabs (in addition to day cabs)
- Neutral at stop capability, 1st lockup operation, load-based and grade-based shift algorithms and Acceleration Rate Management contribute to the overall fuel efficiency of ATs in tractors

EPA and NHTSA must therefore apply the same or greater emission reduction factor to the AT. Not doing so would create an unfair and unsupported disadvantage for ATs relative to the AMTs. This same disadvantage would occur with respect to DCTs; however, as noted above, Allison believes that the agencies lack technical information in the record for this rulemaking to support any credit for DCTs and therefore also lack a rational basis to grant any emission reduction credit in the Final Rule. While DCTs should logically perform better than the MT baseline, EPA and NHTSA must base crediting on adequate...
information placed into the docket; this does not currently exist. Indeed, Volvo has indicated that fuel consumption with the I-Shift Dual Clutch is the same as the I-Shift AMT. 31 [EPA-HQ-OAR-2014-0827-1284-A1 p.18]

In addition, AMTs receive a 1.8% credit in GEM for heavy-haul tractors, yet there is no similar credit for ATs. Although Allison is unaware of statements in the Proposed Rule with regard to the source of the AMT credit, presumably it is for the GHG and fuel efficiency benefits of automation. Since ATs offer similar, if not greater, benefits, they should also receive credit. In addition, neutral-idle recognition should be available as previously discussed in Section III.E. [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

EPA and NHTSA Must Include Automatic Neutral At Stop Into GEM for Tractors

The Proposed Rule expands the incorporation of idle emission systems in GEM, such as Stop-Start systems and AT Neutral-Idle systems. Allison generally supports the agencies’ proposal to expand incorporation of such systems in GEM; our own experience with such systems indicates that they result in significant improvement in fuel efficiency and reduced emissions. The Proposed Rule, however, does not include an idle cycle for tractors, but rather solicits comments as to whether idle systems should be incorporated within GEM for certain tractor types. [EPA-HQ-OAR-2014-0827-1284-A1 p.25]

There is no rational reason not to include automatic neutral in only vocational tractors, but all tractors. Automatic neutral is standard with the Allison TC10 and is available with the Allison 3000 and 4000 Series transmissions; we believe that usage of the technology will be high by 2021. Thus, including Neutral-Idle as a selectable option in GEM is fully justified; allowing its use as a selectable option would both ensure that real world emission benefits would be recognized in GEM and that use of such technology is incentivized. [EPA-HQ-OAR-2014-0827-1284-A1 p.25]

Conversely, there would not appear to be a basis for excluding such technology as a selectable option in GEM, whether or not it is currently utilized in a tractor type of vehicle. Given the long timeframe of this rulemaking, affecting vehicles through at least MY 2027, EPA and NHTSA must recognize and allow for the broader incorporation of Neutral-Idle across many different fleets and vehicle types. There is no technical reason why Neutral-Idle could not be implemented in all tractors and the agencies should allow for its adoption by vehicle manufacturers where it makes commercial sense based on the vehicles’ intended uses. [EPA-HQ-OAR-2014-0827-1284-A1 p.25]

Allison has developed the TC10 transmission that was purpose-designed for the tractor market. The TC10 combines FuelSense® technologies with a blended architecture that combines a traditional AT planetary with a countershaft that results in a very efficient 10-speed powershift automatic transmission. Fleets have reported improvements in excess of 5% higher average fuel economy over their current fleet average with the TC10 and Allison believes that the penetration of the TC10 will grow in tractors based on its performance, reliability and fuel efficiency. [EPA-HQ-OAR-2014-0827-1284-A1 p.25]

Similar to the Allison transmissions for vocational vehicles, the TC10 includes the automatic neutral at stop functionality. This capability must be recognized in all tractor sub-categories. While this benefit would be expected primarily in vocational tractors and day cabs, Allison believes it is significant that over 40% of TC10 sales to date have been into sleeper cabs. This demonstrates market acceptance of the technology due, at least in part, to features of the TC10 that reduce fuel use. [EPA-HQ-OAR-2014-0827-1284-A1 p.25-26]

Although at a much lower penetration rate in tractors than vocational vehicles, Allison’s 3000 and 4000 Series transmissions with automatic neutral at stop technology are also sold into tractors with annual
volume of up to approximately 5000 units. EPA has predicted that the automatic transmission penetration in tractors will grow to 30% in 2027. (RIA Table 2-28). Given this projected adoption – along with the current volume of sales – automatic neutral at stop must be incorporated into GEM in order to ensure the accuracy of the Final Rule, i.e., the ability of the certified emission levels to reflect actual, real world operational emissions. The agencies cannot ignore the emissions and fuel efficiency benefits of a technology which is projected to have sizeable market penetration within the regulatory timeframe of this rulemaking. [EPA-HQ-OAR-2014-0827-1284-A1 p.26]

**EPA and NHTSA Are Correct Concerning Assessment of Hybrids in Tractor Categories**

The agencies have cited to the high costs and “limited utility of hybrids” with regard to tractors for their decision not to include hybrids as part of the standards that are applicable to such vehicles. We share in this overall assessment. In many tractor categories, there is a preponderance of highway driving; incorporating hybrids into most tractors would provide little incremental benefit in terms of reduced emissions and fuel use – while having offsetting effects through the additional weight of hybrid systems. Thus, based on the record before the agency, it is proper for EPA and NHTSA to conclude that hybrids should not factor into the stringency of tractor categories. Investment dollars will yield greater GHG reductions through implementation of other technologies. [EPA-HQ-OAR-2014-0827-1284-A1 p.51]

**EPA and NHTSA Must Account For Weight of Different Transmission Architectures**

The baseline technology for MD/HD automatic transmissions is a planetary gearset. Planetary architectures typically weigh less than countershaft architectures. For vocational vehicles, Allison recommends that a weight penalty be assessed for MT/AMT transmissions with countershaft architectures. For this assessment, the clutch, clutch housing and transmission/clutch shift lever all need to be considered to be part of the transmission to have a relevant comparison to a torque converter automatic transmission. [EPA-HQ-OAR-2014-0827-1284-A1 p.63]

Table III-35 Proposed Phase 2 Weight Reduction Technologies for Tractors includes weight reduction for transmission case, clutch housing and transmission/clutch shift lever. As discussed above for vocational vehicles, a planetary torque converter automatic will weigh less than a comparable manual transmission. Allison recommends that a weight reduction be assigned for planetary automatic transmissions such as the Allison 3000 and 4000 Series in tractors. Our data would suggest a 50 lb savings in Class 8 and much more for Class 7 would be appropriate. Allison expects sales up to approximately 5000 transmissions in tractors this year so there is volume associated with this technology. [EPA-HQ-OAR-2014-0827-1284-A1 p.63]

Allison also suggests a 200 lb penalty for a HHD DCT should be applied given the architecture of this system. [EPA-HQ-OAR-2014-0827-1284-A1 p.64]

---

28 This is not the position we take with respect to DCTs, however. EPA and NHTSA lack technical information in the record to support crediting DCTs within GEM. See Sections II-A, III-B, infra.

31 See “Unique gearbox for heavy vehicles on the Volvo FH.” Attachment 2

82 See comments above in Section I.C.

99 See Attachment 1.
Response:

The agencies’ assessment of the comments is that Allison and Volvo support the proposed two percent effectiveness as an input to GEM for AT and AMT transmission types. The agencies have refined the treatment of transmissions in GEM in the final standards. Using the default transmission input files for AMT and MT, the GEM results for manual transmissions are 2 percent worse than those for an equivalently spec’d automated manual transmission. The agencies have conducted powertrain testing comparing an AMT to Allison’s TC10 automatic transmission (see RIA Chapter 2.8.2.5). Overall, the CO₂ emissions and fuel consumption are equivalent between the two transmissions. However, the agencies have selected default losses for automatic transmissions that are higher than the losses in a TC10 because its efficiency is significantly greater than the average heavy-duty automatic transmission in the market today. Therefore, vehicles that utilize the TC10 transmission will achieve similar CO₂ emissions and fuel consumption as an AMT, and approximately 2 percent better than a manual transmission, by either using the results of either the optional powertrain test (40 CFR 1037.550) or the optional transmission efficiency test (40 CFR 1037.565).

For a vehicle that uses a DCT, the agencies treat it as an AMT in GEM because of the inherent design similarities to AMTs. This is a conservative assumption because in addition to a DCT having mechanical efficiencies similar to an AMT, it also could have lower emissions and fuel consumption due to power shifting capabilities.

The agencies considered the comments, both supporting and raising concerns over idle reduction in day cabs. The agencies determined that neutral idle for automatic transmissions is an appropriate technology for use in tractors. Therefore, vehicles that utilize the TC10 transmission will achieve similar CO₂ emissions and fuel consumption as an AMT, and approximately 2 percent better than a manual transmission, by either using the results of either the optional powertrain test (40 CFR 1037.550) or the optional transmission efficiency test (40 CFR 1037.565).

The agencies are adopting provisions in Phase 2 to recognize neutral-idle in automatic transmissions as an input to GEM. Our analysis shows that neutral idle effectiveness is approximately 0.8 to 1 percent over the composite day cab tractor cycles. The agencies will also include neutral idle as a GEM input for sleeper cabs, though the effectiveness is very low, as shown in RIA Chapter 2.4.8.3. The agencies are predicating the standards for day cabs based on a technology package that includes neutral idle.

After considering the comments, the agencies are continuing the Phase 1 approach of not including hybrid powertrains in our feasibility analysis for Phase 2. Because the technology is still under development for tractors we cannot confidently assess the effectiveness of this technology at this point in time. In addition, due to the high cost, limited benefit during highway driving, and lacking any existing systems or manufacturing base, we cannot conclude with certainty that hybrid powertrains will be available for tractors in the 2021-2027 timeframe. However, manufacturers will be able to use powertrain testing to capture the performance of a hybrid system in GEM if systems are developed in the Phase 2 timeframe.

The agencies are not finalizing a weight penalty for any components since this would require detailed information on conventional and light-weight tractor components to establish a baseline and the weight reduction potential for each component.

The agencies also are not providing a default weight reduction value to transmission type due to the variety of transmissions in the tractor market today. In addition, a 50 pound weight reduction leads to only a 0.06% reduction in CO₂ emissions in sleeper cabs. The manufacturers have the option of requesting off-cycle credits for weight reductions that are not included in 40 CFR 1037.520.

Organization:  Aluminum Association
The Aluminum Association is committed to producing high quality, accurate information for OEMs as well as the EPA and other regulatory agencies on the benefits of aluminum lightweighting in the transportation sector. Mass reduction using aluminum has emerged as a proven and cost effective technology for achieving improved road vehicle fuel economy and CO2 emissions performance and in the past 40 years aluminum use in light and heavy-duty vehicles has increased steadily. In the truck and trailer market specifically, aluminum use has nearly doubled since the recession of 2009 and is trending back toward record levels last seen in the late 1990s and early 2000s. Growth in the use of aluminum in the truck and trailer market has been accommodated utilizing existing production capacity, and where needed, with the addition of new capacity, and the aluminum industry has consistently demonstrated the ability to match supply with demand, including the previous growth of aluminum demand in the aerospace, packaging, and auto transportation sectors. In the auto transportation sector for example, the aluminum industry has publicly announced over 1.5 billion pounds of capacity expansion to come online by 2018 to support that industry’s growth. The long lead times in the proposed rule that require ultimate compliance in the 2027 model year also provide ample opportunity for the alignment of aluminum product supply with any potential for increased demand due to the implementation of lightweighting opportunities in the truck and trailer market. [EPA-HQ-OAR-2014-0827-1260-A1 p.1-2]

The weight and emission benefits that result from using aluminum in heavy-duty trucks are significant. Research conducted by Ricardo Consulting Engineers has shown that an “aluminum-intensive” Class 8 commercial tractor trailer combination can reduce vehicle weight by 3,300 pounds and that for every 10 percent of weight reduction, up to a 5.5 percent improvement in fuel economy is possible. The study also found that substituting the nation’s fleet of Class 8 tractor-trailers with aluminum-intensive models would save 9.3 million tons of CO2 emissions annually. [EPA-HQ-OAR-2014-0827-1260-A1 p.2]

The aluminum industry is also continuously improving its product offering to the heavy truck and trailer transportation market to maximize the benefits of using aluminum in lightweighting applications. Recently, these have included – [EPA-HQ-OAR-2014-0827-1260-A1 p.2]

- Alcoa’s introduction of the ‘ULTRAx Ultra-ONE’ forged aluminum wheel – This wheel is 47% lighter than a comparably sized steel wheel and weighs in at only 40 pounds, thus enabling its potential to save over 1400 pounds in Class 8 service. [EPA-HQ-OAR-2014-0827-1260-A1 p.2]
- Alcoa’s introduction of a new aluminum alloy, ‘Magna-Force’ which is up to 17% stronger than the 6061 alloy it replaces in transportation applications. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
- Novelis’ introduction of the ‘Advanz’ 7000 series next generation high strength aluminum alloy designed to enhance vehicle lightweighting and safety. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
- Sapa’s development and introduction of new aluminum extrusion applications in a variety of tractor componentry including sleeper cabs, seat frames, entry steps/deck plates, and aerodynamic fairings. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
- Rio Tinto’s commissioning of their enhanced state-of-the-art aluminum smelting facility in Kitimat, BC operating solely on clean, renewable, hydropower and using efficient AP40 pot technology to supply aluminum to transportation and other markets in North America and around the world. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

The industry is also pursuing new aluminum joining methods that will enable increased integration of aluminum and non-aluminum components into next generation vocational and heavy-duty vehicles. All the activities noted above continue the aluminum industry’s long history of working with transportation market manufacturers throughout the supply chain to develop vehicle efficiency improvement solutions and that work will continue and become ever more important under the recently proposed Phase 2 standards. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
Lightweighting is well-recognized in the proposed rule as a means to increase trucking efficiency and there are three primary ways that this occurs – [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

1) It lowers rolling resistance, which means it takes less energy to start the vehicle moving and then overcome the friction of its contact with the road, [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

2) It allows carriers to add more cargo to each truck, which reduces the number of trucks on the road and/or trips that need to be made, and, [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

3) It facilitates the adoption of other efficiency technologies, such as trailer tails and side skirting, as it can negate the concerns about the added weight of those technologies. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

Tractor Cab Assemblies

Table 8 of 1037.520 provides weight reduction credits for different individual cab components such as the door, roof, rear wall, and floor. This is appropriate when these components are considered for substitution on an individual basis. However, the Association is aware that in many instances the entire tractor cab is substituted with aluminum and a typical weight reduction associated with this substitution is 500 lbs. Therefore, the Association requests that an additional line item be added to Table 8 reflecting that the “Entire Tractor Cab” be credited with a 500 lb weight reduction if it is switched from steel to aluminum componentry. [EPA-HQ-OAR-2014-0827-1260-A1 p. 7-8]

Response:

The agencies agree with the commenter that there are three primary ways that lightweighting improves efficiency. Weight reductions in GEM are recognized in two ways. The first reduces the mass of the overall vehicle, which in turn reduces the rolling resistance. The second increases the payload of the vehicle in the certification process. In addition, as the commenter notes, lightweighting is a means to offset added weight of other technologies for operators in weight-sensitive operations.

The agencies are not adopting the Aluminum Association’s suggestion to include a weight reduction value for the “Entire Tractor Cab” as an automatic GEM input because cabs come in a variety of sizes and weights. This makes it difficult to assess whether 500 pounds is an appropriate value for both day and sleeper cabs, which have significantly different roof, floor, and side panel areas. We think that the replacement of the entire tractor cab with aluminum can be handled through either the individual components listed in 40 CFR 1037.520 or requested through Off-Cycle credits.

The single most important shortcoming of the proposal is the weakness of the tractor truck engine standard. However, standards for all engine and vehicle classes have room for improvement. [EPA-HQ-OAR-2014-0827-1280-A1 p.6]

Tractor aerodynamics

In the agencies’ compliance package for the 2027 tractor standard, the average CdA value for a high roof sleeper cab (CdA=5.3) is 14.5% lower than the 2017 baseline value, a reduction of 1.6% per year from
the 2017 baseline. This value falls between Bins IV and V, as shown below in figure 1. [EPA-HQ-OAR-2014-0827-1280-A1 p.14]

[Figure 1 can be found on p.15 of docket number EPA-HQ-OAR-2014-0827-1280-A1]

The agencies note: “Since the development of the Phase 1 rules, the manufacturers have continued to invest in aerodynamic improvements for tractors. This continued evolution of aerodynamic performance, both in production and in the research stage as part of the SuperTruck program, has consequentially led the agencies to propose two additional aerodynamic technology bins (Bins VI and VII) for high roof tractors. These two new bins would further segment the Phase 1 aerodynamic Bin V to recognize the difference in advanced aerodynamic technologies and designs” (p.40246). It is therefore important that the standards promote these advances by moving tractor aerodynamics well into the new bins. The 2027 compliance package for a high roof sleeper cab assumes a 25% penetration of these higher aerodynamic bins, but an average that falls short of achieving Bin V. This suggests that the aerodynamic package for the standards is well within reach of the manufacturers over the next decade. [EPA-HQ-OAR-2014-0827-1280-A1 p.15]

**Tractor-trailers**

Since the close of the public comment period, numerous new data on tractor-trailers have been submitted to the docket, including a revised report on fuel efficiency technologies and additional information on tractor aerodynamics. These data continue to show that the agencies have underestimated the technology potential of tractor-trailers and, particularly, tractor engines. Based on this new data, the agencies should tighten the fuel consumption and emissions targets for tractor-trailers and tractor engines. Furthermore, the agencies should improve the aerodynamic testing procedures for tractors to ensure that benefits of the rule are not eroded. [EPA-HQ-OAR-2014-0827-1896-A1 p.1]

**Tractor aerodynamic performance**

Some comments on the proposed rule stated that tractor aerodynamic drag levels assumed in the agencies’ 2027 compliance package were not achievable, at least without a more aerodynamic standard trailer for testing. We are not aware of new information referenced in the NODA that relates directly to this matter; but given comments on the proposed rule, we note here that substantial, additional reductions in drag could be achieved by 2027 through co-optimization and integration of tractor and trailer. These additional drag reductions could be verified by using a more advanced trailer for testing and then correcting for the benefits of the trailer alone, as discussed in greater detail in Appendix 2. [Appendix 2 can be found on p.12 of this docket][EPA-HQ-OAR-2014-0827-1896-A1 p.2]

**Impact on proposal**

There is no evidence provided in the NODA to support weakening of the 2027 aerodynamic targets for tractors. In fact, increased stringency could be achieved by redefining the standard trailer in later years to reflect future improvements to the average trailer and taking advantage of tractor/trailer co-optimization in the compliance package. [EPA-HQ-OAR-2014-0827-1896-A1 p.3]

**Appendix 2: Additional Savings from Tractor-Trailer Co-optimization and Integration**

The agencies’ compliance package for high roof sleeper cabs in the Phase 2 proposal includes aerodynamic improvements that reduce drag by 14% and fuel consumption by 6% in 2027. Manufacturers raised concerns about these levels of drag reductions in their comments, claiming that the expected tractor
drag levels are not achievable using the prescribed “standard” trailer. We do not believe that this concern provides a basis for weakening the aerodynamic performance of high-roof sleeper cabs assumed in the agencies’ compliance scenario. In fact, SuperTruck results indicate that greater aerodynamic improvements than those assumed in the Phase 2 proposal are achievable. [EPA-HQ-OAR-2014-0827-1896-A1 p.12]

Aerodynamic drag (CdA) values and bin levels are shown below for reference. [EPA-HQ-OAR-2014-0827-1896-A1 p.12]

[Figure, 'CdA values and bin levels', can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1896-A1]

Certainty of savings from matching tractor and trailer

The fuel savings benefits of co-optimization and integration of tractor and trailer will not be realized if the equipment is not appropriately paired in real-world operation. Because tractors may tow a variety of trailers, ensuring such pairings would be difficult. This raises a question of whether it is prudent to provide credit for the benefits of tractor-trailer co-optimization and integration as recommended above. [EPA-HQ-OAR-2014-0827-1896-A1 p.14]

Manufacturers and purchasers of co-optimized or integrated tractors and trailers presumably would seek to ensure that the correct pairings were made as a matter of course. The agencies note (p.40245) that “tractor-trailer pairings are almost always optimized.” While this observation was made in the context of roof height and trailer type, the same considerations should apply here. In the case of integration, manufacturers and researchers are clearly working towards designs that would necessitate, or strongly favor, appropriate pairings. Furthermore, it is important to weigh the potential for unearned credits for tractor-trailer pairing against the value of the incentive to accelerate the aerodynamic integration of tractors and trailers. [EPA-HQ-OAR-2014-0827-1896-A1 p.14]

In any case, the likelihood of reasonable agreement between compliance credit for tractor-trailer pairings and the real-world benefits could be increased for example by: [EPA-HQ-OAR-2014-0827-1896-A1 p.15]

• Giving manufacturers credit only for vehicles sold to fleets with well-documented estimates of the percentage of miles traveled with matched set. (Credit computed case by case) [EPA-HQ-OAR-2014-0827-1896-A1 p.15]

• Giving a fixed, partial credit to provide an incentive for co-optimization while recognizing the possibility of mismatches. (Partial credit across the board, e.g. 50%) [EPA-HQ-OAR-2014-0827-1896-A1 p.15]

• Certifying tractors to be used only with certain trailers; this requirement would be shown on the tractor label. (100% credit) [EPA-HQ-OAR-2014-0827-1896-A1 p.15]

• Awarding full credit to tractors having hardware to ensure pairing with appropriate trailers. (100% credit) [EPA-HQ-OAR-2014-0827-1896-A1 p.15]

The agencies could adopt a combination of these approaches. Most fleets at present may be unwilling to accept the loss of flexibility required by the 3rd and 4th approaches, especially given the constraint this may impose on resale of the tractor. However, acceptance should increase over time, as integrated designs
demonstrate major fuel savings, and trailer fleets are managed and optimized in real time. [EPA-HQ-OAR-2014-0827-1896-A1 p.15]

**Tractor Engine Technology Effectiveness**

The Southwest Research Institute (SwRI) completed a comprehensive analysis of fuel consumption reduction technologies applicable to commercial medium- and heavy-duty trucks. Despite downward revisions in technology potential between the draft version of the report available in the proposal and the final report included in the NODA, this research indicates that tractor engines can improve their fuel consumption by at least 8 percent in 2027, nearly double the agencies’ proposed target. [EPA-HQ-OAR-2014-0827-1896-A1 p.1-2]

**Tractor-trailers**

Since the close of the public comment period, numerous new data on tractor-trailers have been submitted to the docket, including a revised report on fuel efficiency technologies and additional information on tractor aerodynamics. These data continue to show that the agencies have underestimated the technology potential of tractor-trailers and, particularly, tractor engines. Based on this new data, the agencies should tighten the fuel consumption and emissions targets for tractor-trailers and tractor engines. Furthermore, the agencies should improve the aerodynamic testing procedures for tractors to ensure that benefits of the rule are not eroded. [EPA-HQ-OAR-2014-0827-1896-A1 p.1]

9 EPA-HQ-OAR-2014-0827-1215.

**Response:**

The agencies disagree with the commenter’s assessment on aerodynamic potential. The aerodynamic data provided in the NODA demonstrates that the high roof tractors tested fall into Bins III and IV. This data does not support increasing the stringency of the aerodynamic technology packages because the majority of this test data was considered in the proposal and all of the tractors tested fell within the range of performance of the vehicles tested prior to proposal. The agencies’ assessment is that only Bins I through V are achievable with known aerodynamic technologies, but that Bins VI and VII have less known technology paths. Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of $C_dA$. See RIA Chapter 2.8.2.2. These aerodynamic improvements have been demonstrated within the program on two vehicles in 2015. In the final rule, the agencies are projecting that truck manufacturers will be able to begin implementing these aerodynamic technologies as early as 2021 MY on a limited scale. We adjusted the adoption rates for MY 2027 in the technology package developed for the final rule to consist of 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors in this segment that we project could successfully apply these aerodynamic packages with this amount of lead time. However, we are including Bins VI and VII in the Phase 2 regulations as a potential Phase 2 technology to recognize the possibility that over the next ten years (until the full implementation of the Phase 2
program) tractor manufacturers may advance their aerodynamic technologies beyond the Bin V levels projected for the Phase 2 standards, and to provide a value to be input to GEM should they do so.

With respect to ACEEE’s recommendation for the agencies to facilitate the transition to more integrated tractor-trailers, such as those demonstrated with SuperTruck, the agencies believe this would require a significant change in tractor-trailer logistics to encourage more matching of specific tractors to specific trailers in operation. We believe that this would be most appropriately handled through the Off-Cycle Credit program.

**Engines**

The Phase 2 engine standards will lead each manufacturer to achieve reductions of 5.1 percent in 2027 MY. For the final Phase 2 rule, we recognize that it could be possible to achieve greater reductions than those included in the engine standard by designing entirely new engine platforms. Unlike existing platforms, which are limited with respect to peak cylinder pressures (precluding certain efficiency improvements), new platforms can be designed to have higher cylinder pressure than today’s engines. New designs are also better able to incorporate recent improvements in materials and manufacturing, as well as other technological developments. Considered together, it is possible that a new engine platform could be 6 percent more efficient without WHR than Phase 1 engines and 8 percent more efficient than Phase 1 if 50 percent of these engines have WHR. We project that 50 percent of tractor engines in 2027 MY will be redesigned engines (i.e. engines reflecting redesigned engine platforms, again based on existing engine platform redesign schedules within the industry) achieving a 6 percent reduction for day cabs and an 8 percent reduction in fuel consumption in sleeper cabs beyond Phase 1. This means the average 2027 MY tractor engine would be 5.4 and 6.4 percent better than Phase 1 for day and sleeper cabs respectively. We have factored these levels into our analysis of the vehicle efficiency levels that will be achievable in MY 2027. These additional engine improvements make more stringent vehicle standards feasible, and the final standards are structured so that these improved engines are not able to generate windfall credits, but rather that their projected performance is reflected in the stringency of the final tractor vehicle standard. We project all vehicle manufacturers will be able to use new platform engines for some of their vehicles. Nevertheless, some may choose not to for business reasons, even though it may be the most cost-effective path. We project that manufacturers that do not achieve this level of engine reduction would be able to make up the difference by applying one of the many other available and cost-effective tractor technologies to a greater extent or more effectively, so that there are multiple technology paths for meeting the final standards. In other words, a manufacturer that does not invest in updating engine platforms in the Phase 2 time frame is likely to be able to invest in improving other vehicle technologies. These reductions will show up in the fuel maps used in GEM to set the Phase 2 tractor stringencies.

**Organization:** American Iron and Steel Institute

In the Proposed Rule, EPA and NHTSA did not assume adoption rates for weight reduction measures and did not consider it 'appropriate or fair across the industry to apply overall weight reductions for compliance.' For different types of vehicles, however, EPA proposes to allow for the crediting of certain identified weight reduction options. [EPA-HQ-OAR-2014-0827-1275-A1 p.15

Regarding tractors, EPA proposes to continue the GEM Phase 1 weight reduction criteria for using certain lightweight materials. [EPA-HQ-OAR-2014-0827-1275-A1 p.15-16]

All of these values serve a regulatory purpose by allowing a credit for different vehicle components, based on the type of vehicle involved. They also implicitly apply a deficit to any materials or components that are not listed, or listed incorrectly. Therefore, like the weight reduction options for trailers, EPA must
supply a basis for these values in the record for this rulemaking or it cannot incorporate them within a final rule. [EPA-HQ-OAR-2014-0827-1275-A1 p.16]

If the agencies intend to pursue identification of specific weight reduction materials and components in a final rule, such a system must be supported by adequate, verifiable data. To this end, we attach to our comments several documents: [EPA-HQ-OAR-2014-0827-1275-A1 p.16]

(1) A/SP Lightweight Suspension, Hannes Fuchs. This report describes the development of lightweight steel suspension front control arms. When contrasted to a baseline forged aluminum component, the study showed that the lightweight steel arms were equivalent in mass. [EPA-HQ-OAR-2014-0827-1275-A1 p.16]

(2) Lightweight Sealed Steel Fuel Tanks (ASP-400), United States Automotive Partnership. This study examined carbon canisters used for fuel evaporative emissions control and compared steel-based alternatives to a plastic tank used in current vehicles. A carbon steel tank for a Lexus vehicle achieved a mass reduction of between 34 to 41%. A stainless steel tank for a Mercedes achieved mass reductions from 25% to 38%. [EPA-HQ-OAR-2014-0827-1275-A1 p.16]

(3) Lightweight Steel Wheel, Steel Market Development Institute Final Report. This project developed a generic wheel design that was equivalent in style, structural performance and mass with an aluminum baseline wheel. [EPA-HQ-OAR-2014-0827-1275-A1 p.16]

(4) SMDI Lightweight Twist Beam Development, Scott Keefer, Multimatic Engineering. This study developed a proof of concept steel twist beam that achieved a 30% mass reduction relative to an OEM baseline assembly while meeting all structural and elastokinematic requirements. [EPA-HQ-OAR-2014-0827-1275-A1 p.16-17]

(5) Abstract: Study Demonstrates Forged Steel Crankshafts are Stronger and More Durable than Cast Iron Crankshafts. Description of a University of Toledo study to develop a forged steel crankshaft where the redesigned shaft achieved an 18% weight reduction without any degradation in performance. [EPA-HQ-OAR-2014-0827-1275-A1 p.17]

(7) Fatigue Performance Evaluation of Forged versus Competing Manufacturing Process Technologies, Prepared for Forging Industry Educational and Research Foundation and AISI by University of Toledo. Determined that forged steel provided a factor of 3 to 5 longer lives compared with cast aluminum and iron in additional to overall weight reduction of 12%. On a life cycle basis, the longer lifetime of a component provides a substantial benefit. [EPA-HQ-OAR-2014-0827-1275-A1 p.17]

(8) WorldAutoSteel FutureSteelVehicle project showed 39% weight reduction in a steel-intensive design for electrified vehicles over the benchmarked vehicle and reduced total life cycle emissions by nearly 70 percent. This was accomplished while meeting a broad list of global crash and durability requirements, enabling five-star safety ratings and avoiding high-cost penalties for mass reduction. [EPA-HQ-OAR-2014-0827-1275-A1 p.17]

In sum, EPA's currently proposed weight reduction values cannot be finalized given the lack of supporting technical analysis regarding their calculation. In addition, EPA should review the research material we have submitted for the docket with respect to the weight and performance benefits of lightweight steel components. While much of this analysis involves components utilized in the LDV
sector, we believe that comparable components and parts in medium- and heavy-duty vehicles would demonstrate similar results. EPA should therefore utilize this information to substantially adjust upward its estimates of the benefits of lightweight steel components in Table V-29 of the draft proposed regulations. [EPA-HQ-OAR-2014-0827-1275-A1 p.17-18]

In the alternative, AISI would recommend that EPA and NHTSA eliminate all weight reduction technology crediting for component parts. As described above, the component parts for which it is proposed that GEM assign a weight reduction benefit lack a sufficient technical basis in the record for this rulemaking. Values contained in Table V-29 are not representative of realistic mass reductions. Among other deficiencies, the table values do not scale weight reduction to the actual size of the part making them inherently arbitrary in a rulemaking that covers a wide range of truck sizes, uses and GVWR. Thus, while we first believe that EPA and NHTSA should incorporate life cycle analysis and adjust weighting accordingly, if this path is not taken by the agencies, the only reasonable result should be to eliminate the weight reduction inputs in their entirety. [EPA-HQ-OAR-2014-0827-1275-A1 p.18]

Response:

The agencies are adopting revised weight reduction tables for Phase 2. The basis for the majority of these technologies was documented in the HD Phase 1 rulemaking (Docket EPA-HQ-OAR-2010-0162). The changes made between Phase 2 NPRM and the final rule were based on comments received. The agencies appreciate the light-duty weight reduction attachments included in AISI’s comments, but most are not directly applicable to heavy-duty, especially when trying to extrapolate from light-duty vehicles to heavy-duty tractors. In certain cases, the agencies did increase the weight reduction level of steel components, such as brake drums and single piece drivelines, when additional reliable information was provided by commenters. Manufacturers have the ability to request approval for lightweight components not included in the Weight Reduction tables through the off-cycle credit program, as specifically stated in 40 CFR 1037.520 (although please note again that improvements in light duty performance cannot be automatically extrapolated to heavy duty vehicles). Please see Chapter 1.4.1 of the RTC for responses to the lifecycle comments.
Specific technology MPRs under the Phase 2 Rule appear to be overly aggressive and must be adjusted downward for fleets to afford flexibility in spec’ing equipment, avoid excessive downtime due to unforeseen maintenance requirements, and maintain equipment affordability. The specific market penetration rates of concern are as follows: [EPA-HQ-OAR-2014-0827-1243-A1 p.6]

6x2 Axle Configurations (60% in 2024)

Single axle 6x2 drive tractors are widely used in European trucking operations and have been for some time. For U.S. regional fleets that make a lot of deliveries, it is often not the best technology choice because of curb cuts and other uneven terrain features that can expose the truck to traction issues. [EPA-HQ-OAR-2014-0827-1243-A1 p.6]

ATA member fleets have not universally endorsed such technology. Recent surveys indicate current market penetration rates of new line-haul 6x2 tractor sales are only in the range of 2%. According to ATA member fleets, reasons for the current low level of adoption include limitations to highway applications, less flexibility, lower residual rates when switching to vocational applications, traction issues, driver dissatisfaction, tire wear and spec’ing, legality of their use, and driver acceptance. While recent improvements in traction control systems can automatically shift weight for short periods of time from the non-driving axle to the driving axle during low-traction events, concerns remain over the impacts to highways caused by such shifting of weight between axles. [EPA-HQ-OAR-2014-0827-1243-A1 p.6]

“Non-liftable” 6x2 axles in the states of North Dakota, Kansas, Indiana, Pennsylvania, Connecticut, Massachusetts, and New Hampshire are currently prohibited. “Liftable” 6x2 axles are legal across the country with the possible exception of Utah. Utah had required that lift axles be steerable. However, it is our understanding that state officials have agreed to revise their language to ensure their legality. Many carriers also conduct cross-border operations with Canada. 6x2 axle configurations are illegal in the province of British Columbia and face regulatory restrictions in other provinces as well. Fleet owners must remain vigilant to deploying 6x2 technologies only to jurisdictions that permit their use. [EPA-HQ-OAR-2014-0827-1243-A1 p.6]

6x2 axle configurations can restrict future resale markets by limiting the types of applications where these types of configurations can be used. Residual values of equipment are critical for fleets in making their purchasing decisions. Since resale values are not calculated into the overall estimated costs under Phase 2, constricting after-market resale opportunities for initial purchasers of equipment will extend the payback periods on 6x2s, making them less cost-effective in many applications. EPA and NHTSA should not assume an overly optimistic 60% market penetration rate for 6x2s in the 2024-2027 timeframe nor, in our opinion, will a 20% adoption rate in 2021 likely be recognized. EPA and NHTSA need to gather further information and modify the anticipated purchase rates accordingly. In addition, both agencies should jointly engage in additional study of any safety and regulatory challenges associated with 6x2 technology applications. [EPA-HQ-OAR-2014-0827-1243-A1 p.6-7]

The agencies should include in its cost calculations the additional tire wear and negative residual values associated with 6x2’s. [EPA-HQ-OAR-2014-0827-1243-A1 p.11]

Auxiliary Power Units and Automatic Engine Shutdown Devices (90% in 2024) The baseline assumes 30%, and up to 90%, of high-roof sleeper cabs will be equipped with non-programmable 5-minute automatic engine shutdown devices when, in fact, very few fleets selected this option under Phase 1. This
5% efficiency allocation is not likely to come to fruition when fleets are unwilling to spec’ out equipment with this option.

Fleets are aware that reduced engine idling results in fuel-savings, reduced engine-wear, and environmental improvements. Fleets have a variety of choices available in providing driver power and comfort in-lieu of idling including use of auxiliary power units (“APUs”), fuel-fired heaters, shore power, battery stand-by, stand-alone anti-idling infrastructure establishments, and hotel accommodations, to name a few. Not all operations require the use of APUs yet the agencies assume that 90% of tractors with sleeper cabs will purchase APUs if an automatic engine shutdown device (“AESs”) is installed. [EPA-HQ-OAR-2014-0827-1243-A1 p.7]

Fleets that already limit idling either via slip-seat operations (where drivers take turns driving on a rotational basis) or use fuel-fired heaters will not get adequate payback from installation of an APU. Fleets may also see reduced load capacity due to the additional weight of an APU and possibly worse aerodynamics from a larger trailer gap if the space for an APU requires a longer wheelbase. [EPA-HQ-OAR-2014-0827-1243-A1 p.7]

Most fleets already purchase “programmable” idle shutdown timers to limit idling due to the national patchwork of anti-idling laws currently in place. These timers are typically set for a given period of time throughout the initial fleet’s ownership period. As witnessed under Phase I, fleets are unwilling to purchase hard-programmed, tamper-proof AESs given their need for flexibility regarding their resale of used equipment on the secondary market. [EPA-HQ-OAR-2014-0827-1243-A1 p.7]

If forced into using AESs and APUs as the agencies propose, fleets will likely pre-purchase vehicles in advance of such requirement. Mandatory AES use should not be considered part of the stringency requirements under Phase 2. ATA supports efficiency credits for idling reduction options installed by fleets (i.e., APUs, direct-fired heaters, etc.) either at the OEM point-of-sale or installed in the after-market. For idling devices installed in the after-market, the agencies should allow OEMs appropriate credit upon receipt of certified proof from fleets of such installations. The agencies’ over-riding assumption should be that a fleet expending capital on an anti-idling device has every intention to utilize such equipment. Such fuel savings and carbon reductions must be recognized and accounted for. [EPA-HQ-OAR-2014-0827-1243-A1 p.7]

The assumption under the rule is that installation of an AES will result in the companion installation of an APU. There are, however, numerous anti-idling alternatives to diesel-powered APUs specific to fleet needs including direct-fueled heaters, electric APUs, shore power, battery power, and certain stationary providers of power and driver comforts. Each of these technologies should be afforded recognition under the rule and recognized in terms of their costs, efficiency attributes, and MPRs [EPA-HQ-OAR-2014-0827-1243-A1 p.11-12]

EPA estimates the cost of APU’s in 2021 and 2027 as $4,899 and $4,327 respectively. APU costs are substantially higher than this figure; being somewhere in the range of two to three times this estimate. EPA needs to use actual APU costs in its calculations. Of further note, the California Air Resources Board (“CARB”) requires particulate filters on diesel APUs. According to suppliers, filtering an APU increases the cost of such a device by up to 20%. Electric APUs are an alternative but such devices will put a strain on deep-cell batteries and will likely require back-up battery power sources, adding additional weight and cost to the tractor. [EPA-HQ-OAR-2014-0827-1243-A1 p.11]

**Automatic Tire Inflation Systems (40% in 2024)**
Phase 2 provides credit only for the use of automatic tire inflation systems (“ATISs”). Tire pressure monitoring systems (“TPMSs”) provide similar benefits but at a lower cost. To the extent efficiency credit is provided for tire pressure maintenance devices, TPMSs should be afforded the same amount of efficiency credit as ATISs. [EPA-HQ-OAR-2014-0827-1243-A1 p.8]

A recent study on truck and tire inflation systems indicates that both ATISs and TPMSs are being utilized in fleet operations. As of 2012, approximately 33% and 10% of surveyed fleets utilize ATISs and TPMSs respectively on their trailers. Roughly 1% of tractors used ATISs. Operators are well aware of the increased fuel consumption, maintenance costs, downtime, and safety concerns associated with operating heavy-duty vehicle with under-inflated tires. These concerns over time have been significant given the historic volatility of diesel prices, the competitive nature of the industry, shipper pressures to reduce costs, and the rising costs of liability. [EPA-HQ-OAR-2014-0827-1243-A1 p.8]

The agencies do not acknowledge TPMSs as a viable menu option since they require user interaction to inflate tires to appropriate pressures. A misguided assumption is that drivers “may” continue to operate a vehicle with underinflated tires. However, in light of continual pressures on fleets to reduce total costs of operation in order to remain competitive and profitable, the agencies should reconsider their rejection of TPMSs as a viable technology option under the rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.8]

Given the ability of fleets to monitor fuel consumption remotely, including the ability to identify causes for increased fuel consumption, drivers are routinely held responsible for proper tire pressure levels on TPMS-equipped vehicles. ATA therefore believes that the agencies should provide efficiency credit for TPMS use under the rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.8]

The cost estimates for tire inflation systems (and TPMS, where applicable) must include warranty limitations, useful life, maintenance and replacement costs, as well as costs of false warnings. [EPA-HQ-OAR-2014-0827-1243-A1 p.12]

Low Rolling-Resistance Tires

The tire market penetration rates projected in the outlying years are indeed technology-forcing. If tire composite advancements and designs do not keep pace with the target years, OEMs will not be able to hit their overall efficiency targets. In addition, since anti-tampering rules require retention of all original features, fleets may likely choose tires with higher rolling resistance (less efficiency) to maintain more flexibility in replacing tires in the field when needed. [EPA-HQ-OAR-2014-0827-1243-A1 p.8]

The agencies err in their tire analysis by using the same rolling resistance for all types of day and sleeper cabs. The need for and benefit of low rolling resistance tires (“LRRTs”) on a high roof sleeper cab is very different from the other tractor categories. The agencies should continue to examine fleet tire data and adjust tire stringency levels to account for fleet and Class variations and different duty-cycle needs. [EPA-HQ-OAR-2014-0827-1243-A1 p.8]

Instead of using current cost data, EPA appears to have based the cost calculations for LRRTs on 1999 data indexed for inflation. Moreover, EPA’s cost figures for LRRTs do not account for increases in lifetime replacement costs due to reduced tire life resulting in fewer retreads. [EPA-HQ-OAR-2014-0827-1243-A1 p.12]

Research Must Confirm Safety of New-Generation LRRTs Before Market Entry
The safety effects of LRRTs are not totally understood. While the "...agencies analysis indicate that this proposal should have no adverse impact on vehicle or engine safety," ATA remains leery of potential unintended consequences resulting from new generation tires that have yet to be developed. This especially holds true in terms of overall truck braking distances. [EPA-HQ-OAR-2014-0827-1243-A1 p.16]

The trucking industry takes safety very seriously. With projected application rates for widely varied LRRTs for Class 7 and 8 trucks ranging from 10% to 60%, new truck purchasers will need to understand which applications may, or may not, be appropriate for these tires. We support all efforts to help maintain and advance our safety agenda. ATA is aware of Transport Canada’s November 2012 study on the winter traction performance of LRRTs on heavy-duty trucks. The analysis involved performance on packed snow as opposed to non-packed snow or ice. The conclusion of that preliminary study indicated that the then-current generation of SmartWay-verified LRRTs offered a similar level of snow traction performance as non-SmartWay-verified tires. Our concern rests in the fact that both Phase 1 and Phase 2 are pushing the limits of rolling resistance to new heights. To our knowledge there has not been any subsequent and comprehensive climatic testing on each new generation of LRRTs. Neither ATA nor your agencies wish to create any unforeseen safety consequences resulting from implementation under either Phase 1 or Phase 2. ATA requests testing and documentation of LRRTs under all weather conditions, including snow and ice, in advance of their entry into the marketplace. ATA asks both agencies, and NHTSA in particular, to ensure that each new generation of LRRTs and retreads not increase braking distances under all weather conditions. [EPA-HQ-OAR-2014-0827-1243-A1 p.16]

Useful Life of LRRTs Must be Considered

LRRTs need to have improved wear rates such that our industry is not adversely impacting the environment by putting more casings into landfills and increasing natural resource use in manufacturing their replacements. The industry commonly sees a 40% reduction in useful life and a 20% reduction in casing life resulting from LRRTs. For example, wide-base single tires have shown poor tread wear in the tighter turning conditions of urban operations.11 This may result in higher wear-out rates if the rule encourages the use of wide-base single tires in these types of operations. When measuring efficiency improvements, it must be done with consideration of cradle-to-grave costs and consequences. [EPA-HQ-OAR-2014-0827-1243-A1 p.16]

Few disciplines are as unforgiving as tire design. Engineer a tire for maximum grip and it may wear too rapidly; specify rubber that will deliver the best fuel economy and it may impact traction. With about 25 million new truck tires sold in the U.S. every year, extending the useful life of LRRTs not only represents a substantial savings of natural and synthetic rubber, but also reduces the fuel consumption and GHG emissions associated with production of their replacements. Lost in the Phase 2 discussions is the fact that it takes 23 gallons of oil to manufacture a new tire and only 8 gallons of oil to retread a tire. [EPA-HQ-OAR-2014-0827-1243-A1 p.16]

Aerodynamic Devices

The actual stringency in the proposed rule is much greater than what EPA has indicated due to errors in EPA’s baselines and testing protocols, such as: [EPA-HQ-OAR-2014-0827-1243-A1 p.13]

- The assumed 2017 aero baseline uses the best aero trucks available, not the average.
- Cab aerodynamic expectations (Bins V, VI, and VII) likely cannot be achieved with the specified test trailer.
Compliance margins for aerodynamic audits have been removed. OEMs therefore must over-design (if plausible) to offset this margin omission and pass routine audits.

In summary, these issues create impossible hurdles that could not be met within the framework of the rule and the agencies must work with OEMs to rectify these matters. [EPA-HQ-OAR-2014-0827-1243-A1 p.13]

Estimated costs of future aerodynamic devices appear low given the historical nature of the proposed changes. The agencies should describe in detail the component packages they expect to satisfy each bin level, cost breakdowns of these individual components, and how this technology will be modified over time to maintain compliance with increasingly stringency levels. [EPA-HQ-OAR-2014-0827-1243-A1 p.12]

Credit for Use of Vehicle Speed Limiters Needs to be Expanded

In addition to safety benefits, reducing speed is a proven way to decrease GHG emissions and fuel consumption. To this end, ATA filed a petition with NHTSA and the Federal Motor Carrier Safety Administration (“FMCSA”) in October 2006 requesting a rulemaking to require vehicle manufacturers to limit the speed of trucks with a gross vehicle weight rating greater than 26,000 pounds to no more than 68 mph. In response to this petition, a joint rulemaking has been initiated which will require the installation of speed limiting devices on heavy trucks. This rulemaking is currently undergoing review at the Office of Management and Budget. [EPA-HQ-OAR-2014-0827-1243-A1 p.19]

While the details of this rulemaking have not been released, it appears that vehicle speed limiters (“VSLs”) will be mandatory equipment on new trucks within the timeframe of the Phase 2 standards. This rulemaking will likely establish new parameters for VSLs which should be accounted for in the final rule. For example, the rulemaking is expected to establish a maximum limited speed. This speed should serve as the baseline and may be different than the current baseline Greenhouse Gas Model (“GEM”) input of 65 mph. Depending upon where the maximum is set, credits should be reflective of speed adjustments below this level. [EPA-HQ-OAR-2014-0827-1243-A1 p.19]

The fact that VSLs are not being used as a compliance strategy despite being widely used among trucking companies is concerning. It appears purchasers are not willing to accept the tamper-proof requirement associated with this technology and instead opt to use them on their own terms. The agencies should explore ways of incorporating the in-use benefits being derived from VSLs. To this end, a more workable solution which provides credit for ordering a new tractor with VSL should be pursued. Possible approaches could include: [EPA-HQ-OAR-2014-0827-1243-A1 p.20]

Allowing manufacturers to accept a purchaser’s commitment to establish a maximum limited speed, as opposed to the tamper-proof option, when acknowledged and affirmed on a vehicle’s purchase agreement. Allowing manufacturers to adjust VSLs at the end of a vehicle’s lease or trade-in and allow the creation of deficits or credits if such adjustments affect the initial credits which were generated. Allowing trucking companies to adjust maximum speeds if company policies change during the ownership cycle with corresponding adjustment to manufacturer credits. [EPA-HQ-OAR-2014-0827-1243-A1 p.20] The agencies should work with truck manufacturers and their customers to identify potential mechanism which will allow the practice of using VSLs be more accurately quantified under the final rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.20]
Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by the commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s. In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

The agencies considered the maintenance impact of 6x2 axles. As noted in the NACFE Confidence Report on 6x2 axles, the industry expects an overall reduction in maintenance costs and labor for vehicles with a 6x2 configuration as compared to a 6x4 configuration. Among other savings, the reduction in number of parts, such as the interaxle drive shaft, will reduce the number of lubrication procedures needed and reduce the overall quantity of differential fluid needed at change intervals. The agencies have

45 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
taken a conservative approach to the maintenance costs for the 6x2 technology where we believe that the overall impact will be zero.

**Idle Reduction Technologies**

With respect to the baseline comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had APUs and 96 percent were equipped with an adjustable AESS. Therefore, the agencies have significantly reduced the number of APUs assumed in the baseline in the final rule. The agencies are projecting for the baseline that 9 percent of sleeper cabs will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS, and none will have tamper-proof AESS.

While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. See RIA Chapter 2.4.8.1. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

EPA considered the comments and more closely evaluated NHTSA’s contracted TetraTech cost report found the retail price of a diesel-powered APU with a DPF to be $10,000. The agencies used a retail price of a diesel-powered APU to be $8,000 without a DPF and $10,000 with a DPF in the cost analysis for this final rulemaking.

**Tire Pressure Systems**

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). See Preamble Section III.D.1.b.iv. This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS, however, we set the effectiveness value of TPMS lower than ATIS to reflect the need for operator intervention.

With respect to costs, all of the agencies’ technology cost analyses include both direct and indirect costs. Indirect costs include items such as warranty. In terms of maintenance, the presence of tire inflation management systems should serve to improve tire maintenance intervals and perhaps reduce vehicle downtime due to tire issues; they may also carry with them some increased maintenance costs to ensure that the tire inflation systems themselves remain in proper operation. For the analysis, we have considered these two competing factors to cancel each other out.

**Low Rolling Resistance Tires**

---

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data.\textsuperscript{49} We found that high roof sleeper cabs are certified today with steer tire rolling resistance levels that ranged between 4.9 and 7.6 kg/ton and with drive tires ranging between 5.1 and 9.8 kg/ton. In the same analysis, we found that high roof day cabs are certified with rolling resistance levels ranging between 4.9 and 9.0 kg/ton for steer tires and between 5.1 and 9.8 kg/ton for drive tires. This range spans the baseline through Level 3 rolling resistance performance levels. Therefore, for the final rule we took an approach similar to the one taken in Phase 1 and proposed in Phase 2 that considers adoption rates across a wide range of tire rolling resistance levels to recognize that operators may have different needs. 76 FR 57211 and 80 FR 40227.

In our analysis of the Phase 1 certification data, we found that the drive tires on low and mid roof sleeper cab tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. But we found only a minor difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. This is also consistent with the approach that we took in setting the Phase 1 tractor standards. 76 FR 57211. In addition, the final rule reflects a reduction in Level 3 adoption rates for low and mid roof tractors from 25 percent in MY 2027 used at proposal (80 FR 40227) to zero percent adoption rate. The technology packages developed for the low and mid roof tractors used to determine the stringency of the MY 2027 standards in the final rule do not include any adoption rate of Level 3 drive tires to recognize the special needs of these applications, consistent with the comments noted above raising concerns about applications that limit the use of low rolling resistance tires. We have estimated the cost of lower rolling resistance tires based on an estimate from TetraTech of $30 (retail, 2013$). We also have applied a “medium” complexity markup value for the more advanced low rolling resistance tires. We expect that, when replaced, the lower rolling resistance tires would be replaced by equivalent performing tires throughout the vehicle lifetime. As such, the incremental increases in costs for lower rolling resistance tires would be incurred throughout the vehicle lifetime at intervals consistent with current tire replacement intervals. A recent study conducted by ATA’s Technology and Maintenance Council found through surveys of 51 fleets that low rolling resistance tires and wide base single tires lasted longer than standard tractor tires.\textsuperscript{50} Due to the uncertainty regarding the life expectancy of the LRR tires, we maintained the current tire replacement intervals in our cost analysis.

ATA stated it is concerned about the safety consequences of next generation low rolling resistance tires at the adoption rates the agencies assume in the proposal. ATA noted that the agencies have not tested next generation low rolling resistance tires for safety purposes.

Federal Motor Vehicle Safety Standard (FMVSS) No. 121, \textit{Air brake systems}, sets forth performance and equipment requirements for trucks, buses, and trailers with GVWRs greater than 10,000 lb. and establishes stopping distances for vehicles equipped with air brake systems.\textsuperscript{51} Although tires are not specifically regulated as part of FMVSS No. 121, tires are part of the system that must meet the performance requirements outlined in that standard. This ensures that new tractors with air brakes compliant with FMVSS No. 121 are meeting safe stopping distances, regardless of tire configuration. In addition, under Federal Motor Carrier Safety Administration regulations, commercial vehicles are to have

\textsuperscript{50} Truckinginfo. TMC Survey Reveals Misinformed View of Fuel-Efficient Tires. March 2015.
\textsuperscript{51} 49 CFR 571.121.
a service brake system that meets the requirements of FMVSS No. 121 in effect on the date of manufacture. These two regulations taken together ensure that new and in-use trucks meet safe stopping distance requirements.

Additionally, in 2015, NHTSA and FMCSA conducted a safety study to evaluate stopping distances for low rolling resistance tires. NHTSA and FMCSA chose representative tires to evaluate in that study, and found that there was a negligible correlation between the coefficient of rolling resistance and the stopping distance of the tires it tested. Moreover, the results showed that the low rolling resistance tires tested in the study performed well within the stopping distances required by FMVSS No. 121. The agencies believe that taken together, the above described research and the stopping distance requirements FMVSS No. 121 and 49 CFR 393.40 will ensure next generation low rolling resistance meet safe stopping distances for tractors.

Aerodynamics

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. The baseline was not determined by or declared to be the average results of the vehicles tested, as some commenters maintained. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for Phase 2. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin C\textsubscript{d}A values.

The agencies’ assessment is that only Bins I through V are achievable with known aerodynamic technologies, but that Bins VI and VII have less known technology paths. Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of C\textsubscript{d}A. See RIA Chapter 2.8.2.2. These aerodynamic improvements have been demonstrated within the program on two vehicles in 2015. In the final rule, the agencies are projecting that truck manufacturers will be able to begin implementing these aerodynamic technologies as early as 2021 MY on a limited scale. We adjusted the adoption rates for MY 2027 in the technology package developed for the final rule to consist of 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors in this segment that we project could successfully apply these aerodynamic packages with this amount of lead time.

The agencies received comments from manufacturers arguing for the agencies to establish compliance margins that would allow actual production vehicles to exceed the standards by some fixed amount.

---

52 49 CFR 393.40.

These comments included specific requests for an aerodynamic compliance margin. We also received comments from UCS supporting the elimination of the aerodynamic compliance margin. As explained in Section I.C.1 of the Preamble, although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor $C_dA$ s and solicited supplemental comments on it. See 81 FR 10825. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur.

The agencies included the technology cost of aerodynamic improvements, such as wheel covers and active grill shutters, in RIA Chapter 2.11.

**Vehicle Speed Limiters**

The agencies considered DOT’s upcoming actions with respect to mandatory vehicle speed limiters for heavy-duty trucks, but could not take it into account in this Phase 2 rulemaking because that rule is not final yet.

The existing VSL flexibilities provide opportunities for manufacturers to account for the impact of VSLs on reducing GHG emissions and fuel consumption, while still allowing the settings to change after an “expiration” time determined by the manufacturer or to include a soft top. At this time, we believe that the Phase 1 flexibilities sufficiently balance the desire to encourage technologies that reduce GHG emissions and fuel consumption while ensuring the benefit in the real world and minimizing the compliance burden of trying to accommodate changes throughout the useful life of the vehicle. Therefore, the agencies are not adopting any new VSL provisions for Phase 2.

**Organization:** American Trucking Associations (ATA) and NHTSA

The discussion topics included potential safety impacts of MDHD Phase 2 fuel efficiency technologies, with specific questions on effects of further reductions in tire rolling resistance entire/vehicle traction and handling. Mr. Kedzie communicated his questions on the subjects. Mr. MacIsaac referred him to two NHTSA safety studies in the Phase 2 Notice of Proposed Rulemaking (NPRM) docket, as well as recent comments from Michelin North America in the related Phase 2 Draft Environmental Impact Statement (DEIS) docket. [NHTSA-2014-0132-0063-A1 p.1]

**Response:**

The agencies considered the safety impacts of the Phase 2 rule, as described in RIA Chapter 9.

---

54 See 40 CFR 1068.5 for a description of “good engineering judgment” and how EPA evaluates it.
We recommend that test methods for automatic tire inflation incorporate robustness to usage and vibration over representative time frames. Different technologies employ different configuration and component complexity such that in-use tire inflation performance is likely to vary by design. [NHTSA-2014-0132-0104 p.2]

We recommend that tractor and trailer solutions be treated differently. On a per-axle basis, tractors account for disproportionately more miles driven and more GHG emitted than trailers. Drive axle tire under-inflation can be solved by installation of Aperia's Halo Tire Inflator and likely other system designs, including central tire inflation systems (CTIS), in the near future. Devices, which differ in their capacity to serve steer, drive and trailer axles should be credited accordingly differently. [NHTSA-2014-0132-0104 p.2]

Response:

The regulations state that the emission standards apply for the full useful life of the vehicle (for example, see 40 CFR 1037.106 and 1037.107).

The agencies treat the ATIS and TPMS installed on tractors and trailers separately. We have considered the technologies mentioned in the comment while setting our adoption rates of ATIS and TPMS in our technology packages.

Organization: Bendix Commercial Vehicle Systems, LLC

However, the agencies request comment on whether we should extend this vocational vehicle idle reduction approach to day cab tractors. [EPA-HQ-OAR-2014-0827-1241-A1 p.6]

Bendix would like to see the vocational vehicle idle reduction approach extended to day cab tractors. Like many companies that perform vehicle level engineering testing, Bendix does instrument vehicles that are in commercial operation to collect particular data of interest. Among the data collected, engine speed, vehicle speed, driver demand for acceleration and braking are typical. We see from this data that there are many applications of day cab tractors that spend a significant portion of their day’s drive time at idle. This is true for most pick-up and delivery type applications and is also true for a growing number of fleets that run hub and spoke type operations. [EPA-HQ-OAR-2014-0827-1241-A1 p.6]

Tire pressure monitoring systems notify the operator of tire pressure, but require the operator to manually inflate the tires to the optimum pressure. Because of the dependence on the operator’s action, the agencies are not proposing to provide a reduction value for tire pressure monitoring systems. We request comment on this approach and seek data from those that support a reduction value be assigned to tire pressure monitoring systems. [EPA-HQ-OAR-2014-0827-1241-A1 p.6]

As noted in a previous section, Bendix does believe that TPMS should be included and an appropriate reduction provided. Our previous comments also support arguments in this area, the key being that drivers, when properly incented by the fleet, through such practices as incentives for improving fuel
economy, data tracking and potential vehicle strategies, have a strong reason to ensure that they maintain tire pressure. Fleets would not be interested in these systems if they were not providing the ROI, achieved through improved tire wear and fuel economy, they need to justify the investment. With significant growth over the past 5 years and expected continuation of growth into the future, TPMS deserves consideration. [EPA-HQ-OAR-2014-0827-1241-A1 p.6]

More choices ensure flexibility to achieve goals [EPA-HQ-OAR-2014-0827-1241-A1 p.6]

Bendix by virtue of our comments does not want our position on TPMS to be viewed as advocating the replacement of ATIS by TPMS, nor to discount the value of ATIS. We agree that ATIS can provide a benefit in some select cases and situations. [EPA-HQ-OAR-2014-0827-1241-A1 p.6]

Along the same lines, the agencies do run the risk of hurting the market for TPMS, and reducing the benefits that fleets could be receiving long ahead of implementation of the Phase 2 regulations. The agencies should not be in the business of picking winners and losers in technology choice, but enabling the market to offer the broadest possible package of possibilities to meet the agencies targets while not inhibiting OEMs, fleets and owner/operators from choosing the best combination to fit their unique operational needs. Therefore, both ATIS and TPMS should be available and receive appropriate credit to help deliver on the expected benefits of the proposed regulation. [EPA-HQ-OAR-2014-0827-1241-A1 p.7]

However, the agencies welcome comment from industry and others on their projected timeline for deployment of hybrid powertrains for tractor applications. [EPA-HQ-OAR-2014-0827-1241-A1 p.7]

The agencies state in the Phase 2 NPRM that “To date, hybrid systems for tractors have been primarily focused on idle shutdown technologies and not on the broader energy storage and recovery systems necessary to achieve reductions over typical vehicle drive cycles. The proposed standards reflect the potential for idle shutdown technologies through GEM.” [EPA-HQ-OAR-2014-0827-1241-A1 p.7]

Bendix appreciates the potential for idle shutdown technologies through GEM and have commented to this fact earlier in this document. While it is true that hybrid systems for tractors have not been focused on broader energy storage and recovery systems, there is in fact further opportunity in this area. Based on previous work, we believe that mild hybrid systems should be included in GEM for fuel consumption reduction credit. This should include stop-start and electrification of accessories as most mild hybrid systems incorporate. [EPA-HQ-OAR-2014-0827-1241-A1 p.7]

Response:

Day Cab Idle

The agencies considered the comments, both supporting and raising concerns over idle reduction in day cabs. The agencies determined that neutral idle for automatic transmissions is an appropriate technology for use in tractors. Therefore, the agencies are adopting provisions in Phase 2 to recognize neutral-idle in automatic transmissions as an input to GEM. Our analysis shows that neutral idle effectiveness is approximately 0.8 to 1 percent over the composite day cab tractor cycles. The agencies will also include neutral idle as a GEM input for sleeper cabs, though the effectiveness is very low. The agencies are predicated the standards for day cabs based a technology package that includes neutral idle.
In terms of stop-start technologies in tractors, the agencies are not including it as a technology input to GEM because we believe the technology needs further development before application to the tractor sector. If this technology is developed in the future for tractors, then manufacturers may consider applying for off-cycle technology credits. Consistent with the technology not being an input to GEM, the agencies are not predetermining the Phase 2 standards based on adoption of stop-start technologies.

It is also worth noting that there are a set of day cab tractors that may qualify as “vocational tractors” and be treated as vocational vehicles. This set of vehicles will be able to utilize the vocational approach to idle reduction.

**Tire Pressure Systems**

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allow manufacturers to show compliance with the CO$_2$ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS, though we have set the effectiveness of TPMS lower than ATIS to reflect the need for operator intervention.

With respect to costs, all of the agencies’ technology cost analyses include both direct and indirect costs. Indirect costs include items such as warranty. In terms of maintenance, the presence of tire inflation management systems, should serve to improve tire maintenance intervals and perhaps reduce vehicle downtime due to tire issues; they may also carry with them some increased maintenance costs to ensure that the tire inflation systems themselves remain in proper operation. For the analysis, we have considered these two competing factors to cancel each other out.

**Hybrids in Tractors**

After considering the comments, the agencies are continuing the Phase 1 approach of not including hybrid powertrains in our feasibility analysis for Phase 2. Because the technology is still under development for the tractor sector we cannot confidently assess the effectiveness of this technology for tractors at this time. In addition, due to the high cost, limited benefit during highway driving, and lacking any existing systems or manufacturing base, we cannot conclude with certainty that such technology will be available for tractors in the 2021-2027 timeframe. However, manufacturers will be able to use powertrain testing to capture the performance of a hybrid system in GEM if systems are developed in the Phase 2 timeframe. In addition, the agencies are recognizing electrified accessories in GEM in Phase 2.

**Organization:** California Air Resources Board (CARB)

**Comment – CARB strongly prefers proposed Alternative 4 Phase 2 Heavy-Duty Combination Tractor Emission Standards**

The NPRM requests comments on the proposed alternatives, with special interest in Alternatives 3 and 4. In total, the NPRM considers five alternatives as summarized in Table II-22 of the NPRM, shown below:[EPA-HQ-OAR-2014-0827-1265-A1 p.42]

[Table II-22 can be found on p. 42 of docket number EPA-HQ-OAR-2014-0827-1265-A1]
For tractors as with all vehicle categories, Alternative 1 is the no action alternative. Alternative 2 would base the standards on the application of off-the-shelf technologies, which is the same approach taken in Phase 1. Alternative 3 is U.S. EPA and NHTSA’s preferred alternative. Alternative 4 is identical in stringency to Alternative 3, but its implementation schedule is accelerated by three years (i.e., from 2027 to 2024). Alternative 5 is the most aggressive alternative, requiring the highest market adoption rate of more advanced technologies amongst the five alternatives. CARB strongly prefers Alternative 4 standards over Alternative 3 standards over all vehicle categories including tractors. [EPA-HQ-OAR-2014-0827-1265-A1 p.42]

For a compliant Phase 2 tractor, U.S. EPA and NHTSA estimate that Alternative 3 standards would achieve up to 24 percent reduction in CO2 emissions compared to a Phase 1 tractor at a cost of approximately $13,000 per vehicle. Alternative 4 achieves the same percent reduction in CO2 emissions and fuel consumption compared to a Phase 1 tractor, but does it three years earlier, at a per vehicle cost of approximately $14,000 per vehicle (i.e., $1,000 more per vehicle than Alternative 3). [EPA-HQ-OAR-2014-0827-1265-A1 p.42]

Alternative 4 is technologically feasible and will result in more emission and fuel consumption reductions from heavy-duty tractors in MYs 2021 through 2026. The increased cost due to the accelerated implementation is minimal – about $1,000 per vehicle as estimated by U.S. EPA and NHTSA. The improved fuel efficiencies resulting from either alternative would decrease fuel use, which equates to fuel savings that would eventually offset the upfront cost of the required technologies. U.S. EPA and NHTSA estimate the payback period for tractor and trailers for both Alternative 3 and 4 is similar at about 2 years. [EPA-HQ-OAR-2014-0827-1265-A1 p.42-43]

When looking more broadly at not only tractors, but also tractor engines and the trailers they pull, Alternative 4 achieves greater emission benefits and greater net societal benefits, than Alternative 3. As summarized in Table 7, Alternative 4 for tractors, tractor engines, and trailers would cumulatively achieve 75.7 more MMT CO2 reductions nationally than Alternative 3 for MYs 2018 through 2029 vehicles. This additional reduction would occur with a $16.7 billion greater net benefit in the U.S. [EPA-HQ-OAR-2014-0827-1265-A1 p.43]

[Table 7 can be found on p.43 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

The tractor vehicle technologies used to set the tractor standards varied by class of tractor (class 7/8), type of tractor cab (day cab or sleeper cab), and height of roof (low roof, mid roof or high roof). Table 9 shows the Alternative 3 and Alternative 4 technology adoption rates for class 8 high roof sleeper cab tractors. The conclusions drawn from comparing these adoption rates of these tractors can be applied to all tractor types addressed by the standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.44]

[Table 9 can be found on p.45-46 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

As shown in Table 9, there is no increase in market penetration between Alternative 3 and Alternative 4 for extended idle reduction, predictive cruise control, automatic tire inflation systems (ATIS), axle lubricant technologies, 6x2 axle or 4x2 axle technologies, direct drive technologies, and dual clutch transmissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.46]

The market penetration rates for aerodynamic technologies and low rolling resistance (LRR) tires show a decrease in the penetration rates for technologies that are equivalent to SmartWay and SmartWay Elite technologies and a higher penetration of more advanced aerodynamic treatments and LRR tire materials and designs. Currently, aerodynamic technologies are dominated by existing, widely-used fairings and
more aerodynamic shapes of the tractor body itself. Bin II represents currently available SmartWay aerodynamic technologies. Bin V through VII tractors incorporate more advanced technologies which are currently in the prototype stage of development, such as advanced gap reduction, rearview cameras to replace mirrors, wheel system streamlining, and advanced body designs. To the extent that these advanced designs use existing technologies in new and innovative ways (i.e., rearview cameras) concerns over reliability are minimal. For the steer and drive tire technologies, level 1 represents rolling resistance equivalent to today’s SmartWay tires. Level 2 represents the best in class rolling resistance tires available today. Level 3 represents a 25 percent improvement over level 2 which should be achievable in the 2024 timeframe. Should more complex systems or advanced materials require more reliability testing prior to MY 2024 tractor production date deadlines, higher applications of one or more of the other proven technologies from the other categories (i.e., level 2 LRR tires, predictive cruise, ATIS, etc.) can be used to meet the 2024 Alternative 4 standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.46]

For transmissions, the market penetrations decrease for manual transmissions and increase for automatic transmissions when comparing Alternative 3 to Alternative 4. This change is reflected in the increase in the application of downspeeding, since advanced transmissions enable downspeeding. With the exception of dual clutch transmission technology, automated manual transmission and automatic transmission technology is mature and should not result in reliability concerns associated with its application in MY 2024 tractors. [EPA-HQ-OAR-2014-0827-1265-A1 p.46-47]

**Comment – Extended idle reduction approach to day cab tractors**

The NPRM requests comment on the applicability of the idle test cycle to day cab tractors. [EPA-HQ-OAR-2014-0827-1265-A1 p.47]

Day cab tractors often idle while cargo is loaded or unloaded, as well as during the frequent stops that are inherent with driving in urban traffic conditions near cargo destinations. To recognize idle reduction technologies that reduce workday idling, U.S. EPA and NHTSA have developed a new idle-only duty cycle that is proposed to be used in GEM for vocational vehicles only, because these types of vehicles spend more time at idle than tractors. However, U.S. EPA and NHTSA request comment on whether they should extend this vocational vehicle idle reduction approach to day cab tractors. [EPA-HQ-OAR-2014-0827-1265-A1 p.47]

CARB staff believes U.S. EPA and NHTSA should extend the idle provision to day cab tractors. Currently, limited numbers of specific types of day-cab tractors (e.g., low-roof bottle delivery tractors) may be reclassified as vocational tractors. These reclassified tractors can take advantage of the vocational vehicle idle reduction approach. See 40 CFR 1037.630. By extending the workday idle provisions to all day-cab tractors, manufacturers would have some incentive to install neutral idle or stop-start systems on mid-roof and high roof day-cabs. Although the first user may not see significant emission reductions from these technologies, many of the high roof and mid roof day cab tractors are used in port and drayage applications in their second life – where start-stop and neutral idle technologies could result in significant emission reductions as these trucks travel in and out of ports and rail yard facilities. [EPA-HQ-OAR-2014-0827-1265-A1 p.47]

Extending the idle provision to day cab tractors would require U.S. EPA and NHTSA to set a fixed GEM composite cycle weighting factor at a value representative of the time spent at idle for a typical day cab tractor. For vocational vehicles in the regional category, the idle cycle weighting factor is 10 percent. U.S. EPA and NHTSA suggest 5 percent may be the appropriate value. Initial reaction is that the factor will probably be between 5 and 10 percent. CARB staff would like to work with U.S. EPA and NHTSA staff to determine the appropriate value for the day cab factor. [EPA-HQ-OAR-2014-0827-1265-A1 p.47-48]
Comment – Tire pressure monitoring system

The NPRM requests comment on whether they should assign a fixed credit in fuel consumption and CO2 emissions for tire pressure monitoring systems, and if so, what would be an appropriate assigned fixed value. Maintaining properly inflated tires can extend tire life, save fuel, and improve safety, so CARB staff generally supports the use of systems that assist in the maintenance of properly inflated tires. However, CARB staff strongly supports U.S. EPA and NHTSA not providing credit for tire pressure monitoring systems for heavy-duty tractors and trailers. Unlike ATISs, tire pressure monitoring systems only monitor pressure and alert the driver regarding the variance between the recommended target pressure and the actual measured pressure in the tire. Tire pressure monitoring systems require action from the drivers to reinflate the affected tire(s), hence the benefit of such systems is dependent on driver behavior. Because there is no guarantee what action, if any, drivers will take in response to tire pressure monitoring systems, CARB staff recommends no credit for such systems in Phase 2. [EPA-HQ-OAR-2014-0827-1265-A1]

In the Tire Pressure Systems – Confidence Report dated August 2013, the North American Council for Freight Efficiency (NACFE) indicated that ATISs are more common than tire pressure monitoring systems by a ratio of about four to one for trailers. The ATIS is designed to monitor and continually adjust the level of pressurized air in tires, automatically keeping tires properly inflated even while the vehicle is in motion. CARB staff concurs with U.S. EPA and NHTSA’s proposal to provide credit in GEM for the installation of ATISs on tractors and trailers. This system was included in CARB’s evaluation of vehicle efficiency technologies for heavy-duty vehicles that would result in improved fuel consumption and reductions in GHG emissions. For more information on ATIS, please refer to CARB’s Draft Technology Assessment: Engine/Powerplant and Drivetrain Optimization and Vehicle Efficiency, June 2015 at: http://www.arb.ca.gov/msprog/tech/techreport/epdo ve tech report.pdf. [EPA-HQ-OAR-2014-0827-1265-A1 p.138]

Comment – Solar control clarification

The RIA includes some incorrect statements, as described further below. First, the RIA states, “Solar control glazing reflects some of the solar energy from the glass.” The implication of this sentence is that solar control glazing is synonymous with solar reflective glazing. However, in fact, solar control glazing includes both solar absorbing glazing and solar reflective glazing. The RIA states, “CARB found that most heavy-duty trucks today use solar absorbing glass.” The Enhanced Protective Glass Automotive Association (not CARB) has indicated that new trucks are typically provided with solar absorbing glazing (total solar transmission of around 60 percent, compared to 88 percent for clear glass). Note also that the statement applies to original glazing and may not be true for replacement glazing. [EPA-HQ-OAR-2014-0827-1265-A1 p.154]

U.S. EPA and NHTSA further note they are “not proposing [solar control paint and glazing] as part of heavy-duty Phase 2, but these types of technologies could be considered under the innovative technology program.” CARB believes it is appropriate to retain the flexibility to consider solar control credits where such controls are shown to reduce overall GHG emissions and agrees that it is appropriate to require demonstration of quantified benefits before credit is granted for class 4-8 vehicles. See CARB docket letter dated December 3, 2014 for a thorough discussion of issues involved in determining appropriate solar control credits for heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.154]

**Comment – VSL Benefit**

According to the NPRM, VSLs were not considered when setting the proposed Phase 2 standards; however, U.S. EPA and NHTSA propose to allow use of VSL as a technology to meet the proposed standards. The NPRM proposes that manufacturers would receive credit for installing tamper-proof VSLs with maximum drive cycle speeds set at 65 mph; the draft GEM appears to offer up to 22 percent credit for use of VSL. [EPA-HQ-OAR-2014-0827-1265-A1 p.155]

CARB staff recommends not giving any credit for VSLs at this time because available data do not fully support whether VSLs result in real-world fuel consumption and CO2 reductions. In addition to the concerns regarding possible tampering of VSLs when in use, which the NPRM mentions, the data are still inconclusive as to whether VSLs can provide real-world fuel benefits, especially for modern trucks. In fact, CO2 emissions were shown to decrease as vehicles’ speed increase (improved fuel economy at higher speeds) in Oak Ridge National Laboratory’s (ORNL) Transportation Energy Data Book (Table 5.11, Fuel Economy for Class 8 Trucks as a Function of Speed and Tractor-Trailer Tire Combination, and Figure 5.3 (shown below – Figure 6), Class 8 Trucks Fuel Economy as a Function of Speed and Tractor-Trailer Tire Combination and Percentage of Total Distance Traveled as a Function of Speed, available at [http://cta.ornl.gov/data/chapter5.shtml](http://cta.ornl.gov/data/chapter5.shtml)). [EPA-HQ-OAR-2014-0827-1265-A1 p.155]

(Figure 6 can be found on p.156 of docket number EPA-HQ-OAR-2014-0827-1265-A1)

The data presented above indicates there may be no benefit through use of VSLs or even possibly a dis-benefit; hence, CARB staff recommends no credit in GEM for VSLs. [EPA-HQ-OAR-2014-0827-1265-A1 p.156]

The issue of whether and what credit to offer for VSLs is timely and important because tamper-proof VSLs may soon be required in the U.S. by federal regulation. In 2006, the American Trucking Association (ATA), Road Safe America and a group of motor carriers petitioned NHTSA to initiate rulemaking to require vehicle manufacturers to install a device to limit the speed of trucks with a GVWR greater than 26,000 lbs to no more than 68 mph. The petitions were based on a desire to reduce the number and severity of crashes involving large trucks. NHTSA in 2011 agreed to consider a rule requiring speed limiters and has stated they intend to propose such a rule later this year ([http://www.regulations.gov/#!documentDetail;D=NHTSA-2007-26851-3854](http://www.regulations.gov/#!documentDetail;D=NHTSA-2007-26851-3854)). As a result, VSLs are likely to be widely utilized in heavy-duty truck fleets in the near future; thus, the issue of understanding whether or not VSLs have an emissions benefit and not offering too much credit for them in GEM is imperative. [EPA-HQ-OAR-2014-0827-1265-A1 p.156-157]

Before offering any credit for VSLs, CARB staff suggests that U.S. EPA and NHTSA should thoroughly evaluate whether they would result in real-world CO2 and fuel consumption benefits. CARB staff is willing to offer our help in this evaluation if needed. [EPA-HQ-OAR-2014-0827-1265-A1 p.157]

If U.S. EPA and NHTSA decide to give credit in Phase 2 GEMs for VSLs, VSL benefit should also be included in premising the proposed standards. If credit for use of VSLs is granted without considering them when setting stringency, use of VSLs will only reduce use of other technologically feasible technologies that were included when setting stringency, without providing further benefit. [EPA-HQ-OAR-2014-0827-1265-A1 p.157]
Comment – VSL credit in GEM

The NPRM proposes that manufacturers would receive credit for installing tamper-proof VSLs with maximum drive cycle speed set at 65 mph or less (the minimum VSL value input in GEM is set at 45 mph). The draft GEM model appears to offer up to 22 percent credit for use of VSL, which is unreasonably high. In addition, as mentioned in the above comment, whether or not use of VSL will provide emissions benefit is still an open question. Thus, CARB staff strongly suggests U.S. EPA and NHTSA remove the credit offered for use of VSL in GEM, pending confirmation of the actual fuel consumption and CO2 benefits VSLs achieve in the real world. [EPA-HQ-OAR-2014-0827-1265-A1 p.157-158]

Comment – Participation of owners in VSLs’ emissions credit transactions

The NPRM requests comment on potential means by which truck owners that use VSLs could directly participate in Phase 2 emission credit transactions. It is not clear what fleet owners would do with Phase 2 credits and allowing fleet owners to garner such credits would unnecessarily complicate implementation and enforcement of the Phase 2 program. As a result, CARB staff recommends not including owners in emission credit transactions for VSL installation. [EPA-HQ-OAR-2014-0827-1265-A1 p.158]

60 See Attachment 7 for California Air Resources Board’s Portable Emissions Measurement System’s Data on 2010 Standard Trucks – Carbon Dioxide Emission Rate vs. Speed.

[Attachment 7 can be found on p.39 of docket number EPA-HQ-OAR-2014-0827-1268-A1]

64 This is estimated based on GEM results for sample GEM input file of tractor. The specified tractor configuration (350 hp with AMT transmission) was run with four scenarios (no VSL - baseline, 45 mph speed limit VSL, 55 mph speed limit VSL, and 65 mph speed limit VSL). Projected CO2 emissions for each scenario were used to calculate percent CO2 reduction from baseline (no VSL use) (22%, 11%, and 0.01% CO2 reduction for VSL set at 45 mph, 55 mph, and 65 mph, respectively).

Response:

Alternative 3 vs. 4

The agencies considered all of the general comments associated with the proposed Alternative 3 and Alternative 4 tractor standards. We believe there is merit in many of the detailed comments received
regarding technologies. These are discussed in detail in the following sections. Instead of merely choosing from among the proposed alternatives, the agencies have developed a set of final tractor standards that reflect our reevaluation of the ability to pull ahead certain technologies, the limitations in adoption rates and/or effectiveness of other technologies, and consideration of additional technologies. In general, the final Phase 2 tractor standards are similar in overall stringency as the levels proposed in Alternative 3, but have been determined using new technology packages that reflect consideration of all of the technology comments, and in several respects reflect greater stringency than the proposed Alternative 3.

**Day Cab Idle**
The agencies considered the comments, both supporting and raising concerns over idle reduction in day cabs. The agencies determined that neutral idle for automatic transmissions is an appropriate technology for use in tractors, as discussed in Section III.D.1.b of the Preamble to the final rule. Therefore, the agencies are adopting provisions in Phase 2 to recognize neutral-idle in automatic transmissions as an input to GEM. Our analysis shows that neutral idle effectiveness is approximately 0.8 to 1 percent over the composite day cab tractor cycles, as shown in RIA Chapter 2.8.2.6. The agencies will also include neutral idle as a GEM input for sleeper cabs, though the effectiveness is very low. The agencies are predetermining the standards for day cabs based on a technology package that includes neutral idle.

In terms of stop-start technologies in tractors, the agencies are not including it as a technology input to GEM because we believe the technology needs further development for tractors. Since the agencies are not predetermining the Phase 2 standards on adoption of start-stop technologies, the agencies are also not including this technology as a GEM input. If this technology is developed in the future for tractors, then manufacturers may consider applying for off-cycle technology credits.

**Tire Pressure Systems**
As noted in earlier responses in this unit, after consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allow manufacturers to show compliance with the \( \text{CO}_2 \) and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS; however, we set the effectiveness of TPMS slightly lower than ATIS to reflect that operators will be required to take some action to ensure that the proper inflation pressure is maintained.

**Solar Control**
The agencies received a letter from the California Air Resources Board prior to the proposal requesting consideration of including technologies that reduce solar heating of the cab (to reduce air conditioning loads) in setting the Phase 2 tractor standards. Solar reflective paints and solar control glazing technologies are discussed in RIA Chapter 2.4.9.3. The agencies requested comment on the Air Resources Board’s letter and recommendations.\(^{55}\) The agencies received some clarifications from ARB on our evaluation of solar technologies and some CBI from Daimler, but not a sufficient amount of information to evaluate the baseline level of solar control that exists in the heavy-duty market today, determine the effectiveness of each of the solar technologies, or to develop a definition of what qualifies

---

as a solar control technology that could be used in the regulations. Therefore, the agencies would consider solar control to be a technology that manufacturers may consider pursuing through the off-cycle credit program. As such, the agencies did not include solar load management technologies in the technology packages used in setting the final Phase 2 tractor standard stringencies.

VSL

The agencies conducted in-use tractor testing at different speeds and in turn used this data to validate the GEM simulations of VSL, as discussed in more detail in RIA Chapter 4.3.2. The agencies are confident that GEM appropriately recognizes the impact of VSL on CO₂ emissions and fuel consumption. The agencies have limited the range of inputs to the VSL in Phase 2 GEM to a minimum of 55 mph to align with the regulations in 40 CFR 1037.631 that provide exemptions for vocational vehicles intended for off-road use. A 55 mph VSL installed on a typical day cab tractor would reduce the composite grams of CO₂ emitted per ton-mile by 7 percent. Similarly, a 55 mph VSL on a sleeper cab would reduce the composite grams of CO₂ per ton-mile emitted by 10 percent. Please see RIA Chapter 2.8.2.10 for additional details of the technology impacts.

Organization: Caterpillar Inc., et al.

As proposed, the regulation will limit or eliminate our ability to meet the basic customer requirements for many of the thousands of widely varying applications we support today. Based on our current analysis, it is not clear that the proposed Alternative 3 targets – which include a number of unrealistic technology penetration rates – can be achieved. [EPA-HQ-OAR-2014-0827-1215-A1 p.7]

Aerodynamic: 60% in Bins V, VI, and VII – Given the proposed aerodynamic testing procedures, the Phase 2 test trailer, and the lack of any audit margin for these highly variable test processes, it is infeasible to design tractors that can achieve even bin V, much less bins VI and VII. In fact, none of the vehicles developed within the Department of Energy’s SuperTruck program are capable of meeting the aerodynamic targets the agencies assumed when setting stringency levels. The agencies must eliminate expected penetration in these higher bins unless they agree to wholesale changes to the aerodynamic testing procedures and restore the audit margin available in the Phase 1 rule. [EPA-HQ-OAR-2014-0827-1215-A1 p.5-6]

6x2’s: 60% - 6x2’s may not be used legally in all 50 U.S. states and in parts of Canada. In particular, six state laws limit tire and axle loading in such a way that 6x2’s cannot be used as intended, and many other states have confusing regulations that effectively prevent usage of 6x2’s. Most fleet owners must purchase tractors that can operate in all 50 states, and many cross the border between the U.S. and Canada. EPA and NHTSA should assume no more than a 5% penetration rate for 6x2’s through 2027 and should engage in additional study of the safety and regulatory challenges associated with 6x2’s. [EPA-HQ-OAR-2014-0827-1215-A1 p.6]

Tire Inflation Systems: 40% - Customers are more likely to purchase tire pressure monitoring systems, which provide all of the benefits of tire inflation systems at a lower cost. In addition, a customer who simply checks tire pressure daily can achieve all of the same benefits without purchasing either technology and incurring its costs. Tire inflation systems should not be forced into the market by assuming any penetration rate. To the extent credit is provided for these systems, both tire inflation systems and tire pressure monitoring systems should receive the same amount of credit. [EPA-HQ-OAR-2014-0827-1215-A1 p.6]
Idle Shutdown Timers (“AES”): 90% - The agencies base stringency on an assumed 90% penetration rate of tamper-resistant idle shut down timers. Notably, most fleets already purchase customer programmable idle shutdown timers which limit idling. However, fleets do not purchase tamper-resistant versions of idle shutdown timers because of the negative perception in the secondary market regarding such technology, and the importance of considering resale value when purchasing a new vehicle. In practice, idle shutdown timers are typically used for the useful life of the vehicle, whether they are customer programmable or tamper-resistant. If forced to purchase mandatory shutdown timers, many fleets will pre-buy vehicles to delay the negative costs associated with such technology. AES’s should not be considered part of stringency, unless the agencies choose to provide credit for programmable versions of AES’s that provide essentially the same environmental benefits as the non-programmable version. [EPA-HQ-OAR-2014-0827-1215-A1 p.6]

Low Rolling Resistance (“LRR”) Tires – Tires must meet the most demanding needs of the customers. LRR tires may suffice for many conditions, but they must meet the demands of all conditions. This includes sloped loading docks, which frequently are not treated or plowed in winter conditions. Unpaved and uneven trailer drop lots also create challenges for traction. In addition, tire casings must have adequate durability to allow as many as 5 retread operations. Including widespread use of LRR tires when determining a baseline from which to apply reductions will result in overly stringent standards. [EPA-HQ-OAR-2014-0827-1215-A1 p.6-7]

In addition, many technologies in the proposal can have unaccounted negative impacts to vehicle fuel economy and the corresponding greenhouse gas emissions (e.g. aerodynamic impact from increased wheelbases due to APU installation, payload loss due to increased weight of hybrid systems, and weight and aerodynamic impacts due to waste heat recovery installation). These losses decrease any expected payback on the technology investment. Some of the assumed technologies also may drive increased cycle times or vehicle trips due to decreased payload, requiring additional trucks and operators in the fleet to perform the same quantity of work. Regardless of the specific technologies an OEM chooses to meet the mandate, the compressed design cycles driven by the Phase 2 regulation’s timing and unrealistic stringencies will drive increases in total cost of ownership for vehicle owners. On top of this, for truck OEMs to remain viable businesses, the billions of dollars in industry development cost must be amortized over the relatively small volumes in the heavy-duty vehicle market, adding many thousands of dollars in cost per vehicle that have not been adequately considered. [EPA-HQ-OAR-2014-0827-1215-A1 p.7-8]

As such, the Truck OEMs request the agencies take a total cost of ownership approach when considering technology feasibility and penetrations, as well as stringency levels and their timing. Failure to do so will result in an unrealistic cost and penetration rate assessment, severely impacting a truck OEM’s ability to meet the mandated fleet reductions. [EPA-HQ-OAR-2014-0827-1215-A1 p.8]

Response:

Aerodynamics

In consideration of these comments, the agencies have adjusted the aerodynamic adoption rate for Class 8 high roof sleeper cabs used to set the final standards in 2021, 2024, and 2027 MYs (i.e., the degree of technology adoption on which the stringency of the standard is premised). The agencies’ assessment for the final rule is that only Bins I through V are achievable with known aerodynamic technologies, but that Bins VI and VII have less known technology paths. Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of C_dA. See RIA Chapter 2.8.2.2. These aerodynamic improvements have been demonstrated within the program on two vehicles in
2015. In the final rule, the agencies are projecting that truck manufacturers will be able to begin implementing these aerodynamic technologies as early as 2021 MY on a limited scale. We adjusted the adoption rates for MY 2027 in the technology package developed for the final rule to consist of 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors in this segment that we project could successfully apply these aerodynamic packages with this amount of lead time. The agencies phased-in the aerodynamic technology adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies. For example, in the 2021 MY technology package, the agencies have assumed that 10 percent of high roof sleeper cabs and 5 percent of high roof day cabs will have Bin V aerodynamic performance. This phase-in structure is consistent with the normal manner in which manufacturers introduce new technology to manage limited research and development budgets as well as to allow them to work with fleets to fully evaluate in-use reliability before a technology is applied fleet-wide. The agencies believe the phase-in schedule will allow manufacturers to complete these normal processes. Overall, while the agencies are now projecting slightly less benefit from aerodynamic improvements than we did in the NPRM, the actual aerodynamic technology being projected is very similar to what was projected at the time of NPRM.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s. In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

Tire Pressure Systems

---

57 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS; however, we set the effectiveness of TPMS slightly lower than ATIS to reflect that operators will be required to take some action to insure that the proper inflation pressure is maintained.

Idle Reduction Technologies

While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found that high roof sleeper cabs are certified today with steer tire rolling resistance levels that ranged between 4.9 and 7.6 kg/ton and with drive tires ranging between 5.1 and 9.8 kg/ton. In the same analysis, we found that high roof day cabs are certified with rolling resistance levels ranging between 4.9 and 9.0 kg/ton for steer tires and between 5.1 and 9.8 kg/ton for drive tires. This range spans the baseline through Level 3 rolling resistance performance levels. Therefore, for the final rule we took an approach similar to the one taken in Phase 1 and proposed in Phase 2 that considers adoption rates across a wide range of tire rolling resistance levels to recognize that operators may have different needs.

In our analysis of the Phase 1 certification data, we found that the drive tires on low and mid roof sleeper cab tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. But we found only a minor difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. This also consistent with the approach that we took in setting the Phase 1 tractor standards. In addition, the final rule reflects a reduction in Level 3 adoption rates for low and mid roof tractors from 25 percent in MY 2027 used at proposal (80 FR 40227) to zero percent adoption rate. The technology packages developed for the low and mid roof tractors used to determine the stringency of the MY 2027 standards in the final rule do not include any adoption rate of Level 3 drive tires to recognize the special needs of these applications, consistent with the comments noted above raising concerns about applications that limit the use of low rolling resistance tires.

The agencies phased-in the low rolling resistance tire adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies. In addition, the levels of rolling resistance used in all of the technology packages are achievable with either dual or wide based single tires, so the agencies are not forcing one technology over another.

**Total Cost of Ownership**

The agencies considered the total cost of ownership during the payback calculations, included in RIA Chapter 7 of the final rule. The payback calculations include the hardware costs of the new technologies and their associated fixed costs, increased insurance, taxes, and maintenance. The agencies found that for each category of vehicle – tractor/trailers, vocational vehicles, and HD pickups and vans - included in the Phase 2 rule that the fuel savings significantly exceed the costs associated with the technologies over the lifetime of the vehicles.

**Organization:** Center for Biological Diversity

**Tractor-Trailers**

Tractor-trailers consume approximately 20 percent of on-road transportation fuel and emit a similar proportion of greenhouse gas emissions. Furthermore, combination tractor-trailers emit two-thirds of the total greenhouse gases from commercial trucks. As such, maximizing efficiency for these vehicles will both carry a significant environmental benefit and save the most fuel among the various classes of trucks subject to the Proposed Rule. We support the agencies’ decision to set standards for both tractors and trailers in this second phase of truck efficiency standards: the Phase 1 standards did not apply to box trailers. The Proposed Rule would result in approximately a 10.4 percent reduction in combined tractor-trailer energy use between 2017 and 2027, but current and future technology would allow reductions of 25 to 27 percent over this same time frame. A stakeholder workshop on tractor-trailer efficiencies generated an impressive suite of technologies that have both short term (before 2018) and longer term (2020 to 2030) potential to reduce fuel use and emissions by up to 38 percent.

A recent analysis indicates that the Proposed Rule does not even meet the potential that has already been demonstrated through the Department of Energy’s SuperTruck program – a clear indication that the standards are not technology forcing. The SuperTruck public-private partnership aims to demonstrate a 50 percent increase in tractor-trailer efficiency and a 20 percent improvement in engine efficiency between 2010 and 2015. Impressive strides have been made reaching – and exceeding – these goals: the Cummins-Peterbilt team achieved a 76 percent increase in tractor-trailer efficiency and more recently the Daimler-Freightliner team achieved a 115 percent improvement in efficiency. Since the agencies already predict such advances, the technology-forcing nature of the

---

Page 718 of 2127
governing statutes requires that they be included in the standards, especially when the proposed time horizon is within the range of tractor redesign cycles. 53

Although the Proposed Rule assumes a wide range of technologies, the penetration rates assumed by the agencies and potential improvements appear to be underestimated. 54 The technology forcing nature of Clean Air Act § 202 and EPCA/EISA requires more aggressive assumptions regarding technology adoption. The agencies are proposing standards that are either already attained or easily attainable, and then hoping that manufacturers will explore and continue to improve technologies of their free will. 55 This is contrary to the specific language, structure, and intent of the statutes: a clear regulatory signal is necessary and intended to drive innovation, ensuring that technology improvements occur as rapidly as possible. 56

In sum, the total reductions of greenhouse gas emissions and fuel usage could be significantly greater if the agencies adopt standards that represent true maximum efficiency improvements, even while remaining economically feasible and safe. The NHTSA may not adopt standards that undermine the purpose of the EPCA/EISA – energy conservation. Yet, the proposed fuel use reductions for tractor-trailers would provide only about one-third of the maximal feasible benefits. This constitutes an arbitrary and capricious balancing of factors that significantly impedes the congressional mandate to promote energy conservation. Likewise, these minimal reductions fail the Clean Air Act’s technology-forcing requirement. [EPA-HQ-OAR-2014-0827-1460-A1 p.11-12]

45 Id. at 8.

48 Id.

50 ICCT SuperTruck blog, supra note 46.

52 Draft RIA at 2-18.

53 Id. at 2-16 (“tractor model lifecycle of up to 10 years”).
For example, dual clutch systems are assumed to provide only up to 2% improvement (Proposed Rule at Table III-7), but the stakeholder workshop assigned this technology approximately 5.5 (+ 2) % improvement (ICCT Tractor-Trailer report, supra note 44); the Proposed Rule omits weight reduction in setting stringency assigning an improvement of 0.3 % (Proposed Rule at 40223), while the stakeholder workshop found over 3 (+ 1) % improvements from weight reduction (ICCT Tractor-Trailer report, supra note 44).

See, e.g., Draft RIA, supra note 43 at 2-16 (“we anticipate manufacturers would continue to apply these techniques [sealing gaps] across their models and continue to explore refinements and re-designs in other areas of the tractor”). But note that the agencies are also fully aware that a regulatory signal is necessary to correct private market failures and “provide regulatory certainty and thus generate important economic benefits in addition to reducing externalities.” Id. at 8-5.

Response:

The proposed Phase 2 program would lead to up to 24% percent reduction in GHG emissions from high roof sleeper cabs and up to 8% from box trailers for greater than 30% reduction in tractor-trailers when compared to a baseline tractor-trailer meeting the Phase 1 standards, not the 10% stated by the commenter. In addition, EPA conducted GEM simulations evaluating both the best projected tractor-trailer in the 2027 timeframe that showed much greater reductions than the 10% stated by the commenter (Docket Entry EPA-HQ-OAR-2014-0827-0050).

The agencies considered all of the general comments associated with the proposed Alternative 3 and Alternative 4 tractor standards. We believe there is merit in many of the detailed technology comments received and these are discussed in detail in the following sections. Instead of merely choosing from among the proposed alternatives, the agencies have developed a set of final tractor standards that reflect our reevaluation of the ability to pull ahead certain technologies, the limitations in adoption rates and/or effectiveness of other technologies, and consideration of additional technologies. In general, the final Phase 2 tractor standards are similar in overall stringency as the levels proposed in Alternative 3, but have been determined using new technology packages that reflect consideration of all of the technology comments, and in several respects reflect greater stringency than Alternative 3.

DOE has partnered with the heavy-duty industry to demonstrate high roof sleeper cab tractor and box trailer combinations (only one of the ten tractor subcategories) that achieve a 50 percent improvement in freight efficiency evaluated as a 65,000 pound vehicle operating on the highway under somewhat controlled circumstances. However, these SuperTrucks are not necessarily designed to handle the rigors of daily use over actual in-use roads. For example, they generally have very limited ground clearance that would likely preclude operation in snow, and would be very susceptible to damage from potholes or other road hazards. In addition, each manufacturer only produced a single high roof sleeper cab for demonstration purposes at a cost of nearly $40-$80 million each. While the agencies cannot simply apply the SuperTruck program achievements directly into the Phase 2 program because of the significant differences in the limited purpose of SuperTruck and the plenary applicability of a regulation to all operating conditions and duty cycles, it is helpful to assess the achievements and evaluate how the technologies could be applied into mass production into a variety of real world applications while maintaining performance throughout the full useful life of the vehicle.

Organization:  Cline, C and J
But, one technical problem exists that permeates throughout the transport industry, including the regulators that reduces safety, damages driver health, and damages our world. [EPA-HQ-OAR-2014-0827-0803-A2 p.1]

We should not be going backwards. Saving fuel to the detriment of other costs, safety, our health, or our world is simply dumb. And the reason for this letter, is something that is so dumb, it simply amazes me that we have let this practice continue for so long. [EPA-HQ-OAR-2014-0827-0803-A2 p.1]

Incorrect Tire Pressures are used throughout the transport industry. Incorrect tire pressures are used in regulations aimed at truck safety. Incorrect tire pressures are promoted as environmentally responsible, yet they aren’t. In fact, correct tire pressures are ignored almost totally. [EPA-HQ-OAR-2014-0827-0803-A2 p.1]

Every quality tire manufacturer, along with all Wheel and Tire Associations recommend that tire pressures must be adjusted to suit the load. Truck Tire ‘Load to Inflation’ tables are easily available on the web. Yet, these are ignored. In any other industry, anyone failing to follow the manufacturer’s recommendations would be liable for litigation, fines, and often imprisonment. Yet, the entire transport industry, including the regulators, do just that. [EPA-HQ-OAR-2014-0827-0803-A2 p.1]

Almost every class 8 steer tire is under inflated. All of the load carrying tires, drive tires, and trailer tires are 30% over inflated, at least, even when fully legally laden. When empty, the load carrying tires can easily be 300% over inflated. [EPA-HQ-OAR-2014-0827-0803-A2 p.1]

For instance, a class 8 tractor tandem or bogie axle set is typically limited to 34,000 pounds. The correct cold tire pressure for this weight, running standard 11R22.5 tires, is only 75 psi. Hence the traditional truck tire cold pressure of 100 to 110 psi is 30% over inflated. [EPA-HQ-OAR-2014-0827-0803-A2 p.1]

According to the Michelin USA site, running a 30% over inflated tire will reduce its life by 20% or more, depending upon where it is placed, drive or trailer. Many trucks are not running maximum weights, so the tires are over inflated even more, with more tire life lost. Again, Michelin states that over inflated tires have less traction, suffer more punctures, and suffer uneven wear and tear. Hence over inflation results in more accidents, more deaths, more blown tires, more damaged vehicles, and more pollution and waste to dispose of. [EPA-HQ-OAR-2014-0827-0803-A2 p.2]

Two years ago, tests in Australia overseen by Australian Road Research Board and Australian Road Transport Suppliers Association did braking tests on a modern semi-trailer rig on a concrete skid pan. The correct tire pressure decreased stopping distances by a whopping 15% on a lightly loaded rig. As empty semi-trailers are considered the most dangerous condition, this amazing improvement in stopping ability is simply that, amazing. It stopped short and straight. [EPA-HQ-OAR-2014-0827-0803-A2 p.2]
Many other tests have been done throughout the world, on the many benefits of optimizing tire pressures. Many tests have been done by various US government departments. A little research will provide numerous tests. Simply google ‘Central Tire Inflation’. [EPA-HQ-OAR-2014-0827-0803-A2 p.2]

Central Tire Inflation is a simple bolt on attachment that makes on the fly tire changes easy. The driver simply pushes a button on the dash mounted controller to raise or lower the tire pressure. CTI is used extensively in logging and other off road/on road transport, throughout the world, especially where traction, and or tire life is difficult. [EPA-HQ-OAR-2014-0827-0803-A2 p.2]

Tire pressures on standard Load to Inflation tables typically show a limited range of loads and pressures. The lowest pressure is often 65 or 70 psi. The reason is that, without CTI, the truck must be considered a load carrying vehicle. With CTI, heavy truck tire pressures usually go to 25 psi as the lowest pressure at light loads, or off road. For instance, at speeds of 50 mph or lower, 25 psi is recommended for a tire load of up to 2,300 pounds per tire (USA Tire and Rim Association hand book). Another example is a Michelin reference paper on 11R22.5 XTE1 tires, where a pressure of 50 psi is recommended at a weight of 2,750 psi per tire, at highway speeds. [EPA-HQ-OAR-2014-0827-0803-A2 p.2]

[Figure, 'Design Guide, Reduced Inflation Pressure Limits for Truck Tires Used Off Highway at Reduced Speed (For Single and Dual Applications, can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-0803-A2]

But, it gets worse. Over inflated tires bounce off of every road irregularity. Just like a super ball, over inflated tires will hammer the truck and the driver to an early grave. Whole Body Vibration is now a proven health hazard. There are many reports on Whole Body Vibration. Conferences are held every year. Damage starts at the brain ocular system, down through the skeletal and organs. Truck drivers suffer from 15 to 20 years shorter life expectancy. Average life expectancy is only 56 years! Over inflated tires are killing our drivers. [EPA-HQ-OAR-2014-0827-0803-A2 p.3]

Yet more: Over inflated tires are killing our roads. Over inflated tires amplify any axle end out of balance, causing excessive vibration that hammers our roads. Over inflated tires input higher loads into the road surface, damaging our crumbling infrastructure. [EPA-HQ-OAR-2014-0827-0803-A2 p.3]

As truck tires consume large quantities of oil and energy to manufacture and transport, and are costly and difficult to recycle or dispose of, wasted tires add significantly to our pollution and climate change levels. [EPA-HQ-OAR-2014-0827-0803-A2 p.3]

To explain the problem further, consider a standard US automobile that weighs around 4,000 pounds empty, or around 1,000 pounds per tire. Fairly typical tire pressures recommended by the manufacturer will be around 32 to 35 psi. An empty tractor will weigh around 18,000 pounds. The weight on the steer axles will be around 11,000 pounds, leaving 7,000 pounds on eight tires, or less than 1,000 pounds per tire. Similarly, a flat top trailer will have even less weight on its 8 tires. Imagine running your Chev or Ford with 100 psi in the tires.... It wouldn’t handle, it wouldn’t ride well, it wouldn’t stop, and tire life would be terrible. Yet this is exactly what we do to our trucks and drivers. [EPA-HQ-OAR-2014-0827-0803-A2 p.3]

More explanation: My company has developed, refined, and manufactures the best Central Tire Inflation for trucks for the last 17 years. We developed this product to serve the intensive logging industry in Australia, which is a great testing ground. We have thousands of heavy class 8 trucks, from log truck, fuel tankers, dump trucks, right through to road trains providing services to mining companies 500 miles from the nearest town. In every case, running the correct tire pressures has reduced tire wear and costs by at
least 30%. In some cases, tire life almost doubled. Many of our customers run 92 psi loaded at speed, 60 psi loaded on gravel roads, or empty on highway, and 30 psi empty on gravel. Note: these are hot pressures that are actually used. These trucks carry slightly more weight than US trucks, and, when empty have the trailers folded up on the back. My own class 6 tray truck runs pressures between 25 and 100, depending upon load. [EPA-HQ-OAR-2014-0827-0803-A2 p.3]

[Images of tires and explanatory text can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-0803-A2]

We’ve witnessed identical trucks, one group operating highways only, with traditional tire pressures, and one group hauling logs on mixed highway and gravel, with CTI and optimal pressures. The highway traditional trucks were simply falling apart, with cracked axles, spring breakages, cabin mount problems, cracked dashes, while the CTI equipped trucks operating in rougher conditions, had twice the miles, and no failures. This single firm operated dozens of highway trucks and a dozen log trucks. [EPA-HQ-OAR-2014-0827-0803-A2 p.3-4]

[Image of truck and explanatory text can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-0803-A2]

Other operators reported doubling the life of transmissions and differentials with optimized tire pressures. Another company did a vibration test at the driver’s seat. The optimized tire pressure truck exceeded their vibration limit 13 times. Three identical trucks, running traditional tire pressures, exceeded the vibration limit by 531, 560, and 573 times! [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

To summarize, almost every truck in America is running the wrong tire pressures. The information is readily available. Unfortunately, no one knows that cares. I believe that many are happy with the status quo. Many of the tire salesmen can’t be bothered to tell their customers, and put up with the arguments, or risk ‘losing face’. And why bother when everyone else is doing the same thing. Truck drivers are often second or third generation. Many fleet operators are ex truck drivers. Traditionally, all trucks ran either 100 to 110 psi, depending upon their preference. This is left over from cross ply/bias ply tire needs. We just haven’t changed our mentality to radial truck tires. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

Regulators should know better, should be well informed, yet, again, the traditional pressures are the law. Even rules regarding road vehicle safety, use the same ridiculous pressures. For instance; ‘a tire that is inflated to a pressure 20 psi below the intended target is considered non serviceable’. In my nearly 20 years of researching tire pressures, I have never found any government in any country that mentions optimizing tire pressures. In fact, I recently read an ‘expert’ report explaining that ‘tire load to inflation pressures’ are the ‘minimum’ tire pressures. ‘In fact, any pressure between this ‘minimum’ pressure and the maximum pressure listed on the side wall is correct.’ Unbelievable, and so wrong. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

Incorrect tire pressures add other problems. Miss matched tires on a dual assembly are known to cause problems, but Bridgestone proved that having just a 5 psi difference caused a 5/16 inch difference in rolling circumference. In a typical tire life, this is equivalent to spinning the tire for 160 miles! Tires are destroyed, rolling resistance increases, burning more fuel and energy. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

Further:
• Throwing away one tire out of three wastes a lot of CO2, in manufacture, in materials, in energy, and in transport. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

• Rough roads increase transport accidents and deaths. Over inflation reduces traction, damages drivers, fatigues drivers, and reduces vehicle control. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

• Whole Body Vibration is a proven cause of health problems, helping to kill our drivers. Optimizing tire pressures lets them absorb road irregularities and vibration, improving driver health and helping to fight fatigue. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

• High vibration damages trucks, drivers, and cargo, needlessly wasting money, energy, fuel, and CO2. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

• Worn out tires, uneven worn tires, damaged carcasses, damaged trucks, and damaged infrastructure add to the cost of everything that our civilization uses. Waste just adds to our problems, with no benefit whatsoever. [EPA-HQ-OAR-2014-0827-0803-A2 p.4]

• High vibration over inflated tires hammer our roads into an early grave. Pot holes, washboards, ruts, are all minimized or eliminated with optimized tire pressures. [EPA-HQ-OAR-2014-0827-0803-A2 p.4-5]

• Damaged roads and infrastructure costs our country and world twice. Perfectly good roads and bridges are damaged, and new roads and bridges cost millions and billions, adding to the Global Warming/Climate change pollutants. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

• Old roads, damaged tires, worn out trucks all cost money and energy to dispose of. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

• New roads, new tires, new trucks all cost money, and energy to manufacture and deliver. If trucks, roads, and tires last longer, much energy and pollution is saved. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

• Why is transport ignoring the manufacturer’s recommendations? [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

• Why are the regulators/governments not following manufacturer’s recommendations? [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

• Why are we ignoring the increased risk, the known health risks, and wasting billions of dollars? [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

Where should we go?

Fuel and pollution reduction is vitally important. Government incentives and requirements motivate manufactures and the industry. But, we mustn’t continue, and we mustn’t allow bad practices to continue, or be promoted. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

Education and regulation is the first step.
Then Tire Pressure Maintenance is the minimum that is must be fitted and regulated. The pressures must be set to optimize the truck and trailer. Central Tire Inflation is required on trucks that travel empty regularly, like dump trucks, bulk grain trucks, tankers, low loaders. When empty, semi-trailers are currently dangerous. Brake balance, significant overly braked, and ridiculously over inflated tires create a condition that jack knifes are probable. Any truck working off highways needs CTI too. Either will eliminate almost every blow out and alligators that litter our highways, if we’re lucky, or kill, if not. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

Over inflation is dangerous, costly, damages health, and damages our world. Over inflation is unacceptable. In the 21st century, we have the ability to optimize our world. Any other option is simply a death certificate for ourselves. The tire manufacturer’s recommendations must be the law, and must be enforced. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

Additional thoughts:

Fitting Truck and Trailer Aerodynamics are common sense. I have been designing and advocating aero for 40 years. Yet, almost no aero trucks exist. I was pleased in my latest 10,000 mile drive around the states that side skirts are being fitted, and the design is reasonably good. There is so much more that can be done. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

Why do proper aero trucks simply not exist on our highways? Where are they? Why do so many waste so much pushing air? [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

A problem exists in truck aero. Most of the manufacturers manufacture a product. They are not aero enthusiasts or even experts. Most are fiberglass manufactures. Aero is just one of their products, along with pots for planting flowers. [EPA-HQ-OAR-2014-0827-0803-A2 p.6]

I regularly see poorly designed aero, and even more often, poorly installed aero. [EPA-HQ-OAR-2014-0827-0803-A2 p.6]

Side skirts often have large gaps between the panel and the bottom of the body. A code of practice is drastically needed. [EPA-HQ-OAR-2014-0827-0803-A2 p.6]

I have had a lifelong obsession with optimizing motor vehicles of all types. Every component can be improved, without costing a fortune. In my 45 years owning, driving, working on, and modifying trucks, I’ve accumulated a lot of practical knowledge. [EPA-HQ-OAR-2014-0827-0803-A2 p.6]

My obsession means I’ve built actual vehicles to test my theories. This white truck was continuously upgraded over the last 20 years. Notice the fit of the cab deflector, the large side skirts, the front spoiler and the self-inflating boat tail, along with AIR CTI on all wheels. [EPA-HQ-OAR-2014-0827-0803-A2 p.6]

As this truck is quite old, I’ve built a new test truck. See below. [Image can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-0803-A2] Front spoiler, that automatically deploys over 30 mph (retracted in the picture), side skirts, small aero mirrors, and aero spats over rear wheels. The tapered tool boxes before and after the rear wheels deflect air around the wheel, and acts like an integral boat tail behind. The tray is aluminum for light weight. The tray is slides rearward and to the ground for loading vehicles, and to swap for the box as shown above. Additionally, AIR CTI is being fitted front and rear. Soon, speed sensitive automatic side skirts, tapered to the center of the truck immediately below the transmission, will drop to 4 inches above the road surface, to drag the air from underneath out and around.
A behind cab self-inflating tray boat tail is also designed. A new 6.7 liter Cummins B series engine and overdrive road ranger transmission is fitted. A FASS fuel air separation system ensures the engine gets pure fuel. We've seen 4 to 8% improvements in fuel economy with the FASS unit. Propane supplementation is another add on that will be fitted soon. As propane is half the price of diesel, propane makes good economic sense, and provides a cleaner running truck. We have seen some great results. We look forward to continuous improvement to help show our industry how to optimize their truck. [EPA-HQ-OAR-2014-0827-0803-A2 p.6]

AIR CTI is undoubtedly the best CTI available. AIR CTI is sold throughout Australia, by all Paccar dealers, and other truck businesses. AIR CTI is operating in South Africa, Malaysia, Indonesia, Papua New Guinea, New Zealand, Canada, USA, Italy, and the Middle East. Working with my brother in Texas, AIR CTI is starting its American debut, bringing me closer to my home country. The benefits of CTI are simply amazing. The reports from customers, and my own experience, along with 50 years of off-roading, from Missouri mud to the Canning Stock Route in outback Australia, CTI works. [EPA-HQ-OAR-2014-0827-0803-A2 p.7]

AIR CTI continues to grow at around 20% annually, our staff includes truck people with hundreds of years of experience. We have electronic experts, welders, mechanics, truck parts specialists, and a structural engineer as staff. I belong to ARTSA, Australian Road Transport Suppliers Association, with members from Paccar to Michelin to Meritor and BPW. I also belong to the National Bulk Tankers Association, and have spoken at several TMC’s run by our ATA. In the states, we’ve joined several logging associations, and concrete associations, as both are great potential users. We exhibited at the Mid America Truck Show earlier this year with more coming up. [EPA-HQ-OAR-2014-0827-0803-A2 p.7]

I have dedicated the rest of my life to improving transport. I will do whatever is necessary to make trucks safer, greener, and more profitable. [EPA-HQ-OAR-2014-0827-0803-A2 p.7]

Response:

Tire Pressure Systems

The agencies agree with the commenter that maintenance of tire pressure is important. The agencies also agree with the consequences discussed by the commenter of incorrect tire pressure – such as higher fuel consumption for underinflated tires and higher tire wear and vibration for overinflated tires. Consistent with the comment, the agencies are adopting provisions in Phase 2 GEM that allow manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520) to help encourage the better management of tire pressure in tractors, trailers, and vocational vehicles. The agencies also utilized tire pressure systems in the technology packages developed to determine the Phase 2 standards. The agencies appreciate the commenter’s information on their AIR CTI system.

Aerodynamics

The technologies cited by the commenter, such as automatic front spoiler, trailer side skirts, small aerodynamic mirrors, and aero spats over rear wheels, are some of the technologies that the agencies considered in developing aerodynamic bins that reflect the performance of technologies like these. Additional discussion on tractor-trailer aerodynamics can be found in RIA Chapter 2.4.1 and 2.8.2.2.

Organization: Convoy Solutions LLC
I think I heard you mention that EPA hasn't put much emphasis on examining or projecting the EPS segment because it didn't seem very significant and because it is 'off-board'. I think that you might have mentioned that, 'a handful of independent truck stops may have invested in small amounts of EPS. But it isn't very important overall in achieving major idle reduction metrics.' [EPA-HQ-OAR-2014-0827-1281-A1 p.1]

If this is your department's position, then I feel obliged to share my own biased opinion that in our current form, IdleAir's version of EPS is at worst, an important bridge-technology to a day of more pervasive adoption of various anti-idling technologies. This 'bridge' can extend for more than 10 years. Our infrastructure is already in the process of morphing into a precursor to eTRU and EV infrastructure along major transport corridors. We are in a growth spurt where it is a struggle to keep up with demand from large fleets for dedicated IdleAir terminals on their private yards. [EPA-HQ-OAR-2014-0827-1281-A1 p.1-2]

To the extent that NACFE's 2014 Idle Alternative Confidence Report has had a significant role in informing EPA of the status of off-board idle reduction technologies, then I think I need to clarify that although we are a financial sponsor of NACFE, we have repeatedly asked NACFE to consider correcting certain items in their report relating to EPS, but these corrections have not taken place. [EPA-HQ-OAR-2014-0827-1281-A1 p.2]

Interesting Comparison to APUs

Our cost per installed electrified parking space ranges from $5 - 10k, this is very similar to what we believe APUs actually cost (though EPA’s number seems to be a surprisingly low $4,800 figure). [EPA-HQ-OAR-2014-0827-1281-A1 p.2]

Most of our hardware is rated to last for more than 25 years as compared to 5 years for the average APU, thus our amortized marginal cost of ownership is much lower than an APU. [EPA-HQ-OAR-2014-0827-1281-A1 p.3]

EPS has comparatively low Carbon Intensity (1lb CO2 per gallon/hour of mitigation versus 4lb CO2 per hour of APU usage). [EPA-HQ-OAR-2014-0827-1281-A1 p.3]

EPS doesn't produce any local criterion pollutants (APUs do) and depending on who owns EPS it can have very low marginal operating cost ($25 - $.50/hour on a fleet terminal) versus $1/hour to operate Diesel or Battery APUs at current fuel price. If APUs were required to have DPF technology, then the $4,800/unit price seems even more unrealistic as an assumption from which to build life-time IRRs from. [EPA-HQ-OAR-2014-0827-1281-A1 p.3]

These EPS metrics all rival the comparable metrics on APUs, yet I don't feel like we have been given a fair chance to state our case in how we can cost-effectively help EPA and NHTSA meet their GHG goals. [EPA-HQ-OAR-2014-0827-1281-A1 p.3]

I'm concerned that the regulations themselves might jeopardize our ability to provide that meaningful transitional role for the 70% of class 8 trucks that don't have APUs of any sort today or the large audience

Page 727 of 2127
of used trucks - especially those typically owned by Owner Operators who tend to be slower to adopt efficiency technologies with a meaningful upfront cost. Market places try to adapt in anticipation of pending regulation, so we fear that if non-adjustable AES is expected by carriers, they may start transitioning away from impactful low GHG choices like EPS even though we are gaining momentum on private fleet yards today. [EPA-HQ-OAR-2014-0827-1281-A1 p.3]

Since more than 80% of new fleet truck purchases do include a fuel fired bunkheater, I believe that the relative window of idle-mitigating relevance for non-adjustable AES is potentially overstated in the ROI/fuel savings calculations since bunkheaters should not be considered part of the incremental cost/benefit of complying with Phase 2. Bunkheaters are essentially a standard option already. That means APUs are primarily necessary for less than 6 months of the year (typically Air Conditioning months) and thus the idle savings they bring should be calculated from less than 900 hours/year as a baseline rather than the 1,800 - 2,000 hours/year that Argonne Labs (and EPA and DOT) estimate trucks idle to generate overnight hotel loads for powering comfort and convenience. I believe that a large number of fleets can achieve compelling GHG and PM reductions at a fraction of the true cost of APUs using a combination of complimentary idle-mitigation solutions as follows: Bunkheater (40% of annual idle needs - cold weather) + EPS (25% idle needs - stationary yard and some truck stop usage) + adjustable AES (25% of idle during OTR activities). The combined upfront cost for users of these technologies is genuinely less than the $4,800 attributed to pre-DPF APUs and the marginal carbon and PM intensity of these technologies is comparable (if not superior) to APUs, but since the technologies can't address 100% of idle elimination, truck buyers would have to get an APU if non-adjustable AES is mandated in order to avoid unacceptable comfort and safety risks posed by not having an on-board summertime idle alternative. [EPA-HQ-OAR-2014-0827-1281-A1 p.3-4]

We are currently in an unexpectedly low diesel price environment which is making the financial ROI calculation for many energy efficiency options more challenging. At the same time, services like IdleAir that typically have no upfront investment requirement for users are on their way to becoming an important idle-mitigation choice of many fleets in their private yards. Many fleets (and drivers) tell us sadly that they think that idling today is cheaper than getting an APU. Fortunately, IdleAir typically prices its dedicated fleet terminal product at an average of $1.35/hour which is arguably less than half the lifetime cost of owning and using an APU and so we are increasingly able to convince fleets TODAY that embracing EPS can immediately pay for itself and is therefore worth doing even if APUs have a more challenging cost/benefit proposition. Since we use grid and renewable electricity as our fuel source, our 1.5kW/h service actually only costs us about $.25/hour, which is comparable to a bunkheater and much lower than the $.75 - $1.00/hour that an APU costs in the current diesel price environment. As we gain market share, fleets may decide to buy EPS outright and pay for their own electrical usage. In that scenario, there is no question that we are much cheaper and cleaner than APUs in stationary applications (like poor neighborhoods with non-attainment status that frequently encircle truck stops and large fleet terminals). [EPA-HQ-OAR-2014-0827-1281-A1 p.4]

In the end, I understand that EPA and NHTSA can only regulate a manufacturer and rewarding AES is not a new concept. However, the ambitious efficiency goal of Phase 2 becomes a de facto mandate of AES. Mandating AES will force the industry towards the only solution that can address 100% of the instances where a truck might need to idle - APUs. An owner cannot risk driver (or pet) safety even one night per year under AES. This is true even for truck owners who have been able to manage nearly all of their idling with a combination of best-cost idle mitigation technologies. An APU might not be the right choice for net GHG reduction for some buyers, but I fear that this rule makes that decision for them and it risks rewarding OEMs for including APUs while neglecting alternative idle-reduction technologies. [EPA-HQ-OAR-2014-0827-1281-A1 p.4]
Response:

The agencies made several changes to the treatment of AES and idle reduction technologies in the final rule. We, however, did not specifically include EPS as one of the technologies on the menu of idle reduction technologies included in GEM due to the lack of data supporting the amount of idle operation that is reduced in the real world through the use of EPS on a given tractor. Tractors manufactured during the Phase 2 timeframe with either the tamper-proof AES or adjustable AESS options would receive a CO₂ emissions and fuel consumption reduction in GEM. EPS paired with an AESS could receive the level of reduction specified in GEM for an Adjustable AESS or Tamper-Proof AESS, depending on whether the AESS is tamper-proof or not. We recognize that EPS could be an important idle reduction technology, but believe the technology should be evaluated in the off-cycle credit program so that data on specific vehicles can be considered.

It is also worth noting that the agencies are not mandating AES under the Phase 2 rulemaking. The agencies have adopted CO₂ emissions and fuel consumption standards based on our analysis of one technology pathway for each level of stringency, but manufacturers will be free to use any combination of technology to meet the standards, as well as the flexibility of averaging, banking and trading, to meet the standards on average.

In the final rule, EPA has started with an estimated APU price of $8,000 (retail price, 2013$). From there, we have adjusted the cost to arrive at a direct manufacturing cost of $5882 (DMC, 2013$, applicable in MY2014)). So the $4800 value mentioned by the commenter has been adjusted upward to $5882, and should be understood to be a direct manufacturing cost which is not comparable to an installed cost of $5-10K for an electrified parking space (which EPA interprets to be an installed price rather than cost). Our total cost for the APU, with markups and in 2018 (i.e., roughly today), is $6248 (total cost, 2013$ in 2018, see Chapter 2.11.6.1 of the final RIA).

Organization: Corwin, Michael

On the issue of aerodynamics, the truck can be made aerodynamic, regardless of the trailer it is pulling, so the regulations should be separate for the tractor and for the trailer. This would allow regulators to take into account the different types of trailers regardless of the truck that is pulling it and no matter what truck pulled it the aerodynamics would be good. The vast majority of companies pull one type of trailer vs multiple types but one truck lease operators may switch companies several times in their careers and pull a different type of trailer each time. By having the requirements separate the long term effects would be better. [EPA-HQ-OAR-2014-0827-0730-A1 p.1]

Response:

The agencies are setting GHG emissions and fuel consumption standards separately for the tractor and trailer. The commenter states one of the reasons it is appropriate for there to be separate standards.

Organization: Cummins, Inc.

Cummins urges the Agencies to establish a more representative Phase 2 baseline gearing [EPA-HQ-OAR-2014-0827-1298-A1 p.36]

The Phase 2 proposal provides a 2018 baseline gearing that is substantially above typical fuel economy recommendations for best efficiency. Figure 14 compares the Phase 2 baseline gearing to Cummins’
recommendations for best FE performance. While Cummins’ recommendation is a minimum value, there is concern that the Phase 2 baseline may not be the appropriate representative gearing and may inadvertently over-represent gearing improvements. Cummins urges the agencies to reevaluate the baseline and establish a more representative gearing for 2018. [EPA-HQ-OAR-2014-0827-1298-A1 p.36-37]

[Figure 14 can be found on p.36 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

Response:

The agencies re-evaluated the final drive ratio (gearing) used in the tractor baseline. We recognize that there is a wide range of final drive ratios being offered in the market today for tractors. Several companies offer fuel economy packages that would include gearing that takes advantage of downspeeding. However, the baseline should represent the average tractor performance in 2018MY. Meritor and Daimler provided CBI to assist us in developing the baseline. Our evaluation of this data supported the final drive ratio of 2.7 (based on a rear axle ratio of 3.70 and top gear ratio of 0.73) used in the NPRM and the baseline for the final rule reflects this ratio.

Organization:  Daimler Trucks North America LLC

8. Technology Penetration and Adoption Rate

- Introductory comment - Several assumptions are wrong about penetration rates of 6x2 axles, regulatory idle shutdown timers, and tires. And these flawed assumptions result in unrealistically difficult stringency. Based on our analysis of the agencies’ assumptions regarding penetration rates of certain technologies in order to meet the proposed standards we caution against a) sweeping assumptions across multiple vehicle subcategories and b) against assuming unrealistically high penetrations, as described below. [EPA-HQ-OAR-2014-0827-1164-A1 p.86]

- HFC Refrigerant from Cabin Air Conditioning (A/C) Systems – The agencies request comment on other possible improvements in the design of air conditioning systems that EPA could recognize for the purposes of compliance with this proposed standard. The agencies propose to provide a credit of 0.5% for tractors with a “high-efficiency air conditioning compressor” without thoroughly defining what that is. (The agencies state that it “includes” the configurations in 40 CFR § 86.1868–12(h)(5) and electrical compressors). Most importantly, [redacted]. Rather, an improvement factor more like [redacted]% is closer to the benefits that the agencies should expect from the technologies they are proposing. Further, we think that a manufacturer should get credit for other improvements to the system rather than simply the compressor. For example, a blend air system, which minimizes pumping losses, should get credit even if it uses a standard compressor. [EPA-HQ-OAR-2014-0827-1164-A1 p.110-111]

a. Aerodynamic Improvements

- Erroneous Estimate of Time By Which Manufacturers Can Improve Tractor Aerodynamics – In section 2.4.1 of the RIA, the agencies state that tractor model lifecycles are “up to 10 years.” This is approximately half of the correct number. The Freightliner Century, an industry benchmark for efficiency, was sold from 1996 to 2009—23 years. The successor vehicle, the Cascadia has been sold for only eight years, since 2007, so we should expect at minimum another fifteen years of production of that vehicle. And more likely, this vehicle will be in production much longer, due to the larger costs of developing so complex and advanced a vehicle. So while it is correct that radical changes to vehicle aerodynamics “occur in a long-term timeframe,” as the agencies state, we think that the statement of that timeframe
being “10-15 years from today [the date of the RIA]” is too short to reflect the industry’s actual patterns and the long time required to amortize the hundreds of millions of dollars necessary for cab redesigns. In short, the agencies need to base the penetration rate of improved aerodynamics on a much longer timeframe for adoption; the aero improvements take much longer than the agencies expected. [EPA-HQ-OAR-2014-0827-1164-A1 p.87]

Improvements Possible - In section 2.4.2.1.4 of the RIA, the agencies state that there are 206 to 460 counts of drag available for improvement on vehicles, based on National Research Council (NRC) of Canada research. But of utmost importance is the baseline. While it may be the case that there were up to 460 counts of drag available on the vehicle that NRC used for its analysis, it is not necessarily the case that the same opportunities exist on vehicle that meet the agencies’ 2017 GHG/FE standards. In fact, as we found in our Super Truck work at Daimler, there are diminishing opportunities on the tractor. Rather we found most of the aerodynamic benefits of our work on the trailer. Moreover, even if all of the drag improvements are theoretically possible, there may be impediments to implementing them all, such as reliability concerns, limitations on accessing the back of cab, etc. [EPA-HQ-OAR-2014-0827-1164-A1 p.88]

Preface: As discussed elsewhere in the EMA comments, the agencies’ assumptions about 1) achievable aero bins for various vehicles are impossibly aggressive and 2) the percent penetrations in each bin are unrealistic. For example, Super Truck vehicles would be in Bins IV or V at best, as opposed to the expected Bin VII, which means that the expectation of (e.g.) 5% penetration in Bin VII is unrealistic, given that Super Truck vehicles are the best vehicles ever made and even then are mere prototype vehicles. The basic idea behind both proposals is to correct the aero bins by approximately one bin width, which rectifies the agencies’ error. [EPA-HQ-OAR-2014-0827-1164-A1 p.56]

For penetration rates used in standard setting, we propose to keep the same weighted-average for the penetration rates in each bin as the agencies assumed in the NPRM. That said, we do not believe the agencies’ proposed penetration rates in each bin are realistic, given that we expect that there will always be Bin I vehicles, because there are market needs (e.g., severe duty tractors that do not get classified as “heavy-haul tractor” for whatever reason). If this is the case, then the agencies cannot just take the penetration rates in Tables III-8, -9, and -10. The agencies may, however, keep the same average. One should not be concerned about the actual penetration rates in any bin. Rather, one should be concerned with the average. [EPA-HQ-OAR-2014-0827-1164-A1 p.58]

This proposal is based on the expectations that 1) there will remain some small need for classic styled vehicles in the future, for example for logging where large cooling packages are needed; 2) we cannot shift all vehicles right away to (for example) Bin VI; 3) Bin VII may never be achievable, but remains an aspirational target only, and thus should not contain a large penetration rate. The result is that in 2021, we would need to average the middle of Bin V, 2024 the bottom of Bin V, and 2027 Bin VI. Clearly, given that the agencies recognize it may not be possible to do better than Super Truck, it would be unreasonable to have the whole target fleet average be below Super Truck level (meaning at 5.3 m2 on Cd*A basis, after the inclusion of a safety margin, or approximately 5.0 m2 based on test data). Therefore, we think that the above proposal shows the maximum possible achievable aero improvement, based on our knowledge today.[EPA-HQ-OAR-2014-0827-1164-A1 p.58]

Day cab high roof: for day cab, we expect that vehicles have different bin designations than sleeper because (generally speaking) it is more difficult to make a short vehicle aerodynamic than it is a similar, long vehicle. So we would adjust the bin definition so that 1) a classic vehicle is in Bin I, 2) the standard setting vehicle in Phase 1 is in Bin III, and 3) future production vehicles would be in Bins IV, V, and VI, and 4) Bin VII reserved for something that looks like Super Truck without a sleeper. But even if we
properly aligned the bin definitions per #1-4 above, the day cab market might reasonably choose a penetration rate with less aerodynamic vehicles, given the lower percentage of the time spent at highway speeds. In other words, we would dispute the EPA’s assumption of the exact same penetration rates in each bin for day cabs as for sleepers. So 5) we should adjust the average of the penetration rates so that the average is somewhat worse than the EPA’s proposed average in Tables III-8, -9, and -10. [EPA-HQ-OAR-2014-0827-1164-A1 p.59]

Below are the landmarks that we used in setting our proposed aero bins for high roof Class 7/8 day cabs: [EPA-HQ-OAR-2014-0827-1164-A1 p.59]

[Tables, listing Cd*A values for various vehicle types and giving BIN numbers for the EPA and DTNA proposals, can be found on p.59-60 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

**Mid- and low-roof, day cab and sleeper** - And we agree with the first step that the agencies took in calculating the penetration rates for mid-/low-roof in 2021 and 2024: they carried over the high-roof penetration rates and the high- to mid-/low- transition methodology. But the agencies missed the crucial second step: adjusting the average bin down (meaning toward Bin I) in recognition of the fact that mid-/low-roof vehicles should have lower penetration rates of aerodynamic vehicles to reflect market needs. That is, for tractors more likely to be used in rough environments or hauling non-aerodynamic trailers, it does not make sense to apply an equivalent aero bin penetration rate as for the high-roof, more aerodynamic, more on-highway vehicles. Furthermore, when we look at 2027, Table III-10, we see an additional problem: Bin VII in raised-roof gets a vehicle into mid-/low-roof Bin IV, and Bin VII is supposed to be unattainable or attainable by only 5% of the market, yet the agencies propose 10% of the mid-/low-roof vehicles be Bin IV (Super Truck equivalents). Considering how much less this portion of the market is affected by aero, this assumption is the wrong direction. So 2027 penetration rates have to be [redacted] using the general procedures described above. [EPA-HQ-OAR-2014-0827-1164-A1 p.60]

a. Tractor Stringency

- **Method of Setting Standards** - The agencies propose to set standards for tractors (and vocational vehicles) by estimating the Fuel Consumption Reductions (FCRs) for various technologies and calculating the achievable penetration rates for each technology. We agree with this approach (although as we discuss below, we do not agree with all of the FCRs or penetration rates). It does not make sense to assume a 100% penetration rate of any technology, even aerodynamic features, given that vehicles have different uses for which some FE technologies do not make sense. [EPA-HQ-OAR-2014-0827-1164-A1 p.68]

- **The Agencies’ FCRs and Penetration Rates Create Unrealistic Stringency Targets** – DTNA analyzed the agencies’ assumptions based on the original aero numbers in the NPRM and our understanding that the agencies would fix a one bin error in the aero binning. Our findings are that the standards of even Alternative 3 are impractically stringent. Below are several scenarios—one of which we are certain we can achieve, and all of which would take years of major development work to achieve—to demonstrate how unrealistically stringent the agencies’ Alternative 3 proposal is. [EPA-HQ-OAR-2014-0827-1164-A1 p.68]

[multiple bullet points redacted]

Below, for reference, we show the same analysis but with the NPRM’s aero bin designations: [much of following section is redacted] [EPA-HQ-OAR-2014-0827-1164-A1 p.69]
As can be seen, even our best vehicles with a host of unrealistic assumptions cannot achieve the standards. [EPA-HQ-OAR-2014-0827-1164-A1 p.70]

Here we repeat the analysis for day cabs. We assume that the aero bin problems are solved so that a current vehicle might be in Bin IV and future vehicles might get (on average) in Bin V—again a big assumption as this requires 1) fixing the aero binning and 2) manufacturers being able to make further aero improvements within the limitations of the Bridge Law and the weight constraints, which are much more stringent for day cabs. [EPA-HQ-OAR-2014-0827-1164-A1 p.71]

Results if we do not assume that the agencies correct the aero bin numbers are shown below: [EPA-HQ-OAR-2014-0827-1164-A1 p.71]

Result – Only by correcting the aero bin errors do we get close to compliance. And then, only by making unrealistic assumptions of FE technology penetration rates can we see achieving the proposed standards of Alternative 3. Therefore, we believe that Alternative 3 is beyond the “greatest degree of emission reduction achievable” (quoting CAA § 202(a)(3)(A)). Note that this is the analysis for our best vehicles; for the other RSCs that contain vehicles focused on more vocational tasks, such that FE is a lower priority, the standards are even more difficult. Important note – We were unable to do such an analysis for vocational vehicles because of the lack of clarity about the normalization and equalization processes. We cannot understand how those regulations will affect us without the agencies clearing up problems in those processes. [EPA-HQ-OAR-2014-0827-1164-A1 p.72]

Vehicle technologies, their FCRs, and achievable penetration rates for setting stringency - The agencies omitted several very important fuel saving technologies (e.g., eCoast, TPMS). If the agencies have concerns about these technologies, then we should address them and count them in Phase 2. For example, if the agencies have concerns about TPMS, then we can document the actual fuel savings and can perhaps agree upon a method of locking in TPMS improvements. Similarly, the aggressive assumptions about tire Crr’s are beyond our capabilities; we do not control tire design and development. [EPA-HQ-OAR-2014-0827-1164-A1 p.74]

Achievable Improvements in Aerodynamics is Poorly Defined – In section 2.4.2.1.4 of the RIA, the agencies state that there are 206 to 460 counts of drag available for improvement on vehicles, based on National Research Council (NRC) of Canada research. But of utmost importance is the baseline. While it may be the case that there were up to 460 counts of drag available on the vehicle that NRC used for its analysis, it is not necessarily the case that the same opportunities exist on vehicle that meet the agencies’ 2017 GHG/FE standards. In fact, as we found in our Super Truck work at DTNA, there are diminishing opportunities on the tractor. Rather we found most of the aerodynamic benefits of our work on the trailer. [EPA-HQ-OAR-2014-0827-1164-A1 p.61-62]

b. Tires

The agencies project unrealistically low Crr’s and in turn come up with unrealistic stringency values – We recommend that the agencies work with our end-of-year reports to see trends like are shown
In short, the agencies made identical assumptions for tire rolling resistance targets across all tractor subcategories despite the vehicles’ differences. Specifically, based on our GHG vehicle data it is evident that there are clear trends when comparing average CRRs of individual subcategories. There is a distinct Crr increase going from high roof to low roof sleepers and there is also a noticeable difference from sleeper cabs to their corresponding day cab categories. We believe that these real world trends need to be taken into consideration when setting the Phase 2 standards; fleets have actual needs for wear-resistant tires for their business. As we project toward the future, we see that in most RSCs, the agencies assumed Crr’s to decrease from today’s actual values by unrealistically large amounts—up to 22%. It is not at all clear that this is possible for tires that still allow work trucks to get into and out of worksites, to turn and bump curbs, to run over obstacles, etc. as HDVs must. In short, we need to work extensively with the agencies to define realistic Crr targets.

[redacted section]

c. 6x2’s

- Gross overestimate of the possible penetration rate of 6x2’s (unless NHTSA and Canadian provinces change the laws) - The agencies’ assumptions of penetration targets of 6x2 tractors are inconsistent with the laws in the US and Canada, and they will lead to tractors that are unusable in many states and provinces during inclement weather. In our tractor population we can see a 6x2 penetration of less than 5% and insurmountable barriers to increasing that value—which makes a 60% penetration for Class 8 High Roof Tractors in 2027 unachievable. It is important to remember that going from a 6x4 to a 6x2 tractor is anything but a clear cut decision. There are many factors involved, for example concerns about 1) the inherent rapid tire wear on the drive axle and 2) the practical inability to drive 6x2’s in several US states because of the traction issues and the limited ability to shift loads onto the drive axle enough to get traction, 3) the inability to drive 6x2’s in one province at all, given that 6x2’s are prohibited at weights at which heavy-duty vehicles often operate. Ultimately, there are a lot of issues to be resolved before 6x2’s can be used by any more than a niche portion of the heavy-duty fleet, and the agencies should not premise regulations on a high penetration rate of a technology that faces such legal obstacles. Until 1) the US agencies, in particular NHTSA, create an allowance to briefly overload a 6x2’s drive axle for traction purposes and 2) the Canadian government allows 6x2’s in all provinces with temporarily shifted weights, the agencies should not predicate a rule on such a high penetration rate.

[The table '6x2 & WBS Tire Compliance - Current Status' can be found on p.90 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

For reference, below are our penetration rates for the various regulatory subcategories and axle configurations. For example, 6x2 is [redacted] of the total population of RSC14 vehicles, Class 8 high-roof sleeper cab tractors. Included with these numbers are the percentages of total sales that each RSC constitutes, so that the agencies can see that [for instance] [redacted] of sales in RSC09 is of little importance given that that RCS constitutes only [redacted] of total sales. Even though our customer base is extremely concerned with fuel efficiency and understands the benefit of 6x2 technology, we see that approximately [redacted] of sleeper customers and less than [redacted] of vocational customers choose 6x2’s - likely because of the difficulty in operating those vehicles.
EPA and NHTSA proposals for 6x2 penetration rates are inconsistent with many states’ laws: the EPA and NHTSA should only push such a high 6x2 penetration rate if the agencies can change the laws such that 6x2’s may be used legally in all 50 states and in all Canadian provinces. Moreover, many Canadian provinces prohibit the axle loading, and British Columbia prohibits 6x2’s altogether. Because heavy-duty vehicles must be designed for cross-country operation in all 50 states and in Canada, the EPA and NHTSA’s use of 60% penetration of a technology is inconsistent with the technology’s being unusable or impractical to use in more than 10% of the states and provinces. The agencies, particularly NHTSA, have the authority to affect US laws on 6x2 usages, but until the agencies do so, they are mandating a high penetration rate of a technology that cannot actually be used. We recommend no more than a 5% penetration rate until the laws change. [EPA-HQ-OAR-2014-0827-1164-A1 p.86-87] Note that we are not discussing penetration rates in this table. So, for example, we do not question 6x2 FCR of 2.5% although we think that the 60% penetration rate is impossibly high. [EPA-HQ-OAR-2014-0827-1164-A1 p.86]

d. AES

FCR of APUs or Other Idle Reduction Devices - The agencies, recognizing that many idle-reduction devices are installed in the aftermarket after a truck manufacturer has sold a vehicle, request comment on other approaches that would appropriately quantify the reductions that would be experienced in the real world besides requiring that the vehicle manufacturer install an idle-reduction device in order to get credit. 80 FR 40224. We agree that manufacturers should get idle-reduction credit for vehicles that clearly do not idle, whether because they have shutdown timers or because they have APUs and the like—in either case, it is clear that the vehicle will not idle. Why would a vehicle owner spend more than thousands of dollars on an APU or the like if he intended to idle frequently? Likely he intends to idle very rarely, thus making the technology worth the cost. If he does happen to order no shutdown timer, there might be a reason, like an occasional job where he needs to idle. But he still clearly intends to do so rarely and thus should be credited accordingly. [EPA-HQ-OAR-2014-0827-1164-A1 p.79]

Regulators Should Credit Normal AESs - Customers almost all take non-regulatory idle shutdown timers of such short duration as to prevent overnight idling, yet none of them will take the regulatory kind. Yet the EPA premises its standards on 80 to 90% penetration of APUs (which the agency uses as equivalent to AESs). We think that this level is unrealistically high, given the agency’s experience. If, however, the agency insists on such a high penetration rate, then we have a proposal below for making the AES requirements more realistic. Additionally, we think that the APU costs that the agency used are an order of magnitude too low: APUs cost [redacted], and if the penetration rate is near 100%, then the average cost will be around [redacted]. Yet the agency assumes approximately $2,000 (see, e.g., Table III-29). [EPA-HQ-OAR-2014-0827-1164-A1 p.91]

Table showing the take rate of non-regulatory AESs in each RSC and the sales percentage that each RSC constitutes (the latter of which helps explain why a [redacted] take rate of AESs in RSC10 is nearly irrelevant, given the [redacted] sales percentage). As can be seen well over 90% of the primary sleeper category, RSC14, takes AESs—but the agencies do not recognize this in their regulations, either today or in Phase 2. [EPA-HQ-OAR-2014-0827-1164-A1 p.91]

Proposal for Crediting Normal AESs – Based on an analysis of our database, looking for the number of customers who chose a non-regulatory AES at or below 5 minutes and then subsequently
disabled it, we find that nearly 99% had not done so. Approximately 1% of our EPA10 engines (manufactured in calendar years 2010/2011/2012) that were initially programmed with a shutdown timer of 5 minutes or less were reprogrammed to a value above 5 minutes or for complete deactivation. This low rate of reprogramming is understandable: why would a person voluntarily buy an item only to disable it? The only AESs that we expected would be disabled would be the regulatory ones if customers were forced into them. In light of the facts that most customers buy AESs, that the agencies would like to take credit for AESs in the fuel or GHG savings, that manufacturers work hard to produce (non-regulatory) AESs that function well and meet our customers’ fuel saving needs while not interfering with their operations, and that customers rarely disable the AESs, DTNA proposes that the agencies credit non-regulatory AESs at 95% of the value of a regulatory one—a little less than the fraction of AESs that remain functional today. We would agree that, in our 270 day end-of-year reports, we would report to the agencies the AESs that remain active, so that the agencies can be sure we are not gaming the system by enabling AESs as vehicles leave the manufacturing plants and disabling them shortly afterward. Following this approach the agencies could claim the targeted savings while avoiding unintended market disruptions. [EPA-HQ-OAR-2014-0827-1164-A1 p.91-92]

e. APUs and Other Idle Reduction Technology

· Credits for AESs, Regardless Whether a Vehicle Has an APU – The agencies discuss idle reduction technology on 80 FR 40223. The goal of reducing fuel consumption during idle can be done through different technologies such as APUs, diesel fired heaters, and battery powered units. The agencies discuss as adopted in Phase 1 of only allowing idle emission reduction technologies which include an automatic engine shutoff (AES). We believe that this is the correct approach. In other words, we believe that that an AES should receive credit if it installed, regardless if there is an APU or battery-powered idle reduction system on the vehicle. Therefore, we recommend the agencies clarify that they recognize this technology as a stand-alone system and provide credit for an AES but no APU on a vehicle. [EPA-HQ-OAR-2014-0827-1164-A1 p.92]

· Cost of APUs With and Without DPFs – The agencies request comment on the cost estimates associated with DPF systems for APUs. As a preface to this comment: the agencies far understated the cost of APUs generally. First, APUs were estimated to cost on the order of $3,000 (which is the listed figure, back-calculating for penetration rate). See III-29 of the NPRM, 80 FR 40241. In reality, APUs are approximately [redacted]. And the DPF-equipped APUs are [redacted] more expensive (depending on the options selected) than the equivalent non-DFP equipped APU. The agencies should consider the accurate final cost of the APU with DPF as in the end the heavy-duty vehicle owner will be forced to bear the price difference. [EPA-HQ-OAR-2014-0827-1164-A1 p.92]

Second, some of the crucial assumptions in GEM are flawed. For example, the agencies assume a flawed value for the effectiveness of an automatic engine shutdown timer (AES). Below are the values for several configurations of AES and auxiliary power unit (APU): [EPA-HQ-OAR-2014-0827-1918-A2 p.1-2]

<table>
<thead>
<tr>
<th>Configuration</th>
<th>Percentage</th>

</tbody>
</table>

As we have shown the agencies, data demonstrates that vehicle owners rarely disable even the non-regulatory AESs, which means that the system will shut down the engine in five minutes or less
(depending on the setting). So the non-regulatory AES will prove effective at shutting down an engine and stopping emissions, unless the driver of a vehicle equipped with an AES stays awake throughout the night to restart his engine or to reset the timer. In fact, to make it such that the non-regulatory AES were (for example) only 1/5 as effective as a non-regulatory AES plus battery APU, the driver would have to restart or reset such that the engine runs for an average of 48 minutes of every hour that the AES and APU functions, meaning he restarts or resets more than nine times per hour for a whole night every night, which is exceedingly unlikely. Rather, the non-regulatory AES is a relatively cheap and effective way to ensure nearly all—if not all—of the emission reductions of all the other configurations listed above, so it should get approximately the same credits; it certainly should not get so small a fraction as the agencies have proposed to give it. [EPA-HQ-OAR-2014-0827-1918-A2 p.2]

f. VSLs

- **Vehicle Speed Limiters and Extended Idle Provisions** - The agencies requested comment on whether it is appropriate to allow vehicle owners to participate in the overall compliance process for vehicle speed limiters and idle reduction. 80 FR 40250. First, we are glad that the agencies recognize the difficulties that manufacturers such as ourselves have encountered trying to push regulatory-compliant VSLs and AESs to a pull market. The agencies discussed the possibility of a means by which fleets could participate in the credit transactions. If the agencies were to follow such a path, then we would need to ensure that regulatory VSLs and AESs factor only into a program regulating fleets and not manufacturers. In other words, if vehicle buyers can choose to buy regulatory VSLs or AESs, and they get the credit for doing so, then manufacturers cannot be expected to accumulate credits for such VSL or AES sales. Rather, in such a case, the vehicle standards would have to be calculated without such features included. Because such a regulatory program is likely unwieldy (How would fleets be regulated? How would their interaction with vehicle manufacturers be regulated?), and because the agencies do not have authority over fleets within the scope of the CAA or EISA sections cited within the NPRM (given that those sections authorize vehicle and engine regulation, not regulation of vehicle users), it is more likely that the agencies will be limited to regulating vehicle features. In that respect, we applaud the agencies' recognition that the Phase 1 AES and VSL standards failed to capture the usage of those two features. In discussions with the agencies, we have presented the option of getting a partial credit for non-regulatory AESs and VSLs based on the rate at which customers leave the features in their operational states. We can show the agencies in a confidential setting that [redacted]. We work hard to make fuel saving features like AESs and VSLs that fleets and vehicle operators will buy; we should get credit for such work. [EPA-HQ-OAR-2014-0827-1164-A1 p.92-93]

- **Vehicle Speed Limiters and Extended Idle Provisions** - The agencies discuss the difficulties of getting heavy-duty vehicle owners to accept regulatory, tamper-resistant VSLs and AESs. 80 FR 40250. The agencies request comments on suggestions how to close the gap between provisions that would be acceptable to industry, which seeks to retain control over its vehicles' operations, and those that would be acceptable to regulators, who seek to ensure that society gets the benefit of speed limiters and decreased idling. Additionally, the agencies request comments on potential approaches which would enable feedback mechanism between the vehicle owner/fleet that would provide the agencies the assurance that the benefits of the VSLs and AESs will be seen in use but which also provides the vehicle owner/fleet the flexibility they may need during in-use operation. As a preface to our comments, we note that our customers overwhelmingly buy AESs and to a lesser extent VSLs. (See the statistics in the VSL and AES table, above). Although we have a large portion of vehicles sold with VSLs that achieve emission reductions and FE benefits, these VSLs do not get regulatory credit because they do not meet the regulatory requirements. HDV owners and fleets want to limit speeds and idling, but they do not want to be locked into a strategy. So our comments revolve around the fact that we wish to get credit for the owners' and fleets' purchases, largely because we have developed AESs and VSLs that meet with a high
level of customer approval, without locking our customers into the agencies' requirements. We recommend that the agencies give partial credit for non-regulatory AESs and VSLs in proportion to the fraction of non-regulatory ones that remained unaltered, based upon our study of our database. Since the introduction of our latest generation of engines we are able to effectively track parameter changes in our proprietary control modules (controllers for vehicle, engine and aftertreatment). [EPA-HQ-OAR-2014-0827-1164-A1 p.93]  

- **VSL** – In section 2.8.3.5 of the RIA, the agencies note that there is such low take-rate of regulatory VSLs that the technology should not be used for standard setting. We agree. We do think, however, that if the agencies were to credit adjustable VSLs—recognizing heavy-duty vehicle operators’ desire for speed reductions but balancing the need to adjust the speeds from time to time—that the technology could factor into standard setting. 2.8.3.5 of the RIA. [EPA-HQ-OAR-2014-0827-1164-A1 p.93-94]  

- **Hybrid timeline for deployment** - The agencies requested comment from industry on the projected timeline for deployment of hybrid powertrains for tractor applications. DTNA is especially situated to comment on hybrids as we had sold hybrid vehicles (mostly vocational vehicles), and we were the sole Super Truck team to use a hybrid system, yet we dropped out of the hybrid market after our hybrid transmission supplier stopped selling the systems. Our response to the agencies' request is that we see no timeline for deploying hybrids in tractors or, for that matter, any heavy-duty vehicles. Quite the opposite: the market for hybrids has fallen apart, as hybrids have proved not cost-effective. In Super Truck, a tractor that was tested largely (but not entirely) on linehaul-type highway routes, the hybrid system provided little benefit beyond what eCoast achieved. See the figure below. The reason for this is that an eCoast system competes with hybrids for energy that might be lost on hills (given that linehaul vehicles spend almost all of their time on highways, rather than in stop-and-go traffic). But eCoast does not suffer the energy conversion loss that a hybrid does when the hybrid converts mechanical energy to electrical and back. Moreover, the hybrid was limited in both the energy that could be stored in the batteries and the power at which the batteries could be charged. When laden the vehicle inertia was so large that braking events could return to much power to be stored in our Super Truck batteries. This was with the Super Truck vehicle loaded to 65,000 lb. If the vehicle were at 80,000 lb., the problem would be worse. In other words, eCoast proved a 'poor man's hybrid,' meaning a far more cost-effective hybrid, optimizing energy transfers from potential to kinetic and vice versa much more efficiently and cheaply than the hybrid system did. Plus eCoast is much cheaper and lighter, as it requires no batteries or motors. So we expect no deployment—or more appropriately re-deployment—of hybrid vehicles in the foreseeable future. [EPA-HQ-OAR-2014-0827-1164-A1 p.96]  

[The table 'Energy Consumption on Highway Route' can be found on p.96 of docket number EPA-HQ-OAR-2014-0828-1164-A1]  

Analysis of DTNA Super Truck performance demonstrating that predictive technologies such as Predictive Cruise Control and eCoast, which help to minimize brake usage, provide essentially all of the FCR benefits of hybridization, which requires much hardware, weight, and cost to regenerate brake energy.

j. Stop-Start Functionality  

- **Start-Stop Technologies (Engine Risks)** - EPA requests information regarding whether or not start-stop or auto-shutdown technologies are being developed for tractors; especially for Class 7 and 8 day cabs that could experience more frequent stops and more time parked for deliveries. To date, DTNA has not validated that stop-start strategies are viable for Class 7 and 8 applications and considers it premature to for EPA to include in its assumptions that stop-start strategies are viable for this class of engines.
Lubrication of critical bearing surfaces is lacking or severely compromised during engine start up due to the lack of lubricating oil pressure. Lack of proper lubrication leads to metal to metal contact, wear, and ultimately failure. In addition, firing pressures inherent to compression ignition engines further exacerbate wear as compared to, for example, spark ignition engines where stop-start technology is being increasingly applied. These known problems, coupled with the extremely long million mile plus service life expectations for this heavier class of heavy-duty engines, together pose a development challenge that is significantly more challenging than that posed to spark ignition engines in passenger cars. In addition to bearing lubrication during startup being a critical function of engine lubricant, lubricant also plays an important role in cooling of components. Heat soak of temperature critical parts and temporary disruption of their lubrication/cooling systems (ex: turbochargers, engine valve train) will have to be understood and possible degradations handled through modifications at either component or system basis, the extent of which is not yet fully quantified. Similarly, on the turbocharger side, the larger speed swings (theoretically all the way from engine ‘off’ to normal over the road operation) will shorten turbocharger wheel life, which is increasingly challenged in vocational applications that are characteristically more transient as compared to the relatively steady operation nature of line haul. Lastly, the design life targets (and associated costs) of today’s starter systems fall far short of what may be to be required for ISS systems. In short, there are a lot of significant hardware issues to be resolved before stop-start can be considered “achievable” for use in setting standards. Even if stop-start is achievable, there remains significant uncertainty about its achievable penetration rate. For example, vocational vehicles generally have a significant need for launch capabilities, given how frequently they stop and start and the variety of conditions under which they must do it (for instance, on hills). Meanwhile, although passenger car stop-start systems often work quite well, rotational inertia inherent to heavy duty engines there are orders of magnitude greater than passenger car engines and pressure (fuel, charge air) build-ups that must occur before the vehicle can pull away from the curb differ significantly. The subsequent compromise to launch capability may ultimately be unacceptable in many applications from a performance standpoint which would lead to lower penetration either via disablement of the feature or rejection of the option. Lastly, it is not uncharacteristic of vocational applications to be laden with equipment that requires idling of engines to sustain system power draw and avoid excessive storage battery drain. The EPA should work with DTNA to establish a clear understanding of actual application needs that justifiably may diminish penetration rates. [EPA-HQ-OAR-2014-0827-1164-A1 p.98]

9. Standards for niche vehicle types
   
i. Heavy-Haul Vehicles

   · **Proposed Heavy-Haul Tractor Standards** - The agencies request comment on the approach of not considering the use of aerodynamic technologies in the development of the proposed Phase 2 heavy-haul tractor standards. 80 FR 40233. We think that this is appropriate. These are vehicles that are already quite heavy (by virtue of need), designed to meet high cooling need (thus having, for example, large grilles), and generally not designed primarily for hauling standard trailers on highways. In addition, these are often designed to be capable of operation off road or on difficult terrain. So mandating aerodynamic values (which pushes manufacturers toward smaller grilles) or aerodynamic components (which are often unsuitable for difficult terrain) could compromise the vehicles’ work. [EPA-HQ-OAR-2014-0827-1164-A1 p.99]

   · **Proposed Heavy-Haul Tractor Standards** - The agencies request comment on the heavy-haul tractor technology path and standards proposed by the agencies (Tables III-19 and -20). 80 FR 40234. First, we think that the agencies are correct not to require manufacturers input into GEM the heavy-haul vehicle’s Cd*A or aero bin. These vehicles are designed for hauling large and heavy loads, so they require large radiators, which forces non-aerodynamic designs. Moreover, the loads may often be much larger...
than the vehicles, so that requiring aerodynamic measurements of a vehicle that will haul loads dramatically interfering with those aerodynamics does not make sense. [EPA-HQ-OAR-2014-0827-1164-A1 p.99]

Second, we believe that the agencies have set overly aggressive tire Crr targets. Heavy-haul vehicles need unusually high traction, given their loads. Moreover, they need unusually high stopping power. Assuming such aggressive reductions in Crr's as the agencies do is not supported by what we currently know about tire manufacturers' capabilities to minimize the Crr's of such heavy duty tires. Third, we think the agencies are correct in assuming no weight reduction in these vehicles. These vehicles need strong frames, axles, etc. in order to carry such heavy loads. Rather than reducing weight, it is consistent to expect that manufacturers will reinforce components as much as is necessary.[EPA-HQ-OAR-2014-0827-1164-A1 p.100]

**Weight reduction credits generally:** Phase 2 should involve a better approach to calculating and crediting vehicle weight than Phase 1. In Phase 1, GEM assumes a fixed vehicle weight then subtracts weight for items made of low density materials (e.g., aluminum) to arrive at any given vehicle’s simulation weight. It may be possible to accurately correct for the amount of weight saved when 1) a low density material is a direct replacement for a high density material and 2) both are of a known volume or weight. However, in other cases the mere use of a low density material does not translate directly into, nor necessarily even correlate with, a weight savings. For example, use of aluminum wheels in lieu of steel ones results in a well-known weight savings. By contrast, use of aluminum in cross members or suspension components does not necessarily result in known weight savings since, to achieve equivalent strength aluminum components generally need to be larger such that weight may actually increase. More generally, crediting individual components that are not one-for-one replacements for another, as EPA proposed to do with a 300 lb. weight credit for engines below 14 liters, is inappropriate: by contrast to aluminum wheels, which are nearly direct replacement for steel ones, swapping one engine for another forces different engine mounts, transmissions, etc. which may or may not have weight advantages. [EPA-HQ-OAR-2014-0827-1164-A1 p.52]

DTNA engineers have done benchmarking studies to identify any weight advantages of its products or areas to investigate for future improvements. In one such case, DTNA compared three vehicles: vehicle A, a 2014 Freightliner Cascadia with a 72 inch raised-roof sleeper, DD15 (15 liter) engine, and DT12 transmission; vehicle B, a concurrently sold competitor vehicle with 73” raised-roof sleeper, a 13 liter engine, and a leading brand of transmission; and vehicle C, also a concurrently sold competitor vehicle with 72” raised-roof sleeper, a 13 liter engine, and the same transmission as vehicle B. The vehicles were configured to be as close as possible in specification given the different manufacturers. Despite the larger displacement of vehicle A’s engine, that vehicle was lighter than B and C by 1,004 and 644 lb. respectively. The result of a program that rewards lightweighting credits based on certain specifications such as engine displacement could be that heavier vehicles will receive lightweighting credits that may not be warranted, which seems misaligned with the intent of the regulation. In addition, such an approach would overlook a manufacturer’s efforts to lightweight a particular engine platform (with the same displacement). Until the EPA has developed a robust procedure for extrapolating from the weight of individual components to a full vehicle, the EPA should seek to credit components only where they are direct replacements of well-known weight savings, (e.g. wheels), but not others. If the rulemaking seeks to truly credit and incentivize lightweighting, an integrated approach may be the best solution. However, such a solution comes with other tradeoffs, such as the effort of developing a robust measuring standard and additional compliance burden to manufacturers. 80 FR 40249. [EPA-HQ-OAR-2014-0827-1164-A1 p.52]
• **Weight Reduction Items That Are Missing From The Agencies’ Approach** – The agencies propose to credit vehicles with use of low density materials, regardless of the amount of material used, but the agencies fail to credit vehicles for decreased use of material altogether. NACFE recently studied weight-reduction options for HDVs and found that, for example, horizontal exhausts save 150 pounds over vertical exhausts. We have encouraged our customers to choose these items for years because of the weight savings. The agencies should similarly recognize the weight savings. Similarly, opting for a short sleeper rather than a full one, smaller fuel tanks than were used in the past, a short Bumper to Back of Cab (BBC) vehicle, etc., should get weight reduction credit. In short, we wish to work further with the agencies to make sure that the agencies’ lightweighting credits align with actual vehicle weights. [EPA-HQ-OAR-2014-0827-1164-A1 p.53]

• **Weight Reduction** – In section 2.8.3.3 of the RIA, the agencies note that there is such high cost and low benefit to weight reduction that weight reduction should not be used for standard setting. We agree. RIA 2.8.3.3 [EPA-HQ-OAR-2014-0827-1164-A1 p.53]

**NGV weight penalty in GEM:** DTNA analysis shows that for the most popular sizes of NG tanks, 120 and 160 diesel gallon equivalent, the NG system is between 1500 and 2100 lb. heavier than the diesel systems. This analysis includes the weight of the diesel aftertreatment, which is not required with NG. Therefore, the 800 lb weight penalty for NGV in GEM is too low. 1037.520(e)(4)(iv). [EPA-HQ-OAR-2014-0827-1164-A1 p.100]

**Response:**

*A/C Systems*

We are interpreting Daimler’s comment related to HFC emissions in air conditioning systems to be related to A/C system efficiency, not an HFC issue. The agencies received several comments on the potential efficiency improvements of accessories. We are adopting as proposed the definition of what qualifies as a high efficiency A/C compressor. In terms of the level of effectiveness of compressors, we are also adopting the 0.5% effectiveness in GEM. Effectiveness of other types of accessory technologies may be demonstrated by manufacturers through the off-cycle provisions.

*Aerodynamics*

The agencies corrected the lifetime of tractors in RIA Chapter 2.

The agencies’ assessment is that the best aerodynamic tractor tested by EPA in 2015 achieved Bin IV performance. This vehicle did not include all of the possible aerodynamic technologies, such as wheel covers or active aerodynamics like a grill shutter or front air dam. Thus, the agencies’ assessment is that Bin V is achievable with known aerodynamic technologies, as discussed in RIA Chapter 2.8.2.2, but agree with the manufacturers that Bins VI and VII have less known technology paths. However, we are including Bins VI and VII in the Phase 2 regulations as a potential Phase 2 technology to recognize the possibility that over the next ten years (until the full implementation of the Phase 2 program) tractor manufacturers may advance their aerodynamic technologies beyond the Bin V levels projected for the Phase 2 standards, and to provide a value to be input to GEM should they do so.

In Phase 1, the agencies determined the stringency of the tractor standards through the use of a mix of aerodynamic bins in the technology packages. For example, we included 10 percent Bin II, 70 percent Bin III, and 20 percent Bin IV in the high roof sleeper cab tractor standard. The weighted average aerodynamic performance of this technology package is equivalent to Bin III. 76 FR 57211. In
consideration of the comments, the agencies have adjusted the aerodynamic adoption rate for Class 8 high
roof sleeper cabs used to set the final standards in 2021, 2024, and 2027 MYs (i.e., the degree of
technology adoption on which the stringency of the standard is premised). Upon further analysis of
simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the
manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of C_dA,
as discussed above and in RIA Chapter 2.8.2.2. Consequently, the final standards are not premised on
any adoption of Bin VI and VII technologies. Accordingly, we determined the adoption rates in the
technology packages developed for the final rule using a similar approach as Phase 1 - spanning three
aerodynamic bins and not setting adoption rates in the most aerodynamic bin(s) - to reflect that there are
some vehicles whose operation limits the applicability of some aerodynamic technologies. We set the
MY 2027 high roof sleeper cab tractor standards using a technology package that included 20 percent of
Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof
sleeper cab tractors that we project could successfully apply these aerodynamic packages with this
amount of lead time. The weighted average of this set of adoption rates is equivalent to a tractor
aerodynamic performance near the border between Bin IV and Bin V. We believe that there is sufficient
lead time to develop aerodynamic tractors that can move the entire high roof sleeper cab aerodynamic
performance to be as good as or better than today’s SmartWay designated tractors.

The agencies phased-in the aerodynamic technology adoption rates within the technology packages used
to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these
technologies. The changes required for Bin V performance reflect the kinds of improvements projected in
the Department of Energy’s SuperTruck program. That program has demonstrated tractor-trailers in 2015
with significant aerodynamic technologies. For the final rule, the agencies are projecting that truck
manufacturers will be able to begin implementing some of these aerodynamic technologies on high roof
tractors as early as 2021 MY on a limited scale. For example, in the 2021 MY technology package, the
agencies have assumed that 10 percent of high roof sleeper cabs will have aerodynamics better than
today’s best tractors. This phase-in structure is consistent with the normal manner in which
manufacturers introduce new technology to manage limited research and development budgets as well as
to allow them to work with fleets to fully evaluate in-use reliability before a technology is applied fleet-
wide. The agencies believe the phase-in schedule will allow manufacturers to complete these normal
processes. Overall, while the agencies are now projecting slightly less benefit from aerodynamic
improvements than we did in the NPRM, the actual aerodynamic technologies being projected are very
similar to what was projected at the time of NPRM (however, these vehicles fall into Bin V in the final
rule, instead of Bin VI and VII in the NPRM). Importantly, our averaging, banking and trading
provisions provide manufacturers with the flexibility (and incentive) to implement these technologies
over time even though the standard changes in a single step.

The agencies also received comment regarding our aerodynamic assessment of the other tractor
subcategories. The agencies recognize that there are tractor applications that require on/off-road
capability and other truck functions which restrict the type of aerodynamic equipment applicable. We
also recognize that these types of trucks spend less time at highway speeds where aerodynamic
technologies have the greatest benefit. The 2002 VIUS data ranks trucks by major use.\textsuperscript{60} The heavy
trucks usage indicates that up to 35 percent of the trucks may be used in on/off-road applications or
heavier applications. The uses include construction (16 percent), agriculture (12 percent), waste
management (5 percent), and mining (2 percent). Therefore, the agencies analyzed the technologies to
evaluate the potential restrictions that will prevent 100 percent adoption of more advanced aerodynamic
technologies for all of the tractor regulatory subcategories and developed standards with new penetration
rates reflecting that these vehicles spend less time at highway speeds. For the final rule, the agencies

evaluated the certification data to assess how the aerodynamic performance of high roof day cabs compare to high roof sleeper cabs. In 2014, the high roof day cabs on average are certified to one bin lower than the high roof sleeper cabs. Consistent with the public comments, and the certification data, the aerodynamic adoption rates used to develop the final Phase 2 standards for the high roof day cab regulatory subcategories are less aggressive than for the Class 8 sleeper cab high roof tractors. In addition, the agencies are also accordingly reducing the adoption rates in the highest bins for low and mid roof tractors to follow the changes made to the high roof subcategories because we neither proposed nor expect the aerodynamics of a low or mid roof tractor to be better than a high roof tractor.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found steer tires with rolling resistance as low as 4.9 and drive tires with as low as 5.1 kg/ton. The average tire rolling resistance that we used in the technology packages to derive the final rule standards are higher than the lowest rolling resistance tires made today, so the technology is feasible.

We also note that the certification data analysis shows that the drive tires on low and mid roof tractors on average had 10 to 17 percent higher rolling resistance than the drive tires on high roof sleeper cabs. We found less of a difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. The agencies phased-in the low rolling resistance tire adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2

---

63 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s.\textsuperscript{64} In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

*Idle Reduction Technologies*

While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

As described in RIA Chapter 2.4.8.1.1, the agencies determined the effectiveness of adjustable AESS through our determination of the split between idling hours using the main engine versus the idle reduction technology. For example, the baseline idle emission rate was assumed to be determined by 100% of the 1800 hours of idling conducted each year was done using the main engine. For APU and battery APU technologies with a tamper-proof AESS, the agencies assumed that these technologies would be operating 100% of the idling time. For automatic start/stop systems with a tamper-proof AESS, the agencies determined that the idling power would come from the battery half of the idling time and the other half would require main engine idling. For fuel operated heaters with a tamper-proof AESS, the agencies assumed that 800 of the idling hours would involve the use of the fuel operated heater and that the main engine would idle for the other 1000 hours per year to supply cooling and other needs. For idle reduction technologies with an adjustable AESS, the agencies discounted the number of hours operated by the idle reduction technology by 20 percent to account for the fact that it is an adjustable (non tamper-proof) system. For adjustable AESS without an additional idle reduction technology, the agencies set the number of main engine operating hours at 25% of the total idle time to also reflect that it is adjustable and that the agencies have less certainty in the continued use of this in the real world. The discount is greater for an adjustable AESS without additional idle reduction technologies because we believe that there is a potentially stronger incentive for vehicle owners to change the setting if they have not invested in the additional technology. Similar to other technologies, manufacturers may demonstrate off-cycle credits to account for additional effectiveness not shown in GEM.

In the final rule, EPA considered the APU cost comments and more closely evaluated NHTSA’s contracted TetraTech cost report which found the retail price of a diesel-powered APU with a DPF to be $10,000. The agencies used a retail price of a diesel-powered APU to be $8,000 without a DPF and $10,000 with a DPF in the cost analysis for this final rulemaking. From there, we have adjusted the cost to arrive at a direct manufacturing cost of $5882 (DMC, 2013$, applicable in MY2014)). Our total cost for the APU, with markups and in 2018 (i.e., roughly today), is $6248 (total cost, 2013$ in 2018, see Chapter 2.11.6.1 of the final RIA). See also Responses in 4.6 below.

**Vehicle Speed Limiters**

The agencies considered DOT’s upcoming actions with respect to mandatory vehicle speed limiters for heavy-duty trucks, but could not take it into account in this Phase 2 rulemaking because that rule is not final yet. The existing Phase 1 VSL flexibilities provide opportunities for manufacturers to account for the impact of VSLs on reducing GHG emissions and fuel consumption, while still allowing the settings to change after an “expiration” time determined by the manufacturer or to include a soft top. At this time, we believe that the Phase 1 flexibilities sufficiently balance the desire to encourage technologies that reduce GHG emissions and fuel consumption while minimizing the compliance burden of trying to accommodate changes throughout the useful life of the vehicle. Therefore, the agencies are not adopting any new VSL provisions for Phase 2.

**Hybrids**

After considering the comments, the agencies are continuing the Phase 1 approach of not including hybrid powertrains in our feasibility analysis for Phase 2 for tractors. Because the technology for tractor applications is still under development we cannot confidently assess the effectiveness of this technology at this point in time. In addition, due to the high cost, limited benefit during highway driving (see Daimler’s comment) and lack of any existing systems or manufacturing base, we cannot conclude that such technology will be available for tractors in the 2021-2027 timeframe. However, manufacturers will be able to use powertrain testing to capture the performance of a hybrid system in GEM if systems are developed in the Phase 2 timeframe, so this technology remains a potential compliance option (without requiring an off-cycle demonstration).

**Stop-Start**

The agencies are not including any technology inputs to GEM reflecting stop-start technology. We believe the technology needs further development for tractor applications. If this technology is developed in the future for tractors, then manufacturers may consider applying for off-cycle technology credits. Since the agencies are not predetermining the Phase 2 standards on adoption of start-stop technologies, the agencies are also not including this technology as a GEM input.

**Heavy-Haul Tractors**

After considering the comments, the agencies are basing the stringency of the final standards on a technology package that does not use aerodynamic improvements, as we proposed.

We received comments from stakeholders about the application of technologies other than aerodynamics for heavy-haul tractors. After considering these comments and the information regarding the tire rolling resistance improvement opportunities, discussed in Section III.D.1.b.iii of the Preamble, the agencies have adjusted the adoption rate of low rolling resistance tires.

**Weight Reduction**

The agencies are maintaining the Phase 1 approach to weight reduction. A more complex approach would require a significant amount of data to develop a baseline because there is a large variation in the baseline weight among tractors that perform roughly similar functions with roughly similar configurations. Therefore, we are limiting the weight reduction to specific components that can be replaced with light weight components. The differences can then be readily quantifiable and well-understood. 76 FR 57151. In addition, a more complex approach would require a significant increase in test burden for the manufacturers because it would require the empty weight of the tractor be measured.
and input into GEM for each configuration built. The agencies at this time do not believe this added burden is necessitated.

For the final rule, the agencies are only adopting weight reduction values that are reductions, not weight penalties (such as natural gas). The agencies are adopting weight reductions in the powertrain (smaller displacement engines and 6x2 axles) because Phase 2 includes the impact of the powertrain in the vehicle’s CO₂ emissions and fuel consumption values. Additional weight reduction, such as the items mentioned by the commenter, may be evaluated as a potential off-cycle credit.

**Organization:** Diesel Technology Forum

**Vehicle Technologies Will Be Critical to Meet Proposed Phase 2 Benefits**

Class 7 and 8 vehicles that today consume about 70 percent of all the fuel used in the medium- and heavy-duty fleet, are expected to achieve a 24 percent improvement in fuel economy and reduction in carbon emissions through the lifetime of the proposed rule relative to the existing Phase 1 standard. Consideration of the Phase 2 proposal will include a suite of technologies from advanced engine designs to lightweight and more aerodynamic materials, innovative and adaptive cruise controls, next generation transmission designs and safety features and many more. All of these technologies build on the continued gains in diesel engine efficiency to consume even less fuel and help to quickly achieve greater fuel savings and greenhouse gas reductions. [EPA-HQ-OAR-2014-0827-1171-A2 p.4]

Technologies envisioned to meet these proposed Phase 2 standards may deliver significant additional fuel economy benefits and greenhouse gas emission reductions on the order of 1.8 billion barrels of crude oil saved and 1 billion tons of carbon emissions eliminated. Unlike Phase 1, where many technologies were already commercially available and proven, in order to achieve the ambitious goals outlined in Phase 2, EPA and NHTSA should proceed with caution in that they have incorporated reliance on adoption of some technologies that are not currently widely tested, proven or commercially available. [EPA-HQ-OAR-2014-0827-1171-A2 p.4]

**Response:**

The agencies carefully considered the lead time required for each individual technology while setting the standards, consistent with the respective statutory requirements to consider lead time as part of the standard setting process.

**Organization:** Doran Manufacturing

Currently, the proposed Phase 2 of the EPA’s and NHTSA’s Greenhouse Gas Emissions Standards includes only automatic tire inflation systems (ATIS) as an acceptable technology for maintaining tire inflation pressures in order to reduce rolling resistance, fuel consumption and associated greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

Historically, tire pressure monitoring systems (TPMS) have not been included in the EPA’s SmartWay program because the Agency had no way to determine the effect this technology had on fuel economy unless each requesting fleet provided a clear description of their compliance strategy. This information was necessary to help the EPA to calculate the associated fuel savings from running on properly inflated tires. The benefit which is calculated was determined to be fleet-specific, since it depends upon a fleet’s individual compliance strategy and was not able to be generalized industry-wide. This meant that tire
pressure monitoring systems were not able to be SmartWay approved at the time, since the fuel savings depended upon the follow-up action by the fleet, rather than the technology itself. [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

Fortunately, a significant amount of development has occurred since the inception of the SmartWay program to help verify the fuel savings and the associated reduction of replacement tires by utilizing TPMS and telematics integrations. [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

-- The Federal Motor Carrier Safety Administration (FMCSA) has studied TPMS for a number of years pointing to the positive impact of TPMS: [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

• 2006: FMCSA found that this technology accurately reported tire inflation pressure values to within 2 to 3 psi of the measured value and accurately created low pressure alerts within 2 to 3 psi of the expected threshold [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

• 2007: performance and durability of TPMS was studied in a field test on transit buses [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

- This study found that using a TPMS display is essential to impact tire maintenance practices, fuel economy and tire life

- In addition, it found that only using diligent tire pressure maintenance did not increase the average tire pressures

• 2011: the FMCSA published the results of a Field Operational Test of tire pressure monitoring systems (TPMS) and automatic tire inflation systems (ATIS) on two fleets that were considered to have good tire maintenance which was conducted over the previous twenty-four months which created the following conclusions: [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

- TPMS or ATIS use will reduce fuel consumption of equipped tractor-trailers with test fleets seeing a 1.4% improvement in fuel economy

- TPMS or ATIS use will reduce road calls for damaged/flat tires of equipped tractor-trailers

- TPMS or ATIS use will not introduce unscheduled maintenance that adversely affects day-to-day fleet operations [EPA-HQ-OAR-2014-0827-1165-A1 p.1]

-- Significant technological advancements related to integrating TPMS data between TPMS providers and telematics companies have occurred over the past few years which creates an even greater effect on fuel consumption and greenhouse gas emission than the original tire pressure monitoring systems which were tested and proven to deliver 1.4% improvement in fuel economy by the FMCSA: [EPA-HQ-OAR-2014-0827-1165-A1 p.2]

• It is recommended that drivers are still required to inspect tires during a pre-trip inspection. Due to the advancements and in-cab monitoring, drivers can know instantly and accurately if any of their tires are under inflated before departing on their trip [EPA-HQ-OAR-2014-0827-1165-A1 p.2]

- In cab display examples, with visual and audible low pressure alert notifications:
- The tire pressure data and alert notifications are also captured and transmitted off the truck to provide real time access for fleet management to increase awareness and improve driver accountability.

- Examples of real-time TPMS data: [sample of TPMS data can be found on p.2-3 of docket number EPA-HQ-OAR-2014-0827-1165-A1]

  - the capability is now being used by a significant and growing number of fleets to not only visually and audibly alert the driver of a low pressure event, but to also transmit tire pressure/temperature data and low pressure alarms off the truck to create e-mail/text message alerts for dispatch or maintenance personnel and/or to generate reports to help fleets quickly identify which trucks/trailers and tires have low pressures that need to be addressed [EPA-HQ-OAR-2014-0827-1165-A1 P.4]

  - In addition, the date/time and GPS location for each low pressure alarm is available which can be used to identify when and where tire pressure events occur and to hold drivers accountable [images can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1165-A1]

  - Below is actual trailer tire data from a fleet that is utilizing a TPMS telematics integration to help monitor tire pressures and temperatures in conjunction with ATIS: [EPA-HQ-OAR-2014-0827-1165-A1 p.4]

  - the tire pressure dropped below 20psi while the trailer was detached and the inflation system wasn’t powered

  - a low pressure alarm was generated by TPMS and transmitted by a telematics provider to a web portal which created the awareness to the potential tire problem

  - the tire was inspected, repaired and put back into service

  - the repair did not correct the problem and the tire began to deflate/inflate again

  - more low pressure alarms were triggered and the tire was inspected/replaced which will help to minimize rolling resistance and improve fuel economy for that trailer

  - most likely, this tire would have continued to have drastic changes in tire pressure resulting in an extended period higher rolling resistance and reduction in fuel economy and ultimately ended with a catastrophic tire failure [chart, ‘TPMS History Summary Report’, can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1165-A1]

  -- 2009-2010: a waste hauling fleet conducted a 12-month comprehensive study on the impact of tire pressure monitoring systems on 60 trucks out of a terminal in Jacksonville, FL [EPA-HQ-OAR-2014-0827-1165-A1 p.5]

  - Overall, the fleet replaced 204 fewer tires (from 1,439 down to 1,235) which is a 14.2% reduction during the 12-month period with TPMS on the vehicles compared to the prior 12-month period without TPMS on the vehicles [EPA-HQ-OAR-2014-0827-1165-A1 p.5]

• According to the Rubber Manufacturers Association, it can take up to 7 gallons of crude oil to produce a single tire [EPA-HQ-OAR-2014-0827-1165-A1 p.5]

- approving the use of an existing and reliable technology that is proven to reduce the number of replaced tires will also help to reduce the carbon footprint and reduce greenhouse gas emissions

Overall, it is Doran’s position that the advancements in technology which have been implemented with the continued development of tire pressure monitoring systems and telematics offerings, should be included in Phase 2 of the Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles. [EPA-HQ-OAR-2014-0827-1165-A1 p.5]

There are simply too many documented conclusions by FMCSA and cases of real-world results in support of improved fuel economy and a reduction in the number of replaced tires from a significant number of fleets across the country which have occurred after SmartWay's initial ruling to not include TPMS in Phase 2 of this Standard. [EPA-HQ-OAR-2014-0827-1165 p.1]

Furthermore, without including this technology, there will not be a system available in this Standard to address tire inflation pressure for powered vehicles because automatic tire inflation systems (which are plumbed inside an axle) are currently only available for trailers. [EPA-HQ-OAR-2014-0827-1165-A1 p.5]

It would be shortsighted to overlook an advanced and proven technology which can dramatically impact the reduction of greenhouse gas emissions in a number of ways. [EPA-HQ-OAR-2014-0827-1165-A1 p.5]

Response:

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allow manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS. However, the effectiveness value in GEM for TPMS is less than that for ATIS, reflecting the loss in efficiency reflecting need for driver interaction. See RIA Chapter 2.4.3.3.

Organization: Eaton Vehicle Group

Phase 2 does not prescribe technology and provides a flexible structure that allows OEM’s to use advanced powertrains, and their significant potential to save fuel, for regulatory compliance. Eaton believes that deep engine-transmission integration, Dual Clutch Technologies and ultra-efficient transmissions are cost-effective methods to save fuel and achieve compliance, without adding the weight, cost and complexity common to some new and/or un-tested technologies. Technologies available to the market today are only partially accounted for in the pathways to compliance and cost analysis. We believe that they offer OEMs increased flexibility to achieve the standards in the NPRM without any significant additional cost, thus reducing the technology and reliability risks required to comply with the proposed standards. [EPA-HQ-OAR-2014-0827-1194-A1 p.5]
Hybrids

In the HD line haul segment the potential for hybridization is driven by improved aerodynamics. An analysis [Vinjamoor 2015] on a typical high speed line haul route, shown in the figure below, compares current and more aerodynamic trucks. A significant improvement in the tractor-trailer aerodynamics from current levels of $\alpha = 0.65$ to $\alpha = 0.45 - 0.52$ and a reduction in tire rolling resistance from $\beta = 6.9 - 7.3$ to $\beta = 5.6 - 5.9$ increases the coasting time and braking loads (and thus the regeneration opportunities). A parallel 100kW hybrid system can further improve the fuel consumption of such a vehicle by more than 5%. In such a configuration, a Waste Heat Recovery system would also make use of the electrical infrastructure to lower its conversion losses, and the combined system could provide more than 8% fuel reduction over the conventional powertrain on a constant speed cycle over a relatively flat road as shown below. These results are consistent with analyses presented by Volvo and Daimler and seen on SuperTruck demonstrators. [EPA-HQ-OAR-2014-0827-1194-A1 p.17]

[Figure 3, HD Line haul route for Hybrid analysis, can be found on p.18 of docket number EPA-HQ-OAR-2014-0827-1194-A1]

We recommend the EPA revisit the assumptions behind the 6x2 impact of 2.5%. Our experience shows a lower value. [EPA-HQ-OAR-2014-0827-1194-A1 p.19]

Response:

After considering the comments, the agencies are continuing the Phase 1 approach of not including hybrid powertrains in our feasibility analysis for Phase 2 tractors. Because the technology is still under development for tractor applications we cannot confidently assess the effectiveness of this technology at this point in time. In addition due to the high cost, limited benefit for tractors during highway driving, and lacking any existing systems or manufacturing base, we cannot conclude with certainty, that such technology will be available for tractors in the 2021-2027 timeframe. However, manufacturers will be able to use powertrain testing to capture the performance of a hybrid system in GEM if systems are developed in the Phase 2 timeframe.

The agencies reassessed the effectiveness of 6x2 axles. Meritor stated in their comments that their internal testing and real world testing supported the 2.5 percent efficiency proposed by the agencies for 6x2 axles. The agencies’ assessments of these technologies show that the reductions are in the range of 2 to 3 percent.65 For the final rule, the agencies are simulating 6x2, 4x2, and disengageable axles within

65 See Section III.D.2.b of the Preamble for further discussion.
GEM instead of providing a fixed value for the reduction. This approach is more technically sound because it will take into account future changes in axle efficiency.

Organization: FedEx Corporation

4. Components Ratings: While the proposal currently states that it is the responsibility of manufacturers to document the contributive benefit of the components installed on the Tractor and or Trailer; fleets such as FedEx need the verified efficiency of the available components separately, and/or when used in combination. There should be a government-provided rating of components to assist a fleet in its deliberation as to which components are the most effective and should be included in future purchases. Implementation would be inhibited if fleets were required to conduct their own evaluations of individual components. [EPA-HQ-OAR-2014-0827-1302-A1 p.4]

Response:

For tractors, the agencies are not adopting a program to provide a rating of components to the fleets or public. The Phase 2 tractor program has been designed to drive reduction of GHG emissions and fuel consumption of new tractors through performance-based standards that are met on average by each manufacturer. We believe this is the most efficient method of driving reductions.

Organization: First Industries Corporation

The following EPA-proposed penetration rates are too aggressive and in our estimation must be adjusted downward: [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

6x2's: 60% - 6x2's may not be used legally and safely in all 50 U.S. states and Canada. In particular, six state laws limit tire and axle loading in such a way that 6x2's cannot be used as intended, and many other states have confusing regulations that effectively prevent usage of 6x2's. Fleet owners must purchase trucks that can operate in all 50 states, and many cross the border between the U.S. and Canada. As long as state and provincial laws limit the use of 6x2's, fleet owners will only purchase the technology in limited areas and quantities. Moreover, while fuel savings can be realized with 6x2's, 6x2's also see an increase in tire wear and associated costs, and have lower resale value. Accordingly, the payback period for 6x2's can be longer, making them cost-ineffective for some applications. EPA should assume no more than a 5% penetration rate for 6x2's through 2027 and should engage in additional study of the safety and regulatory challenges associated with 6x2's. [EPA-HQ-OAR-2014-0827-1145-A2 p.3]

6x2's — EPA should include in its cost calculation the additional tire wear and the negative impact on resale value associated with 6x2's. [EPA-HQ-OAR-2014-0827-1145-A2 p.4]

Auxiliary Power Units ('APUs'): 90% - Many operations do not require APUs, and basing stringency on the assumption that 90% of customers will purchase APUs skews what is actually achievable and ultimately imposes unnecessary costs. Further, no environmental benefit results from the purchase of an APU by a fleet that does not idle. Many fleets use diesel-fired heaters to greatly reduce idling in cooler weather, but still need to use idling when cab cooling is required. Fleets that already limit idling either via slip seat operation (where drivers are rotated) or use of fuel-fired heaters will not get adequate payback from an APU. Fleets will also see reduced load capacity due to the APU weight and possibly worse aerodynamics from a larger trailer gap if the space for an APU requires a longer wheelbase. Notably, most fleets already purchase programmable idle shutdown timers which limit idling. However, fleets do not purchase regulatory versions of idle shutdown timers because of the negative perception in the
secondary market regarding such technology and the importance of considering resale value when purchasing a new vehicle. In practice, idle shutdown timers are typically used for the useful life of the vehicle, whether they are regulatory or not. If forced to purchase APUs or regulatory shutdown timers, many fleets will pre-buy vehicles so as to delay the negative costs associated with such technology. APU’s and AES’s should not be considered part of stringency, unless the agencies' choose to provide credit for non-regulatory versions of AES's that provide essentially the same environmental benefits as the regulatory version. [EPA-HQ-OAR-2014-0827-1145-A2 p.3]

APU’s — EPA estimates on the cost of APUs in 2027 will be $4,327. The cost of the APU today is two to three times above that number. EPA should use the actual cost of APU’s in its calculation and adjust the numbers upward to reflect the future costs. [EPA-HQ-OAR-2014-0827-1145-A2 p.4]

Tire Inflation Systems: 40% - Customers are more likely to purchase tire pressure monitoring systems, which provide all of the benefits of tire inflation systems at a lower cost. In addition, a customer who simply checks tire pressure daily can achieve all of the same benefits without purchasing either technology and incurring its costs. Tire inflation systems should not be forced into the market by assuming any penetration rate. To the extent credit is provided for these systems, both tire inflation systems and tire pressure monitoring systems should receive the same amount of credit. [EPA-HQ-OAR-2014-0827-1145-A2 p.3]

Tire Inflation Systems — The cost estimates for tire inflation systems must include warranty risk and maintenance costs, as well as the cost of false warnings. Consideration of the benefits must factor in system leakage, which forces increased operation of the air compressor and therefore depending on the type of system, could require more fuel to be burned by the truck ultimately creating a penalty to the engine. [EPA-HQ-OAR-2014-0827-1145-A2 p.5]

Lower Low Rolling Resistance ('LRR') Tires — EPA and NHTSA should do an independent study of the LRR tires that they are seeking to push into the market, both in terms of safety and availability. In particular, the agencies should look at the effect on stopping distance and whether such tires should and can be used safely in all weather conditions. Fleets will use LRR tires when appropriate. However, including wide spread use of these tires when determining a baseline from which to apply reductions will result in overly stringent standards. Because EPA's tampering rules require retention of all features that reduce GHG emissions, another unintended consequence of this action is that fleets will likely choose tires with higher rolling resistance (less efficient), so that they have more flexibility in replacing tires in the field when needed. EPA also errs in its tire analysis by using the same rolling resistance for day cabs, sleepers, and raised roof sleepers. The need for and benefit of LRR tires on a raised roof sleeper is very different from the other, categories. EPA should examine fleet tire data and adjust stringency to account for variations and different business needs. [EPA-HQ-OAR-2014-0827-1145-A2 p.3-4]

Lower LRR Tires — EPA erred in its cost calculations for LRR tires by basing its cost figures on 1999 tire data indexed for inflation, rather than using current cost data. Moreover, EPA’s cost figures did not account for additional wear and tear and lifetime replacement costs of LRR tires. Also, EPA should not assume the same level of fuel economy benefit for the life of the tire, since fuel economy associated with higher rolling resistance tires generally improves with wear. [EPA-HQ-OAR-2014-0827-1145-A2 p.4-5]

Aerodynamic Devices — EPA’s estimated cost of future aerodynamic devices appears very low given the historical nature of the proposed changes. In the rule the agencies should describe in detail and on an individual basis what components they expect to be used for compliance, the costs of these individual components, and how this will change over-time to maintain compliance with stricter standards. [EPA-HQ-OAR-2014-0827-1145-A2 p.5]
Response:

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s. In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

The agencies considered the maintenance impact of 6x2 axles. As noted in the NACFE Confidence Report on 6x2 axles, the industry expects an overall reduction in maintenance costs and labor for vehicles with a 6x2 configuration as compared to a 6x4 configuration. Among other savings, the reduction in number of parts, such as the interaxle drive shaft, will reduce the number of lubrication procedures needed and reduce the overall quantity of differential fluid needed at change intervals. The agencies have taken an approach to the maintenance costs for the 6x2 technology where we believe that the overall impact will to be zero.

Idle Reduction Technologies

While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments, the

67 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

EPA considered the comments and more closely evaluated NHTSA’s contracted TetraTech cost report found the retail price of a diesel-powered APU with a DPF to be $10,000. The agencies used a retail price of a diesel-powered APU to be $8,000 without a DPF and $10,000 with a DPF in the cost analysis for this final rulemaking. See also Preamble Section III.C.3 and response 4.6 below.

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO$_2$ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS.

With respect to costs, all of the agencies’ technology cost analyses include both direct and indirect costs. Indirect costs include items such as warranty. In terms of maintenance, the presence of tire inflation management systems, should serve to improve tire maintenance intervals and perhaps reduce vehicle downtime due to tire issues; they may also carry with them some increased maintenance costs to ensure that the tire inflation systems themselves remain in proper operation. For the analysis, we have considered these two competing factors to cancel each other out.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found that the drive tires on low and mid roof tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. But we found less of a difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. The agencies phased-in the low rolling resistance tire adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies.

We have estimated the cost of lower rolling resistance tires based on an estimate from TetraTech of $30 (retail, 2013S). We also have applied a “medium” complexity markup value for the more advanced low rolling resistance tires. We expect that, when replaced, the lower rolling resistance tires would be replaced by equivalent performing tires throughout the vehicle lifetime. As such, the incremental increases in costs for lower rolling resistance tires would be incurred throughout the vehicle lifetime at intervals consistent with current tire replacement intervals. A recent study conducted by ATA’s Technology and Maintenance Council found through surveys of 51 fleets that low rolling resistance tires and wide base single tires lasted longer than standard tractor tires.\textsuperscript{70} Due to the uncertainty regarding the life expectancy of the LRR tires, we maintained the current tire replacement intervals in our cost analysis.

\textsuperscript{70} Truckinginfo. TMC Survey Reveals Misinformed View of Fuel-Efficient Tires. March 2015.
Aerodynamics

The agencies included the technology cost of aerodynamic improvements, such as wheel covers and active grill shutters, in our analysis of aero bin V. The direct manufacturing cost of aero bin V, as shown in RIA Chapter 2.11.9, is $3089 for high roof sleeper cabs and $2660 for high roof day cabs (2013$ in 2014). The agencies did not receive any detailed cost estimates for aerodynamic devices in the comments to the NPRM.

Organization: Gaines, Linda

Similarly, long-haul trucks are evaluated at the manufacturer level, which does not easily take into account the many retrofits, including aftermarket idling reduction devices not installed on initial purchase, or the actual use patterns. It might therefore make sense to measure truck efficiency at the fleet level, using telematics data to infer actual fuel use. Although this could be considered intrusive, at least telematics data measures what is actually of concern rather than a poor proxy. [EPA-HQ-OAR-2014-0827-1357-A1 p.1]

Response:

The agencies developed the Phase 2 rule under their respective authorities. Clean Air Act section 202(a)(1) and (2) authorize EPA to establish standards for emissions of pollutants from new motor vehicle and engines.

Organization: Green Transportation Solutions

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 234-236.]

So beyond the costly vehicle upgrades and modifications that are being discussed here today, it is rather difficult for some of these drivers to purchase some of these things. We usually actually recommend three simple and inexpensive ways to reduce petroleum consumption, and, thus, greenhouse gas emissions with our clients.

The third is to incorporate a tire pressure screening system

It's very important for not only fuel efficiency, but for safety. It is one of the simplest ways to increase your fuel economy. It does take management. It does take participation by the drivers. And also many, many safety improvements having properly inflated tires.

Response:

The agencies have included tire pressure monitoring systems in the menu of technologies recognized in Phase 2 GEM.

Organization: He, Leard, McConnell

We do not directly measure the adoption of these technologies and vehicle design characteristics over time. Instead, the effects of these advances are absorbed by model year fixed effects in our estimation.
Therefore, the time period fixed effects potentially reflect the adoption of a combination of these technologies. [NHTSA-2014-0132-0115-A1 p.3]

2.2 Trade-off Factors

Some truck attributes have a negative correlation with fuel economy, ceteris paribus. We examine closely two of these trade-off attributes, engine displacement and vehicle weight. [NHTSA-2014-0132-0115-A1 p.3]

[Figure 1, 'Theoretical illustration: trade-off between MPG and vehicle weight', can be found on p.4 of docket number NHTSA-2014-0132-0115-A1]

4 Empirics

Our main regression is specified as follows. [NHTSA-2014-0132-0115-A1 p.6]

\[
\ln \text{MPG}_i = \alpha_1 \ln \text{Weight}_i + \alpha_2 \ln \text{CIDs} + \text{MY}_i'y + \text{X}_i'B + E_i
\]  

(1)

\(\text{MY}_i\) are the model year fixed effects. The estimated coefficient \(y\) indicates how technological progress changes over time. A list of controls, \(\text{X}_i\), include body/trailer type, number of axles on the power unit, cab type, whether equipped with air-conditioning, \(\ln\) (odometer reading), main cargo type, vehicle make, fuel type (interacting with model years), survey year fixed effects and region fixed effects. The estimation results are shown as model 1 in Table 1 and Table 2. [NHTSA-2014-0132-0115-A1 p.6]

In the second model, we aggregate the data by fuel type, model year, body/trailer type, vehicle make, number of axles on the power unit and cab type to recover the average fuel economy at the truck model level. We compute the probability weight based on the distribution of each truck model in the original dataset. The estimation results are shown in columns (2) and (4) in Table 1 and Table 2. [NHTSA-2014-0132-0115-A1 p.6]

Third, we apply the Oaxaca/Blinder method of decomposition to estimate the technological progress. The base period is from model year 1973 to 1975. We run the regression as specified in (1) only for observations from the base period, and use the estimated parameters from the base period to fit the fuel economy in each of the following model years. That is to say, we are holding the coefficients of trade-off variables, Weight and CID, constant. The difference between actual and fitted fuel economy can be decomposed into an explained part and an unexplained. The explained part is the effect of changes in trade-off variables; the unexplained part reflects the technological progress. The estimated progress (in percent) in each model year after the base period is shown in the third and sixth columns in Table 1. [NHTSA-2014-0132-0115-A1 p.6]

[Table 1, 'Technological Progress' and Table 2, 'Estimation Results of the Trade-off Variables', can be found on p.7 and 8, respectively, of docket number NHTSA-2014-0132-0115-A1]

Response:

The agencies have analyzed two tractor baselines in the Phase 2 final rulemaking to recognize that there is uncertainty in projecting the future fleet in the absence of Phase 2 standards. The fuel consumption and \(\text{CO}_2\) emissions in the “flat” baseline remains the same over time with no assumed improvements after 2017, absent a Phase 2 regulation. An alternative baseline was also evaluated by the agencies in which
there is a continuing uptake of technologies in the tractor market that reduce fuel consumption and CO₂ emissions absent a Phase 2 regulation. This alternative baseline, referred to as the “dynamic” baseline, was developed to estimate the potential effect of market pressures and non-regulatory government initiatives to improve tractor fuel consumption. The dynamic baseline assumes that the significant level of research funded and conducted by the Federal government, industry, academia and other organizations will, in the future, result in the adoption of some technologies beyond the levels required to comply with Phase 1 standards. As documented in the RIA, the choice of stringency for final standards for each source category was identical under analysis for either of these baselines.

**Organization:** Idle Smart

We believe that automatic stop/start systems like Idle Smart have and will continue to provide significant GHG benefits in addition to providing fleets of all sizes a compelling solution to reduce fuel usage [EPA-HQ-OAR-2014-0827-1128-A1 p.1]

We are concerned that the Phase 2 rulemaking excludes automatic start/stop systems from continuing to play the vital role that it does today in reducing GHG emissions and fuel consumption. As a result, the Phase 2 rulemaking provides an unnecessarily incomplete set of viable alternatives to achieve its stated goals, it underrepresents costs associated with the limited set of onboard idle reduction technology solutions presented, and it creates unintended but very predictable and quantifiable consequences that are counter to successfully achieving Phase 2’s goals. [EPA-HQ-OAR-2014-0827-1128-A1 p.1]

1. The EPA and NHSTA omit and thereby effectively eliminate other viable Extended Idle technologies that have proven market results to reduce fuel consumption. Auxiliary power units (APUs), fuel operated heaters, battery supplied air conditioning, and thermal storage systems are the only solutions presented as viable Extended Idle Reduction solutions, and only one technology – diesel APUs – is modeled economically. By omitting other solutions, notably automatic start/stop systems, and combined with the AES provisions presented in the rulemaking, technologies that have proven to reduce an equal amount of fuel consumption are not provided a level playing field. [EPA-HQ-OAR-2014-0827-1128-A1 p.2]

The proposed rulemaking presumably uses diesel APUs as its exemplar given that it is the only four season idle reduction solution presented, which is understandable. Nevertheless, the singular focus on diesel APUs provides an incomplete analysis, particularly since Idle Smart’s automatic stop/start system has quantifiable and verifiable operational data that yields an identical reduction in fuel consumption when compared to diesel APUs. While we believe some of the modeling inputs are inaccurate (e.g., diesel APU gallons/hour), below we use the operational metrics as provided3 to generate a simple but instructive side-by-side comparison of diesel APUs and Idle Smart in terms of fuel reduction for Extended Idle times: [EPA-HQ-OAR-2014-0827-1128-A1 p.2]

[Table of Extended Idle times fuel reduction comparisons can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-1128-A1]

In its rulemaking, EPA and NHTSA requested comment on other approaches that would appropriately quantify the reductions that would be experienced in the real world. To that end, Idle Smart’s fuel reduction performance metrics provide proven market results that are, at a minimum, at parity with diesel APUs, quantifiable and measurable, and can be achieved using an automatic engine shutdown (AES) with the appropriate override provisions. [EPA-HQ-OAR-2014-0827-1128-A1 p.2]
As mentioned earlier, we are concerned that the Phase 2 rulemaking excludes automatic start/stop systems from continuing to play the vital role that it does today in reducing GHG emissions and fuel consumption. As a result, we would ask that care be given to ensuring a level playing for all viable onboard technologies, including automatic start/stop solutions and appropriate AES override provisions. [EPA-HQ-OAR-2014-0827-1128-A1 p.4]

It is our hope that two of the areas highlighted above, items 1 and 3, speak directly to Idle Smart’s ability to address the stated goals of the Phase 2 rulemaking at a level that is at parity with (fuel consumption) or materially better than (PM2.5 emissions) the implied Extended Idle technology highlighted in the Phase 2 Draft. Automatic start/stop solutions such as Idle Smart have proven themselves in the market, and we have quantifiable data and reporting that supports our ability to offer a viable alternative that meets the collective needs of both fleets and the EPA and NHTSA. [EPA-HQ-OAR-2014-0827-1128-A1 p.4]

4 Idle Smart performance metrics (2014)

Response:

We generally agree with several commenters that encouraged the agencies to consider the effectiveness of a variety of idle reduction technologies. The Phase 2 regulations differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer, including automatic stop/start technologies such as the system described by Idle Smart. See RIA Table 2-5.

Organization: IdleAIR

IdleAir’s core offering, Electrified Parking Spaces (“EPS”), as it is referenced in the proposed rule, provides long-haul truck drivers an alternative to idling their main engines to maintain a comfortable cabin temperature, sustain vehicle battery charge and power electronics such as televisions and laptops during their overnight stays. EPS provides other benefits such as cleaner air with the reduction of black carbon and soot emitted from diesel engines, reduced noise pollution, local job creation, and an increased tax base for the local economy. Drivers benefit from improved sleeping conditions without the noise, vibration and exhaust fumes from idling and are therefore better rested and safer on the road. Dedicated truck site sales staff, national maintenance, nearly 24 x 7 customer support, highway signage, and other important investments have all uniquely contributed to achieve a growing user base of over 40,000 active driver customers. [EPA-HQ-OAR-2014-0827-1250-A2 p.1]

MANDATING AES IS THE MOST EFFECTIVE WAY TO CURB MAIN ENGINE IDLING FOR MODEL YEAR 2021 AND BEYOND, BUT OVERALL FUEL ECONOMY AND AIR QUALITY WILL DECREASE, WHEN ALSO CONSIDERING ALL UNINTENDED CONSEQUENCES

The agencies intend for the market to dictate how an OEM may achieve compliance with the fuel efficiency standard. However, a stringent standard that recognizes Automatic Engine Shutdown (AES) as the only idling mitigant effectively mandates AES. Indeed, the stated goal is 90% adoption of AES. The agencies maintain that its decision to recognize only AES is technology agnostic, since an owner is left to choose among all alternatives to idling. However, a truck owner cannot risk the driver’s safety even one night per year, and therefore must buy and transport a technology that is available wherever the vehicle stops. The GEM model input is either Yes or No for “idle reduction w/ APU,” which suggest a presumption that Auxiliary Power Units (APUs), will be the de facto solution. IdleAir is concerned that mandating AES is effectively mandating APUs, even if a consumer believes that a combination of
alternative technologies are superior. And many do. As stated above, IdleAir has 40,000 active driver customers and fleet agreements with 750 Fleets. Within the last two years, six “mega fleets” built IdleAir facilities within their own terminals and nine more are planned within the next two years. Mandating APU adoption will threaten the continued growth and viability of IdleAir, the electrified truck parking space industry at large. Although some APU owners patronize IdleAir, their savings is too small for IdleAir (and a host of other providers) to operate a viable business. [EPA-HQ-OAR-2014-0827-1250-A2 p.2]

UNACCEPTABLE NEAR TERM IMPACT:

Most trucks in today’s fleet do not have an APU, and therefore need some alternative like EPS. Class 8 trucks have a design life of 2mm miles or 8 or more years. Even if 100% of all trucks are sold with an AES and APU in model year 2021, then in the year 2025, we conservatively estimate that half of all trucks on the road will still have no choice but to idle during their extended stays if IdleAir and other non-APU technologies are regulated out of existence. The slow turnover of durable long haul trucks renders our solution, at worst, an important bridge technology that should not be taken lightly. [EPA-HQ-OAR-2014-0827-1250-A2 p.2]

ELECTRIFIED PARKING SPACES ARE MORE EFFICIENT THAN APUS:

APUs add 400-500 pounds, which increases fuel consumption by about 200 to 280 gallons per year in order to carry the heavier load. At worst, however, the extra weight results in additional vehicle trips. It should be noted that interstate highways and some states have additional weight allowance for APUs, but several state routes do not. Heavy loads have to plan their entire trip for the most stringent state through which it plans to travel. We recommend EPA further study the effect of these additional trips. [EPA-HQ-OAR-2014-0827-1250-A2 p.2]

Diesel APUs:

Diesel APUs consume less fuel, but are generally unfiltered, and therefore generate substantially more emissions tied to respiratory ailments than the main engine. PM emissions from idling trucks are well documented and occur at locations with the greatest impact to human health – congregated on large truck stops where drivers spend the night. Surrounding neighborhoods that are most likely to permit truck stop sitting are least likely to have adequate access to health care services. [EPA-HQ-OAR-2014-0827-1250-A2 p.2]

Our site staff receives complaints that drivers report headaches from neighboring diesel APUs. We encourage additional research on the health impacts of drastically increasing the adoption rate of APUs. We note that the cost of maintenance or filters were not modeled into the rule. Some large fleets have removed all APUs (numbered in the thousands) in light of maintenance alone. [EPA-HQ-OAR-2014-0827-1250-A2 p.2]

Battery Power APUs:

Battery power APUs are predominantly charged by two methods. 1) while the truck is in operation, an oversized alternator creates additional drag on the main engine, and 2) during extended stays, to recharge the battery, the main engine activates in high idle mode to consume more fuel than ordinary idling. Both methods involve fuel consumption and emissions that should be accounted for. [EPA-HQ-OAR-2014-0827-1250-A2 p.3]
Indirect emissions from EPS:

Even electrified parking spaces generate emissions which should not be ignored, however, the carbon footprint of EPS service is orders of magnitude less than an APU, and the difference in PM emissions are even more striking. Through a methodology approved by the American Carbon Registry, the carbon intensity of EPS service is 6% of an idling truck. It should be noted that most of our service is delivered off-peak, when the cleanest power-plants are powering the grid. A side by side comparison of the indirect but substantial and quantifiable emissions caused by EPS and APUs should be considered against the emissions of AES. [EPA-HQ-OAR-2014-0827-1250-A2 p.3]

MORE DATA IS NEEDED TO STUDY A DIESEL APU’S EFFECT ON SLEEP QUALITY:

IdleAir commissioned a third party study to evaluate the effects an idling engine has on sleep quality. The study is published on our website www.idleair.com and will be uploaded separately as supporting documentation. All evidence concluded a significant loss of sleep quality resulted from the idling engine. Staff and customer observations report diesel APUs are actually louder and vibrate more than a main engine, and we encourage NTSHA and EPA to evaluate the impact on sleep quality of drivers. It goes without saying driver alertness requires high quality sleep. [EPA-HQ-OAR-2014-0827-1250-A2 p.3]

RECOMMENDATIONS

Fuel efficiency standards are not the right tool to regulate idling. Idling is a behavioral activity that has a loose relationship to onboard attributes. A regulation with influence over only one small cog (OEM’s) in the large wheel of the idling problem may have adverse consequences on market choice, driver health and safety, and ultimately the environment. On its face, AES with limited override appears technology agnostic, but it instead dictates the subsequent decision in favor of APUs, and not because APUs are superior. The environmental benefits of AES combined with the environmental costs of APUs create an inferior outcome to a regulation that promotes greater flexibility for a range of solutions – even if some main engine idling exists as a backup. [EPA-HQ-OAR-2014-0827-1250-A2 p.3]

If we are forced to improve upon a rule within the confines of on-board solutions to idling, we recommend a scheme that allows for partial credit for adjustable AES or stop start devices, such as those offered by Idle Smart. Telematics can demonstrate the substantial and measurable decrease that adjustable AES has on idle time, and it permits the owner to more flexibly address nearly all of the other instances where the device permits idling. This flexibility is necessary to preserve driver/owner choice for a host of idle mitigation solutions. The comfort of knowing that isolated idling episodes are mechanically possible affords owners the margin of safety necessary to effectively employ bunk heaters, EPS, hotels, screen windows, etc. depending on the circumstances. The adoption rate of AES did not budge after the Phase I forecasted 80% adoption, because flexibility is critically important to the owner, driver, and free market. It is dangerous to underestimate the reasons that OEM’s opted out of AES. [EPA-HQ-OAR-2014-0827-1250-A2 p.3]

Although the current rule does not address whichever additional idle mitigation technology is employed, in the event that it is modified to award credit to technologies other than AES, IdleAir implores the agencies to treat on-board and off-board technologies fairly. It will be challenging for such a modification to avoid picking winners. Off-board technologies are not traditionally provided by manufacturers. IdleAir requests an additional opportunity to comment if such a change is considered. [EPA-HQ-OAR-2014-0827-1250-A2 p.3-4]
As a prior draft of the rule contemplated, however, it is possible to recognize off board behavior at the OEM level. That draft recognized that a buyer of a new truck could enter into a contract with an EPS provider prior to accepting delivery. In a market where owner operators pay high teen interest rates to factor loads, part of the EPS value proposition is the ability to “pay as you go.” In fact, about $765,000 of IdleAir sales last year were cash transactions because many drivers have no additional credit available. We maintain that a commitment to use EPS can be demonstrated with a binding agreement upfront, without the obligation of prepayment. The calculation for hours of idle mitigation should reflect the fact that every hour consumed is an hour that would have otherwise been spent idling. This premise was accepted by the most credible carbon credit verifiers, in part because our service module detects idling and discontinues services. For each hour of service, about .8 to 1 gallon of fuel is saved, and the efficiency credit issued to the OEM can be backed into after discounting the small fraction of waste at the power-plant level. We would want the indirect waste of APU uses to be factored into the efficiency score for APU-enabled trucks, because that inclusion is accurate and important. It should be noted that the network of EPS locations has tripled in the past four years, and the two biggest operators, comprising over 90% of all locations, are willing to cross-honor membership agreements so as to enhance ubiquity. Ultimately, an OEM can have high confidence of sum certain idle reduction if it is presented with an executed agreement between the buyer and an EPS provider specific to a vehicle identification number, and the OEM should receive an improved vehicle credit for the associated VIN. No modification is necessary for existing EPS service procedures in order to document the utilization of a vehicle bearing a specific VIN – all transactions are recorded and vehicle specific. The fairest protocol is not straightforward, but it is accurate, enforceable, and important for market efficiency. [EPA-HQ-OAR-2014-0827-1250-A2 p.4]

Response:

The agencies made several changes to the treatment of AES and idle reduction technologies in the final rule. We, however, did not specifically include EPS as one of the technologies on the menu of idle reduction technologies due to the lack of data supporting the amount of idle operation that is reduced in the real world through the use of EPS on a given tractor. Tractors manufactured during the Phase 2 timeframe with either the tamper-proof AES or adjustable AES options would receive a CO₂ emissions and fuel consumption reduction in GEM. EPS paired with an AES could receive this level of reduction. We recognize that EPS could be an important idle reduction technology, but believe the technology should be evaluated in the off-cycle credit program so that data on specific vehicles can be considered.

It is also worth noting that the agencies are not mandating AES under the Phase 2 rulemaking. The agencies have adopted CO₂ emissions and fuel consumption standards based on our analysis of one technology pathway for each level of stringency, but manufacturers will be free to use any combination of technology to meet the standards, as well as the flexibility of averaging, banking and trading, to meet the standards on average.

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

We have heard repeated concerns from our employers that the proposed emission standards might inadvertently be more stringent than EPA had intended. For example, the assumed 2017 aero baseline uses the best aero trucks available, not the average. This baseline increases stringency by roughly 2.5%. The compliance margin for aerodynamic audits has been removed. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]
Response:

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. The baseline was not determined by or declared to be the average results of the vehicles tested, as some commenters maintained. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for Phase 2. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin \( C_{dA} \) values.

The agencies' assessment for the final rule is that only Bins I through V are achievable with known aerodynamic technologies, but that Bins VI and VII have less known technology paths. Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of \( C_{dA} \). See RIA Chapter 2.8.2.2. These aerodynamic improvements have been demonstrated within the program on two vehicles in 2015. In the final rule, the agencies are projecting that truck manufacturers will be able to begin implementing these demonstrated aerodynamic technologies as early as 2021 MY on a limited scale. We adjusted the adoption rates for MY 2027 in the technology package developed for the final rule to consist of 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors in this segment that we project could successfully apply these aerodynamic packages with this amount of lead time.

The agencies received comments from manufacturers arguing for the agencies to establish compliance margins that would allow actual production vehicles to exceed the standards by some fixed amount. These comments included specific requests for an aerodynamic compliance margin. We also received comments from UCS supporting the elimination of the aerodynamic compliance margin. As explained in Section I.C.1 of the Preamble, although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor \( C_{dA} \) and solicited supplemental comments on it. See 81 FR 10825. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur.

Organization:  International Council on Clean Transportation (ICCT)
Transmissions – Advanced integrated transmissions, including automated manual transmissions that
enable downspeeding and optimal engine operation, by leading companies like Eaton and Volvo, have
already been introduced (Stoltz and Dorobantu, 2014; Greszler, 2014). Automatic transmissions are the
norm in Europe, and increasingly advanced dual-clutch transmissions are being introduced there. The
agencies considered this technology as part of their stringency determination, but more advanced versions
of this technology have been demonstrated in SuperTruck (Delgado and Lutsey, 2014). [EPA-HQ-OAR-
2014-0827-1180-A4 p.4

Tractor-trailers

The ICCT offers several new technical data inputs and suggestions for the agencies to consider in their
final tractor and tractor-trailer stringency determination. We suggest that the agencies consider the two
recent ICCT analyses that include rigorous state-of-the-art tractor-trailer vehicle simulation modeling
(Delgado and Lutsey, 2015) and a detailed synthesis of best-available technology cost inputs (Meszler et
al, 2015) in their final tractor standard determination. The scope of these studies were designed to the
particular technologies under consideration by manufacturers, and the particular simulation, cost, cost-
effectiveness, and benefits calculation methods are matched to those of the agencies analysis in their
light-duty vehicle and initial phase heavy-duty vehicle rulemakings. [EPA-HQ-OAR-2014-0827-1180-A4
p.10]

Our analysis indicates that the technology potential is higher, and the technology cost is lower, than the
agencies assessed. In those studies, we find that technology levels beyond the proposed 2027 standards
can achieve 9 mile-per-gallon tractor-trailers on highly comparable drive cycles to the agencies’ new
cycles, while also delivering payback periods for truck owners of 6 months (under high fuel prices) up to
1.5 years (with sustained low fuel prices). This compares to the agencies’ approximately 8 mile-per-
gallon tractor-trailer standards in 2027, when tractors and trailer improvements are combined. In addition,
we found the total cost of delivering a 9-mpg tractor-trailer is approximately $9,000, which is over 20%
lower than the agencies’ $11,680 projection for tractors complying with the proposed 2027 standards (see
Delgado and Lutsey, 2015; Meszler et al, 2015). As a result, the new ICCT technology assessment – not
included in the proposal’s assessment – demonstrates that the tractor-trailer stringency could be increased
to above 9 mpg in 2027 and would cost several thousand dollars less per tractor-trailer than the agencies
estimated. We recommend that the agencies consider these data inputs in their final technical inputs and

The increased incorporation of incremental engine efficiency technology, discussed above, appears to a
key discrepancy between the ICCT and agencies’ analyses on tractor-trailer efficiency. Based on that
ICCT tractor-trailer analysis and the engine research above, our primary recommendation is to
incorporate the required improvements from greater engine technology, as described above, as equivalent
required tractor efficiency fuel consumption and CO2 reductions that go beyond the proposed 2021, 2024,
and 2027 standards. Including the engine improvements (i.e., 4.2% as proposed, up to 10% in 2027)
would approximately reduce the fuel consumption and emissions across all of the tractor categories in
2027 by 6%. [EPA-HQ-OAR-2014-0827-1180-A4 p.11]

For additional technical context, especially relevant for 2027 standards, the ICCT analyzed the extent to
which the agencies’ assessment of applicable technologies in the proposed tractor stringency differ from
SuperTruck tractor-trailer efficiency. The SuperTruck teams are achieving 10.7 mpg (Peterbilt) and 12.2
mpg (Daimler/Freightliner) in real-world testing (Buchholz, 2014; Daimler, 2015). To rigorously compare
the technologies we utilized the EPA GEM model (Phase 2 GEM v1.0) with the physical attributes and
off-cycle credits just as applied in the agencies’ analysis and on the official GEM test cycles, and assessed
differences for SuperTruck teams’ demonstrated physical attributes (See Lutsey, 2015b). As analyzed, the
regulation would result in tractor-trailers that achieve about 8 miles per gallon on the new regulatory test. SuperTruck technologies would go further, delivering 9-10 mpg for tractor-trailers on the same test cycle. Although the off-cycle credits (e.g., automated manual transmission, 6x2, direct drive, tractor automatic tire inflation) are included for all the technology packages, idling reduction technology is not included in the numbers shown. [EPA-HQ-OAR-2014-0827-1180-A4 p.11]

Based on this Phase 2 GEM analysis of the standards and SuperTruck technology, it appears to be clear that the proposed standards are at considerably lower technology levels than the technical potential as indicated from the U.S. DOE SuperTruck Peterbilt/Cummins and Daimler demonstration prototypes. Considering the very large gap in efficiency between the proposed standards and improvements achieved through the SuperTruck program, and considering the research progress and current uptake of SuperTruck technologies in the marketplace (see Bloch-Rubin and Gallo, 2014), we recommend that the agencies investigate the full spectrum of SuperTruck technologies and assess standards up to those efficiency technology levels. [EPA-HQ-OAR-2014-0827-1180-A4 p.11]

Response:

Transmissions

The agencies have evaluated the various transmission configurations available for heavy-duty tractors. The agencies recognize the effectiveness of these technologies in two ways. First, the agencies recognize the benefit of automation in reducing the variability of drivers which should lead to operation in the optimal gear more often. The second is through the optional transmission efficiency test that will recognize the benefits of improved gear efficiencies. The agencies have built some improvements in transmission gear efficiency into the technology package used to derive the final standards. The agencies have included ICCT’s assessment of transmissions in our transmission technology discussion in Section III.D.1.b.

Overall Stringency

The agencies considered all of the general comments associated with the proposed Alternative 3 and Alternative 4 tractor standards. We believe there is merit in many of the detailed comments received regarding technologies. The agencies have included ICCT’s assessment of tractor technologies in our technology discussion in Preamble Section III.D.1.b. and considered their assessments along with other literature and comments for the final rule. The agencies have developed a set of final tractor standards that reflect our reevaluation of the ability to pull ahead certain technologies, the limitations in adoption rates and/or effectiveness of other technologies, and consideration of additional technologies. In general, the final Phase 2 tractor standards are similar in overall stringency as the levels proposed in Alternative 3, but have been determined using new technology packages that reflect consideration of all of the technology comments, and in several respects reflect greater stringency than the proposed Alternative 3. Specifically, the engine improvements for the final rule reflect greater reductions. Consistent with the commenter, we have incorporated the required improvements from the more stringent engine assessment into the tractor (i.e. vehicle) fuel consumption and CO₂ standards for the final rule.

As noted by the commenter, DOE has partnered with the heavy-duty industry to demonstrate high roof sleeper cab tractor and box trailer combinations (only one of the ten tractor subcategories) that achieve a 50 percent improvement in freight efficiency evaluated as a 65,000 pound vehicle operating on the highway under somewhat controlled circumstances. However, these SuperTrucks are not necessarily designed to handle the rigors of daily use over actual in-use roads. For example, they generally have very limited ground clearance that would likely preclude operation in snow, and would be very susceptible to
damage from potholes or other road hazards. In addition, each manufacturer only produced a single high roof sleeper cab for demonstration purposes at a cost of nearly $40-$80 million each. While the agencies cannot simply apply the SuperTruck program achievements directly into the Phase 2 program because of the significant differences in the limited purpose of SuperTruck and the plenary applicability of a regulation to all operating conditions and duty cycles, it is helpful to assess the achievements and evaluate how the technologies could be applied into mass production into a variety of real world applications while maintaining performance throughout the full useful life of the vehicle.

**Organization:** International Foodservice Distributors Association

IFDA member companies are among the largest private fleet operators in the country using tractors and refrigerated trailers to service their hundreds of thousands of operator customers each day. The Phase 1 emissions regulations currently in effect have resulted in considerable increases in acquisition costs for power units over the last 10 years. The proposed Phase 2 requirements would only add to this already considerable additional expense for member companies. While the proposal maintains that these additional costs will be offset by reduced fuel consumption, we are concerned that the proposal includes unrealistic analyses of the state of technology, rates of adoption of new technologies and the potential return on investment. [EPA-HQ-OAR-2014-0827-1258-A1 p.1

As purchasers of equipment, the burden of meeting the emissions requirements would not fall on IFDA members. Instead the proposal sets emissions targets for original equipment manufacturers (OEMs), yet these companies must rely on adoption of their technology by purchasers to meet these targets. IFDA is strongly concerned that targets should not be set in a manner that would force users such as IFDA members to purchase unproven and unreliable equipment in order for OEMs to meet the requirements. Each company has different transportation requirements depending upon such issues as location and customer base. Many of the solutions anticipated in the proposal would not make sense for different types of transportation operations. Foodservice distributors should not be required to purchase technologies that are not cost effective for their fleets. [EPA-HQ-OAR-2014-0827-1258-A1 p.2

IFDA is also concerned that the foodservice distribution industry would be disproportionately impacted by the technology required to comply with the new targets. Industry drivers are generally not long haul but rather make multiple stops during the day which limits the ability of many technologies to be effective in reducing emissions. Many of the technologies anticipated by the EPA would do little to impact emissions or be impractical for distributors in short haul delivery environments. This is also true for the trailer requirements which generally rely on streamlining improvements which provide little benefit when used over shorter driving distances. As a result, distributors could be forced to pay for technologies that result in little real emissions reductions in their operations. [EPA-HQ-OAR-2014-0827-1258-A1 p.2]

**Response:**

The agencies developed ten tractor and nine vocational subcategories in addition to specialty chassis subcategories that acknowledge that trucks operate under many different conditions and with different driving patterns. We also have included three different drive cycles, ARB transient and cruise cycles at 55 and 65 mph with grade, to cover the range of operation of trucks. On top of this, the agencies also adopted provisions that require manufacturers to meet the standards on average using a suite of technologies and allow the manufacturers to bank and trade credits, along with carry-over credit deficits for three years. Each of these design elements of the program were developed to allow manufacturers to produce products that meet the needs of their customers. In addition, the agencies are adopting provisions in Phase 2, and have existing provisions in Phase 1 (EPA’s 40 CFR 1037.630 and NHTSA’s regulation at 49 CFR 523.2), that allow low-roof tractors intended for intra-city pickup and delivery, such as those that
deliver bottled beverages to retail stores to be treated as vocational vehicles. The vocational vehicle standards are predicated on drive cycles with distance-based weighting factors of 20, 54, or 90 percent transient cycle depending on the type of vocational operation (see 40 CFR 1037.510). The transient cycle is representative of the type of driving cited by the commenter – short haul operations with multiple stops per day.

With respect to the portion of the comment dealing with trailers, the agencies believe the majority of box vans will experience CO$_2$ and fuel consumption reductions with use of the technologies encouraged by this rulemaking. We also believe many of the box vans that operate at lower speeds will have work-performing equipment (e.g., side platforms, rear lift gates) that will allow manufacturers to designate these trailers as partial-aero or non-aero vans. Partial-aero standards are based on adoption of a single aerodynamic device, and non-aero vans have design standards that require installation of tire technologies only with no aerodynamic requirements. A small fraction of the box van industry may not qualify for a partial- or non-aero designation, yet still operate at lower speeds. These vans may not achieve the real-world benefits that their compliance results would suggest or that similar vans experience because they frequently travel at higher speeds. However, we believe that they will still benefit from the technologies, even in urban operation. In RIA Chapter 2.10.2.1.1, we show that even trailers operating under 100% transient conditions will experience a small benefit from use of trailer skirts, and trailers that spend any time at speeds of 55-mph or greater will achieve benefits of at least 1% during that time, compared to operating without skirts.

Organization: Lubrizol Corporation

Higher-performing lubricants will play an important role in helping the OEMs comply with the Phase 2 Rule. Indeed, as shown in Figure 1 below, many of the technologies and strategies that will be used by the OEMs will require HPLs to operate cleanly, efficiently, and without compromising equipment performance and durability. [EPA-HQ-OAR-2014-0827-1325-A1 p.2]

[Figure 1 can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1325-A1]

Response:

The agencies’ assessment of axle improvements, including the use of high performing lubricants, found that axles built in the Phase 2 timeline could be 2 percent more efficient than a 2017 baseline axle.

Organization: Meritor, Inc.

Define Drive Axle Disconnect and Resolve with 6x2 Default FE Credit

Meritor is supportive of the 2.5 percent credit for a constant 6X2 configuration. Our internal testing plus vehicle testing in real-world conditions supports this level of efficiency improvement. [EPA-HQ-OAR-2014-0827-1254-A1 p.9]

On a related note, Meritor believes that the 2.5 percent FE benefit in the proposed rule is excessive and over-credits the technology because it will not be engaged for the amount of time assumed in the model. For example, under the current proposal, a Linehaul Sleeper Cab with a Detachable Tandem would receive an effective credit of 2.38 percent which is nearly identical to the 2.5 percent granted to a permanent 6X2-truck configuration. Meritor does not believe the data support this large credit due to the limitations on the duty cycle. In addition to the transient cycles, the detached axle will be engaged for
certain percentage of the population based on load conditions at 55 mph and 65 mph. For example, a fully loaded tractor trailer cannot disengage one of its axles without a significant impact to grade performance and the life of the engaged axle. This latter point can be countered by upgrading the constantly engaged drive axle to an axle used for a 6X2 configuration, however, this solution has the drawback of additional cost which may not be accepted in the marketplace and the upgraded axle is less efficient than its 6X4 counterpart. Therefore, Meritor recommends that a fuel efficiency benefit of 2.0 percent be assigned to the disengageable tandem for the 55 mph and 65 mph drive cycles to account for the more limited use. [EPA-HQ-OAR-2014-0827-1254-A1 p.11]

Meritor is also supportive of regulations that encourage investment in technologies that disengage a tandem-drive axle. Although this technology is in its infancy, activity in international markets illustrates the potential for this technology to migrate to North America within the regulatory timeframe, therefore, disengageable tandem-drive axles should be included in the proposed regulation. We have some concerns, however, about the proposed rule as it is currently written. [EPA-HQ-OAR-2014-0827-1254-A1 p.9-10]

First, the technology is not well defined in the proposal. It is referred to several times within the Proposal and Regulatory Impact Analysis by different names such as 6X4 “Axle Disconnect,” a 6X2 configuration “that may be engaged only during some types of vehicle operation,” “6x2 axle disconnect” and “part time 6X2.” To ensure clarity and provide consistent definitions, we advocate the use of one name: “DISENGAGEABLE TANDEM” be used along with a definition. [EPA-HQ-OAR-2014-0827-1254-A1 p.10]

Meritor defines DISENGAGEABLE TANDEM as a tandem-drive axle that provides two modes of operation: 1) a “standard” drive mode whereby torque from the transmission is transferred to both axles of the tandem, and 2) a “disengaged” drive mode whereby torque from the transmission is transferred to only one axle of the tandem. Each drive mode is selected based on the vehicle’s operating condition (load, grade, speed, etc.) per the axle manufacturer’s application guidelines. [EPA-HQ-OAR-2014-0827-1254-A1 p.10]

Even with this established definition, there are several possible configurations of DISENGAGEABLE TANDEM, each with a significantly different impact on fuel efficiency: [EPA-HQ-OAR-2014-0827-1254-A1 p.10]

BASIC DISENGAGEABLE TANDEM - In the most basic configuration, the disengaged axle is disconnected from the powertrain input. There are minimal torque-related losses in the disengaged axle but the disengaged axle’s gearset is still connected to the wheels via the axle shafts and remains spinning inside the axle. Therefore, there is still oil churning losses in the disengaged axle and the resulting axle efficiency benefit of this configuration is less than the benefit of a 6x2-axle configuration. Oil churning losses vary greatly, as much as 2 percent depending on the amount of oil in the axle, the type of oil in the axle, the rotational speed of the gearset, and the vertical location of the gearset. [EPA-HQ-OAR-2014-0827-1254-A1 p.10]

ENHANCED DISENGAGEABLE TANDEM - In a more complex disengageable tandem configuration, the axle gear set is disconnected from both the axle input and the wheel input rendering the gears stationary and eliminating the resulting churning losses. This is in addition to the minimal torque-related losses realized in the BASIC configuration. In the ENHANCED configuration, the efficiency benefit as compared to a conventional 6X4 will be close to the benefit of a 6x2 axle configuration while a drive axle is disconnected. [EPA-HQ-OAR-2014-0827-1254-A1 p.10]
LIFTABLE/DISENGAGEABLE TANDEM - In a yet more complex disengageable tandem configuration, the disconnected axle may also be lifted off of the ground to both eliminate churning losses but also bearing friction and tire rolling resistance. In this configuration, the efficiency benefit will be close to that of a 4X2-axle configuration. [EPA-HQ-OAR-2014-0827-1254-A1 p.10-11]

[Chart, 'Axle Configuration Efficiency', can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1254-A1]

Meritor’s recommendation is to define DISNENGAGEABLE TANDEM in the final rule as described above in 2) Enhanced Disengageable Tandem as it is the only configuration that warrants a fuel efficiency credit at this time. [EPA-HQ-OAR-2014-0827-1254-A1 p.11]

Expand and Update Weight Reduction Technologies

As with Phase 1, Meritor supports the inclusion and expansion of weight reduction technologies in the proposed regulation as well as the methodology of implementation via the GEM model. We also agree with NHTSA and EPA that weight reduction in the tractor sector should not be included in the anticipated Technology Adoption Rate given the high cost-to-benefit ratio in this segment. We believe weight reduction has a more substantial role to play in the vocational sector and when weight reduction technologies are implemented, the resulting fuel efficiency credits should be acknowledged. Therefore, Meritor is requesting the expansion of weight reduction technologies to include the following: [EPA-HQ-OAR-2014-0827-1254-A1 p.12]

Aluminum Axle Carrier – Apples-to-apples comparisons between steel and aluminum carriers illustrate consistent weight reductions of 60 pounds for the rear-front-drive axle, 35 pounds for the rear-rear-drive axle and therefore 95 pounds for the tandem. In addition, this technology has been proven in the market and is available with very limited penetration. [EPA-HQ-OAR-2014-0827-1254-A1 p.12]

AL Carrier (Tandem Front-Drive Axle) = 60 pounds [EPA-HQ-OAR-2014-0827-1254-A1 p.12]

AL Carrier (Tandem Rear- Drive Axle) = 35 pounds [EPA-HQ-OAR-2014-0827-1254-A1 p.12]

Aluminum Drum Brake Bracket – The brake bracket which is the main structural component between the air brake actuator and the cam. We anticipate the availability of an aluminum version of this bracket in the timeframe of the regulation which will provide a calculated per vehicle weight savings of 36 pounds for a 6X4 configuration. [EPA-HQ-OAR-2014-0827-1254-A1 p.12]

[Brake Bracket picture can be found on p.13 of docket number EPA-HQ-OAR-2014-0827-1254-A1]

Finally, Meritor believes that weight savings should be credited for the use of single-piece drivelines in excess of 86.” Today, most drivelines in excess of 86” are two piece. A single-piece driveline greater than 86” eliminates a u-joint and center bearing assembly. In addition, it requires the use of a stiffer driveline tube which can be achieved with a larger OD driveline tube made of steel, aluminum or composite. It is relatively straightforward to calculate the weight savings for a typical 110” driveline in each of the three materials listed above: [EPA-HQ-OAR-2014-0827-1254-A1 P.13]

[Chart, 'Driveline Weights @ 110’, can be found on p.13 of docket number EPA-HQ-OAR-2014-0827-1254-A1]
Per the above tables, Meritor requests that the weight savings technology list include options for one-piece drivelines in Class 8 Tractors per the table below. [EPA-HQ-OAR-2014-0827-1254-A1 p.14]

Meritor would also like to correct the current credits for high strength steel drums. The proposed rule currently grants an 8-pound weight savings for non-drive High Strength Steel Drums and 11 pounds for high strength steel drums for Class 8 Drive Axles per vehicle. [EPA-HQ-OAR-2014-0827-1254-A1 p.14]

Our data for currently available drum technologies indicate that a larger weight-reduction credit be awarded. [EPA-HQ-OAR-2014-0827-1254-A1 p.14]

Based on this data, Meritor recommends that a 42-pound weight savings be credited per tractor for using High-Strength Steel Drums on the Steer (non-drive) axle and 74-pound per vehicle for 6X4 Drive-Axle applications. [EPA-HQ-OAR-2014-0827-1254-A1 p.15]

Below is a table representing our recommendation for weight reduction technologies and associated values: [EPA-HQ-OAR-2014-0827-1254-A1 p.15]

**Improve Automatic Tire Inflation Definition and Correct Misstatements about the Market.**

The definition of automatic tire inflation systems (ATIS) listed in Subpart 1, Definitions & Other Reference Information, is not consistent with the historical industry definitions. The Technology Maintenance Council, (TMC), of the American Trucking Association, in their Recommended Practice, RP239A (most recently updated in 2014) uses the following widely accepted definition of ATIS: [EPA-HQ-OAR-2014-0827-1254-A1 p.15]

Automatic Tire Inflation Systems maintain tire pressure at a single preset level and are pneumatically or electronically activated. These systems eliminate the need to manually inflate tires. [EPA-HQ- OAR-2014-0827-1254-A1 p.15]

The current definition included in the rulemaking states: [EPA-HQ-OAR-2014-0827-1254-A1 p.15]

ATIS means a system installed on a vehicle to keep each tire inflated to within 10% of the target value with no operator input. [EPA-HQ-OAR-2014-0827-1254-A1 p.16]

Assigning an arbitrary number of 10 percent is not consistent with the manner in which these systems are used in practice. Tire pressure increases by 15 – 20 percent when the tire is hot and running on a fully loaded vehicle at 75 mph on asphalt roads on a sunny day. Tires cool back down to the specified tire pressure.
pressure after a few hours. The reduced fuel economy and increased greenhouse gas emissions are due to tire under inflation. ATIS systems assure that tires will always be running at the recommended cold tire inflation pressure. [EPA-HQ-OAR-2014-0827-1254-A1 p.16]

Response:

6x2

The agencies reassessed the effectiveness of 6x2 axles and disengageable tandem axles. The agencies’ assessments of these technologies show that the reductions are in the range of 1 to 3 percent. For the final rule, the agencies are simulating 6x2, 4x2, and disengageable axles within GEM instead of providing a fixed value for the reduction. This approach is more technically sound because it will take into account future changes in axle efficiency and accounts for the fact that the technologies will have different effectiveness depending on the drive cycle. See generally RIA section 2.4.5.

Consistent with the comments, EPA has defined a disengageable axle configuration as 6x4D. EPA defines this in 40 CFR 1037.520 as an axle that can automatically switch between 6x2 and 6x4 configuration. When the axle is in the 6x2 configuration the input and output of the disconnectable axle must be mechanically disconnected from the drive shaft and the wheels to qualify.

Weight Reduction

The agencies are adopting an expanded list of weight reduction options which could be input into the GEM by the manufacturers to reduce their certified CO$_2$ emission and fuel consumption levels. As at proposal (and as endorsed by this commenter), the agencies view weight reduction as a technology with a high cost that offers a small benefit in the tractor sector. For example, our estimate of a 400 pound weight reduction will cost $2,050 (2012$) in 2021MY, but offers a 0.3 percent reduction in fuel consumption and CO$_2$ emissions. Therefore, we did not premise the Phase 2 tractor standards on a technology package that included weight reduction.

The agencies are updating the weight reduction value in the table included in 40 CFR 1037.520 for brake drums and adding values for single piece drivelines. The agencies, however, are not including weight reduction for the axle carrier because we cannot be certain that this weight reduction value has not already been included in the weight reduction value of the axle. Manufacturers will continue to have the option in Phase 2 to request for approval weight reduction components not included in the tables of 40 CFR 1037.520.

ATIS

Consistent with this comment, EPA has revised the definition of ATIS in 40 CFR 1037.801 to mean a pneumatically or electronically activated system installed on a vehicle to maintain tire pressure at a single preset level. These systems eliminate the need to manually inflate tires.

Organization: Michelin North America, Inc.

Distinguishing New Generation Wide-Base Single (NGWBS) Tire Technology for the GHG and FE Standards for Medium- and Heavy-Duty Vehicles and Engines

Clarification to assure distinguishing the NGWBS tire technology
New generation single wide tires, which were first introduced in 2000, are designed to replace a set of dual tires on the drive and/or trailer positions. They are designed to be interchangeable with the dual tires without any change to the vehicle. [EPA-HQ-OAR-2014-0827-1286-A1 p.3]

Clarification is needed here to distinguish the technology of the 'super single' or 'wide base single (WBS)', e.g. 385, 425, and 445/65R22.5, drive and trailer tires from the 'new generation wide base single (NGWBS)’ tires, e.g. 445/50, 455/55R22.5. [EPA-HQ-OAR-2014-0827-1286-A1 p.3]

Referring to the DOT Regulatory Impact Statement (RIS), Michelin is not aware of a New Generation Wide Base Single tire dimension known as 435/50R22.5. Also the availability of the 455155R22.5 dimension is not included in the DOT RIS. [EPA-HQ-OAR-2014-0827-1286-A1 p.3]

Availability of stud-piloted wheels for vehicle fitments of NGWBS tires

In addressing the DOT RIS statement that 'if the vehicle does not have hub-piloted wheels, there may be a need to retrofit axle components”, stud piloted 22.6)(14’ wheels have been available for retrofit on vehicles which are not equipped with hub-piloted axle ends. [EPA-HQ-OAR-2014-0827-1286-A1 p.3]

This information will assist users in their considerations for NGWBS tire conversions. [EPA-HQ-OAR-2014-0827-1286-A1 p.4]

Additional information on the NGWBS tire technology on rolling resistance, an environmental Life Cycle Analysis, and summary of the attributes

The NGWBS 445/50- and 455/55R22.5 tires were introduced to be direct replacements for the conventional long haul dual tire sets, e.g. 275/80 or 295/75R22.5, and the 11R22.5, respectively, and offer LRR advantages as defined by the EPA/DOT NPRM Phase 2 Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles —Phase 2. [EPA-HQ-OAR-2014-0827-1286-A1 p.4]

The NPRM defines 'Low rolling resistance tire' as follows: [EPA-HQ-OAR-2014-0827-1286-A1 p.4]

- A tire on a vocational vehicle with a tire rolling resistance level (TRRL) of 7.7 kg/metric ton or lower.
- A steer tire on a tractor with a TRRL of 7.7 kg/metric ton or lower.
- A drive tire on a tractor with a TRRL of 8.1 kg/metric ton or lower.

See the following chart of 'Drive Tire RR vs Time' comparing 'Best Dual' vs 'Best NGWBS' as an example of the NGWBS tire LRR technology development. [EPA-HQ-OAR-2014-0827-1286-A1 p.4]

[Chart can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1286-A1]

Additional support of the NGWBS tire technology performance and use

The Department of Transportation Volpe Center's 2015 report titled 'Review and Analysis of Potential Safety Impacts and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles' summarizes research and analysis findings on potential safety issues associated with both the diverse alternative fuels (natural gas-CNG and LNG, propane, biodiesel, and
power train electrification), and the specific FE technologies recently adopted by the MD/HDV fleets. [EPA-HQ-OAR-2014-0827-1286-A1 p.6]

- These include Intelligent Transportation Systems (ITS) and telematics, speed limiters, idle reduction devices, **tire technologies (single-wide tires)**, and tire pressure monitoring systems-TPMS and Automated Tire Inflation Systems-ATIS), aerodynamic components, vehicle light-weighting materials, and Long Combination Vehicles (LCVs). [EPA-HQ-OAR-2014-0827-1286-A1 p.7]
- The key finding from the literature review and Subject Matter Experts (SME) interviews is that there appear to be no major safety hazards preventing the adoption of FE technologies, or the increased use of alternative fuels and vehicle electrification. [EPA-HQ-OAR-2014-0827-1286-A1 p.7]

With respect to the NGWBS tire technology, the following studies further support the aspects of NGWBS tire technology performance and use. [EPA-HQ-OAR-2014-0827-1286-A1 p.7]

- 'Heavy Truck Driver Workload Investigation using conventional and NGWBS tires for quantifying driver workload for a heavy truck driver through the measurement of muscle activity during four maneuvers' Ryan Pawlowski Tire Society Sept. 2013 [EPA-HQ-OAR-2014-0827-1286-A1 p.7]

**Tire Technology Costs**

[Table, 'Class 7 and 8 Tractor Technology Incremental Costs in the 2021 Model Year Preferred Alternative vs. the Less Dynamic Baseline', can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1286-A1]

From the NPRM Table III-15 above, Michelin believes that the current estimates of additional cost (per vehicle) for the improved RRc tires are underestimated, e.g. from $9 to $81 depending on vehicle class. [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

We would estimate that an appropriate value, taking into account the appropriate recuperation of indirect costs (R&D and Industrialization) would be above $25/tire and, therefore, $250 per truck (tractor 10 tires). [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

- Given that the stated R&D investment of most tire manufacturers varies between 2% and 3.5% of revenues and that a new product line can take between 5 to 10 years of development (especially if it requires new building bricks) and that the initial payback should be expected within 5 years, it would not be unreasonable to use a premium of 2% to 7% (2% R&D *5 years development 15 years payback = 2%, and 3.5% R&D * 10 years development 15 years payback = 7%).
- Applying this to an average cost per tire of $300 to $400, the premium value would range from $6/tire to $28/tire or $60/truck to $280/truck for a 6X4 or 6X2 tractor.
Michelin agrees with the values proposed except for the last one from EPA/DOT for drive tires (@ $121 per truck for 8 tires or $15/tire. This value is too low, however, most importantly; these numbers do not appear to match with the above Table III-15. [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

Recent studies done on over 400 tires (Michelin and others) are showing a conversion rate which appears slower than the assumption made, i.e. all below SmartWay before 2027, unless SmartWay made provisions for vocational applications (on/off, urban, refuse). [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

Today we find that 60% to 70% of all tire tread patterns sold (not weighted) would still be above the 6.5, 6.6, and 5.1 limits for steer, drive and trailer respectively. Many of these are vocational offers that are not yet affected by the California requirements. [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

Despite the above comment, we do not believe that the assumption is too severe and can still be maintained as an important input parameter in setting the ambitions, and, therefore, no change requested. [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

We agree that the development of future generation LRR tires with minimal or no compromise on other important performance characteristics will require significant R&D and industrialization investments. Such additional costs are not currently properly reflected in the current Regulatory Impact Analysis (RIA). [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

The actual assumption on adoption rates by vocation and proportion of vocation by vehicle class would be useful. [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

We believe that the current estimates of additional cost (per vehicle) for the improved RRc tires are underestimated, i.e. from $9 to $81 depending on class. [EPA-HQ-OAR-2014-0827-1286-A1 p.11]

We would estimate that an appropriate value, taking into account the appropriate recuperation of indirect costs for R&D and Industrialization would be above $25/tire and therefore $250 per 10 tire truck tractor. [EPA-HQ-OAR-2014-0827-1286-A1 p.12]

The values proposed for potential evolution of RR by product category (steer and drive) appears reasonable for the drive (even though the 4.5 kg/ton would require a significantly higher adoption rate of the new generation wide base single (NGWBS) tires). [EPA-HQ-OAR-2014-0827-1286-A1 p.12]

However, the value of 4.3 kg/ton for steer is highly unlikely. A more reasonable number based on current evolution, North American sizes and fundamental research conducted would be 5.0 kg/ton. [EPA-HQ-OAR-2014-0827-1286-A1 p.12]

Response:

The agencies appreciate the clarification regarding NGWBS.

The agencies considered the dual and NGWBS rolling resistance information provided by Michelin in developing the rolling resistance considered in the technology packages to demonstrate the feasibility of the final rule standards. Specifically, the agencies have evaluated this comment and find it persuasive. We have accordingly increased the coefficient of rolling resistance for Level 3 tires in the technology packages used to determine the stringency of the final rule standards based on the comments and the certification data. The Level 3 steer tire CRR increased from 4.3 kg/ton in the NPRM to 4.9 kg/ton in the
final rule. The Level 3 drive tire CRR increased from 4.5 kg/ton in the NPRM to 5.0 kg/ton in the final rule. See Section III.D.1.b.iii of the Preamble to the final rules.

The agencies discuss the 2015 report in Section IX.N of the Preamble to the final rule.

We have estimated the cost of lower rolling resistance tires based on an estimate from TetraTech of $30 (retail, 2013$). We also have applied a “medium” complexity markup value for the more advanced low rolling resistance tires. We expect that, when replaced, the lower rolling resistance tires would be replaced by equivalent performing tires throughout the vehicle lifetime. As such, the incremental increases in costs for lower rolling resistance tires would be incurred throughout the vehicle lifetime at intervals consistent with current tire replacement intervals.

**Organizations:** Motor & Equipment Manufacturers Association (MEMA)

**Modify Credits, Operation Time and Fuel Consumption Rate for Idle Reduction Technologies**

There are several aspects regarding idle reduction technologies’ credit in the GEM for the Class 7 and 8 tractor vehicle category. Since the agencies are proposing to carry over the Phase 1 credit into Phase 2, MEMA reiterates our original comments relating to the agencies’ Phase 1 supporting analysis for the idle reduction technology credits. MEMA recommends the agencies modify the credit based on the merit of the individual idle control technology, clarify the definition of “other” and revise the operation time and fuel consumption rates for idle reduction technologies. [EPA-HQ-OAR-2014-0827-1274-A1 p.5-6]

Modify the GEM Credit – The proposed Phase 2 carries over the Phase 1 credit for all idle reduction devices for Class 7 and 8 sleeper cabs, which is 5 percent. This 5 percent was based on Phase 1 Draft Regulatory Impact Analysis of idle control technologies that included: auxiliary power units (APUs); fuel operated heaters (FOHs); battery air conditioning systems (BACs); and, thermal storage air conditioning systems (TACs). The analysis assumed that all idle reduction devices use 0.2 gallons of fuel per hour (gal/hr). However, MEMA urges the agencies to give each idle reduction technology credit based on the fuel consumption and emissions of that technology and assume that all devices consume 0.2 gal/hr. This approach would be consistent with the different levels of credit given to different types of aerodynamics and tires. The various idle control technologies listed in the agencies’ Phase 2 Draft RIA have fuel consumption from the battery APU of almost zero to the diesel engine APU of approximately 0.3 gal/hr fuel consumed and also emit different amounts of GHG. [EPA-HQ-OAR-2014-0827-1274-A1 p.6]

MEMA submitted proposed modifications to the Phase 1 DRIA Table 2-22: Idle Credit Calculation. Below is an excerpted version of MEMA’s original proposed modifications for the agencies’ reference. It shows the recommendation for credit based on the fuel consumption and GHG emissions of each technology. Using middle-idle figures in the table below, MEMA re-submits the following recommendation (also see the Appendix): [EPA-HQ-OAR-2014-0827-1274-A1 p.6]

| [Table, excerpt from MEMA's original proposed modifications to the idle credit calculations, can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1274-A1] |

Also, in the NPRM’s Table III-7 Proposed Phase 2 Technology Inputs, the agencies present a weighting factor percent reduction of 5 percent for APUs with automatic engine shutoff (AES) and of 7 percent for “Other” idle reduction. This appears to be an acknowledgement by the agencies that some idle reduction devices reduce GHGs more than others. MEMA proposes that perhaps an additional incentive could be given to trucks that have idle reduction technologies factory-installed as a way to assure the technology
benefit will be realized. MEMA presumes that “Other” may include idle reduction technologies such as battery powered units. However, since it is not exactly clear in the NPRM, MEMA asks the agencies to clarify and define what is intended to be covered as “Other.” [EPA-HQ-OAR-2014-0827-1274-A1 p.6-7]

**Revise Operation Time and Consumption Rate Assumptions** – MEMA supports the agencies’ proposal that, in order to qualify for credits, it is mandatory that the truck is equipped with an AES. Five-minute mandatory engine shutdown will support increased annual hours of operation for idle reduction equipment. In the supporting analysis from the Phase 1 RIA, the agencies assumed Class 8 sleeper cab spends 1,800 hours in extended idle per year and travels about 250 days per year. MEMA recommends that the agencies use 2,500 annual hours for APUs and 1,250 annual hours for FOHs to better reflect real-world application and experiences. Additionally, the agencies’ analysis assumed that the main engine consumes about 0.8 gal/hr during idling. However, based on our analysis, MEMA recommends that 0.87 gal/hr fuel consumed by the main engine during idle be used in the calculations for credit. [EPA-HQ-OAR-2014-0827-1274-A1 p.7]

Please view the Appendix attached to MEMA’s comments for supporting details. It shows the recommendation for credit based on the recommended hours of operation and fuel consumption rate for various APUs, FOHs and combination units. [EPA-HQ-OAR-2014-0827-1274-A1 p.7]

**Extend Idle Reduction Credit to Class 7 and 8 Day Cab Tractors** [EPA-HQ-OAR-2014-0827-1274-A1 p.7]

The agencies asked for comments in the Phase 2 NPRM about whether or not the proposed vocational idle reduction approach should be extended to Class 7 and 8 day cab tractors. Increasingly, companies that operate day cabs are implementing requirements to reduce their idle time in drive cycles that have a lot of stop-and-go. Examples of these type of drive cycles are operations where the vehicle is making several local/regional deliveries and/or waiting in long lines for pick-up/drop-off and not being allowed to leave the truck at idle, such as at loading docks, container yards or ports. Restrictions on idling impact day cab operators in a very direct way. More and more trucking operations are moving to a more regionalized system to accommodate driver preferences and customer needs, which may result in an increased demand for Class 7 and 8 day cab tractors. Consequently, utilization of day cabs – and associated idling – will likely increase. As the agencies are aware, restrictions on idling are on the rise throughout the country. Examples of limiting idle time include: SmartWay partner shippers do not allow idling on their property; cities, municipalities and regions that face non-attainment of air quality standards enforce strict idling restrictions; and, sustainability practices and company policies of fleet operators. [EPA-HQ-OAR-2014-0827-1274-A1 p.7]

Therefore, MEMA supports extending the sleeper cab neutral idle and stop-start weighting factors to day cab tractors. MEMA recommends that Class 7 and 8 day cabs be credited with 35 percent of the credit given to Class 8 sleeper cabs when equipped with comparable technology. Offering credits for day cabs equipped with idle reduction technologies will result in reduced idling of these vehicles and achieve the desired result of reduced fuel consumption and emissions for the full slate of vehicles in the combination tractor category. [EPA-HQ-OAR-2014-0827-1274-A1 p.7-8]
Response:

Idle Reduction Technology Effectiveness

After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS. Details and calculations regarding the effectiveness of the menu of technologies are included in RIA Chapter 2.4.8.1.1.

Hours of Idle Operation

The agencies reviewed this and other studies to quantify idling operation. The 2010 NAS study assumes between 1,500 and 2,400 idling hours per year. Gaines uses 1,800 hours per year. Brodrick, et al. assumes 1,818 hours per year (6 hours per day for 303 days per year) based on an Argonne study and Freightliner fleet customers. An EPA technical paper states between 1,500 and 2,400 hours per year. Kahn uses 1,830 hours as the baseline extended idle case. Based on the literature, the agencies are finalizing as proposed the use of 1,800 hours per year as reasonably reflecting the available range of information.

Day Cab Idle

The agencies considered the comments, both supporting and raising concerns over idle reduction in day cabs. The agencies determined that neutral idle for automatic transmissions is an appropriate technology for use in tractors, and are predicating the standards for day cabs based on a technology package that includes neutral idle. Therefore, the agencies are adopting provisions in Phase 2 to recognize neutral-idle in automatic transmissions as an input to GEM. Our analysis shows that neutral idle effectiveness is approximately 0.8 to 1 percent over the composite day cab tractor cycles, as shown in RIA Chapter 2.8.2.6. The agencies will also include neutral idle as a GEM input for sleeper cabs, though the effectiveness is very low.

In terms of stop-start technologies in tractors, the agencies are not including it as a technology input to GEM because we believe the technology needs further development. If this technology is developed in the future for tractors, then manufacturers may consider applying for off-cycle technology credits. Since the agencies are not predicing the Phase 2 standards on adoption of start-stop technologies, the agencies are also not including this technology as a GEM input.

Organization: National Association of Manufacturers (NAM)

---

Several NAM members have expressed sharply different opinions on the potential penetration rates for various technologies covered in the proposed rule, and the NAM recommends that the EPA and NHTSA revisit these assumptions as they craft a final rule. For instance, a 60 percent penetration of 6x2 Drive Axle Type may be overly optimistic given that six state laws limit tire and axle loading in such a way that 6x2s cannot be used as intended, and other states are not uniform in their regulations. A 40 percent Tire Inflation Systems assumption may not adequately take into account the viability of alternatives such as tire pressure monitoring systems, which provide similar benefits at a lower cost. Baseline assumptions on widespread use of Low Rolling Resistance (LRR) Tires may not sufficiently take into account the uneven conditions that many medium- and heavy-duty vehicles must face (including sloped loading docks, unpaved and uneven trailer lots, and harsh weather conditions). And a 90 percent penetration rate assumption for tamper-proof idle shutdown timers may be overly optimistic when viewed through the lens of current consumer conduct. [EPA-HQ-OAR-2014-0827-1323-A2 p.2]

Response:

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s. In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

Idle Reduction Technologies

77 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO\textsubscript{2} and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found that the drive tires on low and mid roof tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. But we found less of a difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. The agencies phased-in the low rolling resistance tire adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies.

Organization: National Automobile Dealers Association (NADA)

CLASS 7 AND 8 COMBINATION TRACTORS

Working off a Phase I structure which tailors specific standards based on a tractor’s weight class, roof height, and cab type (sleeper or day), the Phase 2 proposal aims to increase the stringency for this vehicle group by 24 percent overall, starting in MY 2021, ratcheting up in MY 2024, and fully phased in with MY 2027. This is in addition to the 7-20 percent reduction in GHG emissions and fuel consumption the Phase 1 rule seeks to achieve for these tractors over a 2010 baseline. NHTSA and EPA estimate that the costs per vehicle to comply with these new combination tractor standards will be offset by potential fuel savings and will result in a 2 year average payback period. Of course, many customers will actually pay significantly higher costs and will face a longer payback periods. [EPA-HQ-OAR-2014-0827-1309-A1 p.6]

The Phase 2 proposal contemplates that engine and chassis manufacturers will achieve compliance through improvements in engine, transmission, driveline, and aerodynamic design, and through greater use of lower rolling resistance tires and idle reductions technologies. The market penetration rates (MPRs) of various technologies or strategies are critical to the proposal's effectiveness. Unfortunately, several of the proposal's tractor-related MPRs appear unrealistic. As noted above, tractor customers are risk averse and simply will not buy or lease equipment until it is proven to be appropriate for their
operations, to be cost-effective, and to be reliable. And if customers don't buy or lease new equipment, the rule fails. [EPA-HQ-OAR-2014-0827-1309-A1 p.6]

Auxiliary Power Units (APUs) and Automatic Engine Shutdown Devices (AESDs) [EPA-HQ-OAR-2014-0827-1309-A1 p.6]

APUs and AESDs are proven technologies which reduce engine idling, resulting in lower fuel use, engine wear, and emissions. A wide-variety of idle reduction options exist in the marketplace, not all of which involve the use of APUs and AESDs. Curiously, the proposal appears to assume that up to 90 percent of MY2027 sleepers will have an APU/AESD onboard. [EPA-HQ-OAR-2014-0827-1309-A1 p.6]

AESDs are also widely available and often purchased by new tractor (and truck) customers. But these are almost universally “programmable” devices designed to accommodate different operating conditions and driver needs. Importantly, first purchasers view AESD programmability is a critical vehicle resale value issue, recognizing that second and third purchasers likely will have different idle control needs. Clearly, a vehicle’s residual/resale value is an important total-cost-of-ownership criterion. [EPA-HQ-OAR-2014-0827-1309-A1 p.6]

The Phase 2 program should recognize and encourage a wide variety of idle reduction strategies. Idle reduction is not now and will not in the future be a “one-size-fits-all” strategy. [EPA-HQ-OAR-2014-0827-1309-A1 p.6]

For example, customers especially sensitive to weight or space constraints will gravitate toward non-APU technologies. Note that NADA/ATD is not suggesting that a lower MPR be set for idle reduction. Instead, NADA/ATD suggests that all legitimate idle reduction strategies “be counted,” not just those involving APUs and nonprogrammable AESDs. [EPA-HQ-OAR-2014-0827-1309-A1 p.7]

Automatic Tire Inflation Systems (ATISs)

The Phase 2 proposal overvalues automatic tire inflation systems while undervaluing tire pressure monitoring systems (TPMSs). TPMSs can provide comparable benefits at a lower cost. The extra fuel consumption and other problems associated with underinflated tires are well recognized, but it is estimated that only 1 percent of tractors presently are equipped with ATISs. Given the lower cost of TPMSs, the Phase 2 rule should treat them the same (or close to the same) as ATISs. Assuming TPMSs are considered to be appropriate tire inflation control strategies, NADA/ATD can support a 40 percent tractor MPR for MY 2027. If not, NADA/ATD submits that a MY2027 tractor MPR of 10% would make sense. [EPA-HQ-OAR-2014-0827-1309-A1 p.7]

Low Rolling-Resistance Tires (LRRT)

Current LRRT tractor MPRs are low and are not expected to increase significantly any time soon unless significant improvements in design are forthcoming. Moreover, there is no realistic means of ensuring that customers (or subsequent owners) will continue to use LRRTs. While LRRTs can be very effective, their cost, useful life, maintenance, and appropriateness vary widely depending on a customer’s duty-cycle and needs. [EPA-HQ-OAR-2014-0827-1309-A1 p.7]

6x2 Axle Configurations

The 6x2 tractor axle MPR also appears to be unreasonable, given that current sales rates range around 2 percent. The low uptake of this technology reflects state-by-state legal issues, practical highway use
limitations, a low acceptance in the secondary market, traction and tire wear concerns, and low driver acceptance. Given these constraints, NADA/ATD suggests that the proposal’s MY 2027 tractor MPR for be revised downward from 60 to 20 percent. [EPA-HQ-OAR-2014-0827-1309-A1 p.7]

Response:

Idle Reduction Technologies

We agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments (including the comment summarized above), the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO$_2$ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS. Consistent with the comment, we determined that the effectiveness of TPMS is 1%, while ATIS is 1.2%, in tractors. We believe that TPMS will be slightly less effective because it is dependent on operator intervention.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found steer tires with rolling resistance as low as 4.9 kg/ton and drive tires with rolling resistance as low as 5.1 kg/ton. The average tire rolling resistance that we used in the technology packages to derive the final rule standards are higher than the lowest rolling resistance tires made today.

We also note that the certification data analysis shows that the drive tires on low and mid roof tractors on average had 10 to 17 percent higher rolling resistance than the drive tires on high roof sleeper cabs. We found less of a difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. The agencies phased-in the low rolling resistance tire adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of
implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s.

Organization: Navistar, Inc.

The bin structure and baseline proposed for Tractors is unworkable and must be changed for the Proposed Rule to be successful. The bin structure sets the buckets each tested vehicle is placed in and, then, sets the aerodynamic score in GEM. It is thus a key component of the compliance structure since the bin in which each tractor is placed directly determines its GEM input and thus the vehicle’s modeled emissions. The baseline impacts the bin structure, since it sets the beginning point, from which expected future improvements are set. [EPA-HQ-OAR-2014-0827-1199-A1 p.24-25]

- The aerodynamic baselines in the Proposed Rule must be adjusted to accurately reflect the actual baseline for aerodynamics and the bin structure must be corrected accordingly. [NHTSA-2014-0132-0094-A1 p.2]

As a baseline, the Proposed Rule uses a theoretical tractor to represent the average tractor compliant to the phase 1 standard. The Phase 1 aerodynamic C\(d\)A did not include an adjustment for wind average drag and the reference trailer did not include trailer skirts. The average C\(d\)A for a MY17 tractors in Class 8 Sleeper High and Class 8 Daycab High categories are summarized below using the RIA from the Phase 1 regulation (Table 3). These values were then adjusted for wind average drag using the assumption in the Phase 2 regulation and the average delta for a trailer skirt from EPA’s SWRI data for coast-down (Table 4). [EPA-HQ-OAR-2014-0827-1199-A1 p.25]

The calculated baseline differs from EPA’s assumption of the aero baseline for Phase 2 by a full BIN or 6-9% higher C\(d\)A. In addition, EPA tested 3 tractors with sleepers that represent the industry’s best configurations versus the average configuration being sold. From this data, EPA incorrectly assumed in

---

80 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
the RIA that “most tractors today would qualify for Bin III.” We estimate that most sleepers would test on average in bin 2. Also it was found through analysis of the provided Southwest Research Institute data that the coastdown method is sensitive to the range of the high speed segment which is being processed. The proposed CFR changes specify a range of 72-58 mph, while RIA contains CdA values that appear to be based on the vehicle speed range of 70-56mph. This is estimated to report about a 2% lower value than it should be and as a result misplace the proposed baseline vehicle. Baseline must be reviewed and adjusted accordingly as the current proposal is as much as a bin off of the 2017 actual baseline. [EPA-HQ-OAR-2014-0827-1199-A1 p.25]

In fact, the SuperTruck program, a cooperative effort by the manufacturers and the Department of Energy, shows the extent of this issue. SuperTruck is intended to identify the most efficient possible tractor configurations, with a 50% increase in efficiency. Navistar is a participant in the SuperTruck program. Our analysis shows that the SuperTruck program vehicle would test at best in bin 5 with the current test trailer. Bin 6 and bin 7 are unachievable targets with the current test trailer. Many of the aero improvements achieved on SuperTruck are a result of the improved integration of the tractor and trailer, which will not be represented in the Phase 2 coastdown as the trailer selected for testing is a standard trailer with trailer skirts only. In addition, SuperTruck is designed to be the best configuration (sleeper only) and real world requirements will drive some enablers to be removed reducing the aero performance for that vehicle. [EPA-HQ-OAR-2014-0827-1199-A1 p.25]

SuperTruck is a sleeper program only and did not account for day cabs. Day cabs in general have less opportunity for improvement, due to the shorter length and therefore less surface area for optimization. Day cabs are a more diverse fleet, with lower adoption of aero devices since many work regional applications at lower speeds and are more sensitive to weight or damage to devices (e.g. skirts). Despite these facts, the current Phase 2 proposal expects the same percentage of improvement from a day cab as a sleeper. This is an incorrect assumption and needs to be revised. [EPA-HQ-OAR-2014-0827-1199-A1 p.26]

With an incorrect aero baseline and unachievable targets, this alone would make the Proposed Rule infeasible. The Proposed Rule should be modified to reflect the true baseline for MY17 and to set an appropriate and achievable bin structure. [EPA-HQ-OAR-2014-0827-1199-A1 p.26]

Before we comment on the proposed emission standards for tractors, we must again note our issues with the baseline. The baseline is critical to judging the stringency, because if the baseline is wrong, the emission standard stringency is also wrong. To know how far we are being asked to run, we need to know the location of starting line. [EPA-HQ-OAR-2014-0827-1199-A1 p.28]

The feasibility of the standards must be judged by the underlying assumptions as to technology penetration. For the rule to be feasible, the technologies on which it is based must be adopted by customers at the rates assumed by the agencies. We have a number of concerns with various elements underlying the proposed emission standards:[EPA-HQ-OAR-2014-0827-1199-A1 p.28]

Navistar believes that the penetration of tire pressure management systems (auto inflation) is overstated. Fleets adopt tire pressure monitoring systems to perform essentially the same function as a tire pressure management system. The driver alert is simpler and sufficient to ensure tire inflation in commercial applications. This is a significant difference between light and heavy duty. In heavy duty, a professional driver has both the incentive and the knowledge to keep tires adequately inflated, neither of which may necessarily be the case with light duty. Tire pressure monitoring systems are also significantly lower cost to purchase and operate than automatic inflation systems. GEM should recognize monitoring systems as well as management, since monitoring systems are preferred by fleets and effectively perform the same
function. These monitoring systems are often linked to the fleet telematics devices, so that warnings are provided to the driver as well as the fleet service department. [EPA-HQ-OAR-2014-0827-1199-A1 p.28]

Navistar believes that the assumed 6x2 axle penetration rate in the RIA is also too high. Operator concerns with traction loss and tire wear are significant hurdles to overcome for the adoption of this technology. Moreover, the 6x2 configuration is simply not legal in all states.\[^9\] We also disagree with the RIA cost estimates, which we believe understates the costs involved with 6x2. We fully agree with the EMA comments in this regard. [EPA-HQ-OAR-2014-0827-1199-A1 p.28]

For tractors, the adoption of Level 2 and 3 tires for day-cabs, especially 4x2, should not follow the same trends as sleepers as these applications typically purchase tires for traction and durability versus fuel economy. These assumed penetrations underlying the standard are flawed and must to be revisited. [EPA-HQ-OAR-2014-0827-1199-A1 p.29]

Similarly, tamper-resistant idle control systems face acceptance challenges. Although the phase 1 rule predicted 100% penetration of tamper resistant idle systems in Class 8 sleepers there is no acceptance of tamper resistant idle shutdown within fleets.\[^9\] In fact, industry experience has been an adoption rate of zero or near zero. Resale concerns remain a significant issue for customers. The concerns is that the existence of a tamper-resistant idle shutdown or extended idle system negatively impacts resale value of the vehicle, since a subsequent user may have different needs than the original purchasers which do not allow for the use of an idle control system. The agencies should provide credit for the currently used programmable idle shutdown solution. Fleets owners select this to be set on their vehicles at the time of purchase and often never change this setting. The driver is unable to change these settings as this is a fleet strategy for improving fuel economy. [EPA-HQ-OAR-2014-0827-1199-A1 p.29]

These flawed assumptions in the assumed adoption rates directly impact the feasibility of the tractor standard. The emission standards should be adjusted to reflect more realistic adoption rates throughout the period addressed by the Proposed Rule. [EPA-HQ-OAR-2014-0827-1199-A1 p.29]

We are concerned that GEM does not fully capture all of the potential accessory improvements. The Proposed Rule provides a credit for “electrically powered pumps for engine cooling.” This should be revised to include “electronically controlled variable speed coolant pumps” to align with the Preamble descriptions and technology under development as part of the SuperTruck program. Shifting to fully electronic on this pump creates reliability concerns and adds additional complexity due to the size of the necessary pumps (2+ hp). In addition, the increased power load will require a larger alternator and upgraded wiring. [EPA-HQ-OAR-2014-0827-1199-A1 p.29-30]

In addition to a fully electric pump, Dual Displacement power steering should also be included as an accessory improvement. This technology reduces parasitic loads by applying power proportional to steering demand. [EPA-HQ-OAR-2014-0827-1199-A1 p.30]

The benefits included in the regulation for electrified A/C compressor are understated. Our estimates are closer to 1.5% when in use and will be during the use of A/C and during defrost; therefore, the effective benefit should be 1%. Also, these accessory improvements should each be available for the vocational vehicles as well. [EPA-HQ-OAR-2014-0827-1199-A1 p.30]

Navistar feels the following are key areas the agencies must address:[NHTSA-2014-0132-0094-A1 p.2]

- The emission standards must reflect the technology packages customers will actually purchase and use.[NHTSA-2014-0132-0094-A1 p.2]
29 EMA comments lay out a state-by-state comparison of restrictions related to 6x2 configuration.

Response:

Aerodynamics

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for Phase 2. The aerodynamic performance of the tractors tested by EPA were recalculated for the final rule using the final aerodynamic test procedures (including the 72-58 mph high speed range noted by the commenter). See RIA Chapter 3.2.1. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. See RIA Chapter 3.2.1.2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin C_dA values.

In consideration of these comments, the agencies have adjusted the aerodynamic adoption rate for Class 8 high roof sleeper cabs used to set the final standards in 2021, 2024, and 2027 MYs (i.e., the degree of technology adoption on which the stringency of the standard is premised). The agencies’ assessment for the final rule is that only Bins I through V are achievable with known aerodynamic technologies, but that Bins VI and VII have less known technology paths. Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of C_dA. See RIA Chapter 2.8.2.2. These aerodynamic improvements have been demonstrated within the program on two vehicles in 2015. In the final rule, the agencies are projecting that truck manufacturers will be able to begin implementing these aerodynamic technologies as early as 2021 MY on a limited scale. We adjusted the adoption rates for MY 2027 in the technology package developed for the final rule to consist of 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors in this segment that we project could successfully apply these aerodynamic packages with this amount of lead time. The agencies phased-in the aerodynamic technology adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies. For example, in the 2021 MY technology package, the agencies have assumed that 10 percent of high roof sleeper cabs will have Bin V aerodynamic performance. This phase-in structure is consistent with the normal manner in which manufacturers introduce new technology to manage limited research and development budgets as well as to allow them to work with fleets to fully evaluate in-use reliability before a technology is applied fleet-wide. The agencies believe the phase-in schedule will allow manufacturers to complete these normal processes.

The agencies recognize that SuperTruck only include high roof sleeper cabs, one of ten tractor subcategories. We took similar steps in adjusting the adoption rates in the high roof day cab subcategories, such that the high roof day cab had higher adoption rates in lower bins than high roof
sleeper cabs. The aerodynamic adoption rates used to develop these standards for the other tractor regulatory subcategories (low and mid roof tractors) are less aggressive than for the Class 8 sleeper cab high roof tractors. Aerodynamic improvements through new tractor designs and the development of new aerodynamic components is an inherently slow and iterative process. The agencies recognize that there are tractor applications that require on/off-road capability and other truck functions which restrict the type of aerodynamic equipment applicable. We also recognize that these types of trucks spend less time at highway speeds where aerodynamic technologies have the greatest benefit. The 2002 VIUS data ranks trucks by major use.82 The heavy trucks usage indicates that up to 35 percent of the trucks may be used in on/off-road applications or heavier applications. The uses include construction (16 percent), agriculture (12 percent), waste management (5 percent), and mining (2 percent). Therefore, the agencies analyzed the technologies to evaluate the potential restrictions that will prevent 100 percent adoption of more advanced aerodynamic technologies for all of the tractor regulatory subcategories. In addition, the agencies also accordingly reduced the adoption rates in the highest bins for low and mid roof tractors to follow the change made to the high roof subcategories because we neither proposed nor expect the aerodynamics of a low or mid roof tractor to be better than a high roof tractor.

Baseline

In the proposal, the agencies noted that the manufacturers were not using tamper-proof AESS to comply with the Phase 1 standards so the agencies reverted back to the APU adoption rate of 30 percent used in the Phase 1 baseline for the Phase 2 baseline. The agencies received a number of comments regarding this. In response to these comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had auxiliary power units and 96 percent of vehicles are equipped with adjustable automatic engine shutdown systems.83 Therefore, the agencies are projecting that 9 percent of the baseline sleeper cab tractors will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS, and none will have tamper-proof AESS. Additional changes to the baseline for the final rule are discussed in Preamble Section III.D.1.a.

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS. The effectiveness value in GEM is less for TPMS, reflecting the need for driver interaction.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of

---

implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples.\footnote{Fleet Owner, “Meritor Expects to offer new tandem axle in 2013,” http://fleetowner.com/equipment/meritor-expects-offer-new-tandem-axle-2013, December 2012.} In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency.\footnote{Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).} When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s.\footnote{North American Council for Freight Efficiency. “Confidence Findings on the Potential of 6x2 Axles.” January 2014. Page 19.}

In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found steer tires with rolling resistance as low as 4.9 and drive tires with as low as 5.1 kg/ton. The average tire rolling resistance that we used in the technology packages to derive the final rule standards are higher than the lowest rolling resistance tires made today. With respect to the comment about assuming that customers will continue to demand low rolling resistance tires, we set performance-based standards that allow the manufacturers to produce a wide variety of products.

We also note that during the certification data analysis, we found that the drive tires on low and mid roof tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. We found less of a difference in rolling resistance of the steer tires between the tractor subcategories. We did not find a difference in average rolling resistance levels between Class 7 (4x2) and Class 8 tractor subcategories, as suggested by the commenter. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. The agencies phased-in the low rolling resistance tire adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies.

Idle Reduction Technologies

While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow
adjustable (or programmable) AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS. This change in the technology package to adjustable AESS removes the concern about resale noted by the commenter.

Accessories

In response to the comments, the agencies evaluated a set of accessories that can be designed to reduce accessory losses. Due to the complexity in determining what qualifies as an efficient accessory, we are maintaining the proposed language for accessories for tractors which provides defined effectiveness values for only electric air conditioning compressors and electric power steering pumps and coolant pumps. The agencies did not revise the electric coolant pump definition to include “electronically controlled variable speed coolant pumps.” We believe the type of technology suggested by the commenter could be captured during the measurement of the engine fuel map. Manufacturers have the option to apply for off-cycle credits for the other types and designs of high efficiency accessories, such as dual displacement power steering pumps.

Organization: North American Die Casting Association (NADCA)

While NADCA does not endorse a specific weight reduction amount, die castings represent a clear opportunity to help achieve improved fuel efficiency and weight standards. As noted in the NPRM, “some materials work better than others for particular vehicle components,” and NADCA believes regulators should provide manufacturers with the ultimate flexibility to meet realistic standards. [EPA-HQ-OAR-2014-0827-1283-A1 p.2]

NADCA believes that die castings are a central part of any effort to improve fuel efficiency and performance of all vehicles, whether light, medium, or heavy-duty. As demonstrated above, the die casting industry is capable of helping achieve significant efficiency improvements, however, the Association cannot speak directly to questions surrounding the overall feasibility raised by OEMs and others. [EPA-HQ-OAR-2014-0827-1283-A1 p.3]

As demonstrated in Phase I and reinforced in the Phase II proposal, regulators clearly see that aluminum, and therefore cast parts, are an integral component to weight reduction and energy efficiency. We urge the EPA and NHTSA to explore the opportunities metal castings provide. Through its direct research and partnerships with industry and universities, NADCA has a demonstrated track record securing energy and cost savings. [EPA-HQ-OAR-2014-0827-1283-A1 p.3]

Response:

The agencies have provided weight reduction tables in the regulations that allow vehicle manufacturers to demonstrate compliance with the CO₂ emissions and fuel consumption standards with technology packages that include weight reduction in addition to other technologies. For components that are not included in the weight reduction tables, manufacturers have the option of pursuing off-cycle credits.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

The full-vehicle standard should be stronger.
Commensurate with increased engine stringency, the tractor standards should be strengthened to ensure that manufacturers utilize the full suite of appropriate complementary technologies, in addition to engine improvements. [EPA-HQ-OAR-2014-0827-1221-A1 p.3][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.138.]

Response:

The final Phase 2 engine standards will lead each manufacturer to achieve reductions of over 5 percent in 2027 MY relative to the Phase 1 baseline. For the final Phase 2 rule, we recognize that it could be possible to achieve greater reductions than those included in the engine standard by designing entirely new engine platforms. Unlike existing platforms, which are limited with respect to peak cylinder pressures (precluding certain efficiency improvements), new platforms can be designed to have higher cylinder pressure than today’s engines. New designs are also better able to incorporate recent improvements in materials and manufacturing, as well as other technological developments. Considered together, it is possible that a new engine platform could be 6 percent more efficient without WHR than Phase 1 engines and 8 percent more efficient than Phase 1 if 50 percent of these engines have WHR. We project in 2024 MY, that a limited number of engine platforms would be redesigned, and therefore have pulled ahead the reduction expected from the proposed 2027 MY engine standards into the vehicle standards for 2024 MY. In addition, we project that 50 percent of tractor engines in 2027 MY will be redesigned engines (i.e. engines reflecting redesigned engine platforms, again based on existing engine platform redesign schedules within the industry) achieving a 6 percent reduction for day cabs and an 8 percent reduction in fuel consumption in sleeper cabs beyond Phase 1. This means the average 2027 MY tractor engine would be 5.4 and 6.4 percent more efficient than Phase 1 for day and sleeper cabs respectively. We have factored these levels into our analysis of the vehicle efficiency levels that will be achievable in MY 2027. These additional engine improvements make more stringent vehicle standards feasible, and the final standards are structured so that these improved engines are not able to generate windfall credits, but rather that their projected performance is reflected in the stringency of the final tractor vehicle standard.

Organization:  Owner-Operator Independent Drivers Association (OOIDA)

OEMs have voiced very significant concerns regarding the proposed emission standards, which was a significant point in their joint testimony during the Long Beach Public Hearing. These noteworthy concerns included: [EPA-HQ-OAR-2014-0827-1244-A1 p.17]

- The agencies recommendation that the 2017 aero baseline utilizes the best aero trucks available rather than the average, this has an effect of increasing stringency about 2.5%. [EPA-HQ-OAR-2014-0827-1244-A1 p.18]
- The baseline assumes 30% or more sleeper tractors are equipped with non-programmable idle shutdown timers when, in fact, very few customers take this feature. This increases stringency about 1.5% (30% of 5%). [EPA-HQ-OAR-2014-0827-1244-A1 p.18]
- Cab aerodynamic expectations (Bins V, VI, and VII) cannot be achieved with the specified test trailer. This means vehicle OEMs must try to find about 4.5% more fuel economy elsewhere. [EPA-HQ-OAR-2014-0827-1244-A1 p.18]
- The compliance margins for aerodynamic bins have been removed. In contrast, Phase 1 allowed a full bin margin. This means that OEMs would have to declare worse aero performance to
ensure passing an audit, with as much as 5% impact on declared fuel economy that they would need to make up somehow. [EPA-HQ-OAR-2014-0827-1244-A1 p.18]

- No compliance margin is provided for engine fuel map audits, compared to the 3% margin allowed in Phase 1 for engine efficiency. This would require that OEMs declare worse engine efficiency than their certification measurement to ensure passing an audit, considering production and test variability. [EPA-HQ-OAR-2014-0827-1244-A1 p.18]

- In summary, these test and protocol issues add as much as 17% greater reduction in fuel consumption than the proposed rule estimates. [EPA-HQ-OAR-2014-0827-1244-A1 p.18]

When combined, these issues create an impossible challenge that could not be met with any reliable, cost-effective technology, which will negatively affect the owner-operators, professional truck drivers, and the general public that the agencies are hoping to serve. In conversations with EPA staff, OOIDA has been assured that the agencies are working to resolve many of these issues, and that meetings have taken place between respective teams of engineers to resolve them. This will be especially crucial because of the agencies seeming reliance on new technology. The testing methods and protocols must be accurate to avoid an overly stringent regulation which can have several unintended consequences. Without these corrections, this rulemaking will force OEMs to specify a truck optimized for simulated duty cycles which EPA has chosen rather than meet the needs of consumers operating in the real-world, which would ultimately lead to increased fuel consumption and GHG emissions. If these concerns are not adequately addressed, this further endangers the goal of this NPRM and puts the livelihoods of hard working individuals at a grave risk for failure. [EPA-HQ-OAR-2014-0827-1244-A1 p.18-19]

APU’s

Auxiliary power units (APUs) can be used instead of idling the main engine of the truck to provide both power and climate control for the driver. While APU’s unquestionably offer multiple benefits, an adoption rate of 90% that the agencies are estimating by MY 2024 is completely unreasonable. Additionally, while many carriers purchase sleeper cabs because they are the most versatile choice, this does not mean that a driver will routinely be sleeping in the cab of the truck. Depending on the operation and length of haul, a driver might only spend one to two nights a week in the cab. In these types of situations an APU is merely 400 lbs. of extra and unneeded weight and maintenance. [EPA-HQ-OAR-2014-0827-1244-A1 p.21]

Ironically, while the agencies’ NPRM hopes to reduce the weight of a truck, a typical APU adds approximately 400 lbs. to the weight of a truck. Whereas most states allow a 400 lb. exemption for trucks equipped with an APU, the following states do not: CA, DC, HI, KY, MA, NC, and RI. If the agencies mandate the installation of an APU on a truck which operates in one of these states, then the potential income for that carrier will be reduced. This issue was not addressed by the NPRM. [EPA-HQ-OAR-2014-0827-1244-A1 p.22]

Automatic Engine Shutoff

OOIDA is concerned that installing automatic engine shutoff (AES) in a class 8 vehicle may compromise safety in different circumstances. Overall, AES can easily produce negative consequences for long-haul drivers who frequently visit new facilities (warehouses, shippers, receivers, etc.). These facilities rarely have similar check-in procedures, which can be problematic. For example, a driver might leave the truck believing that it will only take a few moments for him or her to access the check-in area and then return. However, this is not always the case and delays can easily ensue. While this might not be an issue for a single truck driver, it can create a safety hazard for team driving operations, if a co-driver was left asleep in the sleeper berth and the truck shut off, he or she could be left out in extreme weather
conditions, which could interrupt the driver’s valuable sleeping time and thus increase fatigue. Additionally, this situation could be especially harmful for drivers with certain medical conditions, such as those who have experienced a heat stroke in the past. [EPA-HQ-OAR-2014-0827-1244-A1 p.22]

According to OOIDA Foundation’s Member Profile Surveys, 16% of OOIDA members indicate that they have a pet with them in their truck. This leads to the same concerns as those presented above. However, a pet will not have the ability to turn the truck back on. Such areas of concern were not a part of the agencies analysis and subsequent costs. [EPA-HQ-OAR-2014-0827-1244-A1 p.22]

**Automatic Tire Inflation**

Automatic tire inflation technology is among the agencies’ list of approved technologies in order for OEMs to achieve compliance goals. The agencies have projected as part of the NPRM that 50 percent of dry van and refrigerated trailers will have automatic tire inflation (ATI) systems installed to maintain optimal tire pressure by MY 2018. This penetration rate is far too high, as many owner-operators would prefer to purchase tire pressure monitoring (TPM) systems rather than ATI systems because of the reduced cost and complexity while achieving similar savings. It is important that ATI systems are not forced onto consumers by assuming such high adoption rates. [EPA-HQ-OAR-2014-0827-1244-A1 p.23]

It is well-accepted that poorly inflated tires decrease a truck’s fuel economy, and that proper tire pressure is essential to avoiding blow outs. Tire failure for an owner-operator is a costly expense, as the driver will both lose productivity while waiting for a replacement tire and will incur costs to purchase the replacement tire. This alone is a proper incentive for owner-operators to ensure that tires are inflated to the proper pressure. While ATI systems are capable of monitoring tire pressure, they are often expensive and unreliable, whereas TPM systems are much less expensive and can be utilized to achieve the same results. [EPA-HQ-OAR-2014-0827-1244-A1 p.23]

**Low Rolling Resistance Tires**

Lower Rolling Resistance Tires can be a useful technology which reduces the energy needed in order to move a truck, but it is important to understand that they do not work for all types of truck operations. Low rolling resistance (LRR) tires are designed to improve fuel efficiency of a tractor pulling a trailer by minimizing its rolling resistance, which consists of energy lost as heat within the rubber itself, as well as aerodynamic drag of the tire, and friction between the tire and the road and between the tire and the rim when the tire is rolling under load; rolling resistance is expressed as the energy consumed per unit distance as the tire rolls under load.\(^23\) [EPA-HQ-OAR-2014-0827-1244-A1 p.23-24]

According to the EPA SmartWay program, for every 5 percent reduction in tire rolling resistance, a 1 percent reduction in fuel savings might be attained. Tests have confirmed that most LRR tires have a long stopping distance at high speeds and lack grip in the corners, both of which could ultimately lead to an accident.\(^23\) Sheldon Brown, an executive program manager at the Toyota Technical Center, has said, “There have been significant trade-offs with this type of tire, namely wear performance and stopping distance.”\(^25\) [EPA-HQ-OAR-2014-0827-1244-A1 p.24]

Regardless of the higher cost of LRR tires and the concerns of its effectiveness in fuel savings, the tire is not designed for all types of operations. An owner-operator running routes in mountainous terrain does not want a tire that has less friction and less traction equipped on their tractor-trailer, especially while driving in extreme weather conditions. The LRR tire may be beneficial on flat terrain, but it is a safety concern in many geographical regions. Steven Bixler, an OOIDA Board Member, who frequently
operates in winter conditions and mountainous terrain, stated “Asking me to run LRR’s would be like asking someone to walk up and down Lombard Street in San Francisco in a pair of smooth soled penny loafers on an inch of ice.” [EPA-HQ-OAR-2014-0827-1244-A1 p.24]

By the very nature of their job, truckers must be prepared for just about any possible situation at all times, whether it is foreseeable or not. In the course of a single day, a truck driver can be faced with many varying situations and scenarios, and a large part of being properly prepared is choosing the right equipment and accessories for a job that can change as quickly as the weather. Understanding this fact is vital because making a poor equipment choice can have dire consequences. The tires on a tractor-trailer are not only a significant financial investment, but can be the difference between safely completing a trip, or not. A LRR tire achieves much of its potential fuel savings benefit by reducing the very component of friction or resistance that a truck driver needs to have faith in, which is not an option for many owner-operators. [EPA-HQ-OAR-2014-0827-1244-A1 p.24-25]

When a truck driver is navigating a curve, static friction is the main force that keeps the truck on the pavement. If an owner-operator is running a route over a mountain pass such as California’s Interstate 5, which is infamously known for its curves as the unforgiving Grapevine, they must be equipped with the proper tire. The heavily traveled Grapevine is part of the Tejon Pass located in the Tehachapi Mountains. The peak reaches over 4,100 feet and has a steep grade of up to 6 percent. In addition, on any given day a driver may encounter conditions such as rain, snow, ice, fog, and condensation. If the static friction is reduced, the driver has a much greater possibility of encountering kinetic friction, or in other words a skid, which may result in a crash. [EPA-HQ-OAR-2014-0827-1244-A1 p.25]

For another example, the Eisenhower-Johnson Memorial Tunnel in Colorado is one of the highest vehicular tunnels in the world with a maximum elevation of 11,158 ft. However, if an owner-operator is transporting hazardous materials, they are not allowed to use the tunnel. Instead, the driver must travel on top of the mountain across Loveland Pass, which is almost another 1,000 ft. higher. For the two routes mentioned, LRR tires are simply not an option. The small fuel saving benefit associated with LRR tires is greatly outweighed by the potential loss of friction that may cause an accident. [EPA-HQ-OAR-2014-0827-1244-A1 p.25-26]

While a much more mundane situation than an accident, without proper traction a truck can get stuck. Unladen truck suspensions do not lend themselves to good traction, even when equipped with tires which have a more aggressive tread depth. The towing bill for a class 8 truck is costly and being extracted is time-consuming. [EPA-HQ-OAR-2014-0827-1244-A1 p.26]

6x2’s

It is obvious that the agencies have not properly researched 6x2 axle configurations, as 6x2’s are not safe for all operations, nor are they legal in all 50 states and Canada. When considering the purchase of a truck, it is imperative for an owner-operator that the vehicle is able to legally operate in all states and provinces. A truck which is not able to do so is not desirable and thereby can have a dramatic effect upon the resale value of the vehicle. EPA should include in its cost and benefit analysis the negative impact on the resale value, as well as the potential for increase tire wear and costs associated with the 6x2 axles. While a 6x2 configuration can lead to fuel savings, a market penetration rate of 60% by 2027 does not appear to be a realistic estimate when considering the potential limitations. [EPA-HQ-OAR-2014-0827-1244-A1 p.26]

Speed Limiters
In the NPRM, the agencies proposed to permit the use of speed limiters in order to grant credits to OEMs as a way to improve fuel economy. However, OOIDA strongly cautions that the agencies must fully consider the significant negative consequences of speed limiters. Julie Cirillo, a former Assistant Administrator and Chief Safety Officer of the Federal Motor Carrier Safety Administration (FMCSA), stated in a sworn affidavit, “it is my opinion that the Speed Limiter Legislation does not increase safety, and in fact decreases safety on the highways travelled by those heavy trucks and can cause dangerous situations to arise.” Specifically, these dangerous situations arise from a differential in speed limits. Mrs. Cirillo also stated, “Jurisdictions responsible for ensuring the safety of the travelling public should not take any action that could result in creating an unsafe situation. Included in these actions would be the establishment and enforcement of differential speed limits for passenger cars and commercial vehicles. Adherence to differential speed limits creates a situation where a significant percentage of traffic is operating more slowly than general traffic.”

In 1964, David Solomon wrote a report entitled Accidents on Main Rural Highways Related to Speed, Driver, and Vehicle published by the Bureau of Public Roads (predecessor to the Federal Highway Administration). In order to define the relationship between speeds, characteristics of drivers and vehicles, and accidents, Solomon collected data from 11 cooperating states on 600 miles of main rural highways. The study recorded 10,000 drivers across 2-lane and 4-lane highways, and discovered vehicles travelling 10-15 mph less than the average speed of all traffic had a much greater chance of being involved in a crash. Solomon presented his findings in a distinguished “U-shape” curve, which has now become famous.

In fact, Solomon wrote that regardless of the average speed on the highway, the more a driver deviates from the average speed, the greater his or her chance of being involved in an accident. Low speed drivers are more likely to be involved in accidents than high-speed drivers are, as 80% of rear-end collisions involving a large truck and a car resulting in a fatality, the passenger vehicle rear-ended the truck.

Additional research studies have been published through the years that support Solomon’s conclusions, such as the Interstate System Accident Research Study II published by the Bureau of Public Roads (now the FHWA) and the Commercial Motor Vehicle Speed Control Devices published in 1991 by the National Highway Traffic Safety Administration (NHTSA). Both studies confirmed the “U-shape” curve established initially by Solomon.

In 2005 Dr. Steven L. Johnson of the University of Arkansas conducted a study entitled Cost-Benefit Evaluation of Large Truck-Automobile Speed Limit Differentials on Rural Interstate Highways which found that differentiating speeds were shown to produce more interactions between vehicles. Moreover, Dr. Johnson found that as the speed of an individual vehicle deviates from the mean traffic speed on a roadway, the number of interactions between vehicles increases and the potential for being involved in accidents increases. The frequency of interactions with other vehicles by a vehicle traveling 10-mph below the posted speed limit is 227% higher than moving at traffic speed.

In similar fashion, in 1993 the Transportation Research Board of the National Research Council published a study by John E. Baerwald, which found that vehicles travelling at or about the same speed minimized the need for overtaking, passing and lane changes and, as a result, caused fewer accidents. This too was supported recently by the United Kingdom, which in April 2015, increased the national speed limit for heavy goods vehicles from 40-mph to 50-mph in order to reduce risky overtakes by frustrated car drivers.
When a truck is artificially limited to a lower speed than other traffic, this will create an obstruction in the traffic flow. As other vehicles approach from behind in traffic there will invariably be situations where they will need to reduce speed before passing. The vehicle will then have to regain their cruising speed. This will cause the vehicle to use more fuel than it would if it could have maintained cruising speed. While this type of interaction will occur in any traffic flow situation, it will occur more frequently if VSLs are mandated. [EPA-HQ-OAR-2014-0827-1244-A1 p.29]

The agencies are correct to note that reducing the speed of all trucks will lead to a greater number of trucks being necessary to haul the same amount of freight. With an artificial reduction in freight capacity, due to a loss in total miles operating within the allowed hours of service, more trucks and drivers would be needed to compensate. This would also require more truck parking spaces, which are already in shortage (cite Jason’s law study) and come with their own GHG footprint. A larger amount of trucks on the road would also add to congestion which would increase GHG emissions. [EPA-HQ-OAR-2014-0827-1244-A1 p.29]

OOIDA is opposed to the utilization of speed limiters as a way for OEMs to receive credits in order to comply with the Phase II fuel efficiency and GHG emission standards. A technology which has been proven to decrease highway safety is completely and utterly inappropriate, and should not be included in any form as part of the proposed rule. [EPA-HQ-OAR-2014-0827-1244-A1 p.29-30]

Weight Reduction

The Notice proposes that heavy duty vehicles would save fuel and lower emissions if trucks were redesigned to use less mass, possibly using lighter, higher strength materials. Before such standards are created, however, OOIDA has and continues to encourage NHTSA to establish a rule for the crashworthiness of trucks. Without a baseline standard for the forces that a truck and its components must withstand in a crash, what guidelines would truck manufacturers follow to ensure that mass reduction designs do not compromise the safety of the truck driver? [EPA-HQ-OAR-2014-0827-1244-A1 p.31]

In the academic world, the idea of reducing the vehicle weight sounds like a good way to tackle fuel inefficiency in CMVs. However, this is a frightening concept for a truck driver. The goal of better fuel efficiency is a noble one, but it is not worth the expense of a weaker and lighter cabs. Currently, the United States does not have any cab crashworthiness standards for vehicles with a gross vehicle weight rating over 10,000 pounds. [EPA-HQ-OAR-2014-0827-1244-A1 p.31]

In 2009, Carl VanWasshnova, an OOIDA member from Port Orange, FL, was killed in a low-speed crash after his day cab collapsed around him. According to the Federal Motor Carrier Safety Administration, approximately 700 truck drivers have died annually the past 10 years in single or multi-vehicle crashes. Accidents involving truck rollovers are among the most deadly as they account for approximately 63 percent of fatal injuries to truck occupants. While millions are being spent to develop new technologies, basic and common sense features such as air bags and truck cab crashworthiness are being left behind. [EPA-HQ-OAR-2014-0827-1244-A1 p.31]

In response to a 20 percent increase of truck occupant deaths in 2011, OOIDA released a statement saying, “What is wrong with this picture? NASCAR drivers walk away from collisions at 200 miles per hour but truck drivers are losing their lives at 30 miles per hour. Families are being destroyed because we are making cabs lighter and lighter while efforts persist to make the loads heavier. Accidents will happen – period. We won’t be able to outsmart that.” Reducing the weight of CMVs in order to improve fuel efficiency should not be a compromise for safety. [EPA-HQ-OAR-2014-0827-1244-A1 p.32]
Section 32201 of the Moving Ahead for Progress in the 21st Century Act (MAP-21) directed the Secretary of Transportation to conduct a comprehensive analysis of the need for crashworthiness standards for property carrying commercial motor vehicles with a gross vehicle weight rating or gross vehicle weight of 26,001 pounds involved in interstate commerce including an evaluation of the need for roof strength, pillar strength, air bags, and other occupant protections standards, and frontal and back wall standards. NHTSA contracted with the University of Michigan Transportation Research Institute to conduct a study on heavy truck fatal and injury crashes. After breaking down the crash data from TIFA, GES, and the LTCCS, and researching SAE’s Recommend Practices, UMTRI identified four primary countermeasures. However, the research team stated that an assessment of the countermeasures’ effectiveness to reduce truck occupant injury and death in crashes was beyond the scope of the study. The countermeasures included:[EPA-HQ-OAR-2014-0827-1244-A1 p.32]

- Measures to increase seat belt usage. These may include the installation of enhanced seat belt warning systems that activate a visual and audible warning when truck drivers and other vehicle occupants fail to use their seat belt. [EPA-HQ-OAR-2014-0827-1244-A1 p.33]

- Increasing the integrity and robustness of cab structures and the protection of cabs particularly with respect to rollover. [EPA-HQ-OAR-2014-0827-1244-A1 p.33]

- The installation of side curtain air bags to prevent occupant ejection through the side windows and head trauma. [EPA-HQ-OAR-2014-0827-1244-A1 p.33]

- Increasing occupant head space during rollover events through installation of automatic pull-down seats. [EPA-HQ-OAR-2014-0827-1244-A1 p.33]

UMTRI also recommend that since SAE’s Recommended Practices and standards were formed over a decade ago with the cooperation of manufacturers and associations from various countries, that SAE reassess and update their Recommended Practices. NHTSA has stated that they will closely follow and participate in this work. OOIDA feels this issue needs to be addressed before other regulations are initiated. [EPA-HQ-OAR-2014-0827-1244-A1 p.33]

26 Affidavit of Julie Cirillo

Response:

The agencies’ responses to OOIDA’s specific comments from the Long Beach Public Hearing are included in each of the subsections below. In general in the final rule, the agencies have revised the aerodynamic test procedures to reduce variability, adjusted baseline tractor configurations, and developed new compliance approaches to alleviate the need for compliance margins. We also have made other revisions, such as the road grade profile, to better match the in-use operation of heavy-duty vehicles. We believe we are adopting accurate test methods and that the trucks designed to meet the Phase 2 standards will also perform well in the real world because we recognize the importance of this issue.

Idle Reduction Technologies

Baseline: In the proposal, the agencies noted that the manufacturers were not using tamper-proof AESS to comply with the Phase 1 standards so the agencies reverted back to the baseline APU adoption rate of 30 percent used in the Phase 1 baseline. The agencies received a number of comments regarding this. In response to these comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had auxiliary power units and 96 percent of vehicles are equipped with adjustable automatic engine shutdown systems. Therefore, the agencies are projecting for the Phase 2 baseline that 9 percent of sleeper cabs will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS, and none will include tamper proof AESS.

APU Mandate: There is a misconception of the proposed Phase 2 program where some stakeholders thought that the agencies were mandating use of APUs. This is incorrect. The Phase 1 and Phase 2 tractor standards are performance standards. The agencies projected an adoption rate of up to 90 percent for tamper-proof AESS in our analysis for determining the stringency level of the proposed standard. We did not propose to differentiate between the various idle reduction technologies in terms of effectiveness and only used the diesel powered APU in terms of determining the cost and effectiveness.

Adoption Rate: The agencies received numerous comments on our proposed adoption rates of tamper-proof AESS. We generally agree with this commenter (and others) that the agencies should consider other types of idle reduction technologies because an automatic engine shutdown system (or an APU) may not be the optimum choice for every tractor. For the final rule, we now differentiate effectiveness based on the specific idle reduction technology installed by the tractor manufacturer. This change is consistent with the commenter’s concern that APUs would not benefit all operators or may lead to a

concern regarding weight in some operations. The agencies note that all but five states and the District of Columbia provide weight exemptions between 400 and 550 pounds for APUs. Thus, we have set the maximum diesel powered APU adoption rate at 40 percent in MY 2027 in the technology package for the final rule. This maximum adoption rate conservatively recognizes that diesel-powered APUs may impact the payload capacity of tractor-trailers traveling in only those five states and only when those tractor-trailers are traveling at maximum GCW of 80,000 pounds (which is estimated to be approximately 30 percent of the miles travelled). For the states with an APU weight exemption and all of the tractor-trailers traveling at less than maximum GCW, the addition of 400 pounds to an 80,000 pound tractor-trailer will only have an impact of on direct fuel consumption of approximately 0.1 percent, and no impact on payload capacity. Additionally, the potential positive implications of other weight reduction efforts could partially or fully offset concerns from added weight of APUs, including the additional fuel use. For the final rule, we recognize a variety of idle reduction technologies – including automatic engine shutdown systems, fuel operated heaters, automatic stop/start systems, and diesel powered APUs. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

Safety: The regulations already provide AESS override criteria that includes ambient temperature if it reaches a level below or above which the cabin temperature cannot be maintained for health and safety of the operator (40 CFR 1037.660(b)(3)). These override allowances are directly related to the concerns raised by the commenter.

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies agree with this commenter and believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS.

Low Rolling Resistance Tires

The agencies recognize that different tractor operations (such as the California Interstate 5 and the Loveland Pass mentioned by the commenter) require different tires. For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found that high roof sleeper cabs are certified today with steer tire rolling resistance levels that ranged between 4.9 and 7.6 kg/ton and with drive tires ranging between 5.1 and 9.8 kg/ton. In the same analysis, we found that high roof day cabs are certified with rolling resistance levels ranging between 4.9 and 9.0 kg/ton for steer tires and between 5.1 and 9.8 kg/ton for drive tires. This range spans the baseline through Level 3 rolling resistance.

resistance performance levels. Therefore, for the final rule we took an approach similar to the one taken in Phase 1 and proposed in Phase 2 that considers adoption rates across a wide range of tire rolling resistance levels to recognize that operators may have different needs. 76 FR 57211 and 80 FR 40227.

Also in our analysis of the Phase 1 certification data, we found that the drive tires on low and mid roof sleeper cab tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. But we found only a minor difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. This is also consistent with the approach that we took in setting the Phase 1 tractor standards. 76 FR 57211. In addition, the final rule reflects a reduction in Level 3 adoption rates for low and mid roof tractors from 25 percent in MY 2027 used at proposal (80 FR 40227) to zero percent adoption rate. The technology packages developed for the low and mid roof tractors used to determine the stringency of the MY 2027 standards in the final rule do not include any adoption rate of Level 3 drive tires to recognize the special needs of these applications, consistent with the comments noted above raising concerns about applications that limit the use of low rolling resistance tires.

The agencies continue to stand behind the low rolling resistance tire research conducted to date, which includes the Department of Transportation Volpe Center’s 2015 report titled “Review and Analysis of Potential Safety Impacts and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles,” along with any research supporting the development, and maintenance, of FMVSS No.121. In addition, DOT’s Federal Motor Carrier Safety Administration and NHTSA sponsored a test program conducted by Oak Ridge National Laboratory to explore the effects of tire rolling resistance levels on Class 8 tractor-trailer stopping distance performance over a range of loading and surface conditions. The objective was to determine whether a relationship exists between tire rolling resistance and stopping distance for vehicles of this type. The overall results of this research suggest that tire rolling resistance is not a reliable indicator of Class 8 tractor-trailer stopping distance. The correlation coefficients (R2 values) for linear regressions of wet and dry stopping distance versus overall vehicle rolling resistance values did not meet the minimum threshold for statistical significance for any of the test conditions. Correlation between CRR and stopping distance was found to be negligible for the dry tests for both loading conditions. While correlation was higher for the wet testing (showing a slight trend in which lower CRRs correspond to longer stopping distances), it still did not meet the minimum threshold for statistical significance. In terms of compliance with Federal safety standards, it was found that the stopping distance performance of the vehicle with the four tire sets studied in this research (with estimated tractor CRRs which varied by 33 percent), were well under the FMVSS No. 121 stopping distance requirements. The agencies agree, though, that continuing research will be important as new tire technologies enter the marketplace, and like the extensive rolling resistance testing conducting to support the Phase 1 regulation and, in part, this final rule, the agencies will continue to monitor developments in the tire supply marketplace through the EPA Smartway program and other, potential, research. NHTSA notes that FMVSS No. 121 will continue to play a role in ensuring the safety of both current and future tire technologies.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as
noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2, enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples.\footnote{Fleet Owner, “Meritor Expects to offer new tandem axle in 2013,” http://fleetowner.com/equipment/meritor-expects-offer-new-tandem-axle-2013, December 2012.} In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency.\footnote{Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).} When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s.\footnote{North American Council for Freight Efficiency. “Confidence Findings on the Potential of 6x2 Axles.” January 2014. Page 19.} In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

With respect to OOIDA’s general comment about safety of 6x2 axles, the agencies considered NACFE’s confidence report on 6x2 axles that identifies a potential benefit of 6x2 axles because they add stability when operating on slippery roads, and possibly prevent jack-knife conditions.\footnote{North American Council for Freight Efficiency. Confidence Findings on the Potential of 6x2 Axles. 2014. Pages 30-33.} Also noted in the NACFE report, technologies such as load shifting can increase the weight over the drive axle to improve traction at low speed to alleviate that concern.

Vehicle Speed Limiters

The agencies are not premising these final Phase 2 standards on use of VSL. However, we are continuing to allow VSL as an input to the GEM simulations. The Department of Transportation Volpe Center’s 2015 report titled “Review and Analysis of Potential Safety Impacts and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles” summarizes research and analysis findings on potential safety issues associated with both the diverse alternative fuels (natural gas-CNG and LNG, propane, biodiesel, and power train electrification), and the specific FE technologies recently adopted by the MD/HDV fleets.\footnote{Brecher, A., Epstein, A. K., & Breck, A. (2015, June). Review and analysis of potential safety impacts of and regulatory barriers to fuel efficiency technologies and alternative fuels in medium- and heavy-duty vehicles. (Report No. DOT HS 812 159). Washington, DC: National Highway Traffic Safety Administration.} These include Intelligent Transportation Systems (ITS) and telematics, speed limiters, idle reduction devices, tire technologies (single-wide tires, and tire pressure monitoring systems-TPMS and Automated Tire Inflation Systems-ATIS), aerodynamic components, vehicle light-weighting materials, and Long Combination Vehicles (LCVs). The safety findings from literature review pertaining to the specific FE technologies implemented to date in the
MD/HDV fleet found that both experience abroad and the cited US studies of trucks equipped with active speed limiters indicated a safety benefit, as measured by up to 50 percent reduced crash rates, in addition to fuel savings and other benefits, with good CMV driver acceptance. Any negative aspects were small and avoidable if all the speed limitation devices were set to the same speed, so there will be less need for overtaking at highway speeds.

Weight Reduction

The Department of Transportation Volpe Center’s 2015 report titled “Review and Analysis of Potential Safety Impacts and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles” summarizes research and analysis findings on potential safety issues associated with both the diverse alternative fuels (natural gas-CNG and LNG, propane, biodiesel, and power train electrification), and the specific FE technologies recently adopted by the MD/HDV fleets. These include Intelligent Transportation Systems (ITS) and telematics, speed limiters, idle reduction devices, tire technologies (single-wide tires, and tire pressure monitoring systems-TPMS and Automated Tire Inflation Systems-ATIS), aerodynamic components, vehicle light-weighting materials, and Long Combination Vehicles (LCVs). The scenario-based hazard analysis, based on the literature review and experts’ inputs, indicates that MD/HDVs equipped with advanced FE technologies and/or using alternative fuels have manageable potentially adverse safety impacts. The findings suggest that the potential safety hazards identified during operation, maintenance, and crash scenarios can be prevented or mitigated by complying with safety regulations and voluntary standards and industry best practices. The study also did not identify any major regulatory barriers to rapid adoption of FE technologies and alternative fuels by the MD/HDV fleet.

Aerodynamics Baseline

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. The baseline was not determined by or declared to be the average results of the vehicles tested, as some commenters maintained. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for Phase 2. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin C_dA values.

Aerodynamics

The agencies’ assessment is that the best aerodynamic tractor tested by EPA in 2015 achieved Bin IV performance. This vehicle did not include all of the possible aerodynamic technologies, such as wheel

---

covers or active aerodynamics like a grill shutter or front air dam. Thus, the agencies’ assessment is that Bin V is achievable with known aerodynamic technologies, as discussed in RIA Chapter 2.4, but agree with the manufacturers that Bins VI and VII have less known technology paths. However, we are including Bins VI and VII in the Phase 2 regulations as a potential Phase 2 technology to recognize the possibility that over the next ten years (until the full implementation of the Phase 2 program) tractor manufacturers may advance their aerodynamic technologies beyond the Bin V levels projected for the Phase 2 standards, and to provide a value to be input to GEM should they do so. In consideration of the comments, the agencies have adjusted the aerodynamic adoption rate for Class 8 high roof sleeper cabs used to set the final standards in 2021, 2024, and 2027 MYs (i.e., the degree of technology adoption on which the stringency of the standard is premised). Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the proposed Bin V level of $C_dA$. The changes required for Bin V and better performance reflect the kinds of improvements projected in the Department of Energy’s SuperTruck program. That program assumes that such systems can be demonstrated on vehicles by 2017. In this case, the agencies are projecting that truck manufacturers will be able to begin implementing these demonstrated aerodynamic technologies as early as 2021 MY on a limited scale. Accordingly, we adjusted the adoption rates for MY 2027 in the technology package developed for the final rule to consist of 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors in this segment that we project could successfully apply these aerodynamic packages with this amount of lead time. Overall, while the agencies are now projecting slightly less benefit from aerodynamic improvements than we did in the NPRM, the actual aerodynamic technology being projected is very similar to what was projected at the time of NPRM.

With respect to the comments related to the aerodynamic test procedures, please see the agencies’ response to the EMA comments in Section 4.5 of this response to comments document.

**Compliance Margin/SEA**

Although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing. EPA developed a different structure for conducting SEAs to evaluate tractor aerodynamics and solicited supplemental comments on it. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur. It is important to note that, although SEAs are directed by EPA, the actual testing is conducted by the manufacturer at their chosen facilities. This minimizes many potential causes of test variability, such as differences in test trailers, test tracks, or instrumentation. Thus confidence intervals need only reflect true test-to-test variability. Also, manufacturers generally rent facilities for coastdown testing as needed, which means EPA will need to provide some advance notice to allow the manufacturer to reserve the appropriate facility. Additional discussion is included in Section III.E.2.a of the Preamble to the final rule.

See the agencies’ response to engine fuel map compliance margins in the Response to Comments Section 3.7.

**Organization:** PACCAR, Inc.
Recent Trends for Technology Development and Acceptance Dictate the Emission Levels and Timing in Alternative 3

During the past 10 years a number of significant new technologies have been developed and introduced into PACCAR brand trucks. These technologies are aimed at improving performance, fuel efficiency, and reducing emissions and include: automatic engine shutdown (AES); selective catalytic reduction (SCR); low rolling resistance tires; hybridization; aerodynamic improvements; our new MX-13 engine and our soon to be introduced MX-11 engine. What PACCAR has experienced with customers with the implementation and growth of each of these technologies aligns with the time frame that it will take to reach the full implementation of Alternative 3. [EPA-HQ-OAR-2014-0827-1204-A1 p.2]

In essence, what PACCAR has found is that its customers – most of which are commercial businesses – need to become comfortable with technologies before they will adopt them on a widespread basis. For example, when diesel particulate filters (DPF) were introduced, customers paced their purchases of new trucks to assure themselves that the trucks would provide the same performance and could be maintained in a reasonable manner. What this led to was slow initial sales that have increased gradually over the past 5-7 years. PACCAR’s experience with our new MX-13 engine followed a similar path. This is an excellent engine that was, and continues to be, highly regarded in its European configuration. Regardless of this, our customers needed time to assure themselves that this engine would meet their needs in the applications for the vehicles and engine reliability and performance levels did not cause undue disruption to their business. Our customers have also moved slowly regarding adoption of aerodynamic improvement changes and low rolling resistance tires. Again, they have examined their business needs to determine when adopting these technologies make sense for them, given their unique circumstances. The penetration rate for Automatic Engine Shutdown (AES) is discussed in greater detail in Section II below. The penetration rate has been significantly lower than the agencies anticipated in Phase I, regardless of the fuel savings and emission reduction. Although AES is widely offered and available, the slow adoption is largely due to customer expectations and needs, as well as the perceived expense of the needed auxiliary systems to provide heating, cooling, and electrical power to the driver during mandated rest periods, and the associated pay-back period. [EPA-HQ-OAR-2014-0827-1204-A1 p.2-3]

What PACCAR’s decades of experience in the heavy-duty truck and engine market demonstrates is that customers consider many factors in their vehicle purchases. Clearly, fuel efficiency is high on their list, but it is not the only factor. They also want to ensure that new technologies meet their duty cycle demands, not cause undue disruption to maintenance protocols, and not significantly more expensive without offering payback within a reasonable period of time. Customers want higher residual prices to offset the initial cost increases for new technologies. [EPA-HQ-OAR-2014-0827-1204-A1 p.3]

PACCAR believes the challenges set out in meeting the standards within the time frame for Alternative 3 are considerable, but provide the greatest likelihood for a successful program. [EPA-HQ-OAR-2014-0827-1204-A1 p.3]

Revisions to Several Aspects of the Alternative 3 Standards are Needed to Make the Final Standards Challenging but Achievable and to Reflect the Current and Expected Rates of Technology Penetration

The Aerodynamics Assessments Must Be Revised

The agencies have proposed a number of changes to aerodynamic assessment in Phase 2 including, increase the number of aerodynamic bins for all roof heights, testing methodologies, data assessment approaches, wind averaged drag versus zero yaw drag determination, and notably increasing the
aerodynamic performance for stringency calculations. PACCAR does agree with the agencies’ approach to increase the number of bins but has identified several issues related to the aerodynamics assumptions used by the agencies that must be addressed. The aerodynamics baseline is incorrect, contributing to aerodynamic stringencies that are unachievable even with the best of currently-available aerodynamic technologies. The proposed aerodynamics testing provisions also must be revised in order to bring the testing process more closely in line with real-world conditions. [EPA-HQ-OAR-2014-0827-1204-A1 p.7]

**Bin Assignments Based on Cda Are too High**

The agencies have proposed to narrow and make more stringent the aerodynamic bins to which trucks must be certified under the Phase 2 program. Currently, all of PACCAR’s vehicles fall into Phase 2 Bin I and Bin II when using zero degree yaw CFD values and applying the regulatory formula CdaAwad = \((\text{CdACFD} \times \text{F}_{\text{alt-aero}}) + 0.80\). This is inconsistent with the baseline the agencies established for Phase 2. [EPA-HQ-OAR-2014-0827-1204-A1 p.7]

The agencies’ bin penetration rates for the baseline and stringency setting fail to take into account that the Phase 2 wind-averaged drag approach on the very best aerodynamic high-roof vehicles in Phase 1 will push some configurations of these vehicles lower down in the bin structure—to the bottom of Bin II, if not into Bin I. These higher aerodynamic drag configurations are the ones that will often be the high-roof equivalent of low-/mid-roof vehicles that are operating with flatbed, tanker, low-boy, or other non-box van trailers. The proposed regulation would then assign these less aerodynamic models into the Phase 2 low- and mid-roof Bin I. The NPRM does not include any Bin I penetration in the stringency setting for these roof heights, which causes concern based on the assessment of current vehicle production using the Phase 2 methodologies. [EPA-HQ-OAR-2014-0827-1204-A1 p.7]

Also, for 2027 stringency, the agencies anticipate a greater percentage of Bin IV low- and mid-roof vehicles than are expected in the “equivalent” high-roof category, Bin VII. The proposal is based on 10% Bin IV low- and mid-roof vehicle penetration, compared for 5% for the high-roof category. PACCAR requests the agencies reconsider the penetration rates for low- and mid-roof tractors. [EPA-HQ-OAR-2014-0827-1204-A1 p.7-8]

Across the board, the low- and mid-roof penetration rates should be concentrated lower in the bin structure (higher Cda values) than the high-roof bins because the low- and mid-roof vehicle configurations cannot use all the same aerodynamic improvement technologies like full length chassis fairings or side extenders. Therefore, these vehicles cannot reach the lower Cda values of the better performing high-roof vehicles for determining the placement in the low-/mid-roof bin structure. PACCAR recommends a change to these penetration rates to better reflect the vehicle configurations that are required by customers in these segments. [EPA-HQ-OAR-2014-0827-1204-A1 p.8]

In addition, the agencies should review the proposed Phase 2 Bin designations for the range of vehicles being offered by OEMs, particularly how baseline vehicles and the concept SuperTrucks would be classified. As currently proposed, the Peterbilt SuperTruck would be placed in Phase 2 Bin IV when assessed with the Phase 2 standard trailer, despite being one of the most advanced aerodynamic vehicles. PACCAR’s understanding is that the Freightliner SuperTruck, also an advanced vehicle in terms of aerodynamic improvements, would be classified as Phase 2, Bin IV or maybe as high as Bin V with the Phase 2 trailer. Once the Peterbilt SuperTruck production opportunity is evaluated, however, it may become clear that not all of the demonstrated aerodynamic improvements can be implemented for real-world use, or that some technologies may not achieve the expected benefits or do not work as well as anticipated in combination with other technologies. PACCAR therefore believes that the proposed vehicle Bin designations are unnecessarily stringent and recommends that the agencies revise the aerodynamic
cut-offs for each bin so that the best-performing SuperTruck is designated as Phase 2, Bin VI. Revising the Bin designations in this manner would reflect the best-available technologies expected to be offered under the Phase 2 program, while also leaving open Bin VII as a target for even greater technological advancement on aerodynamics if they can be developed. PACCAR also makes this recommendation based on our understanding of current aerodynamic technology penetration rates and consumer acceptance patterns, which are discussed more fully below. [EPA-HQ-OAR-2014-0827-1204-A1 p.8]

It is recommended that vehicles maintain their zero-degree yaw Phase 1 aerodynamic bin placement in Phase 2, as one of the agencies’ test vehicles, the Kenworth T700, is shown to do in the image below. To assist in the proper definition of the new aero bins, it is also recommended that the DOE SuperTruck tractors, when assessed with the Phase 2 reference trailer, should be placed in the upper portion of aero Bin VI. The vehicle placement and bin boundaries should use the agencies default wind-average drag factor of 0.80 m2. [EPA-HQ-OAR-2014-0827-1204-A1 p.8]

[Graphics, showing proposed aerodynamic bins, can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1204-A1]

For day cab vehicles, PACCAR believes the agencies have dramatically overestimated the baseline penetration rates, stringency setting bin penetration rates, and assumptions on aerodynamic improvements that are possible. The day cab aero CdA chart below for MY2016 shows that the day cab version of the most aerodynamic sleeper cab models cannot attain Bin IV levels in Phase I, let alone Bin V in Phase 2. Day cabs do not have the same aerodynamic enhancement capabilities that sleeper cabs do so the Phase 2 aerodynamic bin structure must be established to reflect this reality. [EPA-HQ-OAR-2014-0827-1204-A1 p.9]

PACCAR also has concerns about the ability to plan for compliance without knowing how the agencies intend to finalize the Bin designations. If the agencies revise the Bin cut-offs to be aligned with actual current and future vehicle aerodynamic performance, as recommended above, then PACCAR believes the standards will be challenging but potentially achievable, depending on the aerodynamic bin penetration rates. However, if the agencies retain the Bin designations from the proposed rule, compliance will be all but impossible. PACCAR requests that the agencies provide additional information about the intended final Bin cut-offs to enable additional compliance planning and provide the opportunity to provide feedback regarding any changes. [EPA-HQ-OAR-2014-0827-1204-A1 p.9-10]

The Technology Baselines and Adoption Rates Used in Developing the Proposed Standards are Overly Optimistic and Should Be Revised

The agencies’ baseline technology assumptions are too high, particularly as they apply to automatic engine shutdown (AES) for sleepers. EPA and NHTSA have also over-estimated the rate at which manufacturers will be able to offer, and customers will adopt, new emission-reduction technologies. While PACCAR sees this as an issue with regard to Alternative 3 standards, this would be an even greater problem if Alternative 4 were to be adopted. [EPA-HQ-OAR-2014-0827-1204-A1 p.13-14]

The Agencies Overestimate the Current Use of GHG-Compliance Automatic Engine Shutdown Systems in the Marketplace

In the proposal, the agencies developed technology baseline and adoption rates for AES systems based on the current rate of auxiliary power units (APUs) installed in vehicles in-use. The agencies are likely correct that approximately 30% of in-use vehicles have APUs installed, none of which are installed at the manufacturing factories under PACCAR direction. Virtually all tractors in the field have an automatic
shutdown programmed in their engine; however, less than 1% of PACCAR vehicles sold in recent years have fully GHG-compliant AES systems that are triggered in less than five minutes and cannot be reprogrammed for 1.259 million miles. Both of these requirements must be met in order for the AES system to receive full credit under the Phase 1 and Phase 2 GHG programs. Additional PACCAR vehicles have partial-credit AES systems that cannot be reprogrammed for 500,000 miles, but the total of full-credit and partial-credit is still under 1% of all vehicles sold since the start of Phase I in MY2014. [EPA-HQ-OAR-2014-0827-1204-A1 p.14]

The agencies estimate that 80% of all sleeper-cab vehicles would be required to have 1.259 million mile-certified systems by model year 2021 in order to meet the Phase 2 standards. For 2024-27 model years, that percentage increases to 90% of all sleeper-cab vehicles. These are extremely ambitious and unachievable targets considering that less than 1% of current PACCAR sleeper-cab production includes these GHG-compliant AES systems. EMA discussions indicate a similar limited penetration for other OEMs. [EPA-HQ-OAR-2014-0827-1204-A1 p.14]

In addition, many customers do not want 1.259 million mile AES systems, either because of the short time at idle before the AES is triggered or because this technology also requires the use of a diesel or battery APU in order to avoid undesirable sleeping conditions for the driver during Hours of Service required off-duty time. The cost of a diesel or battery-based APU is $8,570 to $11,263 for each chassis that requires this technology, which is much higher than the APU total cost (TC) of $4,899 that EPA estimated for 2021 in RIA Table 2-172 (shown below). The cost of the diesel APU increases by approximately $3,200 if a diesel particulate filter is added to meet the regulatory requirements of California. [EPA-HQ-OAR-2014-0827-1204-A1 p.14]

[The table, Costs for Auxiliary Power Units (APU) Sleeper Cab Tractors, can be found on p.15 of docket number EPA-HQ-OAR-2014-0827-1204-A1]

The agencies also vastly underestimated financial impact to vehicle owners by averaging the compliance costs across the entire industry. These estimates do not adequately demonstrate the full costs to individual owners. Each individual customer who must purchase an AES/APU system will have to pay the full cost of that system and not the average cost that the agencies have included in the RIA calculation. This cost will be incurred for every new sleeper cab tractor that is purchased since APUs stays with the old vehicles when they are sold by the original owner. [EPA-HQ-OAR-2014-0827-1204-A1 p.15]

As was stated previously, nearly all tractors with sleepers utilize an automatic engine shutdown system. The technology adds benefit but the requirement to lock it to a 5-minute or less shutdown for 1.259 million miles devalues the vehicle in the resale market. Since the technology is being used and is infrequently changed by the first owner, PACCAR requests the agencies consider partial credit for AES systems that are programmed to a 5-minute or sooner shutdown but are not tamper-resistant to changes by an owner. PACCAR will work with the agencies to determine the proper credit value based on the fuel savings associated with non-tamper-resistant AES systems. [EPA-HQ-OAR-2014-0827-1204-A1 p.15]

PACCAR urges the agencies to reconsider the expected penetration rate of 1.259 million mile AES systems, based on the number of such systems currently in use, and establish more realistic adoption rates with the current baseline in mind. PACCAR also recommends that the agencies reevaluate the costs of such systems and to recognize that each individual customer purchasing an AES/APU system must bear the full cost of that system. [EPA-HQ-OAR-2014-0827-1204-A1 p.15]

The Drive Tire Rolling Resistance Values Should be Tailored to Each Market Subcategory as in Phase 1
The proposal establishes an industry-wide drive tire rolling resistance value without differentiating between types of vehicles, markets, and location of use. The agencies should revise these values to reflect the reality that different market subcategories require different types of tires with different rolling resistance. A single value for all tractor regulatory subcategories does not fit this industry. Tractors with low- and mid-roof configurations have different tire requirements than tractors hauling trailers down the highway at 55-to-65 miles per hour. Customers with low- and mid-roof configurations typically operate more in urban areas where tires must withstand the abuse of curbs and other obstacles. The tires for these vehicles are designed with additional side wall protection and generally have a higher coefficient of rolling resistance. Also, these vehicles are operated in more on/off road conditions that are typical for flatbed, tanker, and low-boy operations, which use the low and mid-roof configuration vehicles. Because of these two operational needs, the tire rolling resistance penetration values for stringency calculation should be adjusted to reflect the realities and needs of the market. Below is a table showing the rolling resistance change for low- and mid-roof families as compared to the equivalent high roof regulatory subcategory. Individual owners also have preferences about tire rolling resistance, particularly for use in colder, snowier, and icier conditions. [EPA-HQ-OAR-2014-0827-1204-A1 p.15-16]

[The table, Tire Crr Value Differences - High Roof vs. Low and Mid Roof, can be found on p.16 of docket number EPA-HQ-OAR-2014-0827-1204-A1]

The Agencies’ Expectations for Developments in Advanced Transmission Technologies are Overly Optimistic

The agencies’ proposed rule indicates that they expect dual-clutch transmissions to be available in MY2021. However, PACCAR and other OEMs do not currently have heavy-duty dual-clutch transmission prototypes in development, much less close to production for use in MY2021. As with all new technologies, adoption rates differ between vehicles and uses. Some advanced transmissions are likely to be adopted more quickly in some categories of vehicles and more slowly in others. Different types of new transmission technologies are also likely to be implemented at various rates, depending on how much of an advantage the technology offers, the cost, and the payback period for customers. PACCAR recommends that the agencies take a more detailed approach to assessing transmission advances and revise the agencies’ estimate to reflect technologies that are already under true consideration for use in production powertrains. [EPA-HQ-OAR-2014-0827-1204-A1 p.16]

Use of 6x2 Axle Configuration is not Appropriate for All Vehicles in All Circumstances

In the proposal, the agencies assume a broad shift from 6x4 chassis to 6x2 axle configuration and a corresponding GHG reduction/fuel efficiency increase due to the decreased tire drag. However, not all vehicles operating in all conditions can switch to 6x2 axles due to performance considerations. Some jurisdictions also prohibit 6x2 axles in certain areas or under certain operating conditions. A full list of restrictions by state and province can be located as an appendix of the Truck and Engine Manufacturers Association comments. [EPA-HQ-OAR-2014-0827-1204-A1 p.17]

Customers also have preferences regarding 6x4 or 6x2 axles and are likely to resist being pushed toward using the latter for all type vehicles in many locations or driving conditions. PACCAR recommends that the agencies reevaluate the assumptions made about the rate at which the industry can shift to 6x2 axles and take into account the lower penetration rate when establishing the overall stringency of the GHG emission and fuel efficiency standards. PACCAR supports EMA’s comments on this issue. [EPA-HQ-OAR-2014-0827-1204-A1 p.17]
Also, the definition of “composite” should be broadened to include materials other than thermoplastics. PACCAR recommends EPA broaden the materials to thermoplastics, thermostets, and fiber reinforced plastics. [EPA-HQ-OAR-2014-0827-1204-A1 p.31]

Speed Limiters

The Agencies should provide partial credit for speed limiter devices that are set below 65 MPH even if these are not tamper-resistant. PACCAR and its customers’ experience is that drivers cannot change these devices once they are in place and customers make changes, up or down, only if it increases the overall efficiency of the vehicle and the fleet or is required to complete the assigned task within the required time. PACCAR will work with the Agencies to determine the proper credit value based on the fuel savings associated with lower speeds. [EPA-HQ-OAR-2014-0827-1204-A1 p.24]

Tire Pressure Monitoring

The feedback PACCAR has received from its customers is that vehicle operators pay attention to tire pressure monitoring systems (TPMS) and like them. These customers’ maintenance practices allow them to gain the same or near same benefits from a tire pressure monitoring system as they do from a more expensive automated tire inflation system. As is stated in the NPRM, proper tire pressure helps optimize fuel efficiency and reduce GHG emissions. In addition to GHG reduction benefit in GEM for the automated tire inflation system, PACCAR joins EMA in requesting credit in GEM for the TPMS technology. PACCAR will work with the Agencies to develop the proper credit amount. [EPA-HQ-OAR-2014-0827-1204-A1 p.24]

Response:

Alternative 3 Timing

The agencies considered all of the general comments associated with the proposed Alternative 3 and Alternative 4 tractor standards. We believe there is merit in many of the detailed comments received regarding technologies and lead time. Instead of merely choosing from among the proposed alternatives, the agencies have developed a set of final tractor standards that reflect our reevaluation of the ability to pull ahead certain technologies, the limitations in adoption rates and/or effectiveness of other technologies, and consideration of additional technologies. In general, the final Phase 2 tractor standards are similar in overall stringency as the levels proposed in Alternative 3, but have been determined using new technology packages that reflect consideration of all of the technology comments, and in several respects reflect greater stringency than the proposed Alternative 3. In addition, the agencies are fully aware, and agree with, the commenter’s statement that fleet owners do not rush in to purchase new technologies but need a period to assure themselves of a new technology’s efficacy and reliability. The final standards are structured with this phenomenon in mind. Thus, the initial 2021 standards reflect very modest penetration rates for advanced technologies, with greater penetration in MY 2024, and with aggressive penetration rates generally deferred until MY 2027.

Aerodynamics

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. EPA conducted coastdown
testing of the four major tractor manufacturer’s (including one produced by PACCAR) high roof sleeper cab tractors. We tested each in two configurations – (1) using a Phase 1 standard trailer without skirts and the Phase 1 data analysis approach and (2) using a Phase 2 standard trailer with skirts and the Phase 2 data analysis approach. The agencies note that we are not adopting the default 0.8 m$^2$ conversion from zero degree yaw to wind average drag for the final rule because the agencies are adopting a surrogate angle (4.5 degree) approach to reduce the testing burden. Therefore, the default value no longer would serve the purpose of reducing test burden. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for the Phase 2 NPRM. The aerodynamic performance of the tractors tested by EPA were recalculated for the final rule using the final aerodynamic test procedures. See RIA Chapter 3.2.1. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and standard trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. See RIA Chapter 3.2.1.2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin $C_{dA}$ values.

The agencies’ assessment is that the best aerodynamic tractor tested by EPA in 2015 achieved Bin IV performance. This vehicle did not include all of the possible aerodynamic technologies, such as wheel covers or active aerodynamics like a grill shutter or front air dam. Thus, the agencies’ assessment is that Bin V is achievable with known aerodynamic technologies, as discussed in RIA Chapter 2.8.2.2, but agree with the manufacturers that Bins VI and VII have less known technology paths. However, we are including Bins VI and VII in the Phase 2 regulations as a potential Phase 2 technology to recognize the possibility that over the next ten years (until the full implementation of the Phase 2 program) tractor manufacturers may advance their aerodynamic technologies beyond the Bin V levels projected for the Phase 2 standards, and to provide a value to be input to GEM should they do so.

In Phase 1, the agencies determined the stringency of the tractor standards through the use of a mix of aerodynamic bins in the technology packages. For example, we included 10 percent Bin II, 70 percent Bin III, and 20 percent Bin IV in the high roof sleeper cab tractor standard. The weighted average aerodynamic performance of this technology package is equivalent to Bin III. 76 FR 57211. In consideration of the comments, the agencies have adjusted the aerodynamic adoption rate for Class 8 high roof sleeper cabs used to set the final standards in 2021, 2024, and 2027 MYs (i.e., the degree of technology adoption on which the stringency of the standard is premised). Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of $C_{dA}$, as discussed above and in RIA Chapter 2.8.2.2. Consequently, the final standards are not premised on any adoption of Bin VI and VII technologies. Accordingly, we determined the adoption rates in the technology packages developed for the final rule using a similar approach as Phase 1 - spanning three aerodynamic bins and not setting adoption rates in the most aerodynamic bin(s) - to reflect that there are some vehicles whose operation limits the applicability of some aerodynamic technologies. We set the MY 2027 high roof sleeper cab tractor standards using a technology package that included 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors that we project could successfully apply these aerodynamic packages with this amount of lead time. The weighted average of this set of adoption rates is equivalent to a tractor aerodynamic performance near the border between Bin IV and Bin V. We believe that there is sufficient lead time to develop aerodynamic tractors that can move the entire high roof sleeper cab aerodynamic performance to be as good as or better than today’s SmartWay designated tractors.

The agencies phased-in the aerodynamic technology adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these
technologies. The changes required for Bin V performance reflect the kinds of improvements projected in the Department of Energy’s SuperTruck program. That program has demonstrated tractor-trailers in 2015 with significant aerodynamic technologies. For the final rule, the agencies are projecting that truck manufacturers will be able to begin implementing some of these aerodynamic technologies on high roof tractors as early as 2021 MY on a limited scale. For example, in the 2021 MY technology package, the agencies have assumed that 10 percent of high roof sleeper cabs will have aerodynamics better than today’s best tractors. This phase-in structure is consistent with the normal manner in which manufacturers introduce new technology to manage limited research and development budgets as well as to allow them to work with fleets to fully evaluate in-use reliability before a technology is applied fleet-wide. The agencies believe the phase-in schedule will allow manufacturers to complete these normal processes. Overall, while the agencies are now projecting slightly less benefit from aerodynamic improvements than we did in the NPRM, the actual aerodynamic technologies being projected are very similar to what was projected at the time of NPRM (however, these vehicles fall into Bin V in the final rule, instead of Bin VI and VII in the NPRM). Importantly, our averaging, banking and trading provisions provide manufacturers with the flexibility (and incentive) to implement these technologies over time even though the standard changes in a single step.

With respect to the other tractor subcategories, the agencies recognize that there are tractor applications that require on/off-road capability and other truck functions which restrict the type of aerodynamic equipment applicable. We also recognize that these types of trucks spend less time at highway speeds where aerodynamic technologies have the greatest benefit. The 2002 VIUS data ranks trucks by major use.98 The heavy trucks usage indicates that up to 35 percent of the trucks may be used in on/off-road applications or heavier applications. The uses include construction (16 percent), agriculture (12 percent), waste management (5 percent), and mining (2 percent). Therefore, the agencies analyzed the technologies to evaluate the potential restrictions that will prevent 100 percent adoption of more advanced aerodynamic technologies for all of the tractor regulatory subcategories and developed standards with new penetration rates reflecting that these vehicles spend less time at highway speeds. For the final rule, the agencies evaluated the certification data to assess how the aerodynamic performance of high roof day cabs compare to high roof sleeper cabs. In 2014, the high roof day cabs on average are certified to one bin lower than the high roof sleeper cabs.99 Consistent with the public comments, and the certification data, the aerodynamic adoption rates used to develop the final Phase 2 standards for the high roof day cab regulatory subcategories are less aggressive than for the Class 8 sleeper cab high roof tractors. In addition, the agencies are also accordingly reducing the adoption rates in the highest bins for low and mid roof tractors to follow the changes made to the high roof subcategories because we neither proposed nor expect the aerodynamics of a low or mid roof tractor to be better than a high roof tractor.

The agencies also note that we held several discussions with the aerodynamic specialists within the tractor manufacturers between the NPRM and FRM.100 The primary purposes of these discussions were to develop robust aerodynamic test procedures and improve the understanding of the aerodynamic bin development process between all of the involved parties.

Idle Reduction Technologies

In the proposal, the agencies noted that the manufacturers were not using tamper-proof AESS to comply with the Phase 1 standards so the agencies reverted back to the baseline APU adoption rate of 30 percent used in the Phase 1 baseline. The agencies received a number of comments regarding this. In response to these comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had auxiliary power units and 96 percent of vehicles are equipped with adjustable automatic engine shutdown systems.\textsuperscript{101} Therefore, the agencies are projecting for the Phase 2 baseline that 9 percent of sleeper cabs will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS for consideration in the baseline, and none will have a tamper-proof AESS.

While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable (programmable) systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS. The agencies agree with the commenter that nearly all sleeper cabs can utilize an automatic engine shutdown system, and our adoption rates reflect this.

EPA considered the comments and more closely evaluated NHTSA’s contracted TetraTech cost report found the retail price of a diesel-powered APU with a DPF to be $10,000. The agencies used a retail price of a diesel-powered APU to be $8,000 without a DPF and $10,000 with a DPF in the cost analysis for this final rulemaking.

The comment regarding the “averaging vehicle costs across the industry” versus the vehicle equipped with a specific device or devices is an interesting take on our analysis. However, in aggregate, the average cost estimated in our analysis is the best and most meaningful measure of the projected cost of the new standards. We do not expect that a “maximum” or a “minimum” technology tractor will be built. Instead, we estimate that, on average, tractors will gradually improve fuel consumption and decrease GHG emissions such that a variety of prices and performance characteristics will continue to be available. Just because every vehicle is not “average” does not mean that we are underestimating costs, nor are we overestimating costs. In addition, our payback analysis represents the “average” vehicle but in reality some purchasers may experience payback periods that are shorter (or longer) than the average depending on the individual technologies purchased and the operation of the specific vehicle.

\textit{Low Rolling Resistance Tires}

For the proposal, the agencies used the same level of tire rolling resistance across all tractor subcategories. In our analysis of the Phase 1 certification data for the final rule development, we found that the drive tires on low and mid roof sleeper cab tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs.\textsuperscript{102} This finding aligns with the commenter’s concerns raised that low and mid roof tractors require a different mix of tire attributes (fuel efficiency, wear, durability, side wall protection, cost, etc.). But we found only a minor difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our

own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. This is also consistent with the approach that we took in setting the Phase 1 tractor standards. 76 FR 57211. In addition, the final rule reflects a reduction in Level 3 tire (the lowest CRR) adoption rates for low and mid roof tractors from 25 percent in MY 2027 used at proposal (80 FR 40227) to zero percent adoption rate. The technology packages developed for the low and mid roof tractors used to determine the stringency of the MY 2027 standards in the final rule do not include any adoption rate of Level 3 drive tires to recognize the special needs of these applications, consistent with the comments noted above raising concerns about applications that limit the use of low rolling resistance tires.

DOT’s Federal Motor Carrier Safety Administration and NHTSA sponsored a test program conducted by Oak Ridge National Laboratory to explore the effects of tire rolling resistance levels on Class 8 tractor-trailer stopping distance performance over a range of loading and surface conditions. The objective was to determine whether a relationship exists between tire rolling resistance and stopping distance for vehicles of this type. The overall results of this research suggest that tire rolling resistance is not a reliable indicator of Class 8 tractor-trailer stopping distance. The correlation coefficients (R2 values) for linear regressions of wet and dry stopping distance versus overall vehicle rolling resistance values did not meet the minimum threshold for statistical significance for any of the test conditions. Correlation between CRR and stopping distance was found to be negligible for the dry tests for both loading conditions. While correlation was higher for the wet testing (showing a slight trend in which lower CRRs correspond to longer stopping distances), it still did not meet the minimum threshold for statistical significance. In terms of compliance with Federal safety standards, it was found that the stopping distance performance of the vehicle with the four tire sets studied in this research (with estimated tractor CRRs which varied by 33 percent), were well under the FMVSS No. 121 stopping distance requirements.

Advanced Transmissions

The agencies evaluated various types of transmissions. Volvo put into production in 2014 a DCT in Europe for heavy-duty tractors. For the final rule, the agencies projected 5% adoption rate of DCTs in 2021 and 10% in 2024. However, the effectiveness of DCTs is equal to the effectiveness of AMTs (2%). Therefore, if the HD manufacturers do not develop/bring a DCT to the U.S. market during the Phase 2 timeframe, the difference in stringency could be offset by installing an AMT instead, which is currently offered by all HD tractor manufacturers.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used

---

to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMART tandem offered by Meritor is just one of the examples.\textsuperscript{104} In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency.\textsuperscript{105} When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95\% of their new tractors in the past few years with 6x2s.\textsuperscript{106} In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

With respect to PACCAR’s general comment about the acceptance of 6x2 axles, the agencies considered NACFE’s confidence report on 6x2 axles that identifies a potential benefit of 6x2 axles because they add stability when operating on slippery roads, and possibly prevent jack-knife conditions.\textsuperscript{107} Also noted in the NACFE report, technologies such as load shifting can increase the weight over the drive axle to improve traction at low speed to alleviate that concern.

Weight Reduction

The agencies are not broadening the definition of thermoplastics in the Weight Reduction tables included in 40 CFR 1037.520. The values in the table are specific to thermoplastics. Manufacturers have the option to request approval for off-cycle technologies that include weight reduction of components manufactured out of other types of materials.

Speed Limiters

The agencies considered DOT’s upcoming actions with respect to mandatory vehicle speed limiters for heavy-duty trucks, but could not take it into account in this Phase 2 rulemaking because that rule is not final yet. The existing Phase 1 VSL flexibilities provide opportunities for manufacturers to account for the impact of VSLs on reducing GHG emissions and fuel consumption, while still allowing the settings to change after an “expiration” time determined by the manufacturer or to include a soft top. At this time, we believe that the Phase 1 flexibilities sufficiently balance the desire to encourage technologies that

\textsuperscript{105} Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).

reduce GHG emissions and fuel consumption while minimizing the compliance burden of trying to accommodate changes throughout the useful life of the vehicle. Therefore, the agencies are not adopting any new VSL provisions for Phase 2.

**Tire Pressure Systems**

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO$_2$ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies agree with this commenter and believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS.

**Organization:** Plastics Industry Trade Association (SPI)

**The Impact of Aerodynamics and Fuel Efficiency**

Class 8 tractor-trailers, the target of this rule making, can exhibit significant energy savings and better fuel efficiency by improving aerodynamics. [EPA-HQ-OAR-2014-0827-1225-A1 p.3]

The main causes of aerodynamic drag of a tractor-trailer, as noted in the draft Regulatory Impact Analysis, are: [EPA-HQ-OAR-2014-0827-1225-A1 p.4]

- Stagnation pressures at front end [EPA-HQ-OAR-2014-0827-1225-A1 p.4]
- Underside flow; and, [EPA-HQ-OAR-2014-0827-1225-A1 p.4]
- Wake at the rear of the trailer [EPA-HQ-OAR-2014-0827-1225-A1 p.4]

Roof fairing of sleeper cabs and day cabs has been shown to reduce stagnation pressure at the front end of Class 8 vehicles. Computational fluid dynamics modelling in the industry has shown that optimization of day cab roof fairing designs are possible.\(^7\) We encourage the agencies to provide incentive for these types of innovative technologies. [EPA-HQ-OAR-2014-0827-1225-A1 p.4]

3 RIA, p. 3-16.

**Response:**

The agencies are adopting Phase 2 tractors standards based on technology packages that include significant aerodynamic improvements of tractors.
Organization: Rubber Manufacturers Association (RMA)

V. Automatic Inflation Tire System (ATIS) and Tire Pressure Monitoring System (TPMS)

The NPRM proposes that Class 8 tractors and the trailers towed will include the technology of the Automatic Tire Inflation System (ATIS) as inputs into the Greenhouse Gas Emissions Model P2 v1.0. The NPRM GEM input for ATIS will provide a 1.0% and 1.5% CO2 and fuel consumption (FC) reduction for the tractor and trailer, respectively. The agencies solicit comment on whether GEM should also offer a credit for the installation of a Tire Pressure Monitoring System (TPMS). RMA supports a GEM credit for TPMS systems, similar to the credit being proposed for ATIS systems. [EPA-HQ-OAR-2014-0827-1304-A1 p.28-29]

In support of this GEM input credit for ATIS, The NPRM references the 2013 North American Council for Freight Efficiency “Tire Pressure Systems - Confidence Report” which states that tractor-trailers operating with all tires under-inflated by 10 psi have been shown to increase fuel consumed by up to 1 percent. ATIS and TPMS technologies have evolved since the time of the 2003 Federal Motor Carrier Safety Administration “Commercial Vehicle Tire Condition Sensors” report. [EPA-HQ-OAR-2014-0827-1304-A1 p.29]

The NPRM states that the ATIS can maintain tire pressure at a single preset level. They eliminate the need to check tire pressure manually and allow a vehicle to remain in-service despite small air leaks in one or more of its tires. Constant tire inflation systems have no involvement from the driver. They automatically sense the pressure in the tires and inflate as necessary when they lose air. However, the technology of the Tire Pressure Monitoring System (TPMS) for medium-duty and heavy-duty trucks is also another viable tool for alerts and maintenance requirements on tire inflation pressure. Properly used TPMS systems may also achieve equal results as ATI systems. Some modern systems actually notify the fleet central office if an underinflated tire is not dealt with by the vehicle operator in a timely fashion. [EPA-HQ-OAR-2014-0827-1304-A1 p.29]

In the case of TPMS for light duty vehicle tires, the environmental and safety benefits are well documented. In 2011, NHTSA conducted a review of the effectiveness of FMVSS 138, which mandates TPMS systems be installed as original equipment in all passenger cars, multipurpose passenger vehicles and trucks and buses a gross vehicle weight rating (GVWR) of 10,000 pounds or less and manufactured on or after September 1, 2007. The TPMS system must be capable of detecting any combination of tires that is/are at least 25 percent underinflated. Prior to the compliance date, some vehicles met the requirements of FMVSS 138, either voluntarily or according to the phase-in schedule included in FMVSS 138. In its study, NHTSA studied vehicles of model years 2004-2007 and found that the presence of a TPMS system led to a 55.6 percent reduction in the likelihood that a vehicle would have one tire that is significantly underinflated (25 percent or greater). In addition, NHTSA found TPMS to be effective in reducing moderate under inflation (at least 10 percent, under 25 percent), which was reduced by 35.3 percent. For light trucks and vans, the effectiveness rates were even higher, with TPMS reducing severe under inflation by 61.2 percent and moderate under inflation by 37.7 percent. NHTSA found that in 2011, the TPMS systems save $511 million in fuel costs across the vehicle fleet. [EPA-HQ-OAR-2014-0827-1304-A1 p.29-30]

Anticipated improvements in the incidence of under inflation and fuel savings would likely be greater for Class 8 trucks than for light duty vehicles. Since most Class 8 tractors and trailers are managed by professional fleets, tires typically are treated as a valuable commodity and managed as company assets. In addition, since fuel is the largest single cost for a fleet, conserving fuel can mean significant cost savings.

Page 813 of 2127
Due to the larger fuel economy contribution made by tires of Class 8 tractor and trailers, TPMS will spur action more quickly than by a light duty vehicle owner. [EPA-HQ-OAR-2014-0827-1304-A1 p.30]

The choice of using the ATIS or TPMS provides the tools to assure tire inflation pressure maintenance and service requirements beyond the visual and manual tire inspections. [EPA-HQ-OAR-2014-0827-1304-A1 p.30]

Providing efficiency benefits to only ATIS technology neglects the benefits of correctly using TPMS. In addition, both ATIS and TPMS should carry the same benefit in terms of CO2 and fuel consumption reduction. TPMS can also provide the applications to the other Class 2b – 6 medium- and heavy-duty vehicles encompassed in the proposed Phase 2 fuel efficiency standards, in addition to the overall tire performances. [EPA-HQ-OAR-2014-0827-1304-A1 p.30]

In anticipation of the evolution of the TPMS, ATIS, and Central Tire Inflation System (CTIS) technologies, SAE International developed and published proactively, the first of their kind, three (3) standards: [EPA-HQ-OAR-2014-0827-1304-A1 p.30]

- J2848/1_201004 - Tire Pressure Monitoring Systems - For Medium and Heavy Duty Highway Vehicles
- J2848/2_201106 - Tire Pressure Systems - Maintenance (ATIS) Type For Medium and Heavy Duty Highway Vehicles
- J2848/3_201202 - Tire Pressure Systems – Management (CTIS) Type for Medium and Heavy Duty Highway Vehicles

Recently, the ISO (International Standardization Organization) TC22 Working Group 15 has initiated development of “ISO 18633 Road Vehicles – Safety enhancement in conjunction with tire inflation pressure monitoring & automatic tire inflation – Commercial vehicles.” Therefore, both ATIS and TPMS should be considered in the Phase 2 rule and carry the same benefits, i.e. input into the GEM, in terms of CO2 and fuel consumption reduction and offer the industry a choice in the technologies, especially if the Class 2b – 6 vehicles are included. [EPA-HQ-OAR-2014-0827-1304-A1 p.31]

Response:

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO₂ and fuel consumption standards using various
technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS. The agencies appreciate the additional studies related to TPMS provided by the commenter.

**Organization:** Schneider National Inc.

EPA is suggesting various technologies which, while appropriate in some applications, are inappropriate on a fleet-wide basis. Among these technologies:

**6x2 Axle Configurations.** We recognize the benefits of reduced weight and fuel savings which 6x2 axle configurations may provide. There are, however, a number of issues related to this configuration. Some relate to cost. For example, this configuration presents issues related to diminished resale value, tire cost and life. Other issues are less about costs than other impediments. This configuration may not be legally operated in all jurisdictions. As importantly, it is not appropriate for operation in all geographies as the configuration provides noticeably less traction than the standard 6x4 axle configuration. While manufacturers have offered electronic based traction solution, none are as effective as 6x4 axle configurations in providing traction either in the yard or over the road in inclement conditions. Drivers who operate in four season geographies strongly prefer 6x4, and the preference is strong enough to impact driver retention and attraction for hiring. When all costs are considered, the overall cost is unfavorable except for vehicles which are restricted to southern climates without snow and ice. [EPA-HQ-OAR-2014-0827-1201-A1 p.2]

**6x2 Axle Configurations.** The cost should include loss on resale value, increased tire wear, and cost for electronic technology to improve traction. [EPA-HQ-OAR-2014-0827-1201-A1 p.3]

**Auxiliary Power Units (‘APUs’).** Our entire sleeper fleet is equipped with diesel fired heaters, and electric APUs are primarily used in southern climates where drivers are required to sleep in extreme temperatures. The APUs are heavy, expensive, and require significant maintenance. The payback for even the lowest cost APU is unfavorable for a five year tractor life. While APUs are an appropriate approach when dealing with vehicles manufactured prior to 2014, they are not appropriate with more recently manufactured vehicles. Diesel engines produced after 2014 produce a suitable vehicle cab temperature by idling at very low RPMs, consuming .75 gallon per hour of idle, and produce few emissions. Mandating APUs in the context of newer vehicles would reduce vehicle payloads, add the cost of a potentially unreliable APU, and not materially improve air quality or overall energy consumption. [EPA-HQ-OAR-2014-0827-1201-A1 p.2]

**APU** — An electronic APU will have an initial cost of at least $5,000 plus maintenance of $500/year. Engine powered APUs are 2-3x the electric costs, and must also add maintenance costs. [EPA-HQ-OAR-2014-0827-1201-A1 p.3]

**Wide Base Single Tires (‘WBS’).** The fleet uses low rolling resistance tires (‘LRR’) on dual wheels for the majority of the standard fleet while using wide-based single (‘WBS’) tires for weight sensitive portions of the fleet. Regulations should not, in Schneider's estimation, force the use of WBS based solely on rolling resistance advantages without considering the overall performance. Key disadvantages of WBS tires include their wear rate and limited recapping capacity as contrasted to dual tires. Broader use of WBS tires will increase waste, the number of scrapped tire casings and landfill requirements. In addition, WBS tires increase costs as a result of an increase in required service calls and increased downtime when a flat tire is experienced, as well as diminished resale value. LRR dual tires are very comparable to WBS tires.
in fuel efficiency while providing better overall operating and economic efficiency. [EPA-HQ-OAR-2014-0827-1201-A1 p.2-3]

**WBS Tires** — tire costs must include additional service costs, cost of reduced tire life, increased replacement tire costs due to recaps not available, and reduced resale value. [EPA-HQ-OAR-2014-0827-1201-A1 p.3]

For the reasons stated above, the listed technologies should not be required to be adopted on a fleet-wide basis. [EPA-HQ-OAR-2014-0827-1201-A1 p.3]

**Response:**

### 6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s. In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

With respect to Schneider’s comment about the of 6x2 axles in all geographies, the agencies considered NACFE’s confidence report on 6x2 axles that identifies a potential benefit of 6x2 axles because they add stability when operating on slippery roads, and possibly prevent jack-knife conditions. Also noted in

---

109 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
the NACFE report, technologies such as load shifting can increase the weight over the drive axle to improve traction at low speed to alleviate that concern.

The agencies considered the maintenance impact of 6x2 axles. As noted in the NACFE Confidence Report on 6x2 axles, the industry expects an overall reduction in maintenance costs and labor for vehicles with a 6x2 configuration as compared to a 6x4 configuration.\textsuperscript{112} Among other savings, the reduction in number of parts, such as the interaxle drive shaft, will reduce the number of lubrication procedures needed and reduce the overall quantity of differential fluid needed at change intervals. The agencies have taken an approach to the maintenance costs for the 6x2 technology where we believe that the overall impact will to be zero. In addition, the agencies reviewed the NACFE confidence report in terms of resale value. NACFE found in their surveys that some fleets have experienced no issues with resale of tractors with 6x2 axles, while other still believe that it may impact resale. NACFE also noted many believed “that the resale value of 6x2s is rising as the technology is better understood and the industry becomes better educated on its limitations.”\textsuperscript{113}

\textit{Idle Reduction Technologies}

There is a misconception of the proposed Phase 2 program where stakeholders thought that the agencies were mandating APUs. This is incorrect. The tractor standards are performance standards. The agencies merely \textit{projected} an adoption rate of up to 90 percent for tamper-proof AESS in our analysis for determining the proposed standard. We did not propose to differentiate between the various idle reduction technologies in terms of effectiveness and only used the diesel powered APU in terms of determining the cost and effectiveness. Also, because the standards are performance standards, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies (including diesel fired heaters and battery powered APUs) and only projected adoption of idle reduction technologies with adjustable AESS.

The agencies added maintenance costs for diesel powered APUs, battery powered APUs, and diesel fired heaters into the cost analysis for the final rulemaking, as described in RIA Chapter 7.2.3. We have estimated the cost of the battery powered APU technology at $6400 retail price. The agencies used a retail price of a diesel-powered APU to be $8,000 without a DPF and $10,000 with a DPF in the cost analysis for this final rulemaking.

\textit{Wide Base Single Tires}

The agencies have not mandated any use of WBS tires in either the NPRM or the final rule. We have projected technology packages that include lower rolling resistance tires, but at levels that could be achieved with dual tires.

We expect that, when replaced, the lower rolling resistance tires would be replaced by equivalent performing tires throughout the vehicle lifetime. As such, the incremental increases in costs for lower rolling resistance tires would be incurred throughout the vehicle lifetime at intervals consistent with current tire replacement intervals. A recent study conducted by ATA’s Technology and Maintenance

\textsuperscript{113} Ibid. Page 36.
Council found through surveys of 51 fleets that low rolling resistance tires and wide base single tires lasted longer than standard tractor tires.\textsuperscript{114} Due to the uncertainty regarding the life expectancy of the LRR tires, we conservatively maintained the current tire replacement intervals in our cost analysis.

**Organization:** Truck & Engine Manufacturers Association (EMA)

In addition, the proposed standard trailer that is to be used during coastdown testing is configured in such a way that it will actually preclude certification to the more stringent aerodynamic “Bins” incorporated into the Proposed Phase 2 Standards (i.e., Bins V-VII). That, in turn, will preclude “certified” attainment with many of the assumed improvements in aerodynamics and drag, thereby rendering infeasible one of the key premises for the proposed Phase 2 fuel efficiency standards for heavy-duty vehicles. That is a critical issue, which, in essence, undermines a foundational cornerstone of the Proposed Phase 2 Standards for heavy-duty tractors. Later in these comments, EMA describes the necessary revisions to the aerodynamic “baseline” and to the process for certifying aerodynamic improvements and accounting for those improvements in the implementation of the Phase 2 standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.4]

**Aerodynamic Baseline, Bins and Stringency**

Simply stated, the Proposed Phase 2 Standards assume unachievable aerodynamic performance. Since the Phase 2 proposal includes adjustments to the aerodynamic test trailer (adding a skirt) and to the aerodynamic certification process (utilizing wind-averaged drag), the “baseline” drag area coefficient (“CdA”) also must be adjusted for Phase 2. As it stands, the assumption in the draft Regulatory Impact Analysis (“RIA”) that all tractors would qualify for Bin III or better in Phase 2 is incorrect. In fact, it appears that the majority of current tractors may only qualify for Bin II. Even the best anticipated future-technology “SuperTruck” tractor configurations likely would only qualify for Bin IV or possibly Bin V, leaving Bins V, VI and VII largely infeasible and unachievable, which stands in stark contrast to the NPRM’s 2027 projected aerodynamic penetration-rate targets of 35\% for Bin V, 20\% for Bin VI, and 5\% for Bin VII. The agencies’ significant over-estimation of the relevant aerodynamic baseline and performance capabilities must be corrected and accounted for before the agencies finalize any Phase 2 tractor standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.6]

As explained below, the agencies’ use of an over-estimated baseline will result in infeasible aerodynamic standards. For example, EPA and NHTSA assume an average CdA of 6.23 for a “Sleeper High-Roof” vehicle. The RIA states that “most tractors today would qualify for Bin III with varying degrees of opportunity to move into improved bins.” As support for this assumption, the agencies cite to data from three sleeper vehicles tested at Southwest Research Institute (“SwRI”). But those vehicles were not “average” vehicles, as the agencies assert. Rather they were closer to the best vehicle configurations for each manufacturer. The average configuration is much more likely to fall into Bin II (or even into Bin I) for Phase 2 based on the agencies’ proposed aerodynamic test procedures and new requirements for utilizing wind-average drag. Indeed, a conversion of the baseline from Phase 1 (CdA of 6.4) to Phase 2 (with wind-average drag and trailer skirts) falls into Phase 2 Bin II. Consequently, the agencies’ assumed baseline of Bin III for Phase 2 is off by a full Bin. This 1-Bin overestimation would necessitate, on average, an 8.7\% improvement in aerodynamic performance just to reach the defined “baseline,” which, in turn, would render it infeasible to meet the more stringent requirements included in the Proposed Phase 2 Standards. Moreover, the Proposed Standards are set based on assumed significant penetrations of Bins III through VII for the 2021-2027 phase-in period. However, as noted, initial analyses of the performance

\textsuperscript{114} Truckinginfo. TMC Survey Reveals Misinformed View of Fuel-Efficient Tires. March 2015.
of the best configurations from the “SuperTruck” development program do not show attainment with Bin VI or Bin VII aerodynamic performance, with the net result being that the proposed aerodynamic targets are not achievable. [EPA-HQ-OAR-2014-0827-1269-A1 p.6-7]

The following figures depict the manner and extent to which the agencies have overestimated the assumed aerodynamic baseline for “sleeper high-roof” vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.7]

[Figure, 'Sleeper: GHG Phase I to Phase II Baseline Analysis', can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

In addition, it appears that the agencies have overstated the results obtained from the SwRI testing. As noted, the tractors that SwRI tested were “best” configurations, not average configurations. Moreover, while the SwRI report calculated the CdA coastdown results for 3 sleeper tractors as ranging between 5.76-6.37, the agencies have stated those results in the R1A, without any detailed explanation, as ranging between 5.4-5.6 (Bin III). (See Table 3-21, below). [EPA-HQ-OAR-2014-0827-1269-A1 p.8]

[Table, '3-21: Baseline Justification', can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

Other analyses confirm that the upper bins of the proposed aerodynamic standards would not be attainable. In particular, it appears that Bins V-VII will remain out-of-reach with the proposed Phase 2 test trailer, which will only include the addition of side skirts and so will not facilitate high-end aerodynamic performance. The detail of this analysis with respect to sleeper-high tractors is shown below. [EPA-HQ-OAR-2014-0827-1269-A1 p.8]

[Figure, 'Aero Improvements for Sleeper High', can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

- Bin VI & Bin VII are unachievable with the Phase 2 trailer [EPA-HQ-OAR-2014-0827-1269-A1 p.9]
- Bin V is only potentially achievable with mirror-less designs (not currently allowed) and is not possible without the inclusion of a compliance margin [EPA-HQ-OAR-2014-0827-1269-A1 p.9]

The agencies’ incorrect assumption that average high-roof vehicles will fall into Bin III instead of Bin II also will result in the corollary mid- and low-roof vehicles being included in an over-estimated Bin for the baseline as well. (See Table 5 to Proposed § 1037.520, reproduced below). Accordingly, the necessary corrections of the agencies’ over-estimation of the aerodynamic baseline will need to consider the “Mid” and “Low” roof baselines as well, in addition to the “Average” for the “High-Roof” baseline. [EPA-HQ-OAR-2014-0827-1269-A1 p.10]

[Figure, High and Mid/Low bins, can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

[Table 5, 'Bin determinations for Phase 2 Low- and Mid-Roof Tractors Based on Equivalent High-Roof Tractors', can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

In addition, the NPRM asserts that by calendar year 2020 (model year (“MY”) 2021 for heavy-duty vehicles), all new high-roof vehicles will be certified to Phase 1 Bin IV or higher, and low- and mid-roof
vehicles will be in Bin II, corresponding to high-roof Bins III and IV, which essentially would require the installation of the entire suite of SmartWay-verified technologies. However, EPA’s Bin penetration rates fail to take into account that the Phase 2 wind-averaged drag approach, even when applied to the very best aerodynamic high-roof vehicles in Phase 1, will push some configurations of those vehicles lower down in the Bin structure to the bottom of Bin II, if not into Bin I. Those higher aero-drag configurations are the same ones that will be the high-roof equivalent of low-/mid-roof vehicles operating with flatbed, tanker, low-boy, or other non-box van trailers. Consequently, the proposed Phase 2 regulation would actually force those aerodynamic models into low- and mid-roof Bin I. Significantly, and incorrectly, the NPRM does not include any Bin I penetration in the assessed stringency for those vehicle types. [EPA-HQ-OAR-2014-0827-1269-A1 p.11]

For the proposed 2027 stringencies, the agencies are assuming a greater percentage of Bin IV low- and mid-roof vehicles - 10% - than is expected in the high-roof category - 5%. That is illogical and incorrect. The low- and mid-roof penetration rates must be concentrated lower down in the Bin structure (with higher CdA values) than the high-roof Bins, because the low- and mid-roof vehicle configurations cannot use all of the assumed aerodynamic improvement technologies, such as full-length chassis fairings or side extenders, and therefore cannot reach the lower CdA values of the better-performing high-roof Bins [EPA-HQ-OAR-2014-0827-1269-A1 p.11]

With respect to day-cab vehicles, the agencies’ baseline penetration rates, stringency-setting Bin penetration rates, and assumptions regarding potential aerodynamic improvements are all dramatically overestimated. As evidenced by the day-cab aerodynamic CdA chart set forth below for MY2016 day-cabs, even the day-cab version of the most aerodynamic sleeper-cab models cannot attain Bin IV levels in Phase 1, let alone Bin V. Day-cabs simply do not have the same aerodynamic enhancement capabilities as sleeper-cabs. The Phase 2 aerodynamic Bin structure must be amended to reflect this reality. [EPA-HQ-OAR-2014-0827-1269-A1 p.11]

In light of the foregoing, it follows that the day-cab vehicle configurations are impacted even more severely by the agencies’ overestimation of the aerodynamic performance baseline, as depicted below: [EPA-HQ-OAR-2014-0827-1269-A1 p.14]

The salient fact is that the day-cab version of even the most aerodynamic vehicle model is still only in Bin III. Consequently, as depicted below, it is inherently unreasonable for the agencies to assume that day-cab models will be able to achieve similar improvements in aerodynamic performance as those envisioned for sleeper-cab models. [EPA-HQ-OAR-2014-0827-1269-A1 p.14]

- Bins V, VI and VII are unachievable for daycabs [EPA-HQ-OAR-2014-0827-1269-A1 p.15]
- The Aerodynamic Baseline is significantly off [EPA-HQ-OAR-2014-0827-1269-A1 p.15]
- The agencies’ assumed percent reduction for daycabs matches that for sleepers, even though daycabs have less opportunity for aero improvements [EPA-HQ-OAR-2014-0827-1269-A1 p.15]

- SuperTruck capabilities are sleeper-focused, not daycab-focused [EPA-HQ-OAR-2014-0827-1269-A1 p.15]

In sum, the agencies have over-estimated in fundamental ways the potential improvements in vehicle aerodynamic performance. Consequently, the Proposed Phase 2 Standards are infeasible to the extent that they have been derived from those fundamental overestimations. The agencies will need to incorporate correct and significantly revised assessments of aerodynamic performance in any final Phase 2 Standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.15]

Aerodynamics

- The assumptions that Class 7 and Class 8 high-roof vehicles will achieve a 35% penetration rate into Bin V, a 20% penetration rate into Bin VI, and a 5% penetration rate into Bin VII are grossly overstated and unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

The assumed aerodynamic performance improvements to be achieved by daycab and mid and low-roof vehicles are over-estimated by at least one Bin, and so are inherently unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

Automatic Engine Shutdown (AES) Systems

The assumptions that 90% of Class 8 sleeper caps and 90% of long-haul tractor trailers will utilize APUs to achieve extended idle emission reductions is based on grossly underestimated cost estimates and is unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

The agencies have confused the use of an APU with the use of locked-idle technologies in assessing the baseline for the Proposed Phase 2 Standards. Specifically, a 30% penetration rate by APUs is not the same as a 30% penetration rate by locked-idle systems. The assumed baseline is incorrect in that regard.

In the Phase 2 proposal, EPA has developed technology baselines and adoption rates for AES systems based on the current rate of auxiliary power units (APUs) installed in vehicles in-use. In that regard, EPA is correct that approximately 30% of in-use vehicles have APUs installed.4 While virtually all tractors have an automatic shutdown programmed in their engine, less than 1% of vehicles sold in recent years have GHG-compliant AES systems (i.e., systems that are triggered in less than five minutes and that cannot be reprogrammed for 1.259 million miles). Nonetheless, both of those requirements must be met in order for the AES system to receive full credit under the Phase 1 and Phase 2 GHG/FE programs. [EPA-HQ-OAR-2014-0827-1269-A1 p.53]

EPA estimates that 80% of all sleeper-cab vehicles would be required to have the 1.259 million mile-certified AES systems by 2021 in order to meet the Phase 2 standards. For 2024-2027, that percentage increases to 90% of all sleeper-cab vehicles. Those targets, however, are likely unachievable considering that less than 1% of current sleeper-cab production vehicles include those types of GHG-compliant AES systems. [EPA-HQ-OAR-2014-0827-1269-A1 p.53]

In addition, many customers do not want 1.259 million-mile AES systems, either because of the short time at idle before the AES is triggered, or because this technology also requires the use of a diesel or battery APU in order to avoid unhealthy “hours of service” and to provide acceptable off-duty sleeping
conditions for the driver. In that regard, the direct per-chassis cost of a diesel APU is approximately $8,500-$10,100 (the cost is even higher, approximately $11,300, for battery/electric APUs), much higher than the $2,000 per-chassis direct cost that EPA has estimated. Moreover, EPA has vastly underestimated the financial impact to vehicle owners by averaging the compliance costs (also underestimated, as noted) across the entire industry. Those estimates do not adequately represent the full costs to individual owners. While the average cost may be lower than $3,000 per vehicle using the NPRM cost figures, each individual customer who must purchase an AES/APU system will have to pay the full cost for that system and cannot average that cost across other vehicles that do not utilize those devices. [EPA-HQ-OAR-2014-0827-1269-A1 p.54]

As noted, nearly all tractors with sleepers utilize an automatic engine shutdown system. That technology adds benefit, but the requirement to permanently program it to a 5-minute or less shutdown time devalues the vehicle in the resale market. At the same time, since AES technologies are being used and are infrequently changed by the first owner, EMA requests that EPA consider partial credit for AES systems that are programmed to a 5-minute or sooner shutdown, but are not permanently locked against changes by an owner for the full 1.259 million miles. EMA will work with the agencies to determine the proper credit value based on the fuel savings associated with such non-tamper-resistant AES systems. [EPA-HQ-OAR-2014-0827-1269-A1 p.54]

EMA also urges EPA to reconsider the expected penetration rate of 1.259 million mile AES systems, based on the number of such systems currently in use and their actual costs, and to establish more realistic adoption rates with the current baseline and actual full costs in mind. [EPA-HQ-OAR-2014-0827-1269-A1 p.54]

Assumed Penetration of “6x2” Axles

For example, “6x2” axle systems cannot be implemented as the agencies have assumed, since they are not allowed in all localities. Local and state laws pertaining to bridge loads, per-axle weights and tire-patch requirements simply make it impractical to implement “6x2” axle configurations at the rate of penetration that the agencies have forecast. There are similar impracticalities with respect to the agencies’ other forecasted penetration rates as well. As a result, a three-year pull-ahead of already overstated penetration rates would only serve to exacerbate the infeasibility of the proposed vehicle program, cause significant market disruptions, and would result in disproportionately costly and delayed reductions in GHG emissions. [EPA-HQ-OAR-2014-0827-1269-A1 p.55

The agencies’ assumptions regarding the penetration targets of 6x2 tractors are inconsistent with the laws in the U.S. and Canada, and would lead to the manufacture of tractors that are unusable in many states and provinces during inclement weather. Contrary to the agencies’ projections, manufacturers forecast a 6x2 penetration rate of less than 5%, which is far below the agencies’ assumption of a 60% penetration rate for Class 8 High-Roof Tractors in 2027. [EPA-HQ-OAR-2014-0827-1269-A1 p.62]

In that regard, it is important to remember that going from a 6x4 to a 6x2 tractor configuration is not a clear-cut decision. There are many factors involved, including concerns about (i) the inherent rapid tire wear on the drive axle; and (ii) the practical inability to drive 6x2s in six U.S. states – due to the traction issues, and the limited ability to shift loads onto the drive axle to get enough traction – and in one province, where 6x2s are prohibited at the weights at which heavy-duty vehicles often operate. (See Map below depicting 6x2 axle compliance issues). (See also Appended Survey (“Appendix 2”) of State and Provincial Regulations limiting the design and deployment of 6x2 axles). [EPA-HQ-OAR-2014-0827-1269-A1 p.62]
Because heavy-duty vehicles must be designed for cross-country operation in all 50 states and in Canada, the agencies’ use of a 60% penetration rate for a technology that cannot be used in more than 10% of the states and provinces is inherently unreasonable. There are numerous issues that need to be resolved before 6x2s can be used in any more than a niche segment of the heavy-duty fleet, and the agencies should not premise regulations on a high penetration rate of a technology that faces such significant obstacles. Accordingly, until the agencies, in particular NHTSA, create an allowance to briefly overload a 6x2’s drive axle for traction purposes, and the Canadian government allows 6x2s in all provinces with temporarily shifted weights, the agencies should not predicate any aspect of the Proposed Phase 2 Standards on anything more than a 5% penetration rate for 6x2s. [EPA-HQ-OAR-2014-0827-1269-A1 p.62-63]
The assumption that 40% of all Class 7 and 8 vehicles will utilize automated tire inflation systems lacks any factual basis, overlooks the prevalence of tire inflation monitoring systems, and is unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

Response:

Aerodynamics

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. EPA conducted coastdown testing of the four major tractor manufacturer’s high roof sleeper cab tractors. We tested each in two configurations – (1) using a Phase 1 standard trailer without skirts and the Phase 1 data analysis approach and (2) using a Phase 2 standard trailer with skirts and the Phase 2 data analysis approach. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for the Phase 2 NPRM. The aerodynamic performance of the tractors tested by EPA were recalculated for the final rule using the final aerodynamic test procedures and all of the coastdown testing conducted prior to the final rule. See RIA Chapter 3.2.1. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and standard trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. See RIA Chapter 3.2.1.2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin C\textsubscript{d}A values.

The agencies’ assessment is that the best aerodynamic tractor tested by EPA in 2015 achieved Bin IV performance. This vehicle did not include all of the possible aerodynamic technologies, such as wheel covers or active aerodynamics like a grill shutter or front air dam. Thus, the agencies’ assessment is that Bin V is achievable with known aerodynamic technologies, as discussed in RIA Chapter 2.8.2.2, but agree with the manufacturers that Bins VI and VII have less known technology paths. However, we are including Bins VI and VII in the Phase 2 regulations as a potential Phase 2 technology to recognize the possibility that over the next ten years (until the full implementation of the Phase 2 program) tractor manufacturers may advance their aerodynamic technologies beyond the Bin V levels projected for the Phase 2 standards, and to provide a value to be input to GEM should they do so.
In Phase 1, the agencies determined the stringency of the tractor standards through the use of a mix of aerodynamic bins in the technology packages. For example, we included 10 percent Bin II, 70 percent Bin III, and 20 percent Bin IV in the high roof sleeper cab tractor standard. The weighted average aerodynamic performance of this technology package is equivalent to Bin III. 76 FR 57211. In consideration of the comments, the agencies have adjusted the aerodynamic adoption rate for Class 8 high roof sleeper cabs used to set the final standards in 2021, 2024, and 2027 MYs (i.e., the degree of technology adoption on which the stringency of the standard is premised). Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of $C_{dA}$, as discussed above and in RIA Chapter 2.8.2.2. Consequently, the final standards are not premised on any adoption of Bin VI and VII technologies. Accordingly, we determined the adoption rates in the technology packages developed for the final rule using a similar approach as Phase 1 - spanning three aerodynamic bins and not setting adoption rates in the most aerodynamic bin(s) - to reflect that there are some vehicles whose operation limits the applicability of some aerodynamic technologies. We set the MY 2027 high roof sleeper cab tractor standards using a technology package that included 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors that we project could successfully apply these aerodynamic packages with this amount of lead time. The weighted average of this set of adoption rates is equivalent to a tractor aerodynamic performance near the border between Bin IV and Bin V. We believe that there is sufficient lead time to develop aerodynamic tractors that can move the entire high roof sleeper cab aerodynamic performance to be as good as or better than today’s SmartWay designated tractors.

The agencies phased-in the aerodynamic technology adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies. The changes required for Bin V performance reflect the kinds of improvements projected in the Department of Energy’s SuperTruck program. That program has demonstrated tractor-trailers in 2015 with significant aerodynamic technologies. For the final rule, the agencies are projecting that truck manufacturers will be able to begin implementing some of these aerodynamic technologies on high roof tractors as early as 2021 MY on a limited scale. For example, in the 2021 MY technology package, the agencies have assumed that 10 percent of high roof sleeper cabs will have aerodynamics better than today’s best tractors. This phase-in structure is consistent with the normal manner in which manufacturers introduce new technology to manage limited research and development budgets as well as to allow them to work with fleets to fully evaluate in-use reliability before a technology is applied fleet-wide. The agencies believe the phase-in schedule will allow manufacturers to complete these normal processes. Overall, while the agencies are now projecting slightly less benefit from aerodynamic improvements than we did in the NPRM, the actual aerodynamic technologies being projected are very similar to what was projected at the time of NPRM (however, these vehicles fall into Bin V in the final rule, instead of Bin VI and VII in the NPRM). Importantly, our averaging, banking and trading provisions provide manufacturers with the flexibility (and incentive) to implement these technologies over time even though the standard changes in a single step.

With respect to the other tractor subcategories, the agencies recognize that there are tractor applications that require on/off-road capability and other truck functions which restrict the type of aerodynamic equipment applicable. We also recognize that these types of trucks spend less time at highway speeds where aerodynamic technologies have the greatest benefit. The 2002 VIUS data ranks trucks by major use.\footnote{U.S. Department of Energy. \textit{Transportation Energy Data Book}, Edition 28-2009. Table 5.7.} The heavy trucks usage indicates that up to 35 percent of the trucks may be used in on/off-road applications or heavier applications. The uses include construction (16 percent), agriculture (12 percent), waste management (5 percent), and mining (2 percent). Therefore, the agencies analyzed the...
technologies to evaluate the potential restrictions that will prevent 100 percent adoption of more advanced aerodynamic technologies for all of the tractor regulatory subcategories and developed standards with new penetration rates reflecting that these vehicles spend less time at highway speeds. For the final rule, the agencies evaluated the certification data to assess how the aerodynamic performance of high roof day cabs compare to high roof sleeper cabs. In 2014, the high roof day cabs on average are certified to one bin lower than the high roof sleeper cabs. Consistent with the public comments, and the certification data, the aerodynamic adoption rates used to develop the final Phase 2 standards for the high roof day cab regulatory subcategories are less aggressive than for the Class 8 sleeper cab high roof tractors. In addition, the agencies are also accordingly reducing the adoption rates in the highest bins for low and mid roof tractors to follow the changes made to the high roof subcategories because we neither proposed nor expect the aerodynamics of a low or mid roof tractor to be better than a high roof tractor. The agencies also note that we held several discussions with the aerodynamic specialists within the tractor manufacturers between the NPRM and FRM. The primary purposes of these discussions were to develop robust aerodynamic test procedures and improve the understanding of the aerodynamic bin development process between all of the involved parties.

**Idle Reduction Technologies**

In the proposal, the agencies noted that the manufacturers were not using tamper-proof AESS to comply with the Phase 1 standards so the agencies reverted back to the baseline APU adoption rate of 30 percent used in the Phase 1 baseline. The agencies received a number of comments regarding this. In response to these comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had auxiliary power units and 96 percent of vehicles are equipped with adjustable automatic engine shutdown systems. Therefore, the agencies are projecting for the baseline tractor that 9 percent of sleeper cabs will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS, and none will have a tamper proof AESS. This is consistent with the commenter’s assessment that “nearly all tractors with sleepers utilize an automatic engine shutdown system.”

While the agencies do not necessarily believe that customer reluctance in the initial years of Phase 1 should be considered insurmountable, we do agree with commenters that the agencies should allow adjustable AESS to be a technology input to GEM and should differentiate effectiveness based on the idle reduction technology installed by the tractor manufacturer. Phase 2 will allow a variety of both tamper-proof and adjustable systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS, and none with tamper-proof AESS.

EPA considered the comments and more closely evaluated NHTSA’s contracted TetraTech cost report found the retail price of a diesel-powered APU with a DPF to be $10,000. The agencies used a retail price of a diesel-powered APU to be $8,000 without a DPF and $10,000 with a DPF in the cost analysis for this final rulemaking.

The comment regarding the “averaging vehicle costs across the industry” versus the vehicle equipped with a specific device or devices is an interesting take on our analysis. However, in aggregate, the average cost estimated in our analysis is the best and most meaningful measure of the projected cost of the new standards. We do not expect that a “maximum” or a “minimum” technology tractor will be built. Instead, we estimate that, on average, tractors will gradually improve fuel consumption and decrease GHG emissions such that a variety of prices and performance characteristics will continue to be available. Just because every vehicle is not “average” does not mean that we are underestimating costs, nor are we overestimating costs.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples.119 In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency.120 When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s.121 In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS. Because of this change, the agencies have lowered the adoption rate of ATIS in the final rule, but added adoption rates of TPMS.

120 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
The proposed Phase 2 of the EPA’s and NHTSA’s Greenhouse Gas Emissions Standards includes only automatic tire inflation systems as an acceptable technology for maintaining tire inflation pressure in order to reduce rolling resistance, fuel consumption and greenhouse gas emissions. Tire pressure monitoring systems (TPMS) have been totally overlooked. This is most likely because the Federal Motor Carrier Safety Administration (FMCSA) and the Environmental Protection Agency have only tested and/or considered first generation TPMS that were developed over 25 years ago. [EPA-HQ-OAR-2014-0827-1255-A1 p.1]

These older TPMS provide in-cab displays that alert the driver of tire problems when they occur, but no one else is advised. This is a problem for commercial fleets since drivers are paid to deliver goods and most drivers are not interested in being tire technicians as well. If left to their own devices without instruction from their company’s dispatch office, most drivers will not care that a tire problem exists until they get to their final destinations, if then. Since maintenance was only infrequently advised of a problem by the driver, commercial fleets did not purchase these systems since their benefits were minimal. [EPA-HQ-OAR-2014-0827-1255-A1 p.1]

However, in the past 5-10 years there has been an incredible move to integrate electronic TPMS with telematics in order to provide fleet managers and technicians with visibility of their tires 24/7 even when they are hundreds of miles away. These systems analyze tire data for all the tires in the fleet and deliver insightful reports, actionable work orders, and immediate tire alerts that empower fleet management, technicians, and outsourced tire service providers to proactively improve tire maintenance rather than simply react to tire alerts. They form the basis of any good tire maintenance program by enabling fleets to measure as well as verify tire maintenance performance. [EPA-HQ-OAR-2014-0827-1255-A1 p.1]

Today’s second generation TPMS alerts are e-mailed or texted to anyone the fleet designates who has Internet connectivity on their smartphones, tablets, laptops or desktop computers. Alerts contain much more information than is possible with first generation TPMS such as vehicle location, tractor or trailer the vehicle is hooked to, a description of the alert condition, its severity, and even instructions for properly resolving the issue. Some second generation TPMS products also provide the temperature and pressure of all the other tires on the vehicle, so that the technician can be proactive and adjust pressures on any other tires that haven’t triggered an alert but are a few psi off from their target pressure. An example of an alert is to the right. [EPA-HQ-OAR-2014-0827-1255-A1 p.1-2]

If alerts are not cleared right away, technicians can receive a “work order” report that provides a listing of all the vehicles at or near their location that have alert conditions and instructions for resolving their issues. If scheduled to be run in the early morning, technicians can print off this report and address tire problems before the vehicles get on the road thereby preventing tires from running improperly inflated or overheated and reducing enroute, tire-related breakdowns as well. Below is an example of one such report. [EPA-HQ-OAR-2014-0827-1255-A1 p.2]

With the information these advanced systems provide, fleet managers can now verify that maintenance was needed and was performed properly by both their in-house technicians and outsourced tire service
providers. The example of the Daily Service History Report shown below lists alerts that were closed and provides the tire condition (temperature or pressure) of the tire before and after service was performed. It also provides the name of the technician, if known, and the location at which the service was performed. With this report the fleet manager can verify that the tire service was needed, performed to the fleet’s specifications, and hold people accountable if the service was less than satisfactory. [EPA-HQ-OAR-2014-0827-1255-A1 p.2-3]

Tire pressure monitoring systems that are integrated with telematics also are able to provide fleet management with the tools they need to measure and monitor their tire maintenance programs. Since tire data is stored in a database, these systems can provide a snapshot of the state of tire pressures across the entire fleet. Managers can monitor alert response times in both time and mileage and get at a glance an idea of the vehicles types that are prone to overheating issues. An example of such a report is below: [EPA-HQ-OAR-2014-0827-1255-A1 p.3]

[Example of Fleet Management Survey can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1255-A1]

As can be clearly seen, TPMS integrated with telematics is not your father’s tire pressure monitoring system. These systems provide visibility and information that are just not possible with TPMS 1.0 systems. They help fleets ensure that tires are run at their optimal inflation pressures for a much greater percentage of time. And yes, while someone still has to connect an inflation hose to the tire, now many people know it has to be done while in days gone by only the non-communicative driver knew. Today, with the high cost of tires, the need to conserve fuel, and reduce greenhouse gas emissions, fleets are motivated to address tire problems as soon as they can and this technology helps them to do just that. [EPA-HQ-OAR-2014-0827-1255-A1 p.3]

It should be noted that while automatic tire inflation systems (ATIS) provide pressure to tires that are losing air while the trailer runs down the road, there are some distinct disadvantages to them that by pairing second generation TPMS with them can be resolved. The first issue is that when a tire problem occurs on a trailer equipped with ATIS, only the driver is aware that the system is working to pump air to the tire. If he does not inform his vehicle maintenance department or take steps on his own to address the tire issue, no one else knows there is a tire issue. When the trailer is dropped, the tire goes flat until the next driver hooks up to the trailer. As she drives off with the trailer she may notice the light goes on indicating the system is working pumping air to the tire. However, she continues to drive since she knows the ATIS will inflate the tire again. Unfortunately, the tire is dragged flat/underinflated for many miles until it is fully inflated again. With this scenario repeating many times, when the tire is finally removed from the vehicle for low tread depth, the casing is ruined and cannot be retreaded or the tire may fail prematurely from a separation caused by continuing to inflate a punctured tire. This can be avoided by having a TPMS integrated with telematics advise fleet personnel of tire problems. In addition, second generation TPMS will also advise the fleet of the wheel position of the problem tire(s). [EPA-HQ-OAR-2014-0827-1255-A1 p.3-4]

It should be noted that automatic tire inflation systems plumbed through the axle are currently available only for trailers. ATIS for trucks, tractors, and buses must be plumbed externally. Due to their high maintenance and propensity for damage, they are not of interest to U.S. fleets. Advanced TPMS integrated with telematics are ideal for these vehicles. [EPA-HQ-OAR-2014-0827-1255-A1 p.4]

There are several TPMS companies that have either partnered with telematics service providers to transmit tire alerts and data off the vehicle or that have built telematics into their own TPMS products. The world is rapidly adopting telematics to improve safety, performance, and the
environment. TPMS integrated with telematics does all of these things and should be included in the Phase 2 of the Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles. [EPA-HQ-OAR-2014-0827-1255-A1 p.4] Note: Second generation TPMS integrated with telematics are also referred to as TPMS 2.0 systems. For more information on the capabilities of these systems, see: www.TPMS2.com [EPA-HQ-OAR-2014-0827-1255-A1 p.4]

Response:

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allows manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS, especially when linked with telematics. The agencies appreciate the information related to the latest generation of TPMS provided by the commenter.

Organization: Truck Renting and Leasing Association

Stringency is based on a 60% Penetration of 6x2 Drive Axle Type in 2027. There are many complications to such a high penetration of 6x2 drive axle types, most of which are outside of the control of the OEMs, the agencies, the lessor and the customer/lessee. [EPA-HQ-OAR-2014-0827-1140-A1 p.5]

The Agencies’ Low Rolling Resistance Tire Assumptions Do Not Reflect Customers’ Real-World Needs. While it is true that low rolling resistance tires are currently offered in different configurations (id. at 40216), the agencies merely assume that customers will continue to demand higher performing low rolling resistance tires in the future. Id. at 40221 (“the agencies expect that tire manufacturers will continue to respond to demand for more efficient tires and will offer increasing numbers of tire models with rolling resistance values significantly better than today’s typical ... tires”). That is little more than a guess about future consumer behavior. [EPA-HQ-OAR-2014-0827-1140-A1 p.5]

The Agencies Rely Upon Erroneous Assumptions of Market Penetration of Automatic Engine Shutdown Systems. The agencies estimate that 30% of the tractors in the market today already have GHG-compliant automatic engine shutdown systems (AES). Id. at 40219. That assumption is false. While most tractors do have automatic shutdowns activated on the vehicles, there are very few trucks on the road in the United States with AES options that are compliant to the regulation. The systems today allow owners to reprogram the engine to shut down after longer idling periods than the required five minutes so that different applications and seasons can be properly dealt with. The 30% number that the agencies cite could be accurate for the number of vehicles with APUs but that does not mean the vehicle automatic shutdown system is compliant. These regulated systems are seen by the industry as detrimental to fleet operational flexibilities and they hurt the resale market value of a vehicle if they cannot be reprogrammed by the second owner. [EPA-HQ-OAR-2014-0827-1140-A1 p.5]

Response:

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as
noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2, enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s.

In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found steer tires with rolling resistance as low as 4.9 and drive tires with as low as 5.1 kg/ton. The average tire rolling resistance that we used in the technology packages to derive the final rule standards are higher than the lowest rolling resistance tires made today, so the technology is feasible. With respect to the comment about assuming that customers will continue to demand low rolling resistance tires, we set performance-based standards that allow the manufacturers to produce a wide variety of products.

We also note that during the certification data analysis, we found that the drive tires on low and mid roof tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. We found less of a difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. The agencies phased-in the low rolling resistance tire adoption rates within the technology packages used to determine the MY 2021 and 2024 standards so that manufacturers can gradually introduce these technologies.

Idle Reduction Technologies

In the proposal, the agencies noted that the manufacturers were not using tamper-proof AESS to comply with the Phase 1 standards so the agencies reverted back to the baseline APU adoption rate of 30 percent.

---

123 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
used in the Phase 1 baseline. The agencies received a number of comments regarding this. In response to these comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had auxiliary power units and 96 percent of vehicles are equipped with adjustable automatic engine shutdown systems. Therefore, the agencies are projecting for the Phase 2 baseline that 9 percent of sleeper cabs will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS for consideration in the baseline, and none will have a tamper-proof AESS.

Organization: Union of Concerned Scientists (UCS)

TRACTOR VEHICLE STANDARDS

The agencies’ estimate of vehicle improvements to the tractor is largely in agreement with our estimate of the performance feasible within the timeframe of the rule, with the notable exception of improvements to the powertrain. There are two central issues that will lead to a more stringent tractor standard: 1) powertrain integration; and 2) an improved tractor engine. [EPA-HQ-OAR-2014-0827-1329-A2 p.11]

POWERTRAIN TESTING

The agencies have chosen to exclude powertrain integration from tractor-trailers, despite noting its strong effectiveness in the vocational vehicle sector. While the duty cycles of tractor-trailer contain significantly less transient operation than vocational vehicles that does not mean powertrain integration is not applicable. In fact, the SmartAdvantage powertrain from Cummins and Eaton that the agencies cite in the vocational section to justify the powertrain integration is designed for tractor-trailers. For this reason, it is a surprising omissions. [EPA-HQ-OAR-2014-0827-1329-A2 p.11]

As much as 1.3- to 2.0-percent savings from tractor-trailers could be added to the current stringency to reflect the true potential from tractor-trailers—this would further incentivize tractor manufacturers to invest in powertrain optimization, particularly since every major manufacturer already offers at least one “integrated powertrain” option in its long-haul fleet. The agencies’ “alternative engine mapping” procedure is another approach that could better capture transient operation and ensure that the regulations reward real-world operational benefits. [EPA-HQ-OAR-2014-0827-1329-A2 p.12]

IMPROVED TRACTOR ENGINE

An increase in the engine stringency as outlined above will lead to reductions in fuel usage and emissions from the vehicle itself; however, due to differences in test cycle and the agencies’ assumptions between the separate engine and vehicle standards, this relationship is not a one-to-one correlation (i.e., a 10.3-percent increase in engine stringency will not directly lead to a 10.3-percent increase in vehicle stringency). Table 3 illustrates the additional improvements to the vehicle we would expect to see based upon the engine improvements outlined in the sections titled Tractor Engine Standards and Powertrain testing. [EPA-HQ-OAR-2014-0827-1329-A2 p.12]

[Table 3, ‘Powertrain-related Vehicle Improvements’, can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

In particular, the change to the SET cycle that led to improvements on the engine standard will not result in any additional reductions to the fuel consumption or emissions of a vehicle modeled in GEM due to the direct incorporation of the engine map—therefore, we have omitted it as a source of further vehicle reductions. Downspeeding, on the other hand, is only partially captured in the vehicle simulation as it stands currently, since we are proposing a greater level of downspeeding greater than the 16 percent assumed by the agencies—the improvement assessed in Table 3 is calculated by comparing Downspeeding A and B technologies (see Reinhart 2015), since Downspeeding A is the result of 16 percent beyond the baseline DD15 engine, in concert with the agencies’ estimated level of future downspeeding. The other engine improvements are generally applicable across the entire tractor-trailer fleet, with the exception of organic waste heat recovery. While we believe that waste heat recovery is broadly applicable to a range of duty cycles, including regional haul or day cabs, the agencies’ assumed penetration rates do not reflect this assumption. Therefore, we have assumed that improvements to waste heat recovery will be reflected only in the sleeper cab fleet. [EPA-HQ-OAR-2014-0827-1329-A2 p.12-13]

OVERALL INCREASE IN TRACTOR EFFICIENCY

Combining the assessment of engine technologies beyond the agencies’ appraisal in the RIA and the use of powertrain testing for long-haul tractors, we estimated an additional 6-percent improvement by 2024 and 7-percent improvement by 2027 from tractor-trailers (Table 3). In calculating this improvement, we have applied the engine improvements as described above and have applied powertrain testing to only 70 percent (35 percent) of the fleet in 2027 (2024), similar to the fractions applicable in the vocational fleet. As mentioned earlier, though the incremental improvement may not be as great for tractor-trailers, the overall reductions in fuel usage will be similar due to increased vehicle mileage, so we would expect a similarly high uptake of integrated powertrains by 2027. [EPA-HQ-OAR-2014-0827-1329-A2 p.13]

Response:

Powertrain Testing

The agencies acknowledge UCS’s comment about increasing the stringency of the tractor program due to the opportunity to further improve powertrain optimization through powertrain testing. For the Phase 2 final rule, we have made several changes that capture much of the improvement potential highlighted by UCS. First, the required use of a cycle average fuel map in lieu of a steady state fuel map for evaluating the transient cycle in GEM will recognize improvements to transient fuel control of the engine. The agencies are including the impact of improved transient fuel control in the engine fuel maps used to derive the final standards. Second, the optional transmission efficiency test will recognize the benefits of improved gear efficiencies. The agencies have built some improvements in transmission gear efficiency into the technology package used to derive the final standards. This leaves only the optimization of the transmission shift strategy, which would need to be captured on a powertrain test. The agencies believe that the opportunity of shift strategy optimization is less for tractors than for vocational vehicles because a significant portion of the tractor drive cycles are at highway speeds with limited transmission shifting. Therefore, we have not included the powertrain optimization portion only recognized through powertrain testing into the standard setting for the final rule.
Engines

The Phase 2 engine standards will lead each manufacturer to achieve reductions of 5 percent in 2027 MY. For the final Phase 2 rule, we recognize that it could be possible to achieve greater reductions than those included in the engine standard by designing entirely new engine platforms. Unlike existing platforms, which are limited with respect to peak cylinder pressures (precluding certain efficiency improvements), new platforms can be designed to have higher cylinder pressure than today’s engines. New designs are also better able to incorporate recent improvements in materials and manufacturing, as well as other technological developments. Considered together, it is possible that a new engine platform could be 6 percent more efficient without WHR than Phase 1 engines and 8 percent more efficient than Phase 1 if 50 percent of these engines have WHR. We project that by the 2024 MY, a limited number of engine platforms will be redesigned, and therefore have pulled ahead the reduction expected from the proposed 2027 MY engine standards into the vehicle standards for 2024 MY. In addition, we project that 50 percent of tractor engines in 2027 MY will be redesigned engines (i.e. engines reflecting redesigned engine platforms, again based on existing engine platform redesign schedules within the industry) achieving a 6 percent reduction for day cabs and an 8 percent reduction in fuel consumption in sleeper cabs beyond Phase 1. This means the average 2027 MY tractor engine would be 5.4 and 6.4 percent better than Phase 1 for day and sleeper cabs respectively. We have factored these levels into our analysis of the vehicle efficiency levels that will be achievable in MY 2027. These additional engine improvements make more stringent vehicle standards feasible, and the final standards are structured so that these improved engines are not able to generate windfall credits, but rather that their projected performance is reflected in the stringency of the final tractor vehicle standard. We project all vehicle manufacturers will be able to use new platform engines for some of their vehicles. Nevertheless, some may choose not to for business reasons, even though it may be the most cost-effective path. We project that manufacturers that do not achieve this level of engine reduction would be able to make up the difference by applying one of the many other available and cost-effective tractor technologies to a greater extent or more effectively, so that there are multiple technology paths for meeting the final standards. In other words, a manufacturer that does not invest in updating engine platforms in the Phase 2 time frame (i.e. does not have a scheduled redesign within the Phase 2 period) is likely to be able to invest in improving other vehicle technologies. These reductions will show up in the fuel maps used in GEM to set the Phase 2 tractor stringencies.

Overall Increase in Tractor Stringency

The agencies considered all of the comments associated with the tractor technologies. We believe there is merit in many of the detailed comments received regarding technologies. The agencies have developed a set of final tractor standards that reflect our reevaluation of the ability to pull ahead certain technologies, the limitations in adoption rates and/or effectiveness of other technologies, and consideration of additional technologies. In general, the final Phase 2 tractor standards are similar in overall stringency as the levels proposed in Alternative 3, but have been determined using new technology packages that reflect consideration of all of the technology comments, and in several respects reflect greater stringency than the proposed Alternative 3.

Organization: United Parcel Service (UPS)

Tire Pressure Monitoring Systems should be Given Credit under the Rule

UPS fully supports ATA's position repeated below on this issue. As noted above, UPS prefers TPMS over automatic systems because we are alerted that there is a problem that we can fix. UPS makes heavy use of telematics and the TPMS is compatible with telematics. [EPA-HQ-OAR-2014-0827-1262-A1 p.9]
TPMS have not historically been included in the EPA's SmartWay program since the agency had no way to determine the effect these systems have on fuel economy unless each requesting fleet provided a clear description of how it would respond to alerts. This information was necessary so that the EPA could calculate the resulting fuel savings. However, much has transpired since the inception of the SmartWay Program. The Federal Motor Carrier Safety Administration ('FMCSA') has studied TPMS since 2006. It found that these systems accurately reported inflation pressure values within 2 to 3 psi of the measured value and accurately warned of low pressure within 2 to 3 psi of the expected threshold. In 2007, the performance and durability of TPMS was examined in a field test using transit buses. This study found that TPMS-equipped buses did not experience increased average tire pressure due to diligent tire pressure maintenance and the location of the TP1VIS display is essential to impact tire maintenance practices, fuel economy, and tire life. [EPA-HQ-OAR-2014-0827-1262-A1 p.9]

In late 2011 the FMCSA published the results of a field test it conducted over the previous 24 months of tire pressure monitoring and ATISs on two fleets that were considered to have good tire maintenance. The test revealed that both TPMS and ATISs delivered a 1.4% improvement in fuel economy. [EPA-HQ-OAR-2014-0827-1262-A1 p.9]

Technology has greatly advanced since the tests that FMCSA conducted. Today, TPMS is much more advanced than the first generation of TPMS that was tested by FMCSA which just delivers alerts to the driver in the cab through an in-cab display. Second generation TPMS (TPMS 2.0 systems) are integrated with telematics and GPS so that the tire data and alerts are sent from vehicles and delivered to a fleet's Operations and Vehicle Maintenance Department. By providing the fleet with the location and visibility of its tire problems, dispatch can provide instructions to the driver to handle developing tire problems immediately and Maintenance is aware of the exact nature of these issues when the vehicle arrives at the fleet's location. With the reports these systems provide the fleet, problem tires are ensured to be attended to before the vehicle sets out on its next trip, thereby dramatically reducing enroute breakdowns and optimizing the percentage of time tires are run properly inflated. In essence, a fleet is able to build its entire tire maintenance program around this technology and drastically improve its ongoing tire inflation maintenance. Therefore this technology has an even greater effect on fuel consumption and greenhouse gas emissions than TPMS 1.0 systems which were proven to deliver 1.4% improvement in fuel economy by the FMCSA. [EPA-HQ-OAR-2014-0827-1262-A1 p.9]

Due to the advances that have been made in TPMS 2.0 systems and the impact they have on fuel economy and greenhouse gas emissions, the Tire & Wheel (S.2) Study Group of ATAs Technology and Maintenance Council ('TMC') requests that TPMS 2.0 systems, tire pressure monitoring systems ('TPMSs') provide similar benefits of tire inflation systems at a lower cost. In fact UPS in its considerable experience prefers TPMSs over ATISs for two reasons in addition to lower costs. First, TPMSs give the truck owner an affirmative indication that there is a tire pressure problem, so it can
be fixed, whereas the ATIS does not. Second, the ATIS simply keeps adding tire pressure automatically, wasting energy, and the truck owner may never know it. This is the flip side of the concern of some that TPMSs require user interaction — user interaction ensures the truck owner can address the underlying problem. We support ATA's comments on tire inflation systems: [EPA-HQ-OAR-2014-0827-1262-A1 p.4]

'"A recent study on truck and tire inflation systems indicates that both ATISs and TPMSs are being utilized in fleet operations.' As of 2012, approximately 33% and 10% of surveyed fleets utilize ATISs and TPMSs respectively on their trailers. Roughly 1% of tractors used ATISs. Operators are well aware of the increased fuel consumption, maintenance costs, downtime, and safety concerns associated with operating heavy-duty vehicle with under-inflated tires. These concerns over time have been significant given the historic volatility of diesel prices, the competitive nature of the industry, shipper pressures to reduce costs, and the rising costs of liability. [EPA-HQ-OAR-2014-0827-1262-A1 p.4-5]

'The agencies do not acknowledge TPMSs as a viable menu option since they require user interaction to inflate tires to appropriate pressures. A misguided assumption is that drivers 'may' continue to operate a vehicle with underinflated tires. However, in light of continual pressures on fleets to reduce total costs of operation in order to remain competitive and profitable, the agencies should reconsider their rejection of TPMSs as a viable technology option under the rule. [EPA-HQ-OAR-2014-0827-1262-A1 p.5]

'Given the ability of fleets to monitor fuel consumption remotely, including the ability to identify causes for increased fuel consumption, drivers are routinely held responsible for proper tire pressure levels on TPMS-equipped vehicles. ATA therefore believes that the agencies should provide efficiency credit for TPMS use under the rule. [EPA-HQ-OAR-2014-0827-1262-A1 p.5]

Therefore, UPS strongly recommends that under the final rule the truck purchaser should have a choice between ATISs and TPMSs, and that the assumed MPR be higher for TPMSs than for ATISs. [EPA-HQ-OAR-2014-0827-1262-A1 p.5]

Errors in EPA's Baseline and Testing Protocols Result in Overly-Stringent Standards

As ATA points out in its comments, the proposed emission standards are actually more stringent than EPA has indicated. An overly stringent regulation can have several unintended consequences. It could force OEMs to offer a truck optimized for the EPA duty cycles rather than a customer's requirements, which could actually increase fuel consumption and GI-IG emissions, or render the truck inadequate for its intended use. If OEMs cannot provide the trucks that a customer needs, the customer has no choice but to continue using its existing trucks. From UPS's vantage point and the fleet we use, the actual stringency in the proposed rule is greater than what EPA has indicated due to the following error in EPA's baselines and testing protocols: [EPA-HQ-OAR-2014-0827-1262-A1 p.8]

The assumed 2017 aero baseline uses the best aero trucks available, not the average. This has the effect of increasing stringency about 2.5%. [EPA-HQ-OAR-2014-0827-1262-A1 p.8]

Aerodynamic and tire power losses for tractor-van trailer combination\(^8\)

UPS endorses ATA's recommendations in their comments: [EPA-HQ-OAR-2014-0827-1262-A1 p.11]

Response:

Tire Pressure Systems

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allow manufacturers to show compliance with the CO₂ and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS.

Please see the agencies’ responses to ATA’s comments in this Section 4.3 of the response to comments.

Organization: Volvo Group

We find a number of the technology assumptions in the NPRM are not justified because the technology is not demonstrated, does not deliver the assumed efficiency, or cannot be forced into the market at the agencies’ assumed penetration rates. These include aerodynamic drag reduction, start/stop technology, neutral idle, low rolling resistance tires, 6x2 axles, new transmissions, idle shutdown, vehicle speed limiters, hybridization, “deep integration” of driveline, and vehicle weight reductions. [EPA-HQ-OAR-2014-0827-1290-A1 p.19

Baseline Errors Increase Effective Stringency

While the agencies have stated their target efficiency improvement ranges up to 24% over the 2017 baseline for high-rise sleepers, there are significant errors in the baseline from which these targets are established. Two key issues are the assumption that 30% of 2017 sleeper tractors will utilize the regulatory automatic engine shutdown (AES) and the baseline aerodynamic assumptions. [EPA-HQ-OAR-2014-0827-1290-A1 p.19

As of now, nearly two years into mandatory application of the Phase 1 rule, virtually no truck purchaser has been willing to take the AES, nor is there any reason they would ever opt to do so. All tractors come with customer programmable idle shutdown timers. Truck owners program the idle shutdown to suit the needs of their operation while minimizing idle fuel consumption where possible. The regulatory requirement requires locking the timer to shut down after 5 minutes of idling, eliminating the flexibility to set the function to match operational needs or to change it for a second owner. Many fleets use fuel fired heaters to avoid idling in colder weather but choose to idle when cooling is required. Even if a truck is equipped with an APU for hotel operation, an owner may want to enable idling if the APU is not functioning properly, until it can be repaired, thus avoiding a mission disabling failure. Given this situation, it is unreasonable to predict that somehow 30% of purchasers would suddenly opt for the regulatory AES. Since AES is given a 5% GHG/efficiency credit, this faulty assumption amounts to a 1.5% lower baseline. [EPA-HQ-OAR-2014-0827-1290-A1 p.19]
Similarly, there is a fundamental error in the way the aerodynamic drag baseline for 2017 tractors was established. As noted in the EMA comments, the agencies evaluated some of the best aerodynamic tractors available and declared these to be the baseline. In fact, the average tractor, the true baseline, is a full bin worse than these best tractors. This error result in baseline fuel consumption and GHG emissions approximately 4.5% better (lower) than the actual baseline. [EPA-HQ-OAR-2014-0827-1290-A1 p.19]

Together, these two errors add an additional 6% in efficiency that that does not exist, and accordingly would have to be obtained through other measures beyond the agencies’ projected technologies (if even possible) to achieve the Phase 2 targets. This huge, erroneously calculated and infeasible increase in stringency has not been accounted for in any of the agencies’ technology assumptions. [EPA-HQ-OAR-2014-0827-1290-A1 p.19]

Aerodynamic Drag Targets

As noted in comments by the EMA, it is impossible to achieve the targeted aerodynamic drag reductions that ultimately are predicated on 60% of tractors achieving aero bins V, VI, and VII. Our analysis indicates it is physically impossible to achieve these low drag levels with any tractor design coupled to the non-aerodynamic test trailer prescribed in this proposal. In fact, all examples provided in the RIA of combination vehicles that can achieve the targets include a highly aerodynamic trailer. [EPA-HQ-OAR-2014-0827-1290-A1 p.20]

Either the agencies must reduce the aerodynamic targets for tractors or provide for a test trailer with advanced aerodynamics, including, at a minimum, an efficient boat-tail and side skirts. [EPA-HQ-OAR-2014-0827-1290-A1 p.20]

SuperTruck Efficiency is not an Appropriate Target

Although the U.S. Department of Energy’s SuperTruck program is an outstanding freight efficiency research program, some now argue that the results demonstrate capability to regulate to that level of increased freight efficiency. There are several issues with this supposition. The SuperTruck demonstration vehicles are after all “demonstration vehicles” - the technology is demonstrated but far from proven in terms of cost, reliability, durability, and broad applicability. Each project was funded at $40 to $80 million, so technology cost-effectiveness was not a requirement. These trucks were designed for, and demonstrated on, carefully selected routes that enhance their performance. Much of the demonstrated SuperTruck improvement was achieved by careful matching of tractor and trailer aerodynamics. No manufacturer has control of this because tractors and trailers are manufactured by different companies and purchased separately by truck fleets and shippers. In fact, the proposed Phase 2 regulatory test trailer has very limited aerodynamic features, with only side skirts but no other aerodynamic features. This severely limits the potential efficiency of the tractor-trailer combination. In fact, Volvo Group analysis determined that even though our complete SuperTruck combination could achieve aero bin VII, our SuperTruck tractor, coupled with the Phase 2 test trailer, could only achieve bin IV out of the seven Phase 2 aero bins, even though regulators ultimately expect 60% of tractors to achieve bins V, VI, or VII. Even an extremely sleek tractor coupled with a rectangular shaped box trailer cannot achieve the performance required to reach the proposed aerodynamic targets. The test trailer should represent an advanced aerodynamic design that meets the 2027 trailer targets so that future tractors are designed to operate efficiently with future trailers and the combinations can achieve the desired aerodynamic performance. Consequently, with tractors in the fleets that have been optimized for peak performance on the most aerodynamic trailers, the market pull (combined with trailer efficiency regulations) for those most aerodynamic trailers will follow, accelerating efficiency gains. [EPA-HQ-OAR-2014-0827-1290-A1 p.26-27]
Aerodynamic improvements expected to achieve tractor standards are infeasible in the context of the proposed rule and must not be factored into stringency expectations unless the issues are corrected.

As previously noted, even SuperTruck cannot achieve the expected aerodynamic targets. In fact, it is infeasible or impossible to design a tractor with drag results that will achieve bins V, VI, or VII when tested according to the proposal. Section 2.4.2.2.3 of the RIA supposedly provides examples of feasible tractor aerodynamic improvements that are, in fact, completely infeasible due to operational and regulatory constraints (e.g. exceeding length laws) and that are tested and analyzed with a highly aerodynamic trailer rather than the standard regulatory trailer. Inability to achieve the targets is caused by a number of issues with the proposal: [EPA-HQ-OAR-2014-0827-1290-A1 P.27]

- The baseline aero tractors are the best available, not the average expected during 2017.
- The proposed audit process for tractor aero performance eliminates the “one bin” compliance margin granted in the Phase 1 rule, ignoring the tremendous variability of aerodynamic measurements and the differences between possible audit methods. This requires conservative binning to ensure passing an audit.
- The aerodynamic coast-down test procedure fails to account for yaw during the test, increasing the measured drag test result. This means the aerodynamic performance is under-reported as an input to GEM.
- The aerodynamic coast-down test procedure assumes rolling resistance is a constant independent of vehicle speed. In fact, rolling resistance increases substantially with speed. This results in overestimating the vehicle drag force during the testing.
- The test trailer required by the proposal has minimal aerodynamic features. This greatly limits what can be physically achieved by tractor treatments. In fact, the expectation of advanced aerodynamic performance is predicated in the RIA on examples deploying highly aerodynamic trailers. [EPA-HQ-OAR-2014-0827-1290-A1 P.28]

All of these issues are explained more fully in comments submitted by the Truck and Engine Manufacturers. In addition, the four major US tractor manufacturers have provided a detailed proposal to EPA to resolve these issues. [EPA-HQ-OAR-2014-0827-1290-A1 P.28]

Tires

In the technology packages anticipated to set Phase 2 stringency levels, the agencies have further relied on unreasonable expectations for lower rolling resistance tires in all regulatory subcategories. Tire manufacturers have continued to claim that they are able to balance tire life, safety, and traction concerns; however, as the agencies have noted in the Regulatory Impact Analysis section 2.4.3.1, tires with higher rolling resistance are likely designed to address only some of these concerns. We continue to hear customer feedback that low rolling resistance tires often lack adequate traction. The reality is that many of the features that provide for traction, especially deep lugs and pliable sidewalls, also create high rolling resistance, but without these features many customers are finding that attaining adequate traction is nearly impossible under many of the demanding conditions that trucks and tractors experience, such as snow and off-road. Customers have stated that, in some cases, they are being pushed into low rolling resistance tires at the point of sale only to be left with no choice but to replace the tires with higher rolling resistance, traction tires immediately after taking delivery of the new vehicle. [EPA-HQ-OAR-2014-0827-1290-A1 p.21]
In addition, heavy-duty fleets expect to retread tires as many as five times and have concerns that tire casing durability may be compromised with low rolling resistance (LRR) tires. Retreading saves cost and about two thirds of the oil required to produce a new tire (reported to be between 22 and 44 gallons depending on tire size). [EPA-HQ-OAR-2014-0827-1290-A1 p.21]

With respect to highway tractor and heavy-haul tractor penetration and stringency setting the agencies show penetration of Level 3 tires starting in MY 2021. It is unclear how this can be possible given the agencies own determination that this technology “could” be achieved only in the 2025 timeframe. [EPA-HQ-OAR-2014-0827-1290-A1 p.22]

Tire Inflation

In setting vehicle stringencies, the agencies have predicated the standards for tractors on adoption of Automatic Tire Inflation Systems (ATIS), while giving no consideration to Tire Pressure Monitoring Systems (TPMS). [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

All commercial vehicle operators are well aware of the increased fuel consumption, maintenance costs, downtime, and safety concerns associated with operating a heavy vehicle with under-inflated tires. These concerns have been much more significant given the volatile diesel prices, the pricing pressure on fleets due to an unstable economy and consolidation within the industry, the continued ratcheting of safety regulations, and the rising costs of liability, all within the last decade. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

In Section 2.4.3.3 of the RIA the agencies noted that “although most fleets understand the importance of keeping tires inflated, it is likely that a substantial proportion of trucks on the road have one or more underinflated tires.” Their evidence of this assertion are two studies, one industry survey conducted by checking pressures at a truck stop in 2002, and another study conducted by the Federal Motor Carrier Safety Administration (FMCSA) in 2003. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

The agencies have based their lack of credit provisions for TPMS on this outdated data, as well as their assertion that TPMS requires user interaction to re-inflate a tire to the appropriate pressure and therefore a driver “may” continue to operate a vehicle with underinflated tires, even to their final destination. However, in light of continually increasing pressures on fleets to reduce total costs of operation in order to be profitable, Volvo Group disagrees that two studies dating from 12 to 13 years in the past are truly relevant in the decision making process of today’s fleets. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

In addition, given the poor reliability of past ATIS systems, we are skeptical of supplier’s claims of current or future reliability improvements to these systems. Fleets are even more skeptical than truck OEMs, as an ATIS air leak results in increased fuel consumption due to a compressor cycling more frequently and also in potentially significant downtime of the vehicle, even more so than a tire blowout. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

To incentivize truck operators to maintain tire pressure on vehicles equipped with a TPMS system, fleets have the ability to monitor fuel consumption remotely, including the ability to identify causes for increased fuel consumption. This capability is expected to motivate drivers to properly maintain tire pressure on TPMS equipped vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

For these reasons Volvo Group believes that the agencies should provide the same 1% efficiency credit for TPMS as given to ATIS. Volvo Group does not believe this inclusion should be included in the baseline efficiency assumptions or result in a stringency increase, as these systems are an alternative to
Automatic Engine Shutdown (AES) and Extended Idle Reduction

In the Phase 2 Greenhouse Gas proposed regulation the agencies have premised a significant amount of the sleeper tractor stringencies on extended idle reduction and have stated that this will generally require the use of an auxiliary power unit (APU) for hotel loads while parked. The agencies project 80% penetration of APUs in 2021 and 90% in 2024 and 2027; however, there is no provision in 40 CFR Part 1037 for Extended Idle Reduction credit beyond the requirements of § 1037.660 allowing credit for a tamper-resistant five minute idle shutdown timer (AES). [EPA-HQ-OAR-2014-0827-1290-A1 p.23-24]

For AES to be at all feasible and acceptable to fleets and owner-operators requires additional technology for hotel loads. Typically, this means an APU, since most trucks are not on dedicated routes and cannot be assured that their operation will always allow them to overnight in a location with shore power or IdleAir type systems that can provide hotel loads absent idling or an APU. Many fleets have tried APUs and have found them to be unreliable and problematic to secure warranty repairs. As of this writing there is only one OEM with a factory installed APU solution, though all OEMs provide a prep-kit to interface the APU with the vehicle systems. [EPA-HQ-OAR-2014-0827-1290-A1 p.24]

There are many types of APUs available: those powered by small diesel engines driving generators and A/C compressors; battery powered units driving heating and cooling systems whose batteries must be periodically recharged by starting and running the engine; and fuel cell APUs that are still in the early stages of development and, if ever technically feasible, will not likely be on the market in the next decade. Acceptance of any of these solutions to date has been low due to several factors. [EPA-HQ-OAR-2014-0827-1290-A1 p.24]

First and foremost, the number one customer complaint regarding APUs has been reliability issues that have driven customers away from large scale deployment of these systems. Moreover, since most APUs are installed in the aftermarket, the warranty support has been lacking. The reliability issues generate operator safety concerns in both cold and hot ambient conditions. The most reliable hotel support system has proven to be fuel fired heaters, but these do not provide for cooling or electrical and accessory loads, and therefore are not sufficient for the majority of the sleeper tractors in operation. However, use of a fuel fired heater greatly diminishes the need for, and payback of, a full APU system but still requires idling to maintain cab cooling when required. [EPA-HQ-OAR-2014-0827-1290-A1 p.24]

Second, all APUs increase total vehicle weight due to the weight of the units themselves, as well as the additional components required to integrate them into vehicle systems. A battery powered APU can add 400-500 lbs. in batteries alone and have a total system weight of 700 lbs. APUs also require additional open frame rail space for installation, which can lead to weight increases due to increased wheelbase requirements if the customer is unwilling to sacrifice fuel capacity to make room for the APU. To further exacerbate the issue aerodynamic performance can be compromised by the added wheelbase driving increased trailer gaps and an APU that does not fit behind the OEM’s chassis fairings. [EPA-HQ-OAR-2014-0827-1290-A1 p.24]

Due to the limited acceptance of APUs in the marketplace we propose that the agencies provide a compliance option allowing credit for APUs and a partial credit for a fuel fired heater, which does not require a tamper-resistant AES. It is our belief that this would help drive future penetration of APUs, while still allowing for operator comfort and safety without concerns of system reliability. [EPA-HQ-OAR-2014-0827-1290-A1 p.24]
Current Technology Example: Auxiliary Power Units (APUs)

The agencies have assumed an 80% penetration rate of APUs in MY 2021 Class 8 Sleeper Tractors for purposes of determining the proposed MY 2021 standards (Preamble Table III-8). They have also put forth in Table III-15 a proposed incremental cost for MY 2021 of $2,449 for idle reduction with an APU that includes the above adoption rate (which provides for a price of $2,449/80% = $3,061 in 2012$). Yet, section 2.4.8.1.1 of the RIA states that APUs can retail for over $7,000. [EPA-HQ-OAR-2014-0827-1290-A1 p.35-36]

Irrespective of the conflicting information, if we consider that an APU requires auxiliary components to interface with the vehicle systems, the current street price for an installed APU can vary from $9,500 to over $11,000 depending on the type. Even providing for a conversion to 2012$ the agencies are off significantly in their cost assessment. [EPA-HQ-OAR-2014-0827-1290-A1 p.36]

Vehicle Speed Limiters (VSL)

As with Phase 1, the agencies have proposed Phase 2 credit for tamper-resistant vehicle speed limiters set below 65 MPH. However, as has been the experience in Phase 1, truck owners are unwilling to accept this feature since it means they have to give up flexibility in their operations and face reductions in residual value of their used trucks. [EPA-HQ-OAR-2014-0827-1290-A1 p.24-25]

From January 1st of 2013 through January 1st of 2015 Volvo Group built in excess of 50,000 highway tractors for the North American market. Of these, ~15% were shipped with their programmable road speed limiters set at less than 65 mph from the factory. When comparing road speed limiter (RSL) settings data available from in-use vehicles it was determined that there was actually a slight increase of +0.7% in the percentage of the fleet that had in-use settings set below 65 mph compared to the percentage programmed below 65 mph at the factory. This is indicative that the overall fleet RSL settings remain fairly stable. On top of this, 45% of Volvo vehicles leave the factory with an RSL setting of 65 mph and below, and 47% were reported in use with the same setting, even during a period of very low fuel prices. Due to the apparent stability of the RSL settings across the highway tractor populations and, in fact, the slight increase in the in-use population with RSL settings at or below 65 mph Volvo Group requests that the agencies consider crediting manufacturers for reprogrammable speed limiters set at the factory at, or below 65 mph. [EPA-HQ-OAR-2014-0827-1290-A1 p.25]

The regulatory vehicle duty cycles are standardized with maximum speed of 65 mph, so there is no benefit to a speed limiter set at 65 mph, or above, in the regulated cycles. The reality is that more than half of the in-use fleet is running faster, with nearly 48% having speed limiters set at 68 mph or above. Clearly the programmable RSL is yielding benefits, even if set at 65 mph or above, and should be given appropriate credit in the Phase 2 regulation. Volvo Group is willing to continue to work with the agencies to validate the benefits of programmable RSLs, and to develop a means to ensure benefits are verifiable in use. [EPA-HQ-OAR-2014-0827-1290-A1 p.25]

6x2 Penetration

The expected penetration rates of 6x2 axle configurations are infeasible due to operational requirements and confusing or conflicting state and provincial regulations. The maximum penetration rate for highway tractors should be lowered from 60% to 5% in 2027 and 0% for vocational vehicles, including vocational tractors. [EPA-HQ-OAR-2014-0827-1290-A1 P.28]
6x2 axle configurations are only feasible when combined with the capability to transfer load to the driven axle when needed for traction. This may occur on a slippery road, in many off-road situations, and at take-off (either on a grade or at high gross combination weights). Volvo Group has been a leader in developing 6x2 tractor drive systems including both a conventional system where the front tandem is driven and a “pusher” where the rear axle is driven. Both systems are confronted with a hodge-podge of state and provincial regulations that may not allow control of axle load from inside the cab or may require load balance between the tandem axles. A compendium of these regulations is attached to the EMA comments; however, to summarize the major issues, there are nine states and five Canadian provinces which do not allow, or severely limit the amount of load shifting control on variable suspension axles. In some cases the load shifting between axles in a tandem system is limited to either a 60/40 load split (driven/dead axle), or a maximum weight delta of 1,000 kg. In other cases states and provinces have regulations that require that any controls for load distribution be located outside the cab of the vehicle such that the driver is unable to make any load corrections during operation. These regulations appear to be aimed at limiting any ability for load shifting to occur during vehicle operation, but require further rulings from the state and provincial regulatory agencies on a case by case basis. [EPA-HQ-OAR-2014-0827-1290-A1 P.28]

It is unclear, in many cases, how these rules apply or how they would restrict 6x2 application. What is clear is that these rules limit acceptance of 6x2 axles because owners are unsure if they will pass inspections. Unless and until there are federal regulations that clarify what is allowable, we cannot expect high penetration of 6x2 drives. [EPA-HQ-OAR-2014-0827-1290-A1 P.28-29]

With respect to stringency settings (at the above noted penetrations) the agencies project a 2% benefit of the part-time 6x2 on the highway cruise cycles, but have proposed to assign a fixed value in GEM of 2.5 percent over these same cycles (see Preamble Section V.C.1.a.ii). Given the issues noted with the current architecture of the part-time 6x2 systems, the inadequacy for use of 6x2 in HVD vocational applications, and the fixed GEM value at a greater benefit than the agencies expect, it is not feasible to set stringencies at the levels projected based on application of 6x2 systems. [EPA-HQ-OAR-2014-0827-1290-A1 P.29]

Compromising Vehicle Utility

Given the previously stated concerns regarding inability to meet the standards with the agencies assumed technology packages and penetration rates, the far reaching timeframe for the Phase 2 regulation, the uncertainty in the feasibility of the proposed technologies and their penetrations, and the expected increases in fuel economy and GHG performance measured on non-representative duty cycles that are still under revision, Volvo Group is concerned that the proposed regulation will force technologies that are not suited for the specific intended applications and duty cycles. One such example is expected penetration of Waste Heat Recovery on a highway tractor which could serve to limit aerodynamic performance due to increased cooling package size, as well as suitability for weight sensitive applications. If, forced to introduce this technology, OEMs could likely face pre-buy, no-buy, or delayed-buy effects, all of which would result in continued operation of old trucks and large scale rebuilding of older vehicles and engines. This again renders the proposal uncertain to accomplish its intended purpose. [EPA-HQ-OAR-2014-0827-1290-A1 p.31-32]

Response:

Baseline

In the proposal, the agencies noted that the manufacturers were not using tamper-proof AESS to comply with the Phase 1 standards so the agencies reverted back to the baseline APU adoption rate of 30 percent
used in the Phase 1 baseline. The agencies received a number of comments regarding this. In response to these comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had auxiliary power units and 96 percent of vehicles are equipped with adjustable automatic engine shutdown systems.\textsuperscript{126} Therefore, the agencies are projecting for the baseline that 9 percent of sleeper cabs will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS, and none will include tamper proof AESS.

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. The baseline was not determined by or declared to be the average results of the vehicles tested, as some commenters maintained. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for Phase 2 NPRM. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. See RIA Chapter 3.2.1.2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin $C_{dA}$ values.

\textit{Aerodynamics}

The agencies’ assessment is that the best aerodynamic tractor tested by EPA in 2015 achieved Bin IV performance. This vehicle did not include all of the possible aerodynamic technologies, such as wheel covers or active aerodynamics like a grill shutter or front air dam. Thus, the agencies’ assessment is that Bin V is achievable with known aerodynamic technologies, as discussed in RIA Chapter 2.4, but agree with the manufacturers that Bins VI and VII have less known technology paths. However, we are including Bins VI and VII in the Phase 2 regulations as a potential Phase 2 technology to recognize the possibility that over the next ten years (until the full implementation of the Phase 2 program) tractor manufacturers may advance their aerodynamic technologies beyond the Bin V levels projected for the Phase 2 standards, and to provide a value to be input to GEM should they do so. In consideration of the comments, the agencies have adjusted the aerodynamic adoption rate for Class 8 high roof sleeper cabs used to set the final standards in 2021, 2024, and 2027 MYs (i.e., the degree of technology adoption on which the stringency of the standard is premised). Upon further analysis of simulation modeling of a SuperTruck tractor with a Phase 2 reference trailer with skirts, we agree with the manufacturers that a SuperTruck tractor technology package would only achieve the Bin V level of $C_{dA}$. The changes required for Bin V and better performance reflect the kinds of improvements projected in the Department of Energy’s SuperTruck program. That program assumes that such systems can be demonstrated on vehicles by 2017. In this case, the agencies are projecting that truck manufacturers will be able to begin implementing these demonstrated aerodynamic technologies as early as 2021 MY on a limited scale. Accordingly, we adjusted the adoption rates for MY 2027 in the technology package developed for the final rule to consist of 20 percent of Bin III, 30 percent Bin IV, and 50 percent Bin V reflecting our assessment of the fraction of high roof sleeper cab tractors in this segment that we project could successfully apply these aerodynamic packages with this amount of lead time. Overall, while the agencies are now projecting slightly less benefit from aerodynamic improvements than we did in the

NPRM (i.e. because the agencies have reevaluated the efficiencies of these technologies, consistent with this and other comments), the actual aerodynamic technology being projected is very similar to what was projected at the time of NPRM.

With respect to the comments related to the aerodynamic test procedures, please see the agencies’ response to the EMA comments in Section 4.5 of this response to comments document.

Low Rolling Resistance Tires

For the final rulemaking, the agencies evaluated the tire rolling resistance levels in the Phase 1 certification data. We found that high roof sleeper cabs are certified today with steer tire rolling resistance levels that ranged between 4.9 and 7.6 kg/ton and with drive tires ranging between 5.1 and 9.8 kg/ton. In the same analysis, we found that high roof day cabs are certified with rolling resistance levels ranging between 4.9 and 9.0 kg/ton for steer tires and between 5.1 and 9.8 kg/ton for drive tires. This range spans the baseline through Level 3 rolling resistance performance levels. Therefore, for the final rule we took an approach similar to the one taken in Phase 1 and proposed in Phase 2 that considers adoption rates across a wide range of tire rolling resistance levels to recognize that operators may have different needs. 76 FR 57211 and 80 FR 40227.

Also in our analysis of the Phase 1 certification data, we found that the drive tires on low and mid roof sleeper cab tractors on average had 10 to 17 percent higher rolling resistance than the high roof sleeper cabs. But we found only a minor difference in rolling resistance of the steer tires between the tractor subcategories. Based on comments received and further consideration of our own analysis of the difference in tire rolling resistance levels that exist today in the certification data, the agencies are adopting Phase 2 standards using a technology pathway that utilizes higher rolling resistance levels for low and mid roof tractors than the levels used to set the high roof tractor standards. This is also consistent with the approach that we took in setting the Phase 1 tractor standards. 76 FR 57211. In addition, the final rule reflects a reduction in Level 3 adoption rates for low and mid roof tractors from 25 percent in MY 2027 used at proposal (80 FR 40227) to zero percent adoption rate. The technology packages developed for the low and mid roof tractors used to determine the stringency of the MY 2027 standards in the final rule do not include any adoption rate of Level 3 drive tires to recognize the special needs of these applications, consistent with the comments noted above raising concerns about applications that limit the use of low rolling resistance tires.

With respect to the comments about the ability to retread low rolling resistance tires, we have asked fleets and others for data regarding this topic, but we have not received any. In discussions with EPA’s SmartWay, tire manufacturers have claimed that their low rolling resistance tires are as retreadable as those with higher rolling resistance. While there may be individual tire models that do not perform as well in terms of retreadability, we do not believe this is a systematic issue related to low rolling resistance tires.

DOT’s Federal Motor Carrier Safety Administration and NHTSA sponsored a test program conducted by Oak Ridge National Laboratory to explore the effects of tire rolling resistance levels on Class 8 tractor-trailer stopping distance performance over a range of loading and surface conditions. The objective was to determine whether a relationship exists between tire rolling resistance and stopping distance for vehicles of this type. The overall results of this research suggest that tire rolling resistance is not a

reliable indicator of Class 8 tractor-trailer stopping distance. The correlation coefficients (R2 values) for linear regressions of wet and dry stopping distance versus overall vehicle rolling resistance values did not meet the minimum threshold for statistical significance for any of the test conditions. Correlation between CRR and stopping distance was found to be negligible for the dry tests for both loading conditions. While correlation was higher for the wet testing (showing a slight trend in which lower CRRs correspond to longer stopping distances), it still did not meet the minimum threshold for statistical significance. In terms of compliance with Federal safety standards, it was found that the stopping distance performance of the vehicle with the four tire sets studied in this research (with estimated tractor CRRs which varied by 33 percent), were well under the FMVSS No. 121 stopping distance requirements. The agencies agree, though, that continuing research will be important as new tire technologies enter the marketplace, and like the extensive rolling resistance testing conducting to support the Phase 1 regulation and, in part, this final rule, the agencies will continue to monitor developments in the tire supply marketplace through the EPA Smartway program and other, potential, research. NHTSA notes that FMVSS No. 121 will continue to play a role in ensuring the safety of both current and future tire technologies.

**Tire Pressure Systems**

After consideration of the comments, the agencies are adopting provisions in Phase 2 GEM that allow manufacturers to show compliance with the CO2 and fuel consumption standards using various technologies, including either ATIS or TPMS (see 40 CFR 1037.520). See Preamble Section III.D.1.b.iv. This reflects a change from the Phase 2 NPRM, where only ATIS (not TPMS) was a GEM input. The agencies believe that sufficient incentive exists for truck operators to address low tire pressure conditions if they are notified that they exist through a TPMS, however, we set the effectiveness value of TPMS lower than ATIS to reflect the need for operator intervention.

**Idle Reduction Technologies**

The agencies received numerous comments on our proposed adoption rates of tamper-proof AESS. We generally agree with this commenter (and others) that the agencies should consider other types of idle reduction technologies because an automatic engine shutdown system (or an APU) may not be the optimum choice for every tractor. For the final rule, we now differentiate effectiveness based on the specific idle reduction technology installed by the tractor manufacturer. This change is consistent with the commenter’s concern that APUs would not benefit all operators or may lead to a concern regarding weight. For the final rule, we recognize a variety of idle reduction technologies—including automatic engine shutdown systems, fuel operated heaters, automatic stop/start systems, and diesel powered APUs. Phase 2 will allow a variety of both tamper-proof and adjustable (programmable) systems to qualify for some reduction. After consideration of the comments, the agencies have refined the adoption rates of a new menu of idle reduction technologies and only projected adoption of idle reduction technologies with adjustable AESS.

EPA considered the comments and more closely evaluated NHTSA’s contracted TetraTech cost report found the retail price of a diesel-powered APU with a DPF to be $10,000. The agencies used a retail price of a diesel-powered APU to be $8,000 without a DPF and $10,000 with a DPF in the cost analysis for this final rulemaking.

**Vehicle Speed Limiters**

The agencies considered DOT’s upcoming actions with respect to mandatory vehicle speed limiters for heavy-duty trucks, but could not take it into account in this Phase 2 rulemaking because that rule is not
final yet. The existing Phase 1 VSL flexibilities provide opportunities for manufacturers to account for the impact of VSLs on reducing GHG emissions and fuel consumption, while still allowing the settings to change after an “expiration” time determined by the manufacturer or to include a soft top. At this time, we believe that the Phase 1 flexibilities sufficiently balance the desire to encourage technologies that reduce GHG emissions and fuel consumption while minimizing the compliance burden of trying to accommodate changes throughout the useful life of the vehicle. Therefore, the agencies are not adopting any new VSL provisions for Phase 2. With respect to the commenter’s request that the agencies recognize the effectiveness of VSLs set at greater than 65 mph, the agencies’ assessment is that based on truck speed limits in each of the states, weighted by truck miles in each state, that 65 mph is an appropriate speed for one of the cruise cycles. If a manufacturer has sufficient data to support the real world reduction of VSLs set at greater than 65 mph, then they may pursue off-cycle credit approval.

6x2 Axles

Upon further consideration, the agencies have lowered the adoption rates of 6x2 axles in the final rule from those used in the proposal. We projected a 15 percent adoption rate in the technology package used to determine the final 2021 MY standards and a 30 percent adoption rate in the technology package used to determine the 2027 MY standards. This adoption rate represents a combination of 6x2 axles (which as noted by a commenter that liftable axles are expected to be allowed in all states by the time of implementation of Phase 2), enhanced 6x2 axles, disconnectable 6x4 axles, and 4x2 axles. Some axle manufacturers offer enhanced 6x2 products that perform similar to the 6x4 configurations and address concerns regarding traction. SMARTandem offered by Meritor is just one of the examples. In this system, the axle runs 6x2 for most time. Once the conditions that require more traction are experienced, the vehicle activates the system to add more loads into one the powered axle, thus instantly increasing traction. In addition to enhanced 6x2 axles, based on confidential stakeholder discussions, the agencies anticipate that the axle market may offer a Class 8 version of axle disconnect to automatically disconnect or reconnect the one of the tandem axles depending on needs for traction in varying driving conditions. Recently, Dana Holding Corporation has developed an axle system that switches between the two modes based on driving conditions to maximize driveline efficiency. When high traction is required, the system operates in 6x4 mode. When 6x4 tractive effort is not required, the system operates in 6x2 mode. Though the adoption rate of 6x2 axles have been low in the U.S. market, NACFE found in their confidence report that more fleets are adopting 6x2 axles. NACFE found that one large national fleet, Conway Truckload, has purchased around 95% of their new tractors in the past few years with 6x2s. In addition, it is worth noting that the standards are performance standards, therefore, the agencies are not mandating any specific fuel consumption or GHG emission reducing technology. For each standard, we developed one potential technology pathway to demonstrate the feasibility of the standards, but manufacturers will be free to choose other paths.

The agencies have modified how 6x2 axles are recognized in the final rule. In lieu of a fixed improvement, GEM will simulate a 6x2 axle by removing the axle losses of one of the drive axles. The agencies believe this is a more representative approach. See RIA Chapter 4.4.1.2.

Vehicle Utility

129 Dana Holding Corporation Patents (8,523,738, 8,795,125, and 8,911,321).
The agencies understand the potential impact that certain designs of WHR could have on aerodynamics; however, WHR systems have evolved from earlier versions demonstrated in SuperTruck and will continue to evolve over the next 5-10 years (as noted in Cummins’ comments to the rule). The WHR systems continue to reduce weight, improve packaging, and reduce the impact on the aerodynamics. As demonstrated on the Cummins-Peterbilt, the Volvo, and the Daimler SuperTrucks, manufacturers were able to demonstrate tractors that incorporated WHR and simultaneously improved the aerodynamics of the tractor-trailer. We understand the limitations of the DOE SuperTruck program in terms of applying the reductions broadly across vehicle applications and duty cycles, and in terms of durability and cost. However, this program demonstrates that it is possible to design systems that utilize WHR without significant compromise to aerodynamics. In addition, the agencies premised the final Phase 2 standards on engine technology packages that include WHR only on sleeper cab tractors and only on 50 percent of those vehicles in 2027. It is important to also note that manufacturers that do not invest to achieve a level of engine reduction through WHR potentially be able to make up the difference by applying one of the many other available and cost-effective tractor technologies to a greater extent or more effectively, so that there are multiple technology paths for meeting the final standards. See Section 3 of this RTC for additional discussion of WHR technology.

Organization: Werner Enterprises

There are several key areas the agencies need to address: [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

- Due to errors in EPA’s baseline vehicle assumptions (used to determine future achievable stringency) and testing protocols, the actual stringency of the proposed standards is much greater than what EPA had indicated. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

Response:

Baseline

In the proposal, the agencies noted that the manufacturers were not using tamper-proof AESS to comply with the Phase 1 standards so the agencies reverted back to the baseline APU adoption rate of 30 percent used in the Phase 1 baseline. The agencies received a number of comments regarding this. In response to these comments, the agencies reassessed the baseline idle reduction adoption rates. The latest NACFE confidence report found that 9 percent of tractors had auxiliary power units and 96 percent of vehicles are equipped with adjustable automatic engine shutdown systems. Therefore, the agencies are projecting for the baseline that 9 percent of sleeper cabs will contain an adjustable AESS and APU, while the other 87 percent will only have an adjustable AESS, and none will include tamper proof AESS.

While the agencies agree with the commenters that it is important to develop an accurate baseline so that the appropriate aerodynamic technology package effectiveness and costs can be evaluated in determining the final Phase 2 standards, there appears to be some confusion regarding the NPRM baseline aerodynamic assessment. The Phase 2 baseline in the NPRM was determined based on the aerodynamic bin adoption rates used to determine the Phase 1 MY 2017 tractor standards. The baseline was not determined by or declared to be the average results of the vehicles tested, as some commenters maintained. The vehicles that were tested prior to the NPRM were used to develop the aerodynamic bin structure for Phase 2. In both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into

consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that tractors that performed as a Bin III in Phase 1 would also perform as Bin III tractors in Phase 2. The baseline aerodynamic value for the Phase 2 final rulemaking was determined in the same manner as the NPRM, using the adoption rates of the bins used to determine the Phase 1 standards, but reflect the final Phase 2 bin $C_{dA}$ values.
4.4 Proposed Exclusions from the Phase 2 Tractor Standards

**Organization:**  Allison Transmission, Inc.

EPA and NHTSA should amend the definition of heavy-haul tractors to account for lower overall gear reductions with fully automatic transmissions and to provide credits for same. [EPA-HQ-OAR-2014-0827-1284-A1 p.3]

**EPA and NHTSA Should Amend Proposed Definition of Heavy-Haul Tractors To Account for Lower Gear Ratios Used by ATs And Allow For Crediting of AT Architecture and Neutral-Idle**

EPA and NHTSA are proposing to add a tenth subcategory to the tractor category in order to address heavy-haul tractors. This category would be defined with reference to weight (GCWR over 120,000 lb) and with respect to total gear ratio (greater than 57:1) and a frame Resisting Bending Motion of 2,000,000 in-lb. While Allison supports creation of this category, we would recommend that in heavy-haul tractors equipped with an AT, the gear reduction ratio requirements be changed to greater than or equal to 24.9:1. A 57:1 gear reduction requirement is required for a manual/AMT transmission to launch due to heavy haul weights and engine torque being limited to protect a slipping clutch. But this ratio is excessive for a torque converter AT which can launch a vehicle at full power. If the 57:1 requirement was applied to ATs, it would unnecessarily result in poor fuel economy in actual service. [EPA-HQ-OAR-2014-0827-1284-A1 p.37]

Specifically, due to an AT’s torque converter allowing full power at stall, its torque multiplying characteristics and the ability to do full power shifting, deep gear reduction is not required for ATs. The total gear reduction (including torque converter ratio) for an AT in the heavy haul application ranges from 24.9:1 to 144.4:1. Typical (i.e., standard) configurations utilize a range from 24.9 to 48:1 gear reduction ratio. [EPA-HQ-OAR-2014-0827-1284-A1 p.37]

We include with our comments the following data from current heavy haul applications: [EPA-HQ-OAR-2014-0827-1284-A1 p.37]

[Chart, 'Data from current Allison transmission heavy haul applications', can be found on p.37 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

This data supports our view that the total gear reduction ratio for ATs needs to be different from other transmission architectures and request that EPA change the proposed regulatory definition at 40 C.F.R. 1037.801 (which is cross-referenced within NHTSA regulations). Specifically, EPA and NHTSA should adopt the following definition: [EPA-HQ-OAR-2014-0827-1284-A1 p.37]

Heavy-haul tractor means a tractor with GCWR above 120,000 pounds, a total gear reduction at or above 24.9:1 for tractors containing fully automatic transmissions, a total gear reduction at or above 57 for all other tractors, and a frame Resisting Bending Moment at or above 2,000,000 in-lb per rail, or per rail and liner combination. Total gear reduction is the transmission gear ratio in the lowest gear multiplied by the drive axle ratios. A heavy-haul tractor is not a vocational tractor. [EPA-HQ-OAR-2014-0827-1284-A1 p.38]

**Separate Certification Approach for Vocational Tractors**
EPA and NHTSA have proposed to allow vocational tractors to follow the same subcategory assignment process as other vehicles. Allison lacks data upon which to address the agencies’ request for comment on whether vocational tractors, when measured against vocational vehicle baseline configurations, would be deficit-generating vehicles. But as a matter of policy, we believe it would be reasonable to not limit the number of tractors that can be certified as vocational vehicles as was done in Phase 1. This limitation may have been reasonable in the initial years of the program as a precaution against unreasonably assigning too many tractors to the vocational vehicle category. Vehicle configurations, however, change over time. For example, beverage delivery was formerly performed by straight trucks but now primarily occurs using tractors. [EPA-HQ-OAR-2014-0827-1284-A1 p.42]

In Phase 2, EPA and NHTSA have both diversified the vocational vehicle category and include additional elements within GEM for vehicle certification. This regulatory framework seeks to better represent the diversity of vocational vehicles and their differentiated uses that may change over time. Given the scope of the Phase 2 regulations, extending into major vehicle components such as transmissions, axles and tires, it would be correspondingly reasonable to allow manufacturers to certify all HD vehicles, both vocational and tractor, with regard to intended use. This would allow for better alignment of vehicles with duty cycles that are more representative of their real-world operation. [EPA-HQ-OAR-2014-0827-1284-A1 p.42]

Response:

For the FRM, EPA and NHTSA are revising the Phase 1 heavy-haul tractor provisions (and the Phase 2 proposal) to better assure that vehicles are regulated in an appropriate subcategory. Based on our assessment, the tractors with GCWR greater than or equal to 120,000 pounds truly represent heavy-haul applications in the U.S. Therefore, we are adopting criteria only based on GCWR, not the proposed RBM or total gear reduction ratios.

The final version of Phase 2 GEM treats ATs and AMTs the same for heavy-haul tractors as for the other tractors.

The agencies evaluated the sales cap limit proposed for special purpose tractors and the comments addressing the issue of a sales cap. EPA calculated the number of vocational tractors certified in MY 2014 and MY 2015. The number of tractors ranged between approximately 2,600 and 6,200 per year per manufacturer that certified special purpose tractors, but one manufacturer did not use this provision at all. It is apparent that none of the manufacturers are utilizing this provision near the maximum allowable level in Phase 1 (a rolling three year sales limit of 21,000). We also believe that there is more incentive for manufacturers to use the special purpose tractor provisions in Phase 1 because the relative difference in stringency between the tractor and vocational programs is much greater in Phase 1 than in Phase 2. Upon further consideration, we concluded that there is significantly less incentive for the manufacturers to reclassify tractors that are not truly special purpose tractors as vocational vehicles as a pathway to a less stringent standard in Phase 2 primarily due to the fact that the Phase 2 vocational vehicle program stringency is more in line with the tractor program stringency. In addition, the Phase 2 vocational vehicle compliance program and standards better represent the duty cycles expected of these.

vehicles and are predicated on performance of similar sets of vehicle technologies as the primary tractor program (although some of the vocational vehicle standards are predicated on stop start and hybrid technologies, which are not part of the technology path predicated for tractors and vocational vehicle standards are not predicated on aerodynamic technologies). Therefore, we are adopting Phase 2 special purpose tractor provisions without a sales cap.

**Organization:** American Reliability Industries, Co. (ARI)

ARI serves as a second stage manufacturer that improves completed vocational vehicles and heavy duty tractors. ARI does not receive or work on incomplete vehicles and thus 40 C.F.R. § 1037.620 does not apply to ARI’s circumstances. Instead, ARI’s primary focus is to make cab sleeper modifications to vocational vehicles and heavy duty tractors that are considered complete prior to arrival. The vehicles received by ARI for improvement must meet the requirements of the EPA and DOT/NHTSA regulations relevant to the specific vehicle in its completed form. This includes the labeling requirements that an OEM must comply with under Phase 1 and soon to be Phase 2. [EPA-HQ-OAR-2014-0827-1300-A1 p.2]

**EPA and NHTSA’s Intent Related to Second Stage Manufacturers Performing Cab Sleeper Modifications**

Upon review of the proposed regulations and after discussions with representatives of the agencies, ARI believes that it is EPA and NHTSA’s intent to continue to exclude or exempt second stage manufacturers performing cab sleeper modifications from the Phase 2 proposed regulations. ARI appreciates EPA and NHTSA’s recognition of the unique nature of this niche market and the significant adverse effect the proposed regulations could have on small businesses in this market, like ARI. ARI appreciates EPA and NHTSA’s focus on their top priority of obtaining real world emission reductions and recognition that regulating this niche market in addition to the regulations placed upon the OEM would not provide such results. ARI values EPA and NHTSA’s recognition that such regulation would have the unintended consequence of being a barrier to entry and a disruption to the current marketplace. [EPA-HQ-OAR-2014-0827-1300-A1 p.3]

EPA and NHTSA have drafted specific provisions in the proposed regulation to implement the above intent. EPA and NHTSA have also sought comment on several of the drafted sections. Included herein are sections of the proposed regulation that ARI believes are important to consider when implementing the agencies’ intent. ARI will include the specific section(s) with citation below along with ARI’s comments on the section(s). [EPA-HQ-OAR-2014-0827-1300-A1 p.3]

**ARI’s Analysis of Sections of the Proposed Regulation**

Also in Phase 1, EPA determined that manufacturers that met the small business criteria specified in 13 CFR 121.201 for “Heavy Duty Truck Manufacturing” were not subject to the greenhouse gas emissions standards of 40 CFR 1037.106.130 The regulations required that qualifying manufacturers must notify the Designated Compliance Officer each model year before introducing the vehicles into commerce. The manufacturers are also required to label the vehicles to identify them as excluded vehicles. EPA and NHTSA are seeking comments on eliminating this provision for tractor manufacturers in the Phase 2 program. The agencies are aware of two second stage manufacturers building custom sleeper cab tractors. We could treat these vehicles in one of two ways. First, the vehicles may be considered as dromedary vehicles and therefore treated as vocational vehicles. Or the agencies could provide provisions that stated if a manufacturer changed the cab, but not the frontal area of the vehicle, then it could retain the
ARI Comment: ARI recognizes EPA and NHTSA’s desire to limit the small business exemption previously set forth in 40 C.F.R. § 1037.150(c). ARI appreciates EPA and NHTSA’s efforts to propose alternative methods for excluding or exempting those second stage manufacturers performing cab sleeper modifications that previously qualified for the small business exemption under 40 C.F.R. § 1037.150(c). ARI has some concerns related to the methods set forth by the agencies. [EPA-HQ-OAR-2014-0827-1300-A1 p.3-4]

Dromedary Vehicles

ARI understands that the idea behind considering the vehicles as dromedary vehicles and thus vocational vehicles would be that the aerodynamic requirements of the proposed regulation are not applicable to the vocational vehicles. ARI is concerned that treating these vehicles as vocational vehicles will result in three possible issues: (1) other regulations related to vocational vehicles will become applicable and have unanticipated adverse results; (2) the vehicles will be treated as heavy duty vehicles and not vocational vehicles when originally certified by an OEM; and (3) vocational vehicles are often considered the highest polluters of greenhouse gas emissions with the lowest fuel efficiencies, and heavy duty trucks with cab sleeper modifications do not fit this general category. ARI is open to discussing this option further, but does not believe it is the best solution for adopting EPA and NHTSA’s intent under these circumstances. [EPA-HQ-OAR-2014-0827-1300-A1 p.4]

§ 1037.622 Shipment of incomplete vehicles to secondary vehicle manufacturers. This section specifies how manufacturers may introduce partially complete vehicles into U.S. commerce. The provisions of this section do not apply for trailers, except in unusual circumstances. You may not use the provisions of this section to circumvent the intent of this part. [EPA-HQ-OAR-2014-0827-1300-A1 p.5-6]

(a) The provisions of this section allow manufacturers to ship partially complete vehicles to secondary vehicle manufacturers or otherwise introduce them into U.S. commerce in the following circumstances: [EPA-HQ-OAR-2014-0827-1300-A1 p.6]

(2) Small businesses modifying certified tractors. Small businesses that build custom sleeper cabs may modify complete or incomplete vehicles certified as tractors, as long as they do not increase the effective frontal area of the certified configuration. [EPA-HQ-OAR-2014-0827-1300-A1 p.6]

ARI Comment: ARI is first concerned that this section appears in part to only address the shipment of incomplete vehicles, but later permits small businesses modifying certified tractors to modify complete or incomplete vehicles. ARI believes that EPA and NHTSA’s goal is to use this section to adopt the frontal area approach previously discussed. If EPA and NHTSA adopt a frontal area approach for second stage manufacturers making cab sleeper modifications, ARI requests that the section be revised to ensure greater clarity as to the intention and effect of this section. ARI believes that it is important for any final section providing an exemption or an exclusion to directly state that it is an exemption or exclusion from the Phase 2 regulation in order to avoid possible ambiguities arising at a later date. EPA and NHTSA took a direct approach in the small business exemption under the Phase 1 regulation. ARI encourages the agencies to take a similar approach in the Phase 2 regulation. [EPA-HQ-OAR-2014-0827-1300-A1 p.6]
Thank you for recognizing the need for an exemption or exclusion for small businesses engaged in the unique niche market of second stage manufacturers performing cab sleeper modifications. [EPA-HQ-OAR-2014-0827-1300-A1 p.7]

Otherwise, ARI requests that the agencies engage in additional discussions to evaluate what significant changes would need to be made to provide an exemption or exclusion that allows day cabs to be changed to sleeper cabs and permits the addition of aerodynamic technologies. [EPA-HQ-OAR-2014-0827-1300-A1 p.7]

Frontal Area

ARI recognizes that the idea behind permitting a second stage manufacturer to change the cab, but not the frontal area of the vehicle, would permit the second stage manufacturer to keep the original OEM’s certification within a specific aerodynamic bin category. Our primary concerns for this approach is that it does not permit a second stage manufacturer performing cab sleeper modifications to convert a day cab into a sleeper cab or improve the frontal area as a part of the modifications. As the EPA and NHTSA recognize, aerodynamic technologies provide an “opportunity to reduce aerodynamic drag from the tractor.” 80 Fed. Reg. 40216 (July 13, 2015). [EPA-HQ-OAR-2014-0827-1300-A1 p.4]

Depending on the custom cab sleeper modification, ARI may use wind fairings on the sleeper, fuel tank fairings, roof fairings, and side extenders or gap reducing tractor fairings that can modify the frontal area of the vehicle in height and width as compared to the frontal area of the vehicle used to obtain the original certification. These additions will, in some circumstances, result in the vehicle being taken out of its prior certification configuration because roof height is defined to “include[e] any wide accessories such as roof fairings.” 80 Fed. Reg. 40664, 40739 (July 13, 2015). Requiring the small businesses to test the vehicle for recertification or certify the vehicle at the worst case aerodynamic bin for the type of vehicle under these circumstances would not further the intent of EPA and NHTSA and would have a significant adverse impact on small businesses in this niche marketplace. [EPA-HQ-OAR-2014-0827-1300-A1 p.4]

ARI wishes to continue improving the client’s lifestyles, health, and happiness by modifying day cabs into sleeper cabs. ARI also wishes to continue using aerodynamic technologies in connection with the cab sleeper modifications to benefit the clients and further, although modestly, the goals of the EPA and NHTSA. As recognized by the EPA and NHTSA, “fuel tank fairings can reduce the surface area perpendicular to the wind and provide a smooth surface to minimize disruptions of the air flow[,] [r]oof fairings provide a transition to move the air smoothly over the tractor and trailer[;] and [s]ide extenders can minimize the air entrapped in the gap[s] . . . .” 80 Fed. Reg. 40216 (July 13, 2015). ARI is open to discussing this option further, but does not believe it is the best solution for adopting EPA and NHTSA’s intent under these circumstances. [EPA-HQ-OAR-2014-0827-1300-A1 p.4-5]

Basic vehicle frontal area has the meaning given in 40 CFR 86.1803. [EPA-HQ-OAR-2014-0827-1300-A1 p.5]

40 C.F.R. § 86.1803.

Basic vehicle frontal area means the area enclosed by the geometric projection of the basic vehicle along the longitudinal axis, which includes tires but excludes mirrors and air deflectors, onto a plane perpendicular to the longitudinal axis of the vehicle. [EPA-HQ-OAR-2014-0827-1300-A1 p.5]
ARI Comment: ARI is concerned that if EPA and NHTSA adopt a frontal area approach for second stage manufacturers making cab sleeper modifications, that the above definitions are too restrictive and would not permit the addition of beneficial aerodynamic technologies. [EPA-HQ-OAR-2014-0827-1300-A1 p.5]

(d) Examples of prohibited modifications. The following are examples of modifications that are not allowable: [EPA-HQ-OAR-2014-0827-1300-A1 p.6]

(2) No person may remove aerodynamic fairings from tractors that are used primarily to pull box trailers on highways. [EPA-HQ-OAR-2014-0827-1300-A1 p.6]

ARI Comment: Depending on the custom cab sleeper modification, ARI may replace an aerodynamic fairing from the tractor in order to provide better aerodynamic results in light of the cab sleeper modification. ARI does not want to be precluded from continuing to provide these benefits to clients. ARI believes an exception to this section would resolve these concerns. [EPA-HQ-OAR-2014-0827-1300-A1 p.6]

Secondary vehicle manufacturer [means] (sic) anyone that produces a vehicle by modifying a complete or partially complete vehicle. For the purpose of this definition, “modifying” does not include making changes that do not remove a vehicle from its original certified configuration. [EPA-HQ-OAR-2014-0827-1300-A1 p.6]

ARI Comment: ARI recognizes that the purpose of this definition was to further support the frontal area approach. ARI remains concerned that making a day cab a sleeper cab or adding the aerodynamic technology described above will result, in some circumstances, in the vehicle being removed from its original certified configuration. [EPA-HQ-OAR-2014-0827-1300-A1 p.7]

Response:

In response to these comments, EPA is clarifying in 40 CFR 1037.622 that small businesses may modify tractors as long as they do not modify the front of the vehicle and so long as the sleeper compartment is no more than 102 inches wide or 162 inches in height. As an interim provision, to allow for a better transition to Phase 2, EPA is finalizing a more flexible compliance path in 40 CFR 1037.150(r). This option allows small manufacturers to convert a low or mid roof tractor to a mid or high roof configuration without recertification, provided it is for the purpose of building a custom sleeper tractor or for conversion to a natural gas tractor.

Although this more flexible allowance to convert low and mid roof tractors to mid or high roof tractors is being adopted as an interim provision, we have not established an end date at this time. We expect to reevaluate this provision as manufacturers begin to make use of and may decide to revise it in the future, potentially to make it a permanent allowance. To be eligible for this option, the secondary manufacturer must be a small manufacturer and the original low or mid roof tractor must be covered by a valid certificate of conformity. The modifications may not increase the frontal area of the tractor beyond the frontal area of the equivalent high roof tractor paired with a standard box van.

See also Section III.C.5 of the Preamble to the final regulation.
Organization:  Daimler Trucks North America LLC

Elimination of the vocational engine limitation that is no longer necessary in Phase 2 - The agencies propose to remove the prohibition against the use of vocational engines in tractors, given that the performance of the engine would be appropriately reflected in GEM regardless which engine certification procedure was used to certify the engine. We agree that, with the engine properly represented in GEM, there is less need for the prohibition on vocational-only certified engines in tractors. In fact, the agencies’ reasoning shows why the engine-based standards on the FTP or RMC tests are so outdated: the true in-vehicle emissions are represented by the full-vehicle standard. 80 FR 40251. [EPA-HQ-OAR-2014-0827-1164-A1 p.30]

Proposed Heavy-Haul Tractor Definition - The agencies request comment on the proposed heavy-haul tractor definition, including whether Gross Vehicle Weight Rating (GVWR) OR Gross Axle Weight Rating (GAWR) would be a more appropriate metric to differentiate between a heavy-haul tractor and typical tractor. 80 FR 40233. In discussions with the EPA, we originally had suggested using GVWR as a surrogate for Gross Combination Weight Rating (GCWR), given that the vehicle purchaser inputs GCWR while GVWR is calculated from items that are on the vehicle—making GVWR harder a metric to game than GCWR. However, as we dug deeper into the question of whether GVWR or GCWR is better for the regulations, for example analyzing our sales numbers by the agencies’ proposed heavy-haul definitions and by a definition offered by Paccar, we learned that 1) there was not a one-to-one relation between GVWR and GCWR, with some vehicles designed for high GCWR having relatively low GVWR and vice versa, and more importantly 2) our computer system does use GCWR in such a way that a vehicle purchaser would penalize himself if he chose an inaccurately high GCWR in order to avoid having a vehicle regulated as a standard tractor. In conclusion, we think that the agencies’ general proposal for a GCWR-based definition of heavy haul will work, as will Paccar’s, although each one will catch a slightly different set of vehicles. [EPA-HQ-OAR-2014-0827-1164-A1 p.33]

So although either the GCWR- or GVWR-based proposals will work, the question is whether the actual definitions properly catch all of the intended vehicles. As we analyze our vehicles, trying to match vehicles that we expect to be categorized as heavy-haul with those that are, we find several ways to improve the definition. First, the total gear reduction of 57:1 is too high. It will exclude many vehicles that, by our standards, would be heavy-haul. Second, the weight of 120,000 lb. or more (note that, as we discussed with the agencies, many heavy-haul vehicles are specified at 120,000 lb. exactly, so the correct definition is not “over 120,000 lb.” as the agencies propose but “120,000 lb. or more”) is so high that it misses many heavy-haul vehicles. We think that 105,000 lb., which catches 105,500 lb. to 120,000 lb. vehicles and those originally in the agencies’ proposal, is better. This broader weight definition catches a very small number of US vehicles (0.1 to 0.9% of the vehicles, depending on other factors) but catches the large number of Canadian vehicles that are heavy-haul, as shown below. Third, when we look at the vehicles excluded from the heavy-haul category by the use of the agencies’ proposed requirements for a 2 million in-lb. RBM or rail/liner combination plus 57:1 total gear reduction, we see that the RBM and gear reduction criteria exclude a lot of vehicles that are rated to haul either 105,000 lb. or 120,000 lb. and thus are heavy-haul vehicles. [EPA-HQ-OAR-2014-0827-1164-A1 P.33-34]

In conclusion, we propose to go with just a 105,000 lb. GCWR-based definition without a requirement for an RBM or gear reduction; the manufacturers, in building vehicles capable of hauling such a GCWR will do what it takes to meet the hauling requirements, whether through a particular RBM and gear reduction or otherwise. [EPA-HQ-OAR-2014-0827-1164-A1 P.34]
We have invited the agencies to participate in a meeting to go through our vehicle categorization data, and we reiterate our invitation. [EPA-HQ-OAR-2014-0827-1164-A1 P.34]

Proposed Exclusions from the Phase 2 Tractor Standards - The agencies seek comment on whether the proposed rolling 21,000 sales volume limit for special purpose tractors is set at an appropriate level looking into the future. 80 FR 40214. First, we wish to note that we think the agencies are correct in choosing not to apply a sales volume limit to heavy haul vehicles. The agencies are working toward a good definition of these vehicles, as well as reasonable standards for the vehicles, and therefore have no reason to limit the use of the heavy haul provisions to a fixed number of vehicles. Regarding special purpose tractors, we think that with the addition of heavy haul vehicles, there will be less need for a sales volume limit on special purpose tractors. But in the absence of a finalized definition for the heavy haul vehicle, we cannot say how many special purpose tractors there will be. In Phase 1, we sold nearly the sales volume limit of special purpose tractors, indicating that it would be inappropriate for the agencies to lower the limits unless the definition of a heavy haul vehicle were very broad. We wish to work with the agencies further to understand 1) the final heavy haul definition and 2) how this affects the size of special purpose tractor sales volume limit that would be needed to satisfy the industry's need for such vehicles. [EPA-HQ-OAR-2014-0827-1164-A1 p.131-132]

Proposed Exclusions from the Phase 2 Tractor Standards - The agencies discuss two possible approaches for second stage manufacturers that build custom sleepers, that the vehicles be considered 1) as dromedary vehicles or 2) if the manufacturer changed the cab, but not the frontal area of the vehicle, then it could retain the aerodynamic bin of the original tractor. 80 FR 40214. Our main concern is to clarify that where the primary manufacturer has certified a vehicle as a day cab, the second stage manufacturer's actions do not draw the primary manufacturer into noncompliance. In many cases, we do not know a priori that a vehicle will be altered by a second stage manufacturer; we have simply sold (for example) a long wheel base tractor like any other long wheel base tractor. Given the extremely large number of companies that buy our vehicles and alter them or add components to perform the vehicles' intended tasks, we cannot monitor each company to see if it is (for example) adding a sleeper that will enlarge the frontal area. Rather, we sell vehicles as compliant and essentially our obligation ends there (albeit with warranty requirements, etc.). Either way that the agencies propose to regulate these secondary vehicle manufacturers is fine, as long as we the primary vehicle manufacturers can continue to sell vehicles with the expectation that anyone changing them from the compliant state in which we built them will certify those changes. [EPA-HQ-OAR-2014-0827-1164-A1 p.132]

Response:

EPA is adopting the proposed regulatory language in 40 CFR 1037.601(a)(1) that states it is a violation to introduce into U.S. commerce a Phase 1 tractor containing an engine not certified for use in tractors; or to introduce into U.S. commerce a vocational vehicle containing a light heavy-duty or medium heavy-duty engine not certified for use in vocational vehicles.

For the FRM, EPA and NHTSA are revising the heavy-haul tractor provisions to better assure that vehicles are regulated in an appropriate subcategory. Based on our assessment of CBI data provided by a manufacturer, the tractors with GCWR greater than or equal to 120,000 pounds truly represent heavy-haul applications in the U.S. Therefore, we are adopting criteria only based on GCWR, not the proposed RBM or total gear reduction ratios.
The agencies evaluated the sales cap limit proposed for special purpose tractors and the comments addressing the issue of a sales cap. EPA calculated the number of vocational tractors certified in MY 2014 and MY 2015. The number of tractors ranged between approximately 2,600 and 6,200 per year per manufacturer that certified special purpose tractors, but not all manufacturers utilized this provision. From this, we can conclude that none of the manufacturers are utilizing this provision near the maximum allowable level in Phase 1. We also believe that there is more incentive for manufacturers to use the special purpose tractor provisions in Phase 1 because of the relative difference in stringency between the tractor and vocational programs is much greater in Phase 1 than in Phase 2. We therefore concluded that there is significantly less incentive for the manufacturers to reclassify tractors that are not truly special purpose tractors as vocational vehicles. In addition, the Phase 2 vocational vehicle compliance program and standards better represent the duty cycles expected of these vehicles and are predicated on performance of similar sets of vehicle technologies, except for aerodynamic technologies, as the primary tractor program. Therefore, we are adopting Phase 2 special purpose tractor provisions without a sales cap.

In response to these comments, EPA is clarifying in 40 CFR 1037.622 that small businesses may modify tractors as long as they do not modify the front of the vehicle and so long as the sleeper compartment is no more than 102 inches wide or 162 inches in height. As an interim provision, to allow for a better transition to Phase 2, EPA is finalizing a more flexible compliance path in 40 CFR 1037.150(r). This option allows small manufacturers to convert a low or mid roof tractor to a high roof configuration without recertification, provided it is for the purpose of building a custom sleeper tractor or for conversion to a natural gas tractor. Although this more flexible allowance to convert low and mid roof tractors to high roof tractors is being adopted as an interim provision, we have not established an end date at this time. We expect to reevaluate this provision as manufacturers begin to make use of and may decide to revise it in the future, potentially to make it a permanent allowance. To be eligible for this option, the secondary manufacturer must be a small manufacturer and the original low or mid roof tractor must be covered by a valid certificate of conformity. The modifications may not increase the frontal area of the tractor beyond the frontal area of the equivalent high roof tractor paired with a standard box van. See generally Section III.C.5 in the Preamble to the final rule.

Organization: Navistar, Inc.

Navistar supports creating a new Heavy Haul sub-category as this type of vehicle is specified uniquely and is not designed for standard trailers. To appropriately identify the vehicles for this category, the proposed total gear reduction ratio of 57:1 should be revised to 53:1. [EPA-HQ-OAR-2014-0827-1199-A1 p.30]

4x2 tractors with heavy duty powertrains are typically purchased to pull multiple trailers. These tractors should be classified as Class 8 vehicles regardless of their GVWR. [EPA-HQ-OAR-2014-0827-1199-A1 p.30]

Response:

For the FRM, EPA and NHTSA are revising the heavy-haul tractor provisions to balance the certainty that vehicles are regulated in an appropriate subcategory. Based on our assessment, the tractors with GCWR greater than or equal to 120,000 pounds truly represent heavy-haul applications in the U.S.

133 U.S. EPA. Memo to Docket: Special Purpose Tractor Production Volumes.
Therefore, we are adopting criteria only based on GCWR, not the proposed RBM or total gear reduction ratios.

Also for the FRM, EPA adopted regulations (40 CFR 1037.106(f)) that allow manufacturers to optionally certify 4x2 tractors with heavy heavy-duty engines to the standards and useful life for Class 8 tractors, with no restriction on generating or using emission credits within the Class 8 averaging set.

**Organization:** PACCAR, Inc.

PACCAR requests that the definition of special purpose tractors in §1037.630 be maintained as it is for Phase 1. The provision for gross combination weight rating of over 120,000 lb. should be retained since not all heavy hauling vehicles will meet all the requirements of a heavy-haul tractor but will meet the requirements for the Special Purpose Tractor and therefore OEMs should have the option to include them in this vehicle family. A modification to the definition to include “equal to 120,000 GCWR” is also requested. [EPA-HQ-OAR-2014-0827-1204-A1 p.30]

PACCAR supports the current sales limit for vocational tractors at 21,000 per OEM over a 3-year period. [EPA-HQ-OAR-2014-0827-1204-A1 p.30] PACCAR also supports removing the prohibition on the installation of vocational engines into tractors where these engines are appropriate for the customer’s application. [EPA-HQ-OAR-2014-0827-1204-A1 p.30]

**Definitions**

In the definition of “heavy haul tractors,” PACCAR has several suggestions. First, Total Reduction ratio should be 53:1 not 57:1 based on transmission and rear axle ratio combinations that are typically used in heavy-haul tractors meeting the agencies’ definition. Specifically, the ratio change will allow vehicles using 9-speed low-low and 18-speed transmissions with appropriate rear axle ratios, plus Allison heavy-duty 4500 and 4700 series automatic transmissions, to be properly included in the Heavy-Haul Tractor regulatory subcategory. The 14.4 first gear of the 18-speed transmission coupled with the 3.73 rear axle ratio is an example of a significant sales volume combination that meets the recommended 53:1 Total Reduction ratio. Second, the Drive Axle Ratio in Table III-19 of the Preamble needs to be increased numerically so that the Total Reduction ratio (lowest transmission gear multiplied by rear axle ratio) matches the heavy haul tractor definition. In the table, the 12.29 first gear ratio for the 13-speed transmission and the 3.55 drive axle ratio yield a 43.6:1 Total Reduction ratio. Changing the rear axle ratio to 4.31 would reach the 53:1 definition that PACCAR is recommending. Third, an automatic transmission torque converter ratio should be included in the Total Reduction ratio calculation to properly incorporate the slip and first gear ratio combination that is inherent in an automatic transmission. A ratio of 1.5:1 should be the minimum recommended ratio for consideration as the bottom of the range for torque converter ratios, with 2.0:1 being a more fitting ratio at the middle of the range for heavy-haul automatic transmissions. Fourth, the definition of heavy-haul should be revised to be “equal to or greater than 120,000 lb. GCWR” rather than “over 120,000 GCWR.” PACCAR agrees with the agencies’ approach that all heavy-haul tractors should be combined into a single subcategory regardless of roof height/configuration. [EPA-HQ-OAR-2014-0827-1204-A1 p.31]

**Response:**

EPA is maintaining the definition of special purpose tractors in 40 CFR1037.630 for Phase 1, with the exception of including tractors with a GCWR equal to 120,000 pounds.

EPA is retaining the 21,000 special purpose tractor three-year sales cap for Phase 1.
EPA is adopting the proposed regulatory language in 40 CFR 1037.601(a)(1) that states it is a violation to introduce into U.S. commerce a Phase 1 tractor containing an engine not certified for use in tractors; or to introduce into U.S. commerce a vocational vehicle containing a light heavy-duty or medium heavy-duty engine not certified for use in vocational vehicles.

EPA and NHTSA are revising the heavy-haul tractor provisions to balance the certainty that vehicles are regulated in an appropriate subcategory. Based on our assessment, the tractors with GCWR greater than or equal to 120,000 pounds truly represent heavy-haul applications in the U.S. Therefore, we are adopting criteria only based on GCWR, not the proposed RBM or total gear reduction ratios. See generally Section III.C.4.a to the Preamble to the final rule.

**Organization:** Truck & Engine Manufacturers Association (EMA)

**Heavy-Haul Tractor Definition**

EPA’s proposed specifications for heavy-haul tractors are unworkable. More specifically, the relevant vehicles do not actually meet the Agency’s proposed total gear reduction ratio of 57:1 or greater. Even EPA’s baseline heavy-haul vehicle only generates a 43.6:1 total reduction, which is well short of the proposed regulatory mark. Consequently, the Agency needs to lower the benchmark total reduction to 53:1. For example, the Allison 7-speed 4700 transmission and the Eaton 9LL products both are specifically designed for heavy-haul operations, but cannot meet the proposed 57:1 ratio. They could, however, meet a 53:1 specification, which is where the heavy-haul requirement should be set. To that end, the agencies should change the rear axle ratio for the baseline vehicle to attain the 53:1 total reduction ratio.1 [EPA-HQ-OAR-2014-0827-1269-A1 p.43-44]

That said, EMA supports the agencies’ proposed approach of not requiring the use of aerodynamic technologies as a component of the proposed Phase 2 heavy-haul tractor standards. Those vehicles are already quite heavy (by virtue of need), are designed to meet high-cooling needs (thus having, for example, large grilles), and generally are not designed for hauling standard trailers on highways. In addition, those vehicles are often designed to be capable of operation off-road or on difficult terrain. Consequently, mandating aerodynamic values (which could push manufacturers toward smaller grilles) or aerodynamic components (which are often unsuitable for difficult terrain) could compromise the vehicles' work. [EPA-HQ-OAR-2014-0827-1269-A1 p.44]

In addition, the agencies should revise the definition of “heavy-haul tractor” to be “equal to or greater than 120,000 pounds GCWR” rather than “greater than 120,000 pounds GCWR.” The specifications for the heavy-haul market start with and include 120,000 pounds GCWR. [EPA-HQ-OAR-2014-0827-1269-A1 p.44]

**Special Purpose Tractors**

There is a group of special purpose tractors with a gross combination weight rating (“GCWR”) over 120,000 pounds that needs to be accounted for in a separate and distinct manner. Those special-purpose vehicles, in essence, fall in between the regulatory categories for heavy-haul tractors and Class 8 tractors. Such vehicles are still appropriately categorized as “Specialty Tractors” and should be included at the manufacturer’s option in the Vocational Tractor family, even though they may not meet the total gear reduction requirement (which, as noted above, should be 53:1, not 57:1), or the frame rail RBM requirements. Accordingly, the 120,000 GCWR metric should remain as a sufficient defining criteria for Vocational/Specialty Tractors. [EPA-HQ-OAR-2014-0827-1269-A1 p.47]
1. In addition, an automatic transmission torque converter ratio should be included in the total reduction ratio calculation to properly incorporate the slip and first gear ratio combination that is inherent in automatic transmissions. A ratio of 1.5:1 should be considered as the bottom of the range for torque converter ratios, with 2.0:1 being a more suitable ratio at the middle of the range for heavy-haul automatic transmissions.

Response:

EPA and NHTSA are revising the heavy-haul tractor provisions to better assure that vehicles are regulated in an appropriate subcategory. Based on our assessment, the tractors with GCWR greater than or equal to 120,000 pounds truly represent heavy-haul applications in the U.S. Therefore, we are adopting criteria only based on GCWR, not the proposed RBM or total gear reduction ratios. With these Phase 2 changes to the proposed heavy-haul tractor definition, all tractors that would have been considered as Special Purpose Tractors in Phase 1 due to the GCWR criteria listed in EPA’s 40 CFR 1037.630 and NHTSA’s regulation at 49 CFR 523.2 will now qualify as heavy-haul tractors in Phase 2. Therefore, we no longer believe that it is necessary for heavy-haul tractors to be treated as Special Purpose Tractors. See generally Section III.C.5 of the Preamble for additional discussion.

EMA’s comments about aerodynamic limitations for heavy-haul tractors largely echo the agencies’ own concerns voiced at proposal. After considering these comments, the agencies are using a technology package that does not use aerodynamic improvements in setting the Phase 2 heavy-haul tractor standards, as we proposed.

Organization: Volvo Group

The agencies have proposed to add a heavy haul category to Class 8 tractors. We support this addition since heavy haul tractors require large engines and increased cooling capacity. In addition, most heavy haul rigs have some requirement for off-road access to pick up machinery, bulk goods, and unusual loads. For all these reasons, it is infeasible or ineffective to add many aerodynamic features to heavy haul vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.45]

Heavy Haul Tractor Subcategory

Volvo Group supports the agencies’ proposal to provide for a heavy haul tractor regulatory subcategory; however, and in support of the EMA comments, Volvo Group proposes a gross combination weight rating of greater than or equal to 120,000 lbs. and a total gear reduction at or above 53:1. In addition, Volvo Group has concerns regarding the drive cycle weighting for the heavy haul subcategory (19% transient, 17% 55 mph, and 64% 65 mph cycles). [EPA-HQ-OAR-2014-0827-1290-A1 p.45]

In reality, there are multiple types of heavy-haul tractors, each with their own specific characteristics based on operational considerations: high-roof highway sleeper tractors pulling box vans at or above 120k GCWR (e.g. long combination vehicles) that run regional and long-haul operations and can benefit from the same technologies as high-roof sleepers with 80k GCWR and should be credited for the higher payload, low- and mid-roof sleepers that primarily run long-haul routes (e.g. pulling low-boy trailers and heavy equipment), low-roof day cab tractors running regional and shorter routes (e.g. bulk haul), and then what the industry typically refers to as heavy-haul that are extremely high GCWR and can haul above 300 metric tons and sometimes run in multiple tractor configurations that provide for one or more tractor(s) pulling and one or more tractor(s) pushing. [EPA-HQ-OAR-2014-0827-1290-A1 p.45-46]
Volvo Group does not agree that certain segments of the heavy-haul population are appropriately represented by the baseline and technology packages for each stringency step. These types of vehicles typically utilize an 18-speed transmission, since they require the very close gear ratios (as the agencies noted in their technology assessment), would not likely be able to utilize even current SmartWay tires, let alone Level 2 and 3 tires as proposed in the penetration rates, would see no benefit from predictive cruise, sometimes utilize an auxiliary transmission for further reduction or closer ratios, and nearly all heavy-haul tractors have deeper drive axle ratios than the agencies have assumed (3.55). [EPA-HQ-OAR-2014-0827-1290-A1 p.46]

Lastly, Volvo Group does not agree with the proposal in Section III.D.3.d.i “Proposed Heavy-Haul Tractor Standard” that the engine installed in a heavy-haul tractor must meet the tractor engine standard defined in 40 CFR 1036.108. [EPA-HQ-OAR-2014-0827-1290-A1 p.46]

Since the agencies have given the ability for a broad definition of a heavy-haul tractor, but limited that tractor to a day cab tractor duty cycle and tractor engine standard, there is still a significant segment of the heavy-haul market which is unaccounted for. We request that the agencies add a Vocational Heavy-Haul Tractor subcategory that allows for a heavy-haul tractor which benefits from the utilization of a powertrain optimized to meet the vocational operational requirements of this segment, a technology package corresponding to those operational characteristics, and with a corresponding duty cycle and, most importantly, a payload representative of heavy-haul operation. We also request the agencies be clearer on what they perceive to be a “heavy-haul” tractor. Volvo would like to continue to work with the agencies to further define the heavy-haul tractor sub-category and any definition of an additional “Vocational” heavy-haul tractor sub-category. [EPA-HQ-OAR-2014-0827-1290-A1 p.46]

Vocational Tractor Production Limit

During the development of the Phase 1 regulation Volvo Group proposed and led the way for the creation of the Vocational Tractor subcategory. In addition, Volvo Group offered many suggestions on how to identify and categorize these vehicles in order to avoid gaming. The final proposal was based on vocational tractor characteristics and can be outlined as follows: [EPA-HQ-OAR-2014-0827-1290-A1 p.49]

1. Vocational specific model – Volvo VHD, Mack Granite, Titan, and TerraPro Or,
2. GCWR > 120,000k Or,
3. Any three of the following
   1. Configuration other than 4*2, 6*2, 6*4
   2. >14.6k FAL
   3. >46k RAL
   4. >3.00:1 OAR in trans high range
   5. >57.00:1 OAR in trans low range
   6. RBM >=2e6 in*lbs.
   7. >=20° approach angle
   8. >=14” ground clearance as measured from the lowest point of any chassis mounted component [EPA-HQ-OAR-2014-0827-1290-A1 p.49]

The first item denotes any vehicle designed specifically as a vocational vehicle and for any off-road operation. These vehicles typically meet many of the criteria from item 3. [EPA-HQ-OAR-2014-0827-1290-A1 p.49]
The second item was based on the EPA provision to allow for heavy-haul tractors to be categorized as vocational due to their operational considerations. This option will no longer be available in Phase 2 with the creation of the Heavy-Haul Tractor subcategory. [EPA-HQ-OAR-2014-0827-1290-A1 p.49]

The last item was a list of vocational tractor and vehicle characteristics that make a vehicle suitable for off-road operation and the specific tractor in question had to meet at least three of these criteria. Due to the unsuitability of the majority of these characteristics for line haul operation, especially in terms of fuel economy and ride comfort, as well as the significant added costs for these features, the agencies understood that they would provide little opportunity for gaming due to negative incentives to specify a vehicle with these features for purely highway operation, and even noted some of the Volvo proposed characteristics in the Phase I rule. [EPA-HQ-OAR-2014-0827-1290-A1 p.49-50]

Unfortunately, EPA and NHTSA could not gain consensus on these features from other OEMs since, at the time, they were utilizing several models as highway and vocational and could not commit to this approach. Thus, the EPA instituted a volume limit on the number of tractors that could be certified as vocational tractors. [EPA-HQ-OAR-2014-0827-1290-A1 p.50]

In Volvo Group’s opinion, this volume limit is overly constraining and burdensome and should be removed. Given the recent product lineup overhauls across the industry we do not believe that there are many models still on the market that are sold in large numbers into both highway tractor and vocational tractor segments, nor is there sufficient reason that any OEM cannot identify specific vehicle attributes in order to classify a tractor as suitable solely for highway use, or on/off-road use. Given the stringencies proposed in Phase 2, it is not likely that many vehicles will be able to meet the demands of both applications. As well, the agencies have made no mention of any OEM incorrectly or intentionally misapplying the Vocational Tractor provision in order to game the system. [EPA-HQ-OAR-2014-0827-1290-A1 p.50]

For these reasons Volvo Group proposes that the agencies remove the vocational tractor volume restrictions and employ a guideline based on the aforementioned vehicle characteristics, as they have done with the Heavy-haul Tractor subcategory on a much more limited basis. [EPA-HQ-OAR-2014-0827-1290-A1 p.50]

Response:

The agencies are adopting heavy-haul tractor standards for Phase 2. Volvo’s comments about aerodynamic limitations for heavy-haul tractors largely echo the agencies’ own concerns voiced at proposal. After considering these comments, the agencies are using a technology package that does not use aerodynamic improvements in setting the Phase 2 heavy-haul tractor standards, as we proposed.

EPA and NHTSA are revising the heavy-haul tractor provisions to balance the certainty that vehicles are regulated in an appropriate subcategory. Based on our assessment, the tractors with GCWR greater than or equal to 120,000 pounds truly represent heavy-haul applications in the U.S. Therefore, we are adopting criteria only based on GCWR, not the proposed RBM or total gear reduction ratios or the requirement to include a heavy heavy-duty tractor engine. With these Phase 2 changes to the proposed heavy-haul tractor definition, all tractors that would have been considered as Special Purpose Tractors in Phase 1 due to the GCWR criteria listed in EPA’s 40 CFR 1037.630 and NHTSA’s regulation at 49 CFR 523.2 will now qualify as heavy-haul tractors in Phase 2. Therefore, we no longer believe that it is necessary for heavy-haul tractors to be treated as Special Purpose Tractors. See Section III.C.5 of the Preamble to the final rule for additional discussion.
The agencies have revised the baseline heavy-haul tractor to use an 18-speed transmission and a numerically higher axle ratio to better reflect the drivelines used in these types of tractors. After considering the other technology comments and the information regarding the tire rolling resistance improvement opportunities, the agencies have adjusted the adoption rate of low rolling resistance tires.

The agencies considered Volvo’s request for an additional heavy-haul vocational subcategory and analyzed the expected technology package differences between the vocational and tractor program. As described in Section III.D.1 of the FRM Preamble, the agencies are only adopting technologies in the heavy-haul tractor category that would be applicable to the operation of these vehicles. For example, we are not adopting standards that are premised on any improvements to aerodynamics or extended idle reduction. Therefore, we concluded that there is not a need to develop another vocational subcategory to account for heavy-haul tractors.

The agencies also reviewed Volvo’s suggested criteria for Special Purpose Tractors and concluded that the Phase 1 approach and the existing criteria are working well; therefore, we do not foresee the need to adopt more restrictive criteria. The agencies are adopting in Phase 2 provisions (but not revising Phase 1) in EPA’s 40 CFR 1037.630 and NHTSA’s regulation at 49 CFR 523.2 to only allow the following two types of vocational tractors to be eligible for reclassification to Special Purpose Tractors by the manufacturer:

1. Low-roof tractors intended for intra-city pickup and delivery, such as those that deliver bottled beverages to retail stores.
2. Tractors intended for off-road operation (including mixed service operation), such as those with reinforced frames and increased ground clearance.

The agencies evaluated the sales cap limit proposed for special purpose tractors and the comments addressing the issue of a sales cap. EPA calculated the number of vocational tractors certified in MY 2014 and MY 2015. The number of tractors ranged between approximately 2,600 and 6,200 per year per manufacturer that certified special purpose tractors, but not all manufacturers utilized this provision. From this, we can conclude that none of the manufacturers are utilizing this provision near the maximum allowable level in Phase 1. We also believe that there is more incentive for manufacturers to use the special purpose tractor provisions in Phase 1 because of the relative difference in stringency between the tractor and vocational programs is much greater in Phase 1 than it will be in Phase 2. Upon further consideration, we concluded that there is significantly less incentive for the manufacturers to reclassify tractors that are not truly special purpose tractors as vocational vehicles as a pathway to a less stringent standard in Phase 2 primarily due to the fact that the Phase 2 vocational vehicle program stringency is more in line with the tractor program stringency. In addition, the Phase 2 vocational vehicle compliance program and standards better represent the duty cycles expected of these vehicles and are predicated on performance of similar sets of vehicle technologies, except for aerodynamic technologies, as the primary tractor program. Therefore, we are adopting Phase 2 special purpose tractor provisions without a sales cap. See generally Section III.C.5 of the Preamble for additional discussion.

4.5 Compliance Provisions and Flexibilities for Tractor Standards 863

Organization: A de F Limited

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 169-170.]

134 U.S. EPA. Memo to Docket: Special Purpose Tractor Production Volumes.
EPA, it appears, took the approach to carve up the combination tractor-trailer into two regulatory phases. In the first phase, a tractor manufacturer offers a coefficient of drag for their tractor, which in the case of our product is buried within that number and not quantified. Yet, it is known to be a significant contributor in lowering drag.

In the second phase, a collection of various products, largely aerodynamic, are encouraged to be incorporated into a trailer to reach the desired increase in efficiency. The truck and the trailer do not operate independent of one another. Making them more incorporated as a single efficient unit is the ultimate goal. However, EPA collects a coefficient of drag from the manufacturer for their tractor and then relies on its certification methodology for its trailers.

Response:

The agencies have developed regulations that regulate the tractor separately from the trailer for several reasons. First, the manufacturers of the tractor are different entities than those that manufacture trailers. Requiring tractor manufacturers to certify to a proper trailer configuration is thus both unnatural and unfair. The applicable principle, which EPA has applied in numerous certification contexts, is that the entity with most control over the particular vehicle segment due to producing it should normally be the entity which certifies. See 73 FR 59115. Second, tractors and trailers are not typically purchased together. Third, a specific tractor is rarely paired with a specific trailer in-use throughout its life. The agencies have adopted aerodynamic protocols that have the ability to quantify the impact of technologies, such as wheel covers, on the aerodynamic drag of the tractor and trailer independently.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Chassis testing of tractor and vocational vehicles

ACEEE supports the agencies’ proposal that tractor and vocational vehicle manufacturers annually chassis test some of their production vehicles over the GEM cycles to verify that relative reductions simulated in GEM are being achieved in actual production (p. 40190). ACEEE in its 2011 report recommended physical testing (road, track, or chassis dynamometer) for a basic set of well-defined vehicle configurations. The results of these tests should be public information. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]

Such a requirement can benefit the heavy-duty vehicle program greatly by: [EPA-HQ-OAR-2014-0827-1280-A1 p.7]

1. Helping to make further changes to the GEM model that will improve its accuracy in projecting real-world effectiveness of fuel efficiency technology packages, and [EPA-HQ-OAR-2014-0827-1280-A1 p.7]
2. Generating extensive data on vehicle performance that could be used by researchers to evaluate the program. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]

Recommendation: Chassis testing requirements

- Finalize the requirement that manufacturers provide results from annual chassis testing of a small number of vehicles. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]
- Provide the results of this testing to the public in a usable format. [EPA-HQ-OAR-2014-0827-1280-A1 p.7]
Tractor trucks

Road grade in GEM certification

ACEEE supports the agencies’ proposal to include road grade in the constant speed cycles used in vehicle certification. Significant road grade is common much of the country. Driving through the grade demands more power from the engine and hence increases fuel consumption. [EPA-HQ-OAR-2014-0827-1280-A1 p.14]

The grade profile discussed in the proposal was developed by Southwest Research Institute on a 12.5 mile stretch of restricted-access highway during on-road tests. The agencies have requested comment on related work done by the National Renewable Energy Laboratory (NREL). We agree with NREL’s concern that a cycle that requires constant speeds (55-mph and 65-mph) on positive and negative grades misrepresents the real-world operation of MD/HD trucks, because there is a strong correlation between road grade and average speed for these vehicles\textsuperscript{11,12}. The agencies should address this issue before adopting the Phase 2 rule. [EPA-HQ-OAR-2014-0827-1280-A1 p.14]

Measurement issues

We support the agencies’ proposal to shift to wind-averaged drag in the calculation of CdA. This step is necessary to capture the benefits of certain aerodynamic improvements whose primary function is to reduce drag with non-zero yaw. Such devices can provide substantial real-world savings, so the standards should promote their adoption. [EPA-HQ-OAR-2014-0827-1280-A1 p.15]

We take this opportunity to comment on an adjustment EPA proposes to the Phase 1 measurement of Cd. Phase 1 does not call for the measurement of wind-averaged drag but offers manufacturers the option of using wind-averaged drag, together with a downward adjustment factor, to estimate Cd for compliance purposes. Due to an error in the agencies’ specified adjustment factor, however, manufacturers using this option are currently generating unwarranted fuel efficiency and GHG credits. The discrepancy is significant. In order not to lose benefits of the program through the application of credits that do not correspond to real-world savings, the agencies should as soon as possible correct the factor applied to wind-averaged drag to generate Cd values for Phase 1 compliance. [EPA-HQ-OAR-2014-0827-1280-A1 p.15-16]

Recommendations: Tractor aero measurement issues

- Include wind-averaged drag, as proposed, in the final measurement protocol for tractor CdA measurement. [EPA-HQ-OAR-2014-0827-1280-A1 p.16]
- At the earliest opportunity, correct the factor applied to wind-averaged drag to generate Cd values for Phase 1 compliance. [EPA-HQ-OAR-2014-0827-1280-A1 p.16]

Standard trailer for tractor certification

The agencies seek comment on the proposed Phase 2 standard trailer configuration (p.40245). While the agencies’ decision to use a more aerodynamic trailer as the standard trailer than in Phase 1 is welcome, the proposed improvement is not sufficient. The wind tunnel testing results shown in Table 3-10 of the RIA indicates that the addition of a skirt to a trailer achieves a delta CdA of approximately 0.5 on a high roof sleeper. This suggests that the proposed Phase 2 standard trailer is a Bin IV trailer (“advanced skirt or tail,” according to the characterization in RIA Table 2-70).\textsuperscript{13} However, by the time the standard trailer is updated in 2021, the agencies’ compliance package assumes an average delta CdA = 0.66, considerably
better than that of the new standard trailer. By 2027, the compliance package has average delta CdA = 1.1. To the extent that the tractor manufacturers seek to design tractors to tow the more aerodynamic trailers coming into the market over the course of Phase 2, keeping the standard trailer static could be counterproductive. In fact, it does not seem realistic to expect that all tractors would necessarily admit testing with a standard trailer, as advanced aerodynamic designs call for more dramatic changes in cab shape. [EPA-HQ-OAR-2014-0827-1280-A1 p.16]

We recommend that, at a minimum, tractor OEMs be given the option of testing with a trailer more advanced than the proposed standard trailer. This option would help to promote the integration of tractor and trailer, which represents an enormous opportunity for savings in the longer term. Volvo’s SuperTruck project reports that it has already achieved approximately 6% drag reduction from “co-optimization” of tractor and trailer and anticipates additional drag reductions of over 10% from “integrated design.” Major gains in tractor-trailer efficiency through improved aerodynamics will eventually allow these trucks to far surpass the 2027 standards. In discussing the Peterbilt SuperTruck project, which is said to have achieved a 25% gain in fuel economy through aerodynamic improvements, the agencies observe: “This effort represents the first step in the evolution of improving the aerodynamic efficiency of tractor-trailer by radically redesigning today’s tractor-trailer combination, as a wholly integrated system rather each component, tractor and trailer, independently.” (RIA p.2-23) The RIA (p.2-24) also discusses Lawrence Livermore National Laboratory’s advanced aerodynamic research, which developed a prototype tractor-trailer designed to achieve 50 percent reduction in aerodynamic drag. [EPA-HQ-OAR-2014-0827-1280-A1 p.16]

While the standards perhaps should not anticipate that that transition will occur by 2027, Phase 2 should facilitate the transition by promoting full tractor-trailer integration. The current requirement that tractors be tested using a standard box trailer cannot recognize integration and therefore cannot promote it. [EPA-HQ-OAR-2014-0827-1280-A1 p.16-17]

Allowing manufacturers to test their tractors with advanced trailers would yield results reflecting the aerodynamic gains of both tractor and trailer, as well as their integration. To prevent double counting of the drag reductions provided solely by the more advanced trailer under this option, the result of testing would need to be corrected using a “delta CdA” approach, as is discussed in the proposal in connection with trailer aero. Specifically, a manufacturer could assign tractor X to a given bin if CdA of tractor X with aerodynamic trailer + delta CdA of aerodynamic trailer met the bin threshold. Note that the value of second term in this expression would be available from compliance testing for the aerodynamic trailer, so this approach would not increase the test burden on the tractor manufacturer. [EPA-HQ-OAR-2014-0827-1280-A1 p.17]

While tractor X might not always be paired with an aerodynamic trailer in operation and thus might not realize the calculated benefit (just as any tractor might operate with a trailer less aerodynamic than the standard box trailer), manufacturers and purchasers of advanced tractors presumably would seek to ensure that the correct pairings were made as a matter of course. As the agencies note, “tractor-trailer pairings are almost always optimized.” (p.40245) Furthermore, the value of a meaningful incentive to accelerate the aerodynamic integration of tractors and trailers likely outweighs potential costs in fuel savings of mismatched tractors and trailers. However, if the possibility of unrealized benefits poses an obstacle to allowing certification with an advanced trailer, the agencies could require that tractors so certified be used only with advanced trailers and that this requirement be indicated on the tractor label. [EPA-HQ-OAR-2014-0827-1280-A1 p.17]

It should be noted that trailer manufacturers are already given the latitude to test with any tractor of Bin III or better: [EPA-HQ-OAR-2014-0827-1280-A1 p.17]
In order to maintain a minimal level of performance, we are proposing that tractors used in trailer aerodynamic tests meet Phase 2 Bin III or better tractor requirements (see Section III.D.). We believe the majority of tractors in the U.S. trucking fleet will be Bin III or better in the timeframe of this rulemaking, and trailer manufacturers have the option to choose higher performing tractors in later years as tractor technology improves. (p. 40280) [EPA-HQ-OAR-2014-0827-1280-A1 p.17]

Tractor manufacturers should be accorded this flexibility as well. While allowing such flexibility on the tractor side, as well as for the trailer, might appear to invite double counting of tractor-trailer integration benefits that is not the case. If the trailer manufacturer has already taken credit for integration through this mechanism, that trailer’s delta Cda will have been elevated as a result. Hence the (upward) correction of the tractor’s Cda will be greater, and the tractor OEM will gain no integration credits in this situation. [EPA-HQ-OAR-2014-0827-1280-A1 p.17]

Recommendation: Standard trailer for tractor certification

- To promote integration of aerodynamically advanced tractors and trailers, provide manufacturers the option to test tractors with advanced trailers; correct the test result appropriately to account for the benefit provided by the trailer alone. [EPA-HQ-OAR-2014-0827-1280-A1 p.17]

Standard tractor for trailer certification

The Phase 2 proposal would permit manufacturers to test their trailers with tractors meeting Phase 2 Bin III or better (p. 40280). This will allow trailer manufacturers to gain credit for integration with tractors as both tractor and trailer aerodynamics evolve. Above we recommend that tractor manufacturers be given a comparable flexibility in their choice of test trailer while noting that a trailer already certified to a higher delta Cda by virtue of such integration would negate any integration benefits on the tractor side. This is appropriate, since double counting of integration benefits cannot be permitted. However, tractor manufacturers may be far more likely than trailer manufacturers to pursue the development of integrated tractor-trailer aerodynamic designs, so the availability of an integration credit on the trailer side does not diminish the need for such a credit on the tractor side. [EPA-HQ-OAR-2014-0827-1280-A1 p.18-19]

Test trailer

The comments of Volvo Trucks (p.20) state: “Either the agencies must reduce the aerodynamic targets for tractors or provide for a test trailer with advanced aerodynamics, including, at a minimum, an efficient boat-tail and side skirts.” While we do not support the view that the proposed aerodynamic targets are too demanding when the prescribed test trailer is used, making the standard trailer for testing tractors more aerodynamic makes sense. As Volvo says (p.27), “The test trailer should represent an advanced aerodynamic design that meets the 2027 trailer targets so that future tractors are designed to operate efficiently with future trailers and the combinations can achieve the desired aerodynamic performance.” Yet, by 2021, the average trailer will have better aerodynamics (delta Cda = 0.66) than the proposed standard trailer (delta Cda = 0.5). By 2027, the average trailer will achieve delta Cda = 1.1. This trailer would reduce the drag of the 2027-compliant tractor (high roof sleeper with standard trailer, Cda = 5.32) by more than 20%. [EPA-HQ-OAR-2014-0827-1896-A1 p.12]

An insufficiently aerodynamic standard trailer forgoes an incentive for manufacturers to pursue certain improvements in the tractor and elsewhere in the vehicle. As one example, Daimler notes that lower vehicle drag allows greater benefits for its eCoast technology (http://energy.gov/sites/prod/files/2015/07/f24/arravt080_vss_rotz_2015_o.pdf slide 8). As another example, an aerodynamic trailer will reduce vehicle load, which may permit the use of a smaller engine.
A more representative standard trailer will also yield better estimates of the benefits of various technologies. [EPA-HQ-OAR-2014-0827-1896-A1 p.12]

Updating the standard trailer to include an Advanced Combination (skirt and boat tail) gives delta CdA = 1.0 on average (RIA Table 2-70), which approaches the standard for box trailers in 2027. Alternatively, rather than specifying additional aerodynamic devices for the standard trailer, the agencies could simply increase the required delta CdA for the standard trailer to 1.0 and leave it to the manufacturers to select a test trailer. [EPA-HQ-OAR-2014-0827-1896-A1 p.13]

When updating the standard trailer, the agencies will need to make a corresponding (downward) adjustment to the CdA of the tractor-trailer in the compliance package and hence increase the stringency of the tractor truck standard. Otherwise, the effect of updating the trailer would be to demand less improvement from the tractor, which is counterproductive and not the intent of our comment. If the test trailer had delta CdA = 1, for example, rather than the proposed standard trailer of delta CdA= 0.5, then the high-roof tractor compliance package for 2021 should achieve CdA = 5.24, rather than the CdA = 5.74 of the proposal. This adjustment offsets the aerodynamic benefit from the trailer alone, but recognizes any savings achieved through co-optimization of the tractor and trailer. [EPA-HQ-OAR-2014-0827-1896-A1 p.13]

In addition to incentivizing co-optimization, this change to the standard trailer would make it feasible to achieve drag levels better than those in the compliance package. Volvo asserts (comments p.27; table replicated below) that its SuperTruck tractor would reach only bin IV (CdA = 5.43) with the proposed Phase 2 standard trailer, falling slightly short of the 2027 target (CdA = 5.32). However, the table shows that Volvo’s SuperTruck tractor paired with its Super Trailer would achieve CdA = 4.31. A Volvo SuperTruck presentation (http://energy.gov/sites/prod/files/2014/07/f17/vss081_amar_2014_o.pdf, slide 10) suggests that this result is achieved through trailer add-on devices followed by co-optimization. The graphic (replicated below) suggests that co-optimization alone reduces CdA by about 0.27, which is more than sufficient to meet the 2027 target, even after the target has been adjusted to reflect the trailer add-on devices. [EPA-HQ-OAR-2014-0827-1896-A1 p.13]

Beyond bringing the standard trailer up to date, the agencies should consider allowing manufacturers to test tractors with still more advanced trailers; this would promote integration of tractor and trailer. In this case, the modeled fuel efficiency of the tractor would need to be adjusted upward to reflect the delta CdA of the aerodynamic trailer (relative to the standard trailer). [EPA-HQ-OAR-2014-0827-1896-A1 p.14]

Hence, we recommend that the agencies redefine the standard trailer as one having delta CdA matching the average for the appropriate model year. The tractor standard stringency should then be adjusted accordingly. In addition, the agencies should consider allowing testing with more advanced/integrated trailers. [EPA-HQ-OAR-2014-0827-1896-A1 p.14]
In a memo referenced in the NODA, EPA clarified how a vehicle would be determined to pass or fail in selective enforcement audit (SEA) and confirmatory testing of its certified aerodynamic drag (CdA). The EPA memo is responsive to comments of the manufacturers and others regarding the proposed elimination of the compliance margin in these testing processes in Phase 2. It proposes that multiple coastdown tests be performed in SEA or confirmatory testing, and that the vehicle would fail if and only if the testing showed with high statistical confidence that the vehicle lay in a lower-numbered (higher drag) aerodynamic bin than the one to which it had been certified. [EPA-HQ-OAR-2014-0827-1896-A1 p.3]

The proposed approach represents a significant improvement over the one-bin compliance margin in Phase 1. However, it should be further improved by setting the threshold in the statistical test at the bin midpoint, rather than at the upper limit of the bin. Bin limits in the proposal appear to be based on the range of benefits from defined improvements in aerodynamic design or equipment, so a bin midpoint might best represent the result of a typical implementation of those aerodynamic improvements, making it a suitable threshold for the statistical test. Moreover, the bin midpoint is the GEM CdA input for a tractor certified to the given bin, so the midpoint is the proper value for purposes of SEA and confirmatory testing. Using the proposed procedure, by contrast, CdA values could be expected to accumulate around the upper limits of the bins. Tractor bins cover a range of drag values of about 0.5 m², or roughly 10 percent of CdA values; so the half bin between the bin midpoint and upper bin threshold is roughly 5 percent of a typical CdA value. Five percent increase in long-haul tractor-trailer drag increases fuel consumption by about 2 percent. Hence using the upper bin limit in SEA or confirmatory testing would overstate tractor emissions reductions under the standards by about 2 percent. [EPA-HQ-OAR-2014-0827-1896-A1 p.3]

Impact on proposal

The proposed SEA and confirmatory testing procedure would improve upon the current procedure but would still overstate the emissions reductions resulting from the standards. To ensure that the real world benefits of the rule are maintained, we recommend that the approach discussed in the EPA memo be revised to require that the average confirmatory or SEA test results be no higher (statistically) than the midpoint, rather than the upper limit, of the appropriate bin. [EPA-HQ-OAR-2014-0827-1896-A1 p.3]
Response:

Chassis Testing

The agencies are finalizing the tractor chassis test requirement largely as proposed. EPA believes this chassis test program is necessary because of our experience implementing regulations for heavy-duty engines. In the past, manufacturers have designed engines that have much lower emissions on the duty cycles than occur during actual use. The recent experience with Volkswagen is an unfortunate instance. By using this simple test program, we hope to be able to identify such issues earlier and to dissuade any attempts to design solely to the certification test. We also expect the results of this testing to help inform the need for any further changes to GEM. Even though there will be no direct compliance liability for the GHG testing, the agencies would still be able to identify differences in performance that resulted (on purpose or inadvertently) from how the powertrain is installed in the chassis.

Road Grade

After considering the road grade profile comments and using the NREL database, the agencies have independently developed a road grade profile for the final rules for use in the 55 mph and 65 mph highway cruise duty cycles for the Phase 2 final rulemaking. While based on the same road grade database generated by NREL for U.S. restricted-access highways, its design is predicated on a different approach. The development of this profile is documented in the RIA Chapter 3.4.2.1. The road grade in the final rules includes a stretch with zero percent grade and lower peak grades than the profile presented in the NODA. The minimum grade in the final cycle is –5 percent and the maximum grade is 5 percent. The cycle spends 46 percent of the distance in grades of +/- 0.5 percent. Overall, the cycle spends approximately 66 percent of the time in relatively flat terrain with road gradients of +/- 1 percent. A detailed discussion of the road grade profile is included in RIA Chapter 3.4.2.1.

Drive Cycle

After considering these comments and evaluating the final Phase 2 version of GEM, the agencies in the Phase 2 final rules are retaining a constant target speed for the 55 mph and 65 mph cycles, thus continuing this aspect of the Phase 1 approach. However, the addition of road grade to these cruise cycles in Phase 2 marks a significant difference with Phase 1. See Preamble Section III.E.2. The addition of road grade to the cruise cycles brings the GEM simulation of vehicles over the drive cycles closer to the real world operation described by ACEEE. Even though the cruise cycles will continue to have constant target speeds (55 mph or 65 mph), the vehicle may slow down from the target speed of the cycle on an uphill stretch of road due to the addition of road grade in the Phase 2 cycles. If the vehicle does slow down the transmission shift logic built into GEM will downshift the transmission to limit the amount of further vehicle deceleration. Similarly, on the downhill portions of the cycles, the driver control logic built into GEM will allow the vehicle to exceed the target speed by 3 mph prior to braking the vehicle.

Aerodynamic Test Procedures
The commenter suggested that the agencies adopt wind averaged drag aerodynamic assessments in Phase 2. We proposed and are adopting aerodynamic test procedures that take into account the wind averaged drag performance of tractors in Phase 2.

Phase 1 Aerodynamics Equation: EPA proposed a different equation with a ratio of 0.8330 in 40 CFR 1037.525(d) for the case of full yaw sweep measurements to determine wind-averaged drag correction as an amendment to the Phase 1 program. Some commenters argued that this change would impact stringency of the Phase 1 standard, but we disagree because manufacturers are already subject to EPA compliance using both methods (full yaw sweep and ± 6 degree measurements), and this Phase 1 flexibility was not used in setting the level of the Phase 1 standards. Nevertheless, we are adopting the final rule without amending this part of the Phase 1 rules. Commenters persuasively indicated that any such amendment to the Phase 1 rules at this date could upset compliance plans predicated on the rules remaining un-amended. These expectations and reliance are legitimate, and the agencies accordingly are not amending this aspect of the Phase 1 rules. However, the agencies evaluated the status of Phase 1 credit balances in 2015 by sector.135 For tractors, we found that manufacturers are generating significant credits, and that it appears that many of the credits result from their use of an optional provision for calculating aerodynamic drag. However, we also believe that manufacturers will generate fewer credits in MY 2017 and later when the final Phase 1 standards begin. Still, the agencies believe that manufacturers will have significant credits balances available to them for MYs 2021-2023, and that much of these balances would be the result of the test procedure provisions rather than pull ahead of any technology. Therefore, we are increasing the stringency of the CO₂ and fuel consumption tractor standards for MYs 2021-2023 by 1 percent to reflect these credits (see Preamble Section III.D.1b.xiii).

The agencies re-evaluated the proposal to include trailer skirts on the Phase 2 reference trailer after consideration of the comments. We still project that the bulk of trailers that will be in operation during the life of tractors produced early in Phase 2 will be represented by the aerodynamic performance of a trailer with skirts. Therefore, we are adopting the reference trailer as proposed. However, we also want to recognize that the trailer fleet will continue to evolve over the lifetime of tractors built and certified to Phase 2, especially from MY 2027 and later. Based on testing conducted to support the trailer portion of Phase 2, we found that on average a boat tail added to a dry van trailer with skirts reduces wind averaged CₐA by 0.6 m². We recognize that if we do not account for reduced aerodynamic loads in the real world, then we may not be appropriately evaluating the tractor powertrain. We considered changing the standard trailer in MY 2027; however, this would lead to significant testing burden for the tractor manufacturers because they would have to determine new CₐA values for their entire fleet of tractors. Instead, we are adopting Phase 2 GEM that beginning in MY 2027 will take the CₐA input for each vehicle and reduce it by 0.3 m² to reflect the lower aerodynamic loads that are a mix of trailers with skirts and trailers with skirts and boat tails. This change has been accounted for in both the baseline and standard setting of the CO₂ emissions and fuel consumption values.

Unlike the trailer program where the CₐA assessment is in terms of differences in CₐA, the tractor program utilizes the absolute CₐA result from testing. This difference in program structure requires the agencies to treat the standard tractor in the trailer program and the standard trailer in the tractor program uniquely. The impact of the test procedure allowance in the trailer program to use standard tractors that are Bin III or better is appropriately offset by the fact that the tractor aerodynamic performance is constant between the “A” test with no trailer aerodynamics and the “B” test with the trailer being certified. However, in the tractor program, a similar allowance that permitted tractor manufacturers to test with a standard trailer “with equivalent or better aerodynamic performance” would lead to a direct

reduction in the tractor absolute C\textsubscript{d}A performance and unfairly put the tractor in a more aerodynamic bin. Therefore, it is crucial in the tractor program that the standard trailer be well-defined and constant.

With respect to ACEEE’s recommendation for the agencies to facilitate the transition to more integrated tractor-trailers, such as those demonstrated with SuperTruck, the agencies believe this would require a significant change in tractor-trailer logistics to encourage more matching of specific tractors to specific trailers in operation. We believe that this would be most appropriately handled through the Off-Cycle Credit program.

The agencies used the aerodynamic test data included in the NODA to determine the Phase 2 aerodynamic bin boundaries. As shown in the RIA Chapter 3.2.1.2, the tractors tested fell into Bins III and IV. From there, the agencies evaluated additional aerodynamic technologies that could be used to move the best performing tractor tested by EPA into the more aerodynamic bins and used this assessment in developing one technology package used in developing the stringency of the tractor standard.

EPA is adopting SEA provisions for aerodynamics that do not include a one bin compliance margin. However, the aerodynamic bin structure was created such that any tractor that has a C\textsubscript{d}A value that fell within the bin boundaries is treated as compliant with that bin. We are not adopting provisions for SEAs that would essentially require manufacturers to only use the more aerodynamic half of the bin. Therefore, we are adopting the SEA provisions that consider the SEA as a “pass” if the results of the test show that the tractor falls at or below the highest C\textsubscript{d}A boundary of the certified bin. See Section III.E.2.a.ix of the Preamble for discussion on the SEA provisions.

**Organization:** American Trucking Associations (ATA)

**Drive Cycle Weightings Need to be Re-Evaluated**

The proposed rule indicates drive cycle weightings of 5\% of the transient cycle, 9\% of the constant speed 55 mph cycle, and 86\% of the constant speed 65 mph cycle for sleeper cabs. For day cabs, the weightings are 19\% of the transient cycle, 17\% of the constant speed 55 mph cycle, and 64\% of the constant speed 65 mph cycle. ATA believes these weightings are not reflective of real world operations and tend to overestimate the benefits of certain technologies, such as aerodynamics and rolling resistance, and potentially discount others. [EPA-HQ-OAR-2014-0827-1243-A1 p.18]

As discussed in Appendix 2, using 3.6 million spot speed records collected from throughout the U. S. during the month of May 2015, trucks operated at speeds of 55 mph or greater 57\% of the time. This is significantly lower that the weightings being used by EPA (95\% of the time for sleeper cabs and 81\% of the time for day cabs). As shown below, the benefits from a 20\% reduction in the aerodynamic drag coefficient (“C\textsubscript{d}”) diminishes as speed decreases. The power loss (and benefits) associated with the rolling resistance coefficient (“C\textsubscript{rr}”) of tires also diminishes as speed decreases. [EPA-HQ-OAR-2014-0827-1243-A1 p.18]

[Chart, 'Tractor-Trailer Operating Losses', can be found on p.19 of docket number EPA-HQ-OAR-2014-0827-1243-A1][16]

Given the relationship between vehicle speed and technology benefits, it is imperative that EPA and NHTSA develop drive cycle weightings that are representative of real-world operating conditions. The agencies should consult with the American Transportation Research Institute to determine how available data can be used to characterize the speeds at which trucks actually operate and incorporate this
information into the speed weightings and technology assessments. [EPA-HQ-OAR-2014-0827-1243-A1 p.19]

Response:

The agencies considered these comments along with the information that was used to derive the drive cycle weightings in Phase 1. The agencies believe that the study cited by ATA includes weightings of speed records, which represent the fraction of time spent at a given speed. However, our drive cycle weightings represent the fraction of vehicle miles traveled (VMT). The agencies used the vehicle speed information provided in the ATA comments and translated the weightings to VMT. Based on our assessment discussed in RIA Chapter 3.4.3, their findings produce weightings that are approximately 74 percent of the vehicle miles traveled are at speeds greater than 55 mph and 26 percent less than 55 mph. In addition, the study cited by ATA represents “Class 8 trucks” which would include day cab tractors (with drive cycle weightings in Phase 1 and 2 of 19 percent at speeds less than 55 mph and 81 percent at speeds greater than 55 mph), sleeper cab tractors (with drive cycle weightings in Phase 1 and 2 of 5 percent at speeds less than 55 mph and 95 percent at speeds greater than 55 mph), and heavy heavy-duty vocational trucks (with drive cycle weightings in Phase 2 ranging between 20 percent and 54 percent at speeds less than 55 mph). Based on this assessment, the agencies do not believe this new information is significantly different than the drive cycle weightings that were proposed. Therefore, we are adopting the drive cycle weightings for tractors that we adopted for Phase 1 and proposed for Phase 2.

Organization:  California Air Resources Board (CARB)

Comment – Making the constant speed test procedure the reference aerodynamic method

The RIA requests comment whether the constant speed test procedure should be the reference aerodynamic method. CARB staff believes the constant speed test procedure should not be made the reference method until it can be demonstrated to be superior to the coastdown type methods. The constant speed test procedure requires invasive and costly vehicle modifications in preparation for testing. Namely it requires installation of physical torque meters in either multiple wheel hub positions or in a custom driveshaft location. Nevertheless, while CARB staff believes it is pre-mature at this time to deviate from the accepted industry practice of the coastdown method, we also believe the constant speed procedure holds merit as a potential alternative to the coastdown method. CARB staff looks forward to working with U.S. EPA and NHTSA to examine the full potential and applicability of the constant speed procedure. [EPA-HQ-OAR-2014-0827-1265-A1 p.119]

Response:

After consideration of all of the comments, the agencies are continuing to use the Phase 1 approach of establishing coastdown testing as the reference method for aerodynamic assessment in Phase 2. See Section III.E.2.a of the Preamble and RIA Chapter 3.2 for the Phase 2 aerodynamic assessment discussion.

Organization:  Caterpillar Inc., et al.

Protocols must be clearly defined and accommodate production and test variability
There are a number of new or updated test procedures in the Phase 2 proposal including aerodynamic coast-down, fuel mapping procedure, powertrain test procedure, rear axle efficiency, Selective Enforcement Audits (SEA), and in-use chassis dyno testing. The current proposal does not include compliance margins for modified or new procedures, such as aerodynamic and engine fuel map audits. To reduce some of the variability that is inherent in the proposed test procedures, we recommend that the agencies perform confirmatory and SEA tests using the same method and location that the manufacturer used to certify the vehicle or component. Furthermore, we have worked with the agencies to improve the accuracy of the procedures, for example we have recommended the inclusion of the yaw angle in the coast-down procedure to reduce the impact of wind conditions. To account for the remaining variability, compliance margins must be included in the Phase 2 regulation. If not corrected, these issues will subject manufacturers to risks simply as a result of expected test variation that can only be mitigated by downgrading our declared certifications to levels significantly worse than the actual test results, so as to cover the range of production and test variability. We estimate these issues have the impact of raising the de facto targets by approximately 12.5%; that is, we need to achieve 36.5% efficiency improvement to meet the stated 24% target for high-rise sleeper tractors. [EPA-HQ-OAR-2014-0827-1215-A1 p.8]

Response:

The agencies have made several changes to the aerodynamic test procedures for the final rule to reduce test-to-test variability. Although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor $C_dA$'s and solicited supplemental comment on it. This new structure reflects an approach that would be consistent with the following principles:

- Test-to-test variability for individual coastdown runs can be high, so compliance determinations should be based on average values from multiple runs.
- Coastdown testing of a single vehicle is expensive and time consuming, so testing should focus more on repeat tests for the same vehicle than on tests for multiple vehicles. However, manufacturers should not be required to conduct more than 100 valid coastdown runs on any single vehicle.
- Compliance determinations should be based on whether or not the true value for the $C_dA$ falls within the bin to which the vehicle was certified, rather than on whether or not the true value for the $C_dA$ exceeds the value measured for certification.
- Given the limited ability to eliminate uncertainty, compliance determinations should consider the statistical confidence that a true value lies outside a bin.

Commenters were generally very supportive of these principles and the proposed structure. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing (or on testing that does not account for legitimately occurring test-to-test and performance variability). Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur.

Under this approach, EPA would select a production vehicle for coastdown testing, and the manufacturer would be required to perform up to 100 valid coastdown runs to demonstrate whether or not the vehicle was certified to the correct bin. EPA will address uncertainty in the measurement using a confidence
interval around the mean \( C_dA \) value. For example, the result of the testing could be a \( C_dA \) value of 5.9 ± 0.05, which would fall entirely within Bin III. If the vehicle had been certified to Bin III or lower, this would be considered a passing test. If it had been certified to Bin IV or higher, this would be considered a failing test. For each vehicle that fails, the manufacturer would be required to test two additional vehicles up to a maximum of 11 vehicles. Manufacturers would have the option to select the same vehicle configuration, or they could choose to have EPA select another configuration within the family. It is appropriate to allow manufacturers the opportunity to retest the same failed configurations because they would only do so where there had reasonable confidence that the failure did not accurately reflect the true value.

It is important to note that, although SEAs are directed by EPA, the actual testing is conducted by the manufacturer at their chosen facilities. This minimizes many potential causes of test variability, such as differences in test trailers, test tracks, or instrumentation. Thus confidence intervals need only reflect true test-to-test variability. Also, manufacturers generally rent facilities for coastdown testing as needed, which means EPA will need to provide some advance notice to allow the manufacturer to reserve the appropriate facility.

In selecting the original configuration and subsequent selections, EPA would likely consider vehicles with measured \( C_dA \) values near the top of the bin since they could be most likely to be mis-certified based on inaccurate results. However, EPA could select any configuration. For subsequent testing if the first vehicle fails, manufacturers would be allowed to retest the same configuration (but not the same exact vehicle). EPA believes this would not decrease the risk of failure for subsequent vehicles, but could allow a manufacturer the opportunity to show its design was actually compliant.

With respect to confirmatory testing, which is testing EPA conducts during certification rather than during production, EPA has generally considered its test results to be the official test results. However, we recognize that we need to treat confirmation of a manufacturer’s \( F_{alt-aero} \) differently because small changes in its value would be spread over an entire family. Therefore, EPA is adopting an interim provision that would apply the SEA confidence interval approach for confirmatory testing with respect to \( F_{alt-aero} \). EPA would also attempt to use the same test trailers, test locations, and instrumentation that the manufacturer. Nevertheless, we expect to revisit this issue in the future.

The agencies have also improved the engine test procedures and compliance provisions to reduce the agencies’ and the manufacturers’ uncertainty of engine test results. For example, in the agencies’ confirmatory test procedures we are requiring that the agencies use the average of at least three tests (i.e., the arithmetic mean of a sample size of at least three test results) for determining the values of confirmatory test results for any GEM engine fuel maps. This is in contrast to the agencies’ usual convention of utilizing a sample size of one for confirmatory testing. This at least triples the test burden for the agencies to conduct confirmatory testing, but it also decreases confirmatory test result uncertainty by at least 42 percent. Based on improvements like this one, and others described in Section 1.4 of the RTC, we believe that SET, FTP and GEM’s steady-state, cycle-average and powertrain test results will have an overall uncertainty of +/-1.0 percent. To further protect against falsely high emissions results or false failures due to this remaining level of test procedure uncertainty, we have included a +1 percent compliance margin into our stringency analyses of the engine standards and the GEM fuel map inputs.

\[136\] The statistical formula for standard error, which is a well-accepted measure of uncertainty, is the standard deviation times the reciprocal of the square root of the sample size. For a sample size of three, the reciprocal of the square root of three is approximately 0.58, which results in a 42% reduction in uncertainty, versus a sample size of one.
used to determine the tractor and vocational vehicle standards. In other words we set Phase 2 engine and vehicle standards 1 percent less stringent than if we had not considered this test procedure uncertainty.

Organization: Cummins, Inc.

Cummins supports the development of representative road grades for the vehicle GHG/FE program [EPA-HQ-OAR-2014-0827-1298-A1 p.37]

The initial Phase 2 proposed road grade profiles (see Figure 15) do not contain sufficient grade to fully exercise the vehicle powertrain, and the grade distributions do not match that of real world roads. The data in Figure 15 do not have a normal distribution of grades and only span a range of +/-2%. Data of North American roads suggest a distribution of road grades of +/-6%. The agencies have recently suggested alternative road grades (see Figure 16) that are more representative of the roads that HD vehicles encounter. Cummins supports further Agency discussions to establish more representative road grades that better represent the North American highway system. [EPA-HQ-OAR-2014-0827-1298-A1 p.37]

[Figure 15 and 16 can be found on p.37 and 38 of docket number EPA-HQ-OAR-2014-0827-1298-A1]

Response:

After considering the road grade profile comments and using the NREL database, the agencies have independently developed a road grade profile for the final rules for use in the 55 mph and 65 mph highway cruise duty cycles for the Phase 2 final rulemaking. While based on the same road grade database generated by NREL for U.S. restricted-access highways, its design is predicated on a different approach. The development of this profile is documented in the RIA Chapter 3.4.2.1. The road grade in the final rules includes a stretch with zero percent grade and lower peak grades than the profile presented in the NODA. The minimum grade in the final cycle is –5 percent and the maximum grade is 5 percent. The cycle spends 46 percent of the distance in grades of +/- 0.5 percent. Overall, the cycle spends approximately 66 percent of the time in relatively flat terrain with road gradients of +/- 1 percent. A detailed discussion of the road grade profile is included in RIA Chapter 3.4.2.1.

Organization: Daimler Trucks North America LLC

In-use aero testing, § 1037.401(b): The EPA proposes unrealistic in-use aero tests, contrary to the well-established procedures developed for IUT of engines. In engine IUT, the EPA recognizes that it would be unfair to a manufacturer to test an engine when its owner has improperly maintained it, but in the proposed aero IUT the EPA provides vehicle manufacturers no such protection. Moreover, the EPA proposes to allow itself to use any aero test procedure with no margin for compliance. Truck aero testing is subject to variability and the uncertainty of test results is compounded if the EPA can choose any test procedure—even one that the manufacturer never used. Even in engine IUT, the test procedure (the PEMS) is constrained to something with which manufacturers have familiarity. To expect that, in the case of aerodynamics, manufacturers would either become familiar with all possible test procedures, and their impact on all vehicle, or would build into every vehicle's GEM values a buffer against any aero test—when the EPA did not use such a buffer in setting standards—is not realistic. The EPA should rectify this situation by 1) constraining IUT to the test procedure(s) that the manufacturer used to derive a particular vehicle's bin and 2) assigning a realistic compliance margin of 5%, which (based on the EPA's own data) is the test-to-test variability and in turn the smallest margin that reflects statistical confidence in the differences between the agency's tested value and the manufacturer's. [EPA-HQ-OAR-2014-0827-1164-A1 p.8]

We appreciate the EPA’s recognition that “[w]ith coastdown testing, … test-to-test variability is expected to be larger relative to production variability” than for other types of testing subject to SEAs and “[c]oastdown testing of a single vehicle is expensive and time consuming” such that important changes are necessary relative to the longstanding SEA principles. We appreciate the EPA’s use of a bin approach that recognizes test-to-test variability by not expecting the SEA test value of a vehicle to exactly mirror the originally submitted test value but instead to fall within the appropriate bin. And we appreciate the agency’s having proposed some improved procedures relying only on statistically significant results. Moreover, we agree that similar issues apply to confirmatory tests, so we agree with the EPA’s approach of focusing such tests on F_alt_aero and of relying only on statistically significant results. [EPA-HQ-OAR-2014-0827-1918-A2 p.8]

We further appreciate the EPA’s willingness to work with us to minimize disruption for customers. Each vehicle is custom built for a purchaser who has waited for the vehicle and needs it to complete a job. We cannot simply grab the next vehicle on the assembly line and give it to the disrupted customer. At the same time, coast-down testing and the preparation for that testing takes a long time and must be done at a specific track, the reservation of which must be done a long time in advance. So finding a way to do the testing yet minimize the disruption is very important. [EPA-HQ-OAR-2014-0827-1918-A2 p.8]

In the proposed regulation § 1037.301(d)(1)(i), the EPA proposes to require that manufacturers coastdown a vehicle “in its production configuration.” The data submitted to the agencies as part of certification, however, involve putting each vehicle at a predefined tractor-trailer gap of 45 ± 2 inches, in order to reduce test burden for every actual gap. The regulations should state that we either test at the regulatory gap or use good engineering judgment to correct actual tests to reflect test results if we used the regulatory gap. (We generally have “rule of thumb” estimates for the increase in Cd*A due to a particular increase in gap). [EPA-HQ-OAR-2014-0827-1918-A2 p.8]

Making available any F_alt_aero vehicle for EPA audits: We agree with the agencies’ approach in 1037.201(g). The agencies recognize that we cannot store indefinitely a large number of test vehicles, nor can we guarantee that on any given day we will have exactly the configuration of vehicle that the EPA demands in 1037.201(g). Rather, if the EPA intends to require testing of a lot of full-scale vehicles, either through coast-down or constant-speed testing, the EPA should understand that we need to sell some of those vehicles. In turn the EPA should agree to work with manufacturers to find acceptable test vehicles at acceptable times, which perhaps means that the EPA’s first choice of vehicle is not available on the day the agency requests it. But the agencies have proposed that manufacturers be able to produce similar vehicles, not the original test vehicles. We agree with this approach. 1037.201(g) / 80 FR 40617 [EPA-HQ-OAR-2014-0827-1164-A1 p.10]

1. SEAs, generally

**Aero audits and compliance:** The test procedures dictate the need for additional compliance margins. The agencies propose to authorize audits of vehicles’ aerodynamics with no compliance margin. 40 C.F.R. §§ 1037.150(k) and 1037.401(b) (proposed). However, in setting stringencies for vehicle standards, the agencies did not consider the safety margin that manufacturers would need in order to certify under such a regime, thus making the agencies’ proposed standards impossibly stringent. The variability of coast-down testing is on the order of +/- 5%, based on the EPA's test data using our Cascadia vehicle under very controlled conditions (low wind, the same flat test track, skilled driver, and so on). (See the chart below, showing the EPA’s measured data plotted relative to DTNA’s measurement...
of the same vehicle) If the EPA expects a manufacturer to certify vehicles with no safety margin in the rules to account for this 5% variability, then the manufacturers will have to certify vehicles at 5% above their true Cd*A. In turn, the agency’s stringency numbers need to be decreased to reflect the fact that what the agency believes is achievable improvements in aerodynamic minus the 5% safety margin is all that can go into GEM. Alternatively, and better for the EPA, is to recognize the variability in audit procedures and to say that a vehicle fails an audit if it’s Cd*A is more than 5% above the certified level. 1037.150(k) [EPA-HQ-OAR-2014-0827-1164-A1 p.6-7]

[Aero SEAs needs to operate in the manner proposed by the EMA - First, the EPA needs to add in a compliance margin or else to relax the emission standards, as manufacturers would need to use compliance margins to account for the test-to-test variability associated with truck aero testing--yet the EPA did not factor such margins into the standard setting, thus rendering the agency standard values unachievable. In addition, the EPA’s proposal to have SEAs involve testing two or six additional vehicles, beyond those originally planned for testing, is untenable. Testing will have to take place at a specific track in Cape Canaveral, Florida, given the constraints on test facilities. There is no guarantee the Cape Canaveral facility will be available for the life of the phase 2 program. And data analysis takes time. For manufacturers to know that vehicles might fail an SEA (e.g., due to test-to-test variability inherent in truck aero procedures) and to get two or six additional vehicles out to the test facility within a test window is not possible. Rather the EPA should 1) assign a realistic compliance margin, as the agency did in Phase 1, and 2) allow realistic SEA procedures like testing another vehicle at a later date. 1037.301(d), 80 FR 40623. [EPA-HQ-OAR-2014-0827-1164-A1 p.7-8]

Audits using constant speed testing – Similar to the previous comment, the agencies propose to adopt procedures for constant speed testing and, as we understand the NPRM and our subsequent discussions with the EPA, to allow for confirmatory tests and SEAs using the constant-speed test procedure. Having vehicles auditable through a procedure with which we are not familiar is very problematic: we cannot ensure compliance if we are not familiar with the test. There is no time to properly study if constant speed testing is equivalent or better than coast down testing to determine the aerodynamic drag coefficient. The complex and time consuming test procedure would require multiple studies to determine the reproducibility of the results and comparison to results from coast down test. We recommend that the constant speed as an alternative or allow more time to study the proposed procedure. In the meantime, we recommend that the agencies confirm that the constant speed test is an alternative procedure for use solely at the manufacturer’s discretion. [EPA-HQ-OAR-2014-0827-1164-A1 p.55-56]

Chassis Dynamometer Tests

The agencies must find a more reasonable approach for the In-Use Testing (IUT) requirements in § 1037.665. Although we support the agencies’ efforts to validate that FE improvements from the regulatory realm translate to actual on-road improvements, the agencies’ proposed method is burdensome yet will not get the agencies the information they purport to want. [EPA-HQ-OAR-2014-0827-1164-A1 p.6]

* Unnecessary Burden of In-Use Tractor Testing With Chassis Dyno - We support auditing vehicles. However, the In-Use Testing (IUT) requirements in § 1037.665 are burdensome and will not get the EPA the information the agency purports to want, a validation that GEM’s measured trends are observed in the real world. In particular, regarding burden: the agencies note that there are few heavy-duty chassis test sites in the country. We do not have one, and we are the largest manufacturer of heavy-
duty vehicles in the country. Other manufacturers may have them, and indeed the agencies’ state that they “have seen an increased interest in building new sites.” 80 FR 40178. However, we are not aware of any of our competitors building them. (They may be doing so, but we are not aware of it). We do know that the “EPA is currently building a heavy-duty chassis dynamometer.” Id. If the agency decides to push forward with chassis dyno testing then, with the EPA having a facility and some or all manufacturers not, the best course of action is for the EPA to test vehicles in its facility rather than requiring the manufacturers to do so, or to work with industry on developing other methods of validating GEM results. We would be more than willing to support the agency in performing tests at its facility, helping with the set-up and preconditioning of the vehicles, etc. On a more minor level, the agency should clarify that the stated production volumes are annual, as the time frame over which the 20,000 applies is unstated. 80 FR 40657. [EPA-HQ-OAR-2014-0827-1164-A1 p.11]

- **Chassis Dynamometer Testing Costs** - The agencies request comment on the costs (and efficacy) of the chassis dyno data submission requirement. 80 FR 40178. (Efficacy is addressed in the next comment, below). Although Daimler Trucks North America is the largest heavy-duty vehicle manufacturer in the country and has some of the most expansive test facilities, including the industries only full-scale wind tunnel, we do not have a chassis dyno facility that is capable of the type of measurements that the agencies propose to require of manufacturers. Moreover, we would need to build such a facility and expect that it would cost us the same as it costs the EPA, who is building such a facility right now. While we are not certain how much that is, the agency should know better than us. But in any case, costs are in the millions of dollars, and facilities would be needed to test only five vehicles per year on a test cycle that fails to replicate the on-road operation of vehicles. In other words, this would be a costly way to get data; it is not cost effective. [EPA-HQ-OAR-2014-0827-1164-A1 p.11]

- **Efficacy of Chassis Dyno Testing and Better Alternatives** - The EPA and NHTSA propose chassis dyno testing with the explanations that the agencies 1) need to validate the GEM simulation tool on a continuous basis and 2) foresee the need to continue to track the progress of the Phase 2 program throughout its implementation. We strongly support validating GEM and tracking the Phase 2 program to ensure that real-world FE improvements translate into the regulatory realm and vice versa. The agencies request comment on the efficacy of their proposed requirement that manufacturers conduct and submit data from annual chassis dynamometer tests of three sleeper cabs tractor and two day cab tractors (and provide corresponding GEM results). Although we support validation and correlation to real-world testing, we wish to ensure that the testing actually validates GEM and actually correlates to real-world FE. [EPA-HQ-OAR-2014-0827-1164-A1 p.11]

Unfortunately, the agencies’ proposal will not achieve its aims. In order to be able to track incremental improvements, measurement tools must have the capability to measure with requisite accuracy and repeatability, and the test process must be able to emulate the vehicle features that cause those FE gains. The limited number of existing chassis dynamometer facilities are largely of unknown quality relative to their ability to conduct repeatable, comparable or accurate tests for the purposes intended by EPA. Moreover, chassis dyno testing cannot replicate the real-world conditions like intelligent coasting on grades (“eCoast”), predictively adjusting vehicle speed on hills, adapting ride height at speed, using advanced cooling system controls, etc. In other words, the chassis dyno testing will miss many important FE benefits and consequently should not be expected to correlate to real-world FE improvements. [EPA-HQ-OAR-2014-0827-1164-A1 p.12]

Additionally, without conducting separate tests to re-quantify aerodynamic characteristics and tire rolling resistance (which account for more than 70% of a vehicle’s load factor) for the trucks being tested, the tests will capture only powertrain impacts. We do not recommend adding to vehicle manufacturers’ workload by requiring that they retest aerodynamics and that they delve into tire testing (which is now the
responsibility of tire manufacturers). But without such testing, the chassis dyno test may as well be a simple powertrain test or, because of the limited gear shifting involved in the drive cycles for linehaul vehicles (see our “Detailed proprietary transmission shift logic” comments below), just an engine test. In short, the testing can be done much more simply. [EPA-HQ-OAR-2014-0827-1164-A1 p.12]

As an alternative that will get at fleet-averaged characteristics as the agencies want, we propose tracking of GEM input data. That is, the agencies better achieve their goal of tracking manufacturers’ progress in improving critical vehicle attributes by tracking those attributes, rather than sampling a limited number of vehicle variants, as the agencies proposed. As another alternative, DTNA recommends that agencies and industry revisit the concept of chassis dyno testing and its potential uses in a cooperative manner through a cooperative program similar in nature to past programs, for example those conducted to establish protocols for in-use emissions measurement. [EPA-HQ-OAR-2014-0827-1164-A1 p.12]

1.8 % Downspeeding credit for GEM - The agencies propose to credit vehicles whose powertrains allow for downsped operation. 80 FR 40221. The agencies propose that the credits would not be part of a pull-down menu-type or post-processing-type credit but 'demonstrated through the Phase 2 GEM inputs of transmission gear ratio, drive axle ratio, and tire diameter' as well as engine fuel map. Id. We agree that this is the correct approach. And to be clear, although the agencies project that downspeeding will 'improve the fuel consumption by 1.8 percent' (Id.), we understand the agencies are not proposing to give a post-processing-type credit for downsped engines. If we understand correctly, then we agree with the agencies. If however the agencies do plan post-processing credits for vehicles somehow characterized as downsped, then we disagree with the agencies' approach, as it will double-count benefits of technologies and will involve a difficult definition of what exactly is a downsped vehicle. [EPA-HQ-OAR-2014-0827-1164-A1 p.20] [redacted] [EPA-HQ-OAR-2014-0827-1164-A1 p.21]

Continuing the same tractor categorization – The agencies propose to continue the same tractor categories, except with the improvement of adding a heavy-haul category. We agree with the agencies. 80 FR 40142. [EPA-HQ-OAR-2014-0827-1164-A1 p.31]

Heavy-haul Regulatory Sub-Category (RSC) added - We agree with and strongly support the agencies’ proposal to add heavy-haul regulatory categories. This is very important, certainly in the US where heavy-haul vehicles have been mischaracterized and regulated improperly as normal highway, high-speed vehicles, but particularly in Canada which allows higher weights than the US and has a greater fraction of vehicles designed for heavy-haul operation. [EPA-HQ-OAR-2014-0827-1164-A1 p.33]

Artificially Biasing Drive Cycles and Weightings - The agencies describe the fact that for tractors the agencies retain the same weightings of the three speed cycles (the 65 mph, 55 mph, and ARB transient cycles) as in Phase 1. The agencies request comment on the need to include segments of lower or variable speed operation in the nominally 55 mph and 65 mph drive cycles used in GEM and how this may or may not impact the strategies manufacturers would develop. We have discussed at length with the agencies the need to match the regulatory drive cycles to real-world driving. We support the agencies' work with NREL to use real-world data measured on a statistically representative sample of vehicles in order to characterize the actual split between operation at high speeds, mid-speeds, and low speeds and then to weight the various drive cycles accordingly. If the work with NREL shows a different weighting is necessary for some regulatory sub-category, then we support changing to that weighting so as to maintain alignment with real-world operation. That said, we do not see a benefit to increasing the amount of low speed operation for tractors. These vehicles consume the largest portion of their fuel at high speeds and are thus designed around such operation. [EPA-HQ-OAR-2014-0827-1164-A1 p.40-41]
On the other hand, we do see a benefit to allowing increased variability in the vehicle speeds during high speed cycles. In particular, with systems such as Soft Cruise and Predictive Cruise Control, vehicles optimize fuel consumption by allowing deviations from a set cruise speed. The tighter a speed band that a vehicle is forced to maintain, the larger the torque excursions are required to maintain the speed within that band. If a vehicle can slow down and speed up within a larger band around the set cruise speed during hill climbs and descents, the better the vehicle can minimize fuel consumption. So when the agencies create a very narrow acceptable speed band and apply it to engine or powertrain testing, the agencies limit manufacturer’s ability to apply a known fuel saving strategy. We recommend further discussion about how to constrain speeds within testing. 80 FR 40242. [EPA-HQ-OAR-2014-0827-1164-A1 p.41]

Representing Traffic - The agencies request comment on whether we should consider varying the vehicle target speed over the 55 mph and/or 65 mph duty cycles to simulate human driver behavior reacting to traffic congestion. 80 FR 40242. DTNA believes that, for regulatory purposes, using constant speed cycles with representative long haul road grade profiles are appropriate. In fact, DTNA uses the same type of drive cycles for internal development purposes. First, we run actual test vehicles over a number of long-haul routes that we frequently use (and that we have come to understand are representative of nationwide average driving) to prove out the real world effect of each technology's fuel consumption reduction potential. Second, we run simulations on the same routes in various DTNA simulation tools for the purposes of validation as well as projection of future fuel economy improvements. These routes, tested and simulated, are largely highway routes with minimal time spent stuck in traffic. We have found very good correlation between these two development approaches and support the agencies in adopting the proposed approach for the high speed drive cycles in GEM. In short, we do not see any value in implementing traffic related information into GEM. While varying traffic patterns certainly occur in the real world it would be extremely difficult to come up with traffic patterns that represent a national average. We believe that a regulatory simulation tool should not get into this kind of, in this case unnecessary, detail. [EPA-HQ-OAR-2014-0827-1164-A1 p.41]

Empty Weight and Payload Used in GEM - The agencies propose to carry over the empty weight and payload from Phase 1 to Phase 2. 80 FR 40242. These weights were based on data from in-use vehicles. There is, of course, a large spread in weights across any one regulatory subcategory given the variety of different features that a vehicle might incorporate, in order to perform its task. So it is difficult to say that the agencies the exact weight correct or to refute the agencies' weight estimates. That said, the agencies' estimated Class 8 sleeper cab tractors are heavier than ours but seem to match with some of our competitors' vehicles. So these seem to be reasonable. The day cab weights, however, might be about 500 lb. too high, perhaps from underestimating the average weight of a sleeper. The deltas from high to mid- and low-roof in both sleeper and day cabs seems reasonable, again given the large variety of vehicles. The payload weight is even harder to pin down, given that weights can change from good economic times to bad, and given that a number of carriers (like [redacted]) are trying to minimize dead volume thus driving weight per load up. Due to this trend, the agencies might consider increasing the payload weight for the regulatory subcategories. [EPA-HQ-OAR-2014-0827-1164-A1 p.50-51]

Weight reduction credits, specifically - Hoods and fairings are not credited enough for the difference between steel and thermoplastic: for example, a thermoplastic hood is not a mere 65 lb. less than a steel one. § 1037.520 Table 4. [EPA-HQ-OAR-2014-0827-1164-A1 p.51]

Weight reduction credit for <15L engines - The agencies requested comment on the weight reduction credit for engines less than 15L. 80 FR 40249 Table III-36. We oppose the arbitrary credit for DemanDetroit.com. [EPA-HQ-OAR-2014-0827-1164-A1 p.51-52]
Qualifying a transmission as automatic or automated manuals – The agencies propose to give a credit to automatics and AMTs based on, among other things, the fact that these transmissions eliminate the problems faced by bad drivers. Then, it should not be necessary for vehicle manufacturers to expend a lot of effort certifying the transmissions as eligible for the credits, as little benefit is added. Rather, the agencies should write into the rule that a transmission qualifies upon a very simple showing that 1) there is no clutch pedal and 2) the driver can leave the transmission in a “drive” position and not have to shift gears as the vehicle accelerates through the gears. [EPA-HQ-OAR-2014-0827-1164-A1 p.78-79]

Additional technologies that should be considered for fuel saving technology credits – The agencies request comment on recognizing additional technologies that should get post-processing credits in GEM. The table 'Vehicle Side Fuel Saving Technologies' can be found on p.82-86 of docket number EPA-HQ-OAR-2014-0828-1164-A1. The technologies include e-Coast, autonomous vehicles, battery APU, fuel fired heater, diesel APU, driver coaching, safety technologies, fan power demand reduction, advanced cooling systems, air compressor and other accessories, cab insulation, high efficiency glass, high efficiency lighting, air conditioning system improvements, reduced tractor-trailer gap, and dynamic ride height. [EPA-HQ-OAR-2014-0827-1164-A1 p.82].

Allowing credits from Phase 1 to be used in Phase 2 is the correct approach to smooth transition into the new program, which would otherwise be very difficult in an industry so complex as HDV manufacturing. That is, with such a variety of products, it is impossible to change over an entire product portfolio at one time, as we have described to the EPA on numerous occasions (e.g., during our staggered transition to aftertreatment devices). If the Phase 2 rules drive large technology changes, it will be crucial for manufacturers to stagger transitions, which means use of credits. Thus the agency's choice to continue credit carry-over is the correct approach. 1037.701(j) [EPA-HQ-OAR-2014-0827-1164-A1 p.116]

Aerodynamics (wind average drag, coast down, constant speed testing)

Aero test procedures - The agencies requested comments on aero test procedures. We have worked with the EMA on our comments about 1) improving the coast-down test procedures, 2) minimizing the number of $F_{alt\_aero}$ tests required, and 3) delaying the constant-speed test procedures for another rulemaking. We incorporate those comments as if they were our own. [EPA-HQ-OAR-2014-0827-1164-A1 p.55]

- **Constant speed testing** – The agencies request comment on the need to change the reference method for the Phase 2 final rule to constant speed testing, including comparisons of aerodynamic test results using both the coast down and constant speed test procedures. 80 FR 40244. The EPA should not change the reference method for Phase 2 to constant speed testing. More time is required to determine if constant speed testing would be a better alternative to the coast down test procedure. We propose to keep constant speed testing only as an alternative to the coast down test, for use at a manufacturer’s discretion. [EPA-HQ-OAR-2014-0827-1164-A1 p.55]

- **CFD Procedures** - The agencies proposed some revisions to the CFD procedures in § 1037.531 and requested comment on them. The agencies proposed to change certain aspects of the CFD regulation but to leave unchanged the simulated vehicle speed of 55 mph. We recommend changing to 65 mph to align with the coast-down testing's high speed range and to better align with the regulatory drive cycles. Otherwise, the agencies' changes are fine. [EPA-HQ-OAR-2014-0827-1164-A1 p.56]

- **Additional Aero Components On The Reference Trailer** - The agencies propose to add side skirts to the trailer used for tractor certification and request comment on whether to add other aerodynamic features. 80 FR 40245. First, we strongly agree with the agencies' proposal to add side skirts. We see the industry heading toward trailers with skirts, and we design our tractors to perform
optimally with such features. So it is appropriate that the agencies test the tractors that way. To do otherwise would be to lock in old style trailers with future aerodynamic tractors, which would compromise tractor designs, as the agencies note. Second, on the question of additional features, we think that trailer features need to be addressed as part of the larger aero package that we discuss in the present comments and in the EMA comments. In particular, given that the agencies’ current aero bin and penetration rate proposals (in the NPRM) create impossible targets—for example, putting Super Truck’s tractor in Bin V because of the use of the regulatory trailer, as we have explained to the agencies—we could rectify this problem by either a) correcting the aero bin Cd*A entry criteria or b) adding trailer aero features like a boat tail, in either case to align with the agencies’ desired qualitative criteria. (These proposals are discussed more fully below). After all, as we explained earlier, the Super Truck tractor and trailer will fall in Bin VII (assuming no compliance margin is needed) as the agency had expected, so the lack of trailer features is part of the misalignment problem. That said, we would prefer option a, to correct the aero bins and keep the trailer as the agencies proposed in the NPRM, thereby minimizing cost and complexity of testing. If the agencies choose option b, we need more specifics about the trailer to understand what the agencies propose and whether that aligns with real-world trailers. [EPA-HQ-OAR-2014-0827-1164-A1 p.56]

Full Yaw Sweep versus Surrogate Angle for Wind Average Drag - The agencies request comment on whether to use a full yaw sweep to determine the wind averaged drag, as specified in Appendix A of the SAE recommended practice number J1252 ‘SAE Wind Tunnel Test Procedure for Trucks and Buses.’ 80 FR 40245. As we have discussed with the agencies since the NPRM’s publication, the use of a full yaw sweep is not overly burdensome when a manufacturer is testing a vehicle in a scale model wind tunnel; rather, the model may be turned and measured very easily. So we agree with the use of a full yaw sweep (or at least a number of important yaw angles, omitting unimportant ones at large yaw angles) at a scale model wind tunnel. On the other hand, in CFD, where a full yaw sweep is very resource- and cost-intensive, we believe that use of a surrogate angle is the better approach. The reason for this is that, although in theory a surrogate angle is potentially less accurate than a full yaw sweep, we and other manufacturers found through analysis of aero data that most vehicles have a wind-averaged drag Cd that fall extremely close to the Cd at 4.5 degrees yaw, when measured at 65 mph. (See table below). Therefore that angle is sufficiently accurate that we believe the minor deviation from the true wind-averaged drag is a small price to pay for the great savings in resources and money for testing. We should note that we had told the agencies in Phase 1 that 6 degrees yaw is an appropriate surrogate angle. That was for 55 mph vehicle speed. But as we focus on 65 mph, the wind angle becomes smaller, and 4.5 degrees is appropriate.

[Table, listing yaw angle for various vehicle configs, can be found on p.61 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

These are six DTNA sleeper configurations, multiple model years of various technology levels, all with the yaw angle for wind averaged drag within 0.3 degrees of the 4.5 degree surrogate that we suggest. In short, we believe that for scale model wind tunnels, a full yaw sweep or abbreviated yaw sweep is appropriate, while for CFD the use of a surrogate angle is best. [EPA-HQ-OAR-2014-0827-1164-A1 p.61]

No carryover of aero data from Phase 1 to Phase 2: Given the changed test procedures and trailer specifications, this seems appropriate. 1037.150(r) [EPA-HQ-OAR-2014-0827-1164-A1 p.61]

We agree with the agencies’ proposal to continue a procedure where we can use high-roof test data in lieu of testing mid-/low-roof vehicles; we strongly support continuing that.
Aero bin boundaries and penetration rates –

The agencies must resolve problems with aerodynamic test procedures and binning, as the problems make the agencies’ proposed standards impossible. [EPA-HQ-OAR-2014-0827-1164-A1 p.5]

Proposal A: The bottom line is that we propose to align the agencies’ aero bins with the agencies’ expectations of where the aero bins should be, and we propose to align penetration rates with aggressive but hopefully achievable rates. Note that this proposal is contingent on 1) revised aero testing procedures and 2) some compliance margin in the case of SEAs. If the agencies do not agree to these related proposals, then the whole package falls apart and we cannot ensure that the present proposal remains reasonably achievable. Below are the landmarks that we used in setting our proposed aero bins for raised roof Class 8 sleepers:[EPA-HQ-OAR-2014-0827-1164-A1 p.57]

[Table, with Cd*A values for various vehicle types, can be found on p.57 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

Note that we set Bin III as we understood the agencies intended to set it: we took the vehicle that the agencies used in setting Phase 1 targets (2010 vehicles) and translated its Cd*A into the wind-averaged drag space, added the implicit compliance margin, and put this in the middle of Bin III. Note that the baseline remains Bin III, as the agencies intended. To provide upper and lower bounds for our bins, we 1) put classic styled vehicles in Bin I and 2) assumed that a Super Truck was in Bin VII, as the agencies intended to allow room for improvement from ST. Since improvement is not possible from there, we think ST should be in Bin VII. [EPA-HQ-OAR-2014-0827-1164-A1 p.57]

Note additionally that we included a compliance margin in the landmark vehicles, because we are not yet certain that the agencies will amend the NPRM proposal to allow a compliance margin on confirmatory tests or SEAs. [EPA-HQ-OAR-2014-0827-1164-A1 p.57]

Using these landmarks, and trying to keep the aero bins to approximately the same widths as the agencies’ proposed ones (wider in the worse bins, narrower in the better bins, reflecting the increasing difficulty of making improvements as one improves through the bins), we get the following proposed bin targets, which we show next to the original proposal for the sake of comparison: [EPA-HQ-OAR-2014-0827-1164-A1 p.57]

[Table, showing BIN targets of EPA and DTNA proposals, can be found on p.57 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

Note that we are essentially just shifting approximately one bin (e.g., where Bin I was 7.3 m2 or worse, now Bin II is now at 7.3 m2 or worse) and trying to keep the bin widths approximately the same as originally proposed. [EPA-HQ-OAR-2014-0827-1164-A1 p.58]

Also in that table are the inputs to GEM that would correspond. Note that by changing the inputs to GEM from those in the NPRM, the agencies will have to change the stringency levels by rerunning GEM to determine the corrected g CO2/ton-mile numbers. If the agencies determine that there is sufficient penetration in the market of trailers with boat-tails, then the agencies would not change the test trailer for certification but would update the Cd*A results of each bin, bumping them down by 0.5 m2 to reflect in GEM the actual on-road aero load. This is reflected in the rightmost column of the chart, as compared to the second-to-right. [EPA-HQ-OAR-2014-0827-1164-A1 p.58]
Proposal B: Another alternative is to re-define the test trailer to include a boat tail. This would effectively shift all tractors one bin better than in the current NPRM. The EPA can then maintain the bin definitions and the baselines as proposed in the NPRM. This also achieves their stated goal of Super Truck being in Bin VII. Further, it has the effect of providing GEM the correct aero loads when boat tails do become widely adopted, such that GEM in turn calculates an accurate engine torque and fuel consumption rate. The boat tail adoption rate issue can be addressed in a manner similar to Proposal A above, but the Cd*A inputs into GEM are adjusted upwards by ~0.5m² only for a first period of Phase II (“Step 1”), after which time boat tails are relatively widespread and we shift to Step 2: [EPA-HQ-OAR-2014-0827-1164-A1 p.58]

[Table, hi-roof sleepers for Phase II NPRM and Proposal B, can be found on p.59 of docket number EPA-HQ-OAR-2014-0827-1164-A1]

There are two advantages to this proposal:

1) It defines the trailer up front without the risk of changes mid-way through Phase II [EPA-HQ-OAR-2014-0827-1164-A1 p.59]
   a. The EPA has hinted at this and maybe forced by boat tail adoption rates
   b. This would add certification burden via reference test and an updated Falt-aero

2) It forces the EPA to reconcile the test trailer with a “Super Truck” based stringency [EPA-HQ-OAR-2014-0827-1164-A1 p.59]
   a. The trailer has a majority contribution to the aero improvement in Super Truck
   b. It’s impossible to achieve Super Truck aerodynamics without a “Supertrailer”
   c. [redacted]

We propose working with the agencies on setting bin boundaries for the other RSCs in the same manner as above: [EPA-HQ-OAR-2014-0827-1164-A1 p.59]

Post Useful Life Modifications - The EPA clarifies that 1) it is allowable to modify a vehicle prior to the end of its regulatory Useful Life in the case that the modification does not increase regulated emissions and 2) the agency specifically wrote 1037.655 to allow modifications after the UL where the modifier has a good faith reason to believe that the modification will improve the vehicle's efficiency in its operation. 80 FR 40252. But the agency requests comment on the continuation of the provision that it is generally prohibited for any person to remove or render inoperative any emission control device installed to comply with the requirements of part 1037. We think that the agency has the correct approach in allowing modifications where there is a good reason to believe that it will provide improved the fuel efficiency in use, and we think that this should not be limited until after the UL--as the EPA clarifies in the NRPM. That is, a vehicle may be used for many different tasks, it may have many different sets of equipment on it, and it may have different tires according to driving conditions. And where these choices improve actual in-use fuel efficiency, the agency should not interpret the law to prohibit such improvement--certainly not if it is done before the arbitrary time of the UL. We think that the agency is correct to clarify that if regulated emissions do not increase, a modification is legal, and we think that the agency should go further by allowing modifications in good faith before the UL. [EPA-HQ-OAR-2014-0827-1164-A1 p.120]
Response:

*In-use Aerodynamics Testing*

The agencies considered the comments related to the proposed in-use aerodynamic testing regulations (40 CFR 1037.401). Any in-use testing would be limited to full-scale testing and would be required to be correlated to coastdown testing. Thus, the likely testing would be coastdown testing. The provisions of 40 CFR 1037 subpart F would apply, along with the compliance margin built into the aerodynamic bins. With respect to the “improperly maintained” comment, the agencies note that any recall action under the provisions in 40 CFR 1068.505 would require EPA to make a determination that a “substantial number of properly maintained” engines or equipment do not conform to the regulations.

*SEAs*

Although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor $C_dA$'s and solicited supplemental comments on it. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur. It is important to note that, although SEAs are directed by EPA, the actual testing is conducted by the manufacturer at their chosen facilities. This minimizes many potential causes of test variability, such as differences in test trailers, test tracks, or instrumentation. Thus confidence intervals need only reflect true test-to-test variability. Also, manufacturers generally rent facilities for coastdown testing as needed, which means EPA will need to provide some advance notice to allow the manufacturer to reserve the appropriate facility. Additional discussion is included in Section III.E.2.a of the Preamble to the final rule.

EPA adopted SEA provisions that state that we may conduct aerodynamic testing using either the coastdown (reference) test method or the aerodynamic method used by manufacturer to certify the tractor. We would not conduct a constant speed test for SEA if it was not used by the manufacturer to certify the tractor.

In Section III.E.2.ix, the agencies state that although SEAs are directed by EPA, the actual testing is conducted by the manufacturer at their chosen facilities. This minimizes many potential causes of test variability, such as differences in test trailers, test tracks, or instrumentation. Thus confidence intervals need only reflect true test-to-test variability. Also, manufacturers generally rent facilities for coastdown testing as needed, which means EPA will need to provide some advance notice to allow the manufacturer to reserve the appropriate facility.

With respect to the comment regarding trailer gap, EPA specified the tractor-trailer gap in 40 CFR 1037.501 of less than or equal to 45 inches. However, we also note in 40 CFR 1037.525(b)(6), that if the tractor-trailer cannot be configured to meet the gap requirements, then manufacturers should use good engineering judgment.
The agencies are adopting provisions in 40 CFR 1037.201(g) that provides the manufacturers to choose to deliver another vehicle or component that is identical in all material respects to the test vehicle or component, or a different vehicle or component that we determine can appropriately serve as an emission-data vehicle for the family.

**Tractor Chassis Dyno Testing**

After consideration of the comments, the agencies are requiring tractor manufacturers to annually chassis test five production vehicles over the GEM cycles to verify that relative reductions simulated in GEM are being achieved in actual production. See 40 CFR 1037.665. We do not expect absolute correlation between GEM results and chassis testing. GEM makes many simplifying assumptions that do not compromise its usefulness for certification, but do cause it to produce emission rates different from what would be measured during a chassis dynamometer test. Given the limits of correlation possible between GEM and chassis testing, we would not expect such testing to accurately reflect whether a vehicle was compliant with the GEM standards. Therefore, we are not applying GHG compliance liability to such testing. Rather, this testing will be for informational purposes only. However, we do expect there to be correlation in a relative sense. Vehicle to vehicle differences showing a 10 percent improvement in GEM should show a similar percent improvement with chassis dynamometer testing. Nevertheless, manufacturers will not be subject to recall or other compliance actions if chassis testing did not agree with the GEM results on a relative basis. Rather, the agencies will continue to evaluate in-use compliance by verifying GEM inputs and testing in-use engines. (Note that NTE standards for criteria pollutants may apply for some portion of the test cycles).

EPA believes this chassis test program is necessary because of our experience implementing regulations for heavy-duty engines. In the past, manufacturers have designed engines that have much lower emissions on the duty cycles than occur during actual use. By using this simple test program, we hope to be able to identify such issues earlier and to dissuade any attempts to design solely to the certification test. We also expect the results of this testing to help inform the need for any further changes to GEM.

As also noted in Section II. B. (1), it can be expensive to build chassis test cells for certification. However, EPA has structured this pilot-scale program to minimize the costs. First, this chassis testing will not need to comply with the same requirements as will apply for official certification testing. This will allow testing to be performed in developmental test cells with simple portable analyzers. Second, since the program will require only five tests per year, manufacturers without their own chassis testing facility will be able to contract with a third party to perform the testing. Third, EPA is applying this testing to only those manufacturers with annual production in excess of 20,000 vehicles. Finally, 40 CFR 1037.665(c) states that we may approve a request to perform alternative testing that will provide equivalent or better information compared to the specified testing. We may also direct you to do less testing than we specify in this section.

EPA estimates that the cost to conduct chassis testing at a third party facility would be approximately $30,000 per tractor, for a total of $150,000 per year per manufacturer. RIA Chapter 7.2.1.2 includes the compliance costs of the program, including the increased level of reporting in the tractor program.

**Downspeeding**

Daimler is correct in their assessment of downspeeding. The agencies proposed and adopted provisions to account for the gearing of vehicles such that CO₂ emissions and fuel consumption benefits of a downspeeded vehicle operation would be recognized in GEM.

**Tractor Subcategories**
The agencies are adopting a standards for a set of ten tractor subcategories, aligned with Daimler’s comment.

Drive Cycle

The agencies considered these drive cycle comments along with the information that was used to derive the drive cycle weightings in Phase 1. The agencies did not receive any new drive cycle weighting data for tractors from the EPA-NREL work. Based on our assessment on the only comment that included speed data (i.e. the comment from ATA, addressed above), the agencies do not believe this new information is significantly different than the drive cycle weightings that were proposed (as explained in that comment response). Therefore, we are adopting the drive cycle weightings for tractors that we adopted for Phase 1 and proposed for Phase 2.

After considering the comments on the use of constant speeds in the 55 and 65 mph cycles and evaluating the final Phase 2 version of GEM, the agencies are adopting in the Phase 2 final rules constant target speed for the 55 mph and 65 mph cycles, as adopted in Phase 1. We are not adopting drive cycles that include traffic congestion, which is consistent with Daimler’s recommendation. One key difference in Phase 2 is the addition of road grade in these cruise cycles. The addition of road grade to the cruise cycles brings the GEM simulation of vehicles over the drive cycles closer to the real world operation described by Daimler. Even though the cruise cycles will continue to have constant target speeds (55 mph or 65 mph), the vehicle may slow down from the target speed of the cycle on an uphill stretch of road due to the addition of road grade in the Phase 2 cycles. If the vehicle does slow down the transmission shift logic built into GEM will downshift the transmission to limit the amount of further vehicle deceleration. Similarly, on the downhill portions of the cycles, the driver control logic built into GEM will allow the vehicle to exceed the target speed by 3 mph prior to braking the vehicle. The agencies also note that the technologies noted in the comment regarding the recommendation to increase the variability of the vehicle speed will not be simulated over the drive cycles. The impact of predictive cruise control will be applied as a fixed percent reduction in CO\textsubscript{2} emissions and fuel consumption after the simulation is complete, but still within GEM, for Phase 2.

Curb Weight and Payload

In the absence of newer data or other compelling comments, the agencies continue to believe that it is appropriate to continue using the Phase 1 tractor payloads and tractor curb weights for all of the Class 7 and 8 tractors, as proposed, except for heavy-haul.

Weight Reduction

In the absence of additional details, the agencies are not adopting different weight reduction values for hoods and fairings. The manufacturers have the option of requesting off-cycle credits for weight reductions that differ from those included in 40 CFR 1037.520. Also, in Phase 2, we recognize the potential CO\textsubscript{2} emission reduction opportunities in the powertrain and drivetrain systems as part of the vehicle inputs into GEM. Therefore, we believe it is appropriate to also recognize the weight reduction associated with both smaller engines and 6x2 axles.

Transmissions

EPA is adopting simple definitions of AMTs and ATs in 40 CFR 1037.801. The manufacturers only need to utilize transmissions that meet these definitions as their demonstration for certification.
Additional Technologies

The agencies considered the additional fuel saving technologies that Daimler suggested in their comments. For the technologies where the agencies could determine, for each of the ten tractor subcategories, the baseline 2017MY vehicle architecture, clearly define what qualifies as the technology, the effectiveness of the technology, and the current and potential adoption rates of the technology, we adopted specific values for post-processing in GEM. This set of technologies includes Neutral Coast, diesel APU, battery APU, and fuel fired heater. For the other technologies enumerated in the comment, the agencies could not appropriately determine some aspect of the technology. Therefore, the manufacturers may consider applying for off-cycle credits for some of these technologies. There may be technologies, such as some safety technologies that would not be considered under off-cycle technology credits (see 49 CFR 535.7(F)).

Phase 1 Credits

The agencies are allowing Phase 1 vehicle credits to be used in Phase 2. However, the existing five year credit life still applies for heavy heavy-duty vehicle credits. See Preamble Section I.C.1.b.i for details.

Aerodynamic Test Procedures

- After consideration of the comments, the agencies are continuing to use the Phase 1 approach of using coastdown testing as the reference method for aerodynamic assessment in Phase 2, which is consistent with Daimler’s recommendation. We believe that there are practical implications of selecting a different reference method, such as CFD or scaled wind tunnel testing. Coastdown testing and constant speed testing are the only two options that allow testing of the actual tractor. While the agencies have conducted a significant amount of constant speed testing, we agreed with the manufacturers’ potential concerns about developing robust constant speed test procedures in time for the final Phase 2 rule. Instead, we focused our activities on developing more robust coastdown test procedures for the final rule. We have made enhancements to the Phase 2 coastdown procedures to improve the robustness of the results when compared to Phase 1 or those proposed for Phase 2. See RIA Chapter 3.2.
- The agencies are adopting provisions to align the speed at which CFD is conducted in Phase 2 (65 mph) with the average of the coastdown high speed range.
- Phase 2 reference trailer: We still project that the bulk of trailers that will be in operation during the life of tractors produced early in Phase 2 will be represented by the aerodynamic performance of a trailer with skirts. Therefore, we are adopting the reference trailer with a trailer skirt, as proposed. However, we also want to recognize that the trailer fleet will continue to evolve over the lifetime of tractors built and certified to Phase 2, especially from MY 2027 and later. We recognize that if we do not account for reduced aerodynamic loads in the real world, then we may not be appropriately evaluating the tractor powertrain. We considered changing the standard trailer in MY2027; however, this would lead to significant testing burden for the manufacturers because they would have to determine new $C_D A$ values for their entire fleet of tractors. Instead, we are adopting Phase 2 GEM that beginning in MY2027 will take the $C_D A$ input for each vehicle and reduce it by 0.3 m² to reflect the lower aerodynamic loads that are a mix of trailers with skirts and trailers with skirts and boat tails. This change has been accounted for in both the baseline and standard setting of the CO₂ emissions and fuel consumption values. We are not electing Daimler’s (b) suggestion to address the Phase 2 aero bin concerns, and instead have aligned the definition of the Phase 2 aero bins to the final aerodynamic test procedures and lowered the adoption rates of Bins VI and VII to zero for the final rule. The agencies discuss our response to
Daimler’s specific comments regarding the aero bin penetration rates in Section 4.3 of this RTC document.

- The agencies are adopting aerodynamic testing provisions that use a 4.5 degree surrogate angle in lieu of a full yaw sweep because it is technically equivalent to the full yaw sweep but it also reduces the testing burden for aerodynamic assessments (see RIA Chapter 3.2.1.1.3). Our approach in the final rule is consistent with the recommendation from Daimler.

The agencies are adopting the provision that allows manufacturers to use high-roof test data in lieu of testing mid-/low-roof vehicles. **Aerodynamic Bins**

The agencies have refined the aerodynamic test procedures, developed a new SEA approach, revised aerodynamic bin boundaries, and adjusted aerodynamic bin adoption rates in the technology packages for the final rule. This package of changes as a whole is in response to the set of detailed comments from stakeholders. The changes to the coastdown test procedures reduce the test-to-test variability of the CdA results (See RIA Chapter 3.2). The new SEA approach appropriately balances EPA’s need to assure that manufacturers are acting in good faith and meaningful incentives to do so with manufacturers’ need to avoid compliance actions based on inaccurate testing. The high roof bin values being adopted in the HD Phase 2 final rulemaking differ from those proposed due to the changes in the coastdown and other aerodynamic test procedures. However, in both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that a tractor that performed as a Bin III in Phase 1 would also perform as a Bin III tractor in Phase 2. Please see RIA Chapter 3.2.1.2 for the derivation of the aerodynamic bins.

**Post Useful Life Modifications**

In 40 CFR 1037.655 EPA clarifies that certain vehicle modifications are allowed after a vehicle reaches the end of its regulatory useful life. This section applies for all vehicles subject to 40 CFR part 1037. This section states (as examples) that it is generally allowable to remove tractor roof fairings after the end of the vehicle’s useful life if the vehicle will no longer be used primarily to pull box trailers, or to remove other fairings if the vehicle will no longer be used significantly on highways with vehicle speed of 55 miles per hour or higher. More generally, this section clarifies that owners may modify a vehicle for the purpose of reducing emissions, provided they have a reasonable technical basis for knowing that such modification will not increase emissions of any other pollutant. This essentially requires the owner to have information that will lead an engineer or other person familiar with engine and vehicle design and function to reasonably believe that the modifications will not increase emissions of any regulated pollutant. Thus, this provision does not provide a blanket allowance for modifications after the useful life.

This section also makes clear that no person may ever disable a vehicle speed limiter prior to its expiration point, or remove aerodynamic fairings from tractors that are used primarily to pull box trailers on highways. It is also clear that this allowance does not apply with respect to engine modifications or recalibrations.

This section does not apply with respect to modifications that occur within the useful life period, other than to note that many such modifications to the vehicle during the useful life and to the engine at any time are presumed to violate section 202 (a)(3)(A) of the Act. EPA notes, however, that this is merely a presumption, and it does not prohibit modifications during the useful life where the owner clearly has a reasonable technical basis for knowing that the modifications would not cause the vehicle to exceed any applicable standard.
We are pleased to see in the proposed ruling that computational fluid dynamics, also known as CFD, will continue to be one of the allowed methods for heavy vehicle aerodynamic assessment. The confidence our customers have in our tool has been built from many years of experience performing correlations to other test methods, including the full- and reduced-scale wind tunnel testing, SAE type II fuel economy testing, coast-down testing, constant speed aerodynamic testing, and full-scale drag meter testing. Thus, the decision to certify the use of CFD for the regulation of greenhouse gas and fuel efficiency will fit well within the aerodynamic design processing used today, help our customers to be efficient and to deliver superior products to the benefit of society.

The proposed ruling does, however, introduce challenges from the variations that we expected in the predicted drag coefficients, from not only the allowed methods, coast-down, wind tunnel, and simulation, but also within these tools themselves. For example, wind tunnel drag coefficients are highly dependent on the facility chosen. And wind average drag, the drag associated with varying ambient wind conditions may vary by as much as 10 percent between wind tunnel facilities.

It is not clear that the proposed aerodynamic bin structure and the F-alt factor, the aerodynamic factor for alternate tools, will alleviate these challenges as we expect the absolute drag values will differ substantially between different test methods and different facilities.

Correlating simulation results with any non-road physical testing requires accounting for many specific details of the test setup that are not representative of the on-road conditions. CFD offers the advantage of creating a virtual test environment that is more representative of the on-the-road performance.

The preferred setup used by our customers for design and development is a domain that replicates the open road, including a moving ground, rotating tires, open grill with realistic engine, bay details, and other factors.

Further, our customers also regularly evaluate different wind conditions by considering yaw flow. They can even evaluate the impact of the real-world conditions due to the environmental or traffic-generated winds. The setup details are necessary for producing results that are representative of on-the-road performance.

It is our suggestion that the EPA and NHTSA require a certification procedure for an alternate tool that includes broad validation suite, including different vehicle types from aerodynamic sleepers to less aerodynamic day cabs. In the proposed program, the coast-down method is a proposed standard to measure the vehicle aerodynamic performance. However, we feel this test procedure does not relate closely to real-world fuel efficiency.

Since these types of vehicles experience significant changes in aerodynamic drag with relatively small changes in wind, a better predictor of real-world fuel economy is used as a use of wind average drag. Coast-down testing is limited to near-zero wind yaw angle and does not accurately represent the aerodynamics experienced on the road due to wind.
Because of the significant impact of real-world efficiencies due to the wind yaw effects, we feel it is imperative that wind effects be part of the standard for both tractors and trailers.

The negative consequences of not adopting wind effects into the standard for tractors and trailers include truck and trailer buyers, not realizing the fuel savings implied by the levels of which the truck and trailers are certified and the overall emission reductions promised for the program will not be achieved.

Some of the proposals attempt to address the inadequacies of the coast-down results by adjusting the coast-down results through the use of alternate tools for when they have the drag. We feel, as stated above, that the variations of wind average drag between the tools and facilities themselves is too significant and it would be an adverse consequence to allowing alternative tools for adjusting coast-down results. A standard that holds all the tools accountable to a real-world measure of the wind average drag performance of a vehicle, such as constant speed aerodynamic testing, is imperative in ensuring predictable behavior.

Response:

After consideration of the comments, the agencies are continuing to use the Phase 1 approach of establishing coastdown testing as the reference method for aerodynamic assessment in Phase 2. We believe that there are practical implications of selecting a different reference method, such as CFD or scaled wind tunnel testing. Coastdown testing and constant speed testing are the only two options that allow testing of the actual tractor. While the agencies have conducted a significant amount of constant speed testing, we agreed with the manufacturers’ potential concerns about developing robust constant speed test procedures in time for the final Phase 2 rule. Instead, we focused our activities on developing more robust coastdown test procedures for the final rule. We have made enhancements to the Phase 2 coastdown procedures to improve the robustness of the results when compared to Phase 1 or those proposed for Phase 2. See RIA Chapter 3.2.

We are adopting aerodynamic assessments that consider the real world wind conditions through the use of wind averaged drag. We are also continuing to allow alternative test methods, such as CFD, while correlating the results to the reference method using Falt-aero. We are requiring manufacturers to determine Falt-aero using both sleeper cabs and day cabs. Manufacturers also are required to determine a unique Falt-aero value for each wind tunnel facility and each type of CFD software that they use for certification to account for variability between the methods.

Organization: International Council on Clean Transportation (ICCT)

Compliance and real-world validation

Per agency discussion within the proposed rulemaking, there appears to be some discrepancies across various companies regarding the precise times when model years fall within a given calendar year (e.g., engines within tractors could have differing model years). Importantly, the agencies’ analysis is based on a thorough investigation of the ability to introduce, and deploy in larger percentages, technologies in future years. We support the agencies’ approach to technology implementation timing, without including any delay in implementation due to industry-adopted convention for model years that differs across various regulated vehicle and engine manufacturers. Especially considering companies’ latitude in selling products of given model years, that are independent of calendar year, any delay in technology deployment or stringency determination due to how companies’ decisions about naming and marketing products by model year would be unwarranted. [EPA-HQ-OAR-2014-0827-1180-A4 p.16]
The agencies propose a production vehicle chassis dynamometer testing program to complement the new full vehicle standards. This is consistent with recommendations from Sharpe, Delgado, Muncrief (2014) that CO2 reductions over the certification tests correlate to reductions in the real world, as it is extremely important that end users and other stakeholders have confidence that the benefits from the rule are real. In order for the real-world testing program to be successful it is critical that results from the program are shared publicly and that the program start as soon as possible (as discussed in the proposal, the purpose of the data collection program is to look for trends, not absolute values). If possible, the program start date would be the same year the rule is finalized (2016) in order to maximize the amount of data that is collected. There is no reason to delay the start of the testing program, since the data is not being used for regulatory compliance and sufficient testing facilities are readily available. In addition, we suggest that the agencies give more detailed guidance to the OEMs on the precise vehicles selected for production testing. This data collection effort will be the most useful if similar, best-in-class models are tested year to year. [EPA-HQ-OAR-2014-0827-1180-A4 p.16]

Response:

Phase 2 is requiring a significant number of changes that apply to both the engine and the vehicle so it is necessary for alignment of model years between engines and tractors. In the final standards, stringency of the vehicle reflects in part engine improvements. See Section III.D.1.b of the Preamble. By aligning the model years of the tractors with the engines, this essentially provides some additional lead time for the tractor manufacturers. The current practice among tractor manufacturers is that the tractor model year starts in the January-April timeframe in the year preceding the calendar year. This additional lead time was considered by the agencies in setting the tractor stringency levels. For example, the technology package developed by the agencies for setting the 2027 MY tractor standards included both a relatively high adoption rate of waste heat recovery and new engine platforms that will require some modifications to the vehicle; therefore, the vehicle standard cannot take effect before the engine standards.

The agencies are finalizing the tractor chassis test requirement largely as proposed. Past experience has shown us that including a broad range of testing discourages manufacturers from focusing their development efforts on a single narrow test procedure. Even though there will be no direct compliance liability for the GHG testing, the agencies would still be able to identify differences in performance that resulted (on purpose or inadvertently) from how the powertrain is installed in the chassis. We are starting this requirement in 2021 MY to allow manufacturers time to either build chassis dynamometer cells or identify locations to conduct the testing.

Organization: Motor & Equipment Manufacturers Association (MEMA)

Aerodynamics – MEMA supports the agencies’ expanded recognition of aerodynamics as it allows the GEM to be more closely aligned with actual performance on the road. The additional bins offer a wider range of drag coefficient values and incentivizes adoption of aerodynamic improvements. The agencies asked for input regarding the proposed constant speed testing. Because research has demonstrated that constant speed tests offer stability, reliability and repeatability as compared to coast down tests and since a constant speed test is required in European aerodynamic test protocols, MEMA supports the inclusion of a constant speed test. [EPA-HQ-OAR-2014-0827-1274-A1 p.8]

Suppliers with specific products and materials impacted by these categories will submit detailed commentary on the Phase 2 NPRM. [EPA-HQ-OAR-2014-0827-1274-A1 p.8]
Response:

The agencies are adopting additional aerodynamic bins for Phase 2 to recognize improvements in the future. After consideration of the comments, the agencies are continuing to use the Phase 1 approach of establishing coastdown testing as the reference method for aerodynamic assessment in Phase 2. We believe that there are practical implications of selecting a different reference method, such as CFD or scaled wind tunnel testing. Coastdown testing and constant speed testing are the only two options that allow testing of the actual tractor. While the agencies have conducted a significant amount of constant speed testing, we agree with the manufacturers’ potential concerns about developing robust constant speed test procedures in time for the final Phase 2 rule so that it could be used as the reference aerodynamic test method. Instead, we were able to focus our activities on developing more robust coastdown test procedures for the final rule. We have made enhancements to the Phase 2 coastdown procedures to improve the robustness of the results when compared to Phase 1 or those proposed for Phase 2.

Organization: Navistar, Inc.

The Proposed Rule requires in-use testing utilizing a chassis dynamometer in order to correlate to GEM. We understand that this considerable extra cost is proposed to assist with future regulatory development and not to confirm compliance with current rules. While we support the agencies collecting data in support of future rules, we think that the agencies ought to bear the cost of this regulatory development. This is very similar to the testing EPA conducts through its contractors; with the single difference being that here it would not pay for the proposed new testing. We do not think this is fair or appropriate. [EPA-HQ-OAR-2014-0827-1199-A1 p.16]

Moreover, this data will not correlate exactly to GEM as the impacts of many technologies will not show up in the dynamometer test (e.g., predictive cruise and tire pressure management). Requiring five tests a year from each manufacturer is an excessive burden and cost with no direct benefit to the agencies. While we oppose this requirement in its entirety, the same goal could be achieved by chassis testing the best configuration from each manufacturer in the chassis dyno during the compliance years (when significant changes will be made to both the engine and vehicle). If this requirement is maintained, Navistar proposes this burden be reduced to one vehicle in each of the following years: MY2021, MY2024, and MY2027. This correlation to GEM will demonstrate a downward trend with this proposal. [EPA-HQ-OAR-2014-0827-1199-A1 p.16]

To be implemented successfully, MD/HD chassis testing requires a significant staffing, time and capital commitment. The availability and capability of existing facilities are limited and expensive when compared to an equivalent engine dynamometer facility which is commonplace at most engine OEMs. In addition, the typical test constraints for a chassis dynamometer are not easily and cost effectively controlled. [EPA-HQ-OAR-2014-0827-1199-A1 p.17]

The Proposed Rule requires the measurement of gaseous emissions. There is simply no good reason to require any data other than CO2 and/or fuel consumption data for comparison to GEM outputs. Any requirement for measurement of NOx, PM, CO, NMHC, CH4, and N2O emissions should be dropped from the requirements of this section. The additional cost burden for either powertrain or chassis testing will be considerable, when compared to stand alone engine testing. In addition, the RIA does not appear at all to take into account the costs of this testing. This provision should be dropped from the Proposed Rule. [EPA-HQ-OAR-2014-0827-1199-A1 p.17]
The NPRM discusses proposed changes to §1037.135(c)(6) to remove the requirement for emission control information from the vehicle GHG labels. Navistar supports the elimination of the requirement to list emission control information on vehicle labels. [EPA-HQ-OAR-2014-0827-1199-A1 p.19]

Navistar supports coastdown as the only certification input procedure in this rule. However, we are concerned with test variability, trailer gap and other elements of the test procedure. In general, Navistar echoes EMA’s comments and concerns regarding the coastdown test procedure. In particular, we are concerned with the assumption of zero yaw angle, an assumption that the test will be conducted in near windless conditions. We recommend the yaw correction detailed in the EMA comments. If held to this test procedure without such a correction, manufacturers will be forced, due to that assumption of zero wind speed, to wait for a very calm day in order to ensure accurate, measurements. We are also concerned that if EPA conducts confirmatory testing, it will not necessarily wait for that condition and may test under windier conditions, thus arriving at a different result than the manufacturer, simply due to the test conditions. EPA’s number would then become the de facto input. [EPA-HQ-OAR-2014-0827-1199-A1 p.26]

There should not be a set trailer gap or range. EPA should have the authority to approve an open range of trailer gaps proposed by the manufacturer. Trailer gap should be defined by manufacturer depending on the truck configuration and the manufacturer’s recommendation to customers. As technology and designs evolve, the trailer gaps will be tighter for real--world fuel economy improvements. Alternatively, a maximum trailer gap could be defined in the regulation, but the minimum for the aero test should be driven by manufacturer vehicle recommendations. Confirmatory and SEA testing must utilize the manufacturer’s certified trailer gap. [EPA-HQ-OAR-2014-0827-1199-A1 p.26]

As in Phase 1, only one aerodynamic adjustment factor, $F_{alt-aero}$ should be required. Proposed section 1037.525(b)(3) would require determining separate adjustment factors for “a high-roof day cab and a high-roof sleeper cab corresponding to each major tractor model.” This additional test burden is not necessary as the $F_{alt-aero}$ factors will be the same. Navistar has tested a daycab ProStar and sleeper ProStar at the same facility using the Phase 2 methods and found the $F_{alt-aero}$ to be less than 1%. In addition, EPA’s data in the RIA for 3 different sleepers tested at the same facility show $F_{alt-aero}$ values within 0.4 %. See Table 3-21, below (from RIA) There is no data included in the proposal or available from our experience that supports the need for more than one $F_{alt-aero}$. Navistar recommends that the requirement should remain as the requirement currently is in the Phase 1 regulatory text (1037.525 (b) (1)-(2)) and eliminate the new Phase 2 requirement for multiple $F_{alt-aero}$ values. $F_{alt-aero}$ is not vehicle dependent. [EPA-HQ-OAR-2014-0827-1199-A1 p.26-27]

[Table 3-21, Wind Average Equivalent Coastdown Values, can be found on p.27 of docket number EPA-HQ-OAR-2014-0827-1199-A1]

The standard trailer as defined in the coastdown test procedures must be more aerodynamic. The Proposed Rule currently adds only side skirts over the assumed Phase 1 trailer. This certainly cannot be an accurate reflection of the trailers over the life of this Proposed Rule, due in part to the Proposed Rule itself. The hypothetical test-only trailer incorporated into the procedure ensures that no tractor will achieve bins V through VII. [EPA-HQ-OAR-2014-0827-1199-A1 p.29]

The issues with the standard trailer go to the feasibility of the emission standard for tractors as well. The standard trailer must be modified to reflect the more efficient trailers expected to be in use during the time the rule is in effect. [EPA-HQ-OAR-2014-0827-1199-A1 p.29]
Navistar, in general, agrees with EMA’s comments on constant speed testing. Navistar does not believe that constant speed testing should be adopted as a compliance test at this point, even as an alternative. However, with significant further work, constant speed testing may be suitable as an optional test in the future. For example, among other refinements: [EPA-HQ-OAR-2014-0827-1199-A1 p.30]

- There would need to be an effective definition of what constitutes a windy day;
- A full yaw curve should be defined;
- Preconditioning procedures including instrument calibrations should be developed; and
- Torque sensors should be added. [EPA-HQ-OAR-2014-0827-1199-A1 p.30]

We do not think the development of the method is sufficient mature at this point to even include it as an optional test as part of this Proposed Rule. Navistar believes that a future rulemaking is the appropriate method for the adoption of this test in the future. We therefore request that this be dropped from the final rule and considered only in the future in a subsequent rulemaking. [EPA-HQ-OAR-2014-0827-1199-A1 p.30]

Aerodynamic testing, such as coastdown, is inherently variable. There are a number of conditions that can cause test result variations even when controllable parameters are unchanged from test to test. Navistar agrees with EMA’s comments related to aerodynamic compliance margin. The lack of any accounting for test variability effectively increases the stringency of the rule. EPA’s own data shows the level of variation that is possible when testing vehicles. [EPA-HQ-OAR-2014-0827-1199-A1 P.27]

For sleeper cabs, the agencies justified this elimination of a compliance margin in the Proposed Rule based on coastdown testing of one sleeper from each manufacturer. That is not a sufficient data set upon which to eliminate the compliance margin from the rule. We note that while the agencies may point out that the bins themselves constitute a compliance margin, it is more accurate to characterize the bin structure as a design limitation, rather than a compliance margin. Manufacturers will design the tractors to fit within a particular bin and the potential for manufacturing variation will be accounted for in that design. It is too much to also assume that the bin structure would also account for test variation. [EPA-HQ-OAR-2014-0827-1199-A1 P.27]

We should again repeat that, while aerodynamic testing of vehicles has been around for some time, it has only been about 21 months since it has been used across the heavy duty industry for compliance purposes. Navistar does not believe we are yet at a place where we can state that simple test variation has been reduced, or even understood, to the point where it can be essentially ignored in certification tests. [EPA-HQ-OAR-2014-0827-1199-A1 p.27-28]

Navistar’s recommendation is to maintain the one bin compliance margin from the Phase 1 regulation to account for this variability. [EPA-HQ-OAR-2014-0827-1199-A1 p.28]

III. Selective Enforcement Audit and Confirmatory Testing for Aerodynamics

Another example of this issue is the difference between the coastdown test procedure done for certification and the SEA procedure. Manufacturers certify their vehicles utilizing the alternative aerodynamic test methods (wind tunnel or CFD); however, the regulation allows for SEA testing of a vehicle using the reference method (coastdown) which introduces significant variability (grade corrections, road surface, instrumentation, wind, temperature, driver, etc.). As the manufacturer did not certify the vehicle configuration with coastdown, the SEA should not be utilizing coastdown due to the variability. The compliance margin to account for these differences should be sufficient to account for
that variability. SEA should validate the method of certification that the manufacturer utilized. [EPA-HQ-OAR-2014-0827-1199-A1 p.11]

In short, an SEA must be conducted under conditions representative of the process the manufacturer used to certify. For example, if the manufacturer conducted the test with zero winds, EPA should conduct the test under zero winds. It is the same with other test parameters; they should be representative of the testing that was conducted, not just within those parameters allowed by the rules. Beyond that, as noted, the rule should account for normal test variability. Anything else would lead to an unfair, unrepresentative and arbitrary result. [EPA-HQ-OAR-2014-0827-1199-A1 p.11]

Confirmatory testing is an area where the Proposed Rule must provide that testing be done in a manner consistent with and representative of the conditions the manufacturer used to certify. Coastdown testing, in particular, includes several variables that are beyond the manufacturer’s control (e.g. wind, temperature, and driver) as well as variables from differences in particular facilities (e.g. grade, road surface). A confirmatory test allows EPA to test with up to 6 mph winds, which can result in a significant increase in Coefficient of drag-area (CdA) due to yaw effect. The manufacturer cannot make any adjustment for wind and has to assume zero yaw during the test procedure. Several of these factors could be eliminated if SEA and confirmatory testing were held at the same facility that the manufacturer used for certification. In addition, variation from instrumentation and the trailer could also be reduced by utilizing the manufacturer’s trailer and anemometer. Compliance margin is necessary to account for all other variations that cannot be controlled. [EPA-HQ-OAR-2014-0827-1199-A1 p.11-12]

Navistar has reviewed the Memorandum entitled “Additional Discussion of Selective Enforcement Audit and Confirmatory Testing for Aerodynamic Parameters for Combination Tractors and for Trailers” identified in the NODA (“SEA Memorandum”) and has the following comments. The SEA Memorandum discusses potential approaches to Selective Enforcement Audits (SEAs) and confirmatory testing. [EPA-HQ-OAR-2014-0827-1919-A2 p.4-5]

Of initial concern, the memorandum states that “EPA is considering applying some or all of these approaches to the Phase 1 tractor program.” That is, the agencies apparently intend to change the approach in the Phase 1 rule, which is currently in place and has been since model year 2014. However, there is no method to account for Yaw correction in the Phase 1 coast down method. Therefore, any SEA performed would not account for Yaw and could have very large test variability involved. Navistar believes the Phase 1 coast down method is not conducive to a fair SEA test process due to the large test variability as discussed in the referenced Memo and no Yaw correction in the test method. SEA coast down testing should not be performed in the Phase 1 program. [EPA-HQ-OAR-2014-0827-1919-A2 p.5]

As noted in the memo the constants “a” and “b” are yet to be defined. The value of these numbers have a large effect on the ability to meet an SEA with all of the test variability as discussed in the Memo. Therefore, until the value of the constants are defined and can be evaluated Navistar cannot support the adoption of the strawman outlined. When the values are know we can then evaluate the concept and comment if the method is indeed reasonable and realistic given the large variability inherent in coast down testing and other aerodynamic test methods. [EPA-HQ-OAR-2014-0827-1919-A2 p.5]

26 1037.527-1. We are also concerned that despite this assumption in the coastdown test procedure, the Selective Enforcement Procedure allows EPA to test with up to 6mph of winds.
Response:

Chassis Dyno Testing

After consideration of the comments, the agencies are requiring tractor manufacturers to annually chassis test five production vehicles over the GEM cycles to verify that relative reductions simulated in GEM are being achieved in actual production. See 40 CFR 1037.665. We do not expect absolute correlation between GEM results and chassis testing. GEM makes many simplifying assumptions that do not compromise its usefulness for certification, but do cause it to produce emission rates different from what would be measured during a chassis dynamometer test. Given the limits of correlation possible between GEM and chassis testing, we would not expect such testing to accurately reflect whether a vehicle was compliant with the GEM standards. Therefore, we are not applying compliance liability to such testing. Rather, this testing will be for informational purposes only. However, we do expect there to be correlation in a relative sense. Vehicle to vehicle differences showing a 10 percent improvement in GEM should show a similar percent improvement with chassis dynamometer testing. Nevertheless, manufacturers will not be subject to recall or other compliance actions if chassis testing did not agree with the GEM results on a relative basis. Rather, the agencies will continue to evaluate in-use compliance by verifying GEM inputs and testing in-use engines. (Note that NTE standards for criteria pollutants may apply for some portion of the test cycles).

EPA believes this chassis test program is necessary because of our experience implementing regulations for heavy-duty engines. In the past, manufacturers have designed engines that have much lower emissions on the duty cycles than occur during actual use. By using this simple test program, we hope to be able to identify such issues earlier and to dissuade any attempts to design solely to the certification test. We also expect the results of this testing to help inform the need for any further changes to GEM.

As also noted in Section II. B. (1), it can be expensive to build chassis test cells for certification. However, EPA has structured this pilot-scale program to minimize the costs. First, this chassis testing will not need to comply with the same requirements as will apply for official certification testing. This will allow testing to be performed in developmental test cells with simple portable analyzers. Second, since the program will require only five tests per year, manufacturers without their own chassis testing facility will be able to contract with a third party to perform the testing. Third, EPA is applying this testing to only those manufacturers with annual production in excess of 20,000 vehicles. Finally, 40 CFR 1037.665(c) states that we may approve a request to perform alternative testing that will provide equivalent or better information compared to the specified testing. We may also direct you to do less testing than we specify in this section.

EPA estimates that the cost to conduct chassis testing at a third party facility would be approximately $30,000 per tractor, for a total of $150,000 per year per manufacturer. RIA Chapter 7.2.1.2 includes the compliance costs of the program, including the increased level of reporting in the tractor program.

Emission Control Labels

The number of emission control systems for greenhouse gas emissions in Phase 2 has increased significantly. Due to the complexity in determining greenhouse gas emissions as in Phase 2, the agencies do not believe that we can unambiguously determine whether or not a vehicle is in a certified condition through simply comparing information that could be made available on an emission control label with the components installed on a vehicle. Therefore, EPA proposed to remove the requirement to include the emission control system identifiers required in 40 CFR 1037.135(c)(6) and in Appendix III to 40 CFR part 1037 from the emission control labels for vehicles certified to the Phase 2 standards. After considering the comments, EPA is finalizing the proposed tractor labeling requirements. This approach is consistent with the recommendation in Navistar’s comments.
Aerodynamics

- The agencies are keeping the reference aerodynamic test method as coastdown for Phase 2.
- The agencies also received comments from other HD manufacturers stressing that coastdown testing does not produce $C_{dA}$ values at zero yaw. Even at calm test conditions, the resulting yaw angle is something greater than zero degrees. The agencies evaluated our aerodynamic test data and agree with the manufacturers. Therefore, we are adopting Phase 2 provisions that use the effective yaw angle determined by the actual testing (instead of an assumed zero degree) from coastdown testing to determine the Falt-aero value (see 40 CFR 1037.525). See RIA Chapter 3.2.1 for additional detail.
- Trailer gap: The agencies believe that it is necessary to specify a range for the trailer gap used in aerodynamic testing. It is well-accepted that gap influences the overall $C_{dA}$ value, with smaller gaps producing lower $C_{dA}$ values. Therefore, EPA specified the tractor-trailer gap in 40 CFR 1037.501 of less than or equal to 45 inches. However, we also note in 40 CFR 1037.525(b)(6), that if the tractor-trailer cannot be configured to meet the gap requirements, then manufacturers should use good engineering judgment.
- Falt-aero: The agencies determined the Falt-aero values for all of the tractors tested using different aerodynamic methods for Phase 2 using the aerodynamic test procedures and data analysis finalized for Phase 2. As shown in further detail in RIA Chapter 3.2.1, the Falt-aero values ranged between 1.13 to 1.20 for multiple sleeper and day cab tractors tested with the same CFD software. Therefore, the agencies concluded that a single Falt-aero value is not sufficient for determining the correlation of test methods for all tractors. Based on the comments and further refinement of our selective enforcement audit (SEA) provisions in the Phase 2 final rule, we are adopting provisions that require manufacturers to determine Falt-aero for a minimum of one day cab and one sleeper cab in MYs 2021, 2024, and 2027. The Falt-aero testing requirements in the final rule are less than the number proposed, but still balance the need for accuracy with the associated test burden.
- Phase 2 standard trailer: We still project that the bulk of trailers that will be in operation during the life of tractors produced early in Phase 2 will be represented by the aerodynamic performance of a trailer with skirts. Therefore, we are adopting the reference trailer with a trailer skirt, as proposed. However, we also want to recognize that the trailer fleet will continue to evolve over the lifetime of tractors built and certified to Phase 2, especially from MY 2027 and later. We recognize that if we do not account for reduced aerodynamic loads in the real world, then we may not be appropriately evaluating the tractor powertrain. We considered changing the standard trailer in MY2027; however, this would lead to significant testing burden for the manufacturers because they would have to determine new $C_{dA}$ values for their entire fleet of tractors. Instead, we are adopting Phase 2 GEM that beginning in MY 2027 will take the $C_{dA}$ input for each vehicle and reduce it by 0.3 m$^2$ to reflect the lower aerodynamic loads that are a mix of trailers with skirts and trailers with skirts and boat tails. This change has been accounted for in both the baseline and standard setting of the CO$_2$ emissions and fuel consumption values. The agencies respond to Navistar’s more detailed comments on Bins V through VII in RTC Section 4.3.
- Constant Speed Testing: The agencies conducted a significant number of constant speed tests both prior to issuing the NPRM and between the NPRM and FRM. See RIA Chapter 3.2.1.1.3.3. While constant speed testing is not the reference aerodynamic method for Phase 2, it is allowed as an alternative method under both Phase 1 and Phase 2. The agencies addressed Navistar’s specific suggestions for refinements in 40 CFR 1037.534. Additional requirements were included for testing on a windy day through constraints on the yaw angle distribution. Our analysis showed that meeting these requirements resulted in a yaw characteristic with sufficient confidence. Torque instruments must also be calibrated and zeroed as specified in 40 CFR.
1037.534. Many aspects of the constant speed test procedure, including preconditioning procedures and road/track characteristics, refer to the coastdown test procedure detailed in 40 CFR 1037.528.

SEA and Confirmatory Aerodynamic Testing

With respect to Navistar’s concern about changing the Phase 1 tractor program related to aerodynamic testing of tractors, EPA is not revising the Phase 1 tractor aerodynamics provisions in terms of SEA or confirmatory testing. The agencies note that we maintained the provision in 40 CFR 1037.150(k) which allows a one bin compliance margin for in-use testing.

Although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor \(C_d\)As and solicited supplemental comments on it. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur. It is important to note that, although SEAs are directed by EPA, the actual testing is conducted by the manufacturer at their chosen facilities. This minimizes many potential causes of test variability, such as differences in test trailers, test tracks, or instrumentation. Thus confidence intervals need only reflect true test-to-test variability. We are adopting provisions in 40 CFR 1037.305 that detail the SEA procedures for aerodynamic testing, including the definition of “a” and “b.” We set “a” equal to 1.5 and “b” equal to 0.03 (the middle of the range discussed in the NODA). These provisions also define the top of the bin boundary to be the value specified in 40 CFR 1037.520 plus 0.05 m² to account for rounding. We are also adopting provisions in 40 CFR 1037.150(s) which states that EPA will make our determination using a statistical analysis consistent with the principles of SEA testing in 40 CFR 1037.305. Also, manufacturers generally rent facilities for coastdown testing as needed, which means EPA will need to provide some advance notice to allow the manufacturer to reserve the appropriate facility. EPA adopted SEA provisions that state that we may conduct aerodynamic testing using either the coastdown (reference) test method or the aerodynamic method used by manufacturer to certify the tractor. Additional discussion is included in Section III.E.2.a of the Preamble to the final rule.

Organization: Owner-Operator Independent Drivers Association (OOIDA)

Furthermore, it is imperative to note that fuel economy has a non-linear relationship with the percent of fuel consumed. The agencies have created confusion on this topic which must be addressed. “Fuel economy” is not used in reference to heavy-duty vehicles as it can be misleading based on the type of freight hauled, route, traffic conditions, speed limits, driver skill, etc. Therefore, a technology which might increase the fuel economy by 24% does not necessarily equate to fuel consumption savings. In fact, there is a higher probability that the fuel consumption savings will be much less. While the agencies claim that the Phase II regulations will be based upon performance standards, they still do not properly address the diversity which exists in the trucking industry and in the various duty cycles (type of freight, weight, routes, etc.). According to NAS 2010 research analysis entitled Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles, “in [h]eavy vehicles the most meaningful metric of fuel efficiency must be viewed in relationship to the work performed.” They call
this load-specific fuel consumption (LSFC). This vital metric is missing in the agencies testing and analysis. According to the NAS study, “Regulators need to use a common procedure to develop a baseline LSFC data for various applications, to determine if separate standards are required for different vehicles that have a common function.” [EPA-HQ-OAR-2014-0827-1244-A1 p.6-7]

The Oak Ridge National Laboratory performed a study in 2011 in partnership with the Department of Energy (DOE) and industry to research the impact real-world conditions can have on the fuel efficiency of Class 8 trucks (trucks with a gross vehicle weight rating (GVWR) of 33,001 pounds). Oak Ridge collected data on over 1,000 trips covering some 700,000 miles of primarily highway travel. When looking at the fuel efficiency of Class 8 trucks by weight over flat terrain and traveling 65 miles per-hour (“mph”), the result demonstrates that fuel economy/mpg is not an appropriate measure of fuel efficiency for the heavy-duty industry due to the effects of the weight of the load. [EPA-HQ-OAR-2014-0827-1244-A1 p.7-8]

The Oak Ridge study also monitored the weight, speed, fuel efficiency, and actual road location/grade of certain trucks. When the fuel economy of the same truck carrying the same load over different terrain was analyzed, results show that fuel economy can vary substantially even for the same truck. On severe uphill sections of terrain, fuel economy of the same truck can be 60 percent worse, while on severe downhill grades, the same truck’s fuel economy is 221 percent better. The opportunities for inappropriate mpg claims to be made for heavy-duty vehicles are almost infinite, especially when operational differences are factored in. For example, using the data from Figure 1 it can be shown that the gain/loss from going uphill or downhill is not equivalent. This means that a truck traveling up and back down a hill with no net elevation change will only get approximately 70 percent of the fuel economy as the truck would on level ground. [EPA-HQ-OAR-2014-0827-1244-A1 p.8]

**Response:**

**Metric**

The agencies agree with the commenter that fuel economy is not the appropriate metric for heavy-duty vehicles. The metrics used in the rules are grams of CO$_2$ per ton-mile and gallons per 1,000 ton-mile. These metrics align with the load-specific fuel consumption metric recommended by NAS. In addition, the agencies discussed the non-linearity between fuel economy and fuel consumption and more details on the metric in the Preamble to Phase 1. 76 FR 57148. We are retaining the same metrics between Phase 1 and Phase 2.

**Grade**

The agencies agree with the commenter’s concern that the program should reflect real world operation. As discussed in Section III.E.2.b of the Preamble to the final rules, the agencies have adopted drive cycles that include road grade. The agencies also cite the study conducted by Oak Ridge National Laboratory discussed in the comments.

**Organization:** PACCAR, Inc.

The Wind-Averaged Drag Assessment can be Greatly Simplified and Still Provide Accurate Measurements of Aerodynamic Drag
The agencies have proposed to require wind-averaged drag evaluation to include nine separate wind angles. Due to the broad number of cab/sleeper combinations that make up PACCAR’s product offerings, conducting eight additional evaluation points will be extraordinarily burdensome. PACCAR currently conducts simulations on just under 250 combinations offered under the Kenworth and Peterbilt brands, totaling nearly 500 simulation points. If the agencies finalize the proposal and requires nine different wind angles for each of these combinations, PACCAR would be conducting approximately 4,000 additional simulations, as well as several dozen additional mid-point simulations. [EPA-HQ-OAR-2014-0827-1204-A1 p.12]

Instead of requiring a 9-angle wind averaged drag evaluation, PACCAR recommends that the agencies allow manufacturers to use a surrogate angle of 4.5 degrees. PACCAR and other OEM analysis has demonstrated that this approach provides nearly identical test results as the more burdensome 9-angle sweep, within a minimal margin of error. The chart and table below show the data and findings. In the charts below, PACCAR has provided more information regarding our tests and assessments that result in the recommended 4.5 degree wind angle, which compares very favorably to the 9-angle sweep. PACCAR can provide more information to the agencies on this subject as needed and is willing to work with the agency on other possible methods of reducing the wind-averaged drag testing burden. [EPA-HQ-OAR-2014-0827-1204-A1 p.12]

Low- and Mid-roof Tractor Compliance Effort Should be Reexamined

In the review of the NPRM tractor stringency levels, it was determined that the compliance effort to meet low- and mid-roof tractor configurations is not consistent with the effort that is needed on high-roof tractors. It is expected that the change of a vehicle spec from a high-roof tractor to a low- or mid-roof tractor should not require additional vehicle GHG-reducing technologies for the lower roof vehicle configuration to be compliant to the GHG regulation. [EPA-HQ-OAR-2014-0827-1204-A1 p.22-23]

Currently the GEM output for a low- and mid-roof vehicle in Phase 2 Aero Bin II, III, or IV will require some-to-significant levels of additional technology to make up the 3-5 g/ton-mile shortfall as compared to the high-roof equivalent. The added cost of the technologies for vehicles operating tankers, flatbeds, and low-boys could lead to the unintended consequence of the purchase of a high roof vehicle to operate in a low- or mid-roof application. This would clearly be an adverse impact as a result of this GEM assessment. [EPA-HQ-OAR-2014-0827-1204-A1 p.23]

Performance of a low- and mid-roof aero Bin III tractor should have the same or near same performance as its equivalent aero Bin VI tractor when the same technologies are applied to both configurations. PACCAR requests the agencies review the low- and mid-roof relationship to high-roof tractors in order to balance the compliance effort for these tractors. [EPA-HQ-OAR-2014-0827-1204-A1 p.23]

The Proposed Coastdown Testing Requirements Should be Streamlined

The agencies have proposed to require coastdown for each major model in both a day cab and sleeper-cab configuration and would require manufacturers to test up to six models, or up to 12 vehicles, per year, until all models have been tested. Due to the large number of models and configurations that PACCAR companies offer, this would impose an extremely high testing burden on our operations. PACCAR would be faced with at least three or four years of testing, which may have to be repeated as models change or new models are introduced. [EPA-HQ-OAR-2014-0827-1204-A1 p.20]
PACCAR has provided EPA with testing results that show that coastdown test-to CFD analysis results yield extremely similar comparisons for the aerodynamic adjustment factor, $F_{alt-aero}$, across three different truck models. The spread of the $F_{alt-aero}$ values is less than 0.3%. PACCAR recommends that a single coastdown test can be used to represent multiple models, if not the entire model lineup from an OEM. The aero adjustment factor compares favorably when assessed with a given OEM’s coastdown test process and alternate aero assessment method (i.e. CFD, or reduce scale model wind tunnel testing). [EPA-HQ-OAR-2014-0827-1204-A1 p.20]

PACCAR strongly recommends that the agencies reduce the number of coastdown tests that must be conducted each year to a single vehicle, as well as provide coastdown testing flexibilities. PACCAR suggests that the agencies allow OEMs the option to extrapolate coastdown test data and $F_{alt-aero}$ determination for each alternative aerodynamic test method from one model to all other models. [EPA-HQ-OAR-2014-0827-1204-A1 p.20]

The Agencies Should Not Penalize The Industry if it Corrects an Error in the Phase 1 Aerodynamics Equation

As part of the Phase 1 rule, the agencies issued an equation for calculating wind-average drag that included a factor which the agency now believes results in overly generous wind-average drag values. The agencies have proposed to correct this factor as part of the Phase 2 rule, which would increase vehicle CdA values by 3.3%. This change would effectively move many vehicles to a lower aerodynamic bin designation. While PACCAR agrees that the agencies did not use this equation or factor in calculating the stringency of the standards, PACCAR does not agree that the agencies should revise the factor now and retroactively lower the bin designations, i.e. higher CdA value GEM input, for many PACCAR vehicles. We estimate that approximately 50% PACCAR tractors would move from Bin V to Bin IV if this change is made. These lower bin classifications would affect our overall ability to comply with the Phase 1 standards and to generate credits that may be necessary for compliance with the Phase 2 program. PACCAR and other OEMs have relied on the current equation for three model years and future product plans have been based on the Bin designations using the current equation. If the agencies revise the factor now for future model years, it will have serious implications for our product planning and future compliance. A retroactive application of a revised factor would have a devastating effect on our overall compliance strategy. [EPA-HQ-OAR-2014-0827-1204-A1 p.13]

PACCAR understands that the agencies now believes the factor to result in slightly lower numerical wind-averaged drag values than what the agencies would like to have used for aero bin determination. However, the agencies should not make any changes now that affect credits that PACCAR and other companies have already generated, nor should the agencies make changes to an equation that has large implications for our compliance planning. PACCAR recommends that the agencies leave this factor unchanged. To do otherwise would undermine the existing program and greatly complicate compliance, and the agencies should not retroactively penalize the industry. [EPA-HQ-OAR-2014-0827-1204-A1 p.13]

ii. A Compliance Margin is Required for Aerodynamic Confirmatory Testing

The agencies have proposed to narrow the Bin ranges in the Phase 2 rule, which has significant implications for confirmatory and Selective Enforcement Audit (SEA) testing. All testing has variability. This variability, combined with narrowed compliance Bins, could mean that a vehicle might be dropped to a lower bin (higher CdA) in confirmatory testing, when in fact conforms to a higher bin. PACCAR has compiled the range of high roof sleeper cab and day cab CdA values of tractors since the start of the year. These are seen in the charts below. The agencies’ proposed compliance margin of requiring the
aerodynamic CdA during the confirmatory or SEA test to fall in the same bin as the OEM’s stated bin for that chassis does not take into account the testing variabilities. Any testing variation could cause the aerodynamic CdA value to be slightly higher, pulling vehicles that are near a bin boundary into a worse aero bin, thus making them non-compliant. This is an unacceptable outcome. [EPA-HQ-OAR-2014-0827-1204-A1 p.10]

[Graphs, Sleeper Bin Concentration, Day Cab Bin Concentration, can be found on p.10-11 of docket number EPA-HQ-OAR-2014-0827-1204-A1]

EMA’s comments provide extensive details on the sources and extent of variability in aerodynamic test runs. As this supporting information shows, moderate variability can be expected, but the agencies should not finalize a rule that does not account for this aspect of testing. Without such compliance margin PACCAR will be required to move a large section of vehicles that tested in a higher Bin to a lower Bin, i.e. from Bin IV or Bin V, to enforce an internal compliance margin. This compliance margin would need to be applied to all PACCAR vehicles in bins above Bin I. [EPA-HQ-OAR-2014-0827-1204-A1 p.11]

In the Phase 1 rule, the agencies provided a 1-Bin compliance margin for confirmatory testing. If manufacturers certified vehicles to a particular Bin designation, the agencies would consider the vehicle in compliance as long as the confirmatory or SEA testing did not show the vehicle as moving down more than a single Bin. PACCAR recommends that the agencies continue to provide the same compliance margin in the Phase 2 rule, or provide another type of compliance margin to reflect the variability in confirmatory or SEA test results. This could be in the form of an allowable CdA value or percentage difference from the certification standards. PACCAR is willing to work with the agencies on establishing the proper compliance margin for this testing; a compliance margin cannot be specified that is smaller than the variability of the test process executed within weather and other constraints. [EPA-HQ-OAR-2014-0827-1204-A1 p.11]

**In-Use Vehicle Testing Should be Eliminated**

The agencies have proposed highly burdensome in-use testing that is intended only to generate data to validate the GEM model used by EPA and NHTSA. The proposed in-use testing will largely replicate the powertrain integration testing that manufacturers are already highly motivated to conduct as part of the certification process. These in-use testing requirements are not aimed at confirming compliance and the agencies have existing and effective tools for ensuring that in-use performance is consistent with certification test results. PACCAR therefore recommends that the agencies eliminate the in-use vehicle testing requirement in its entirety. At minimum, the agencies should reduce the number of vehicles that must be tested, share the expense and effort of the testing program, or conduct a one-time GEM validation test program. In addition, PACCAR supports EMA’s comments on in-use testing burdens. [EPA-HQ-OAR-2014-0827-1204-A1 p.23]

**Rear Axle Efficiency**

The agencies recognize that this technology has benefits; however, the requirement to conduct testing to demonstrate the benefit of rear axle efficiencies that are reflective of real world products is quite burdensome given the amount of credit that might be generated. PACCAR recommends that the agencies eliminate the testing burden by providing credit amounts based on calculated values. [EPA-HQ-OAR-2014-0827-1204-A1 p.25]

**Continue Phase I Approach for Class 7 Cabs**
There are few Class 7 sleeper-cabs produced each year. PACCAR has produced less than 50 each year since GHG regulations began. Vehicles that have sleepers added should be allowed to comply with Class 7 day cab standards as is the case in Phase 1. PACCAR agrees with the agencies that no change in policy is needed. [EPA-HQ-OAR-2014-0827-1204-A1 p.30]

Response:

Aerodynamics

Wind Average Drag Assessment: Consistent with the commenter’s suggestion, the agencies are adopting aerodynamic testing provisions that use a 4.5 degree surrogate angle in lieu of a full yaw sweep.

Low/Mid Roof Tractors: In Phase 1, the agencies adopted only two aerodynamic bins for low and mid roof tractors. The agencies limited the number of bins to reflect the range of aerodynamic technologies effective in low and mid roof tractor applications. High roof tractors are consistently paired with box trailer designs, and therefore manufacturers can design the tractor aerodynamics as a tractor-trailer unit and target specific areas like the gap between the tractor and trailer. In addition, the high roof tractors tend to spend more time at high speed operation which increases the impact of aerodynamics on fuel consumption and GHG emissions. On the other hand, low and mid roof tractors are designed to pull variable trailer loads and shapes. They may pull trailers such as flat bed, low boy, tankers, or bulk carriers. The loads on flat bed trailers can range from rectangular cartons with tarps, to a single roll of steel, to a front loader. Due to these variables, manufacturers do not design unique low and mid roof tractor aerodynamics but instead use derivatives from their high roof tractor designs. As Phase 2 looks to further improve the aerodynamics for high roof sleeper cabs, we believe it is also appropriate to expand the number of bins for low and mid roof tractors too. For Phase 2, the agencies proposed to differentiate the aerodynamic performance for low and mid roof applications with four bins, instead of two, in response to feedback received from manufacturers of low and mid roof tractors related to the limited opportunity to incorporate certain aerodynamic technologies in their compliance plan. However, upon further discussions with EMA, it became evident to the agencies that the most straightforward approach would be to include the same number of low and mid roof aero bins as we have for high roof tractors. Therefore, we are adopting seven aero bins for low and mid roof tractors in Phase 2. In addition, we proposed and are adopting provisions in 40 CFR 1037.520(b)(3) that allow low and mid roof tractor aerodynamic bins to be determined based on the aerodynamic bin of an equivalent high roof tractor. These modifications, along with the adjustments to the adoption rates of the low and mid roof aerodynamic bins discussed in RTC Section 4.3, should address the concerns raised by the commenter.

Coastdown Test Requirements: The agencies determined the Falt-aero values for all of the tractors tested using different aerodynamic methods for Phase 2 using the aerodynamic test procedures and data analysis finalized for Phase 2. As shown in further detail in RIA Chapter 3.2.1, the Falt-aero values ranged between 1.13 to 1.20 for multiple sleeper and day cab tractors tested with the same CFD software. Therefore, the agencies concluded that a single Falt-aero value is not sufficient for determining the correlation of test methods for all tractors. Furthermore, based on the comments and further refinement of our selective enforcement audit (SEA) provisions in the Phase 2 final rule, we are adopting provisions that require manufacturers to determine Falt-aero for a minimum of one day cab and one sleeper cab in MYs 2021, 2024, and 2027. While this significantly reduces the test burden from the levels proposed, it also only represents a minimum requirement.

138 See Section III.E.2.a.ix for details on the SEA requirements.
Phase 1 Aerodynamics Equation: EPA proposed a different equation with a ratio of 0.8330 in 40 CFR 1037.525(d) for the case of full yaw sweep measurements to determine wind-averaged drag correction as an amendment to the Phase 1 program. Some commenters argued that this change would impact stringency of the Phase 1 standard, but we disagree because manufacturers are already subject to EPA compliance using both methods (full yaw sweep and ±6 degree measurements), and this Phase 1 flexibility was not used in setting the level of the Phase 1 standards. Nevertheless, we are adopting the final rule without amending this part of the Phase 1 rules. Commenters persuasively indicated that any such amendment to the Phase 1 rules at this date could upset compliance plans predicated on the rules remaining un-amended. These expectations and reliance are legitimate, and the agencies accordingly are not amending this aspect of the Phase 1 rules.

Aerodynamics Compliance Margin:
The widths of the aerodynamic bins represent a balance between narrower bins to further differentiate the performance of aerodynamic technologies versus wider bins to allow less test burden (more tractors fall within a given bin). The range of Phase 1 aero Bin IV is 0.5 m². The agencies set the Phase 2 aerodynamic bin boundaries in the final rule with a range of 0.5 m² for Bins I through III and 0.4 m² for Bins IV through VI. The agencies held discussions with the tractor manufacturers to discuss bin widths post-proposal to help us achieve the proper balance.139

Although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor C_dAs and solicited supplemental comments on it. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur. It is important to note that, although SEAs are directed by EPA, the actual testing is conducted by the manufacturer at their chosen facilities. This minimizes many potential causes of test variability, such as differences in test trailers, test tracks, or instrumentation. Thus confidence intervals need only reflect true test-to-test variability. We are adopting provisions in 40 CFR 1037.305 that detail the SEA procedures for aerodynamic testing, including the definition of “a” and “b.” We set “a” equal to 1.5 and “b” equal to 0.03 (the middle of the range discussed in the NODA). These provisions also define the top of the bin boundary to be the value specified in 40 CFR 1037.520 plus 0.05 m² to account for rounding. We are also adopting provisions in 40 CFR 1037.150(s) which states that EPA will make our determination using a statistical analysis consistent with the principles of SEA testing in 40 CFR 1037.305. Also, manufacturers generally rent facilities for coastdown testing as needed, which means EPA will need to provide some advance notice to allow the manufacturer to reserve the appropriate facility. EPA adopted SEA provisions that state that we may conduct aerodynamic testing using either the coastdown (reference) test method or the aerodynamic method used by manufacturer to certify the tractor. Additional discussion is included in Section III.E.2.a of the Preamble to the final rule.

In-Use Testing Requirement

After consideration of the comments, the agencies are requiring tractor manufacturers to annually chassis test five production vehicles over the GEM cycles to verify that relative reductions simulated in GEM are being achieved in actual production. See 40 CFR 1037.665. We do not expect absolute correlation between GEM results and chassis testing. GEM makes many simplifying assumptions that do not compromise its usefulness for certification, but do cause it to produce emission rates different from what would be measured during a chassis dynamometer test. Given the limits of correlation possible between GEM and chassis testing, we would not expect such testing to accurately reflect whether a vehicle was compliant with the GEM standards. Therefore, we are not applying compliance liability to such testing. Rather, this testing will be for informational purposes only. However, we do expect there to be correlation in a relative sense. Vehicle to vehicle differences showing a 10 percent improvement in GEM should show a similar percent improvement with chassis dynamometer testing. Nevertheless, manufacturers will not be subject to recall or other compliance actions if chassis testing did not agree with the GEM results on a relative basis. Rather, the agencies will continue to evaluate in-use compliance by verifying GEM inputs and testing in-use engines. (Note that NTE standards for criteria pollutants may apply for some portion of the test cycles).

EPA believes this chassis test program is necessary because of our experience implementing regulations for heavy-duty engines. In the past, manufacturers have designed engines that have much lower emissions on the duty cycles than occur during actual use. By using this simple test program, we hope to be able to identify such issues earlier and to dissuade any attempts to design solely to the certification test. We also expect the results of this testing to help inform the need for any further changes to GEM.

As also noted in Section II. B. (1), it can be expensive to build chassis test cells for certification. However, EPA has structured this pilot-scale program to minimize the costs. First, this chassis testing will not need to comply with the same requirements as will apply for official certification testing. This will allow testing to be performed in developmental test cells with simple portable analyzers. Second, since the program will require only five tests per year, manufacturers without their own chassis testing facility will be able to contract with a third party to perform the testing. Finally, 40 CFR 1037.665(c) states that we may approve a request to perform alternative testing that will provide equivalent or better information compared to the specified testing or we may also direct you to do less testing than we specify in this section.

**Rear Axle Efficiency**

The agencies’ assessment of axle improvements found that axles built in the Phase 2 timeline could be 2 percent more efficient than a 2017 baseline axle. In lieu of a fixed value for low friction axle lubricants, the agencies are adopting an axle efficiency test procedure (40 CFR 1037.560), as discussed in the NPRM. The axle efficiency test is optional, but will allow manufacturers to recognize in GEM reductions in CO₂ emissions and fuel consumption through improved axle gear designs and/or mandatory use of low friction lubricants. We believe the testing approach better differentiates the effectiveness of the variety of axle technology improvement paths, such as lubricants or low friction gears, than developing a fixed improvement value and trying to define what technologies qualify.

**Phase 1 Approach to Class 7 Tractors**

The agencies have not changed the approach of requiring Class 7 tractors with sleepers to comply with the Class 7 all cab style standards in 40 CFR 1037.106.

**Organization:** Plastics Industry Trade Association (SPI)
Recognizing Aerodynamic Improvements

The Phase 2 proposal suggests the addition of two additional bins for aerodynamic metrics (drag coefficient). This will provide increased incentive to adopt aerodynamic advances. Additionally, the increased yaw angles added to wind tunnel testing and an average wind coefficient of drag will enhance the ability to simulate drag under real life highway and wind conditions. [EPA-HQ-OAR-2014-0827-1225-A1 p.3]

The new requirements for constant speed tests may also help isolate aerodynamic drag from the vibration, mechanical and friction encountered at low speeds because constant speed tests provide better repeatability than coast down tests. Finally, this will provide an opportunity for harmonization with European testing which already requires constant speed tests. [EPA-HQ-OAR-2014-0827-1225-A1 p.3]

The proposed rule also seeks to model tractors with a standardized trailer, and model trailers with a standardized tractor, which is a wise approach to encourage improved aerodynamics. The proposed reference trailer, with skirts between the fifth wheel and the trailer body to restrict underbody air flow, is representative of trailer aerodynamic improvements likely to emerge during the term of Phase 2. [EPA-HQ-OAR-2014-0827-1225-A1 p.3]

Response:

The agencies are adding two additional aerodynamic bin definitions (Bins VI and VII) in the Phase 2 regulations with the understanding that aerodynamics will continue to improve over the next ten years until the full phase-in of the Phase 2 program and to provide a value to be input to GEM should they do so. However, we considered the comments and discuss the adoption rates of the more aerodynamic bins in Section III.D.1.c.i of the Preamble, which ultimately concludes that the standards should be predicated only on performance of aerodynamic technologies reflecting up to Bin V. We are also adopting an aerodynamic assessment at a yaw angle of 4.5 degrees, which is representative of a wind averaged value. The agencies are adopting constant speed testing as an alternative aerodynamic testing method in Phase 2, which will allow manufacturers to harmonize with their European testing. We are also adopting as proposed the standard trailer for tractor aerodynamic testing that includes a skirt for Phase 2.

Organization: SABIC Innovative Plastics US LLC

Under Phase 2, the measured frontal drag area (CdA), which is drag coefficient (Cd) multiplied by frontal area (A), would be calculated rather than predefined. This should help capture the reduction in drag achieved by tractor designs with optimized frontal areas. [EPA-HQ-OAR-2014-0827-1207-A1 p.3]

Likewise, the agencies propose using several yaw angles to better approximate highway and wind conditions that introduce drag on the side areas of the vehicle. It is particularly important to account for lateral yaw in this rulemaking because of the relatively large lateral areas of a tractor-trailer combination. As Exa Corporation testified at the Long Beach public hearing: [EPA-HQ-OAR-2014-0827-1207-A1 p.3]

Because of the significant impact to real world efficiencies due to wind yaw effects; we feel it is imperative that wind effects be part of the standard ... [EPA-HQ-OAR-2014-0827-1207-A1 p.3]

The agencies note that a 'wind averaged drag coefficient is about 15 percent higher than the zero degree coefficient of drag.' This is directionally consistent with findings from SABIC's work with Exa to model the aerodynamic benefits of the optimized Class 8 Day Cab roof fairing. That research showed an 8-10 percent higher wind-averaged drag coefficient, based on the use of both zero degree and 6 degree yaw in
We believe the proposal to include yaw effects in CFD modelling for Phase 2 will result in more realistic estimates of on-road aerodynamic performance. [EPA-HQ-OAR-2014-0827-1207-A1 p.3-4]

Revised Aerodynamic Bin Structure

Under the Phase 2 proposal, wind-averaged measured frontal drag area (WACdA) would replace Cd as the aerodynamic input into the GEM. WACdA will be used to place tractors into bins with similarly performing tractors. The boundaries of the Phase 1 bins have been modified and additional bins proposed to 'recognize further advances in aerodynamic drag reduction beyond what was recognized in Phase 1.' SABIC supports adjustment of the bin structure to accommodate coming advances in tractor aerodynamics. [EPA-HQ-OAR-2014-0827-1207-A1 p.4]

SABIC’s research with Exa included close to 100 roof fairing design concepts and were modeled using CFD. Significantly, multiple designs demonstrated in excess of 2 percent fuel savings compared to a baseline roof fairing representative of the current market. [EPA-HQ-OAR-2014-0827-1207-A1 p.4]

The best performing concept is pictured in Figure 1 and utilizes a double-walled thermoplastic construction featuring internal air ducts to accelerate airflow through the fairing and around the trailer. In CFD analysis, this model achieved a 5.8 percent reduction in drag compared to the baseline roof fairing and thereby yields a fuel efficiency improvement of nearly 3 percent. SABIC plans to fabricate a full-scale prototype to undergo on-road testing to corroborate CFD results. [EPA-HQ-OAR-2014-0827-1207-A1 p.4]

A noteworthy finding from this research was the potential for a single, critically placed component (in this case, a roof fairing) to provide significant aerodynamic benefits. SABIC is confident that other areas along the tractor and trailer present opportunities for drag reduction, resulting in substantial cumulative improvements in mileage and emissions. Given this, the revised bin structure should help incentivize adoption of advanced aerodynamic features and packages. [EPA-HQ-OAR-2014-0827-1207-A1 p.4-5]

Constant Speed Testing

Also for Phase 2, the agencies have for the first time proposed specific requirements for conducting the constant speed test, which would remain an alternative to coast-down testing. Constant speed testing may help isolate aerodynamic drag from the vibration, mechanical and friction encountered at low speeds. Research suggests that constant speed tests may provide better repeatability than coast-down tests. Also, the constant speed test is required in European aerodynamic testing for trucks, and its use in the U.S. could promote harmonization. [EPA-HQ-OAR-2014-0827-1207-A1 p.5]

Trailer Aerodynamics

Consistent with the 2010 National Research Council report, the agencies recognize that aerodynamic efficiencies can best be obtained through the optimized pairing of trailers and tractors. The agencies note some challenges in modelling the large number of combinations that might occur in the marketplace (e.g., due to different manufacturers, useful lives and owners). Because the matching of tractor and trailers on any given vehicle—or any given run—is impossible to predict, the agencies have wisely proposed to model tractors with a standardized trailer, and model trailers with a standardized tractor. The proposed
reference trailer features aerodynamic improvements likely to emerge during the term of Phase 2, including skirts between the fifth wheel and the trailer body to restrict underbody airflow. [EPA-HQ-OAR-2014-0827-1207-A1 p.5]

SABIC supports the recognition of trailer aerodynamics in the GEM program, and the expansion of the bin structure to accommodate anticipated improvements in tractor and trailer aerodynamics during Phase 2. [EPA-HQ-OAR-2014-0827-1207-A1 p.6]

Response:

The agencies are adopting aerodynamic testing provisions that represent wind averaged drag, but are also adopting the use of a 4.5 degree surrogate angle in lieu of a full yaw sweep.

The agencies appreciate the information and data shared by SABIC in terms of opportunities for aerodynamic improvements. The agencies included this information in the RIA of the final rule in Chapter 2.4.2.1.2.

The agencies are keeping the reference aerodynamic test method as coastdown for Phase 2, while allowing constant speed testing as an alternative aerodynamic test method. We believe this is the appropriate approach because the agencies were able to develop more robust coastdown test procedures for Phase 2 and it builds on the experience that the agencies and tractor manufacturers have gained during Phase 1 aerodynamic testing.

Phase 2 reference trailer: We still project that the bulk of trailers that will be in operation during the life of tractors produced early in Phase 2 will be represented by the aerodynamic performance of a trailer with skirts. Therefore, we are adopting the reference trailer with a trailer skirt, as proposed.
HD Phase 1 included five aerodynamic bins to cover the spectrum of aerodynamic performance of high roof tractors. Since the development of the Phase 1 rules, the manufacturers have continued to invest in aerodynamic improvements for tractors. This continued evolution of aerodynamic performance, both in production and in the research stage as part of the SuperTruck program, has consequently led the agencies to propose and adopt two additional aerodynamic technology bins (Bins VI and VII) for high roof tractors. However, we have not predicated the use of either Bins VI or VII in setting the stringency of the Phase 2 standards.

Organization: SmartTruck

As an Aerodynamic Device Manufacturer, SmartTruck is keenly aware of the challenges that are inherent in aerodynamic testing protocols and have dedicated countless hours of research in this area with our aerodynamic scientists and engineers. SmartTruck’s Chief Science Officer and aerodynamicist, Michael Henderson, spent 32 years at Boeing in senior engineering and management positions as well as helping to develop one of the first Computational Fluid Dynamics (CFD) programs (Naiver-Stokes). Since founding SmartTruck, our aerodynamic engineers have conducted over 1,000 coastdown test runs and have over 75 years of combined experience with CFD analysis. We therefore direct these comments to the Supplemental Aerodynamic Data from EPA Testing Docket No. EPA-HQ-OAR-2014-0827-1624, specifically the testing methods used to determine the performance of aerodynamic devices on medium and heavy duty vehicles. [EPA-HQ-OAR-2014-0827-1923-A1 p.1-2]

We support the use of various test methods such as Coastdown, CFD, Wind Tunnel, and Constant Speed in order to provide aerodynamic device manufacturers the option to use their preferred method and as a way to achieve alignment with the tractor regulations in the Phase 1 rule. However, to ensure accuracy and comparability between all parties regardless of testing methodology we believe testing protocols across all methods should include calibration standards, that coastdown testing protocols should account and correct for non-linear speed related mechanical drag, and that there should be more test facilities and technology types involved in the comparison between different testing methods. [EPA-HQ-OAR-2014-0827-1923-A1 p.2]

All testing methods have strengths and weaknesses related to assumptions that are utilized in each test. For example, coastdown and constant speed testing are dependent upon the data regression techniques used for their analysis.¹ CFD is dependent upon its grid density and its location on the model to ensure accurate results. Wind Tunnel testing utilizing scaled models can produce Reynolds Number Effects, Wall Effects, and Jet Effects that influence the test results of components that interact with the boundary layer.² [EPA-HQ-OAR-2014-0827-1923-A1 p.2]

CFD and wind tunnel testing methods could both be calibrated with an Ahmed Body style analysis to ensure both separation predictions and wake drag are accurately accounted for. A two stage drag spoiler analysis could be used with coastdown and constant speed testing to ensure that a difference in drag is predicted accurately with minimal cost to users. Using a calibration process across all testing methodologies would also provide a more accurate comparison between tests. [EPA-HQ-OAR-2014-0827-1923-A1 p.2]

The current coastdown methodology, specifically SAE J1263 and SAE J2263, has two fatal flaws; it is assumed that rolling resistance, or more aptly denoted as Mechanical Drag, is constant over the course of a coastdown test session and Mechanical Drag is linear with speed. Firstly, current coastdown methodology tests for the complete road load force or total drag, which is the sum of the Aerodynamic Drag and the Mechanical Drag. Current methodology assumes the Mechanical Drag is constant during a test and therefore a change in Aerodynamic Drag is equivalent to the change in Total Drag. Therefore a
simple test is performed to calculate the Road Load Force. At SmartTruck we have seen first-hand that this method leads to inaccurate results. If the vehicle’s oil, lubrications, metals, tires, and brakes are not completely warmed up and maintained at a near consistent state for an entire test session (eight Baseline Segments and eight Aerodynamic Segments as outlined in CFR 1066.310) the Mechanical Drag is subject to change, or creep, throughout the day. [EPA-HQ-OAR-2014-0827-1923-A1 p.2]

Secondly, the Mechanical Drag is not just the rolling resistance of the tires. During a coastdown test when the vehicle is shifted into neutral, the vehicle is not only experiencing aerodynamic drag and tire rolling resistance, but it is also back driving the transmission and differential gears in addition to all the bearings between the tires, axles, and drive shafts. The back driving of the mechanical drive components of the vehicle is highly non-linear with speed. For example, with the differential gear there is a ring gear engaged to a pinion gear which are suspended in oil and/or air. As they are being back driven, and spinning within their case, they are rotating through oil and through the air and thusly subject to two separate sources of drag. These sources of drag are well known and vary with speed to the order of velocity squared, not linearly. In addition to the two separate sources of drag, the differential gear will be subject to wet friction while the teeth are engaged in the oil. With two rear gears, a transmission, a multitude of bearings, axles and drive shafts all being driven, all having their own Wet Friction and/or Aerodynamic Drag, the final Mechanical Drag will be a combination of the tire’s rolling resistance and the non-linear drag associated with the drive components of the vehicle. [EPA-HQ-OAR-2014-0827-1923-A1 p.3]

If current coastdown methodology does not account for both the creep of Mechanical Drag throughout a test session as well as its non-linear variation with speed, any and all Aerodynamic Drag associated will be subject to unknown non-measured errors rendering its solutions unreliable. There are reliable, inexpensive ways of accomplishing this. [EPA-HQ-OAR-2014-0827-1923-A1 p.3]

Also, while the agencies have proposed a formula for normalizing wind tunnel, CFD, and constant speed to coastdown testing, specifically relating to Docket Number EPA-HQ-OAR-2014-0827 concerning Selective Enforcement Audits (SEAs), that formula is based solely on the results of one wind tunnel facility to the results of one coastdown facility. Due to the variables and assumptions that are utilized at different locations we would prefer to see multiple testing facilities used in normalizing data from one method to another. For example, CFD calibrations could be done similar to the American Institute of Aeronautics and Astronautics’ Drag Prediction Workshop (DPW). Also, for further refinement and correlations, more technology types, such as boundary layer manipulation devices, should be utilized in normalization to further strengthen claims. [EPA-HQ-OAR-2014-0827-1923-A1 p.3]

---

3 CDA = D/(0.5ρV^2)

Response:

As noted in the comments, coastdown testing measures all of the losses associated with the vehicle, including aerodynamics, rolling resistance, and driveline losses. To isolate the aerodynamic $C_dA$, it is important to remove the losses for the driveline and tire rolling resistance. For the final Phase 2 rules, the agencies are incorporating into the coastdown procedure a modified SAE J2452 test procedure that requires manufacturers to measure the speed dependence of the tire rolling resistance for each of the steer, drive, and trailer tire models used on the article undergoing a coastdown test. The tire rolling resistance must be adjusted to the ambient temperature during the coastdown test using the correction mentioned in ISO 28580. The agencies are also requiring that manufacturers measure the speed dependence of the spin losses of the model of the drive axle(s) used on the article undergoing a coastdown test. We did not observe strong evidence of mechanical drag creep in our testing and did not receive data to correct for this. The testing we conducted was overnight with minimal fluctuations in ambient temperature. Repeat testing of tractors on different days showed acceptable repeatability. Testing requires a warming up phase as well as driving at high speeds, which help to keep the vehicle warmed up.

Due to the various technologies and geometries that we would expect to be implemented from this rule, the agencies are finalizing wind tunnel and CFD test procedures based largely on industry standards SAE J1252 and SAE J2966, respectively. We believe that adopting industry standards is a sound basis for these complex areas of testing, which encompass many facilities and software codes. Modest exceptions to the SAE standards are required for greater precision or to align with specific aspects of the rulemaking. The CFD test procedure can be found in 40 CFR § 1037.532. Furthermore, for the tractor program, CFD and wind tunnel tests are required to be adjusted to a coastdown equivalent value using $F_{alt-aero}$ determined from a reference coastdown test. Any modifications to simulation parameters would require a recalculation of this adjustment factor, leading to corresponding changes in the certification drag area values for non-reference tractors.

Organization: Truck & Engine Manufacturers Association (EMA)

Standard Trailer

As referenced above, the configuration of the standard trailer proposed for use in Phase 2 coastdown testing should be more aerodynamic. Proposed section 1037.501(g) specifies that the standard trailer for coastdown testing will be similar to the Phase 1 standard trailer, with the sole addition of aerodynamic side skirts. A more aerodynamic trailer, however, would better reflect the trailers expected in 2027 and beyond, and would be better suited for the advanced tractor-trailer aerodynamic performance assumed and required under the Proposed Phase 2 Standards. As it stands, the agencies have failed to demonstrate that any tractor can achieve aerodynamic Bins V through VII when pulling the defined test trailer. To the contrary, all designs envisioned for achieving those Bins are matched with a highly streamlined trailer.

Aerodynamic Compliance Margin

EPA also has proposed to narrow the Bin ranges in the Phase 2 program, which has significant implications for confirmatory testing. All testing has variability. This variability, combined with narrowed compliance Bins, could result in a vehicle appearing to have dropped into a lower Bin in confirmatory testing. One OEM has compiled the range of high-roof sleeper-cab and day-cab $C_dA$ values from wind-averaged and non-yaw averaged vehicle tests conducted since the start of 2015. Those $C_dA$ values are plotted in the charts below. EPA’s proposed compliance requirement - that the aerodynamic $C_dA$ during any confirmatory test or SEA must fall in the same Bin as the OEM’s stated Bin - does not take into
account the several relevant testing variabilities. Current testing variation could cause the aerodynamic CdA value to be slightly higher, pulling vehicles that are near a Bin boundary into a lower Bin, thereby making them “non-compliant.” This is an unacceptable situation that could result in an infeasible rule. A 1-Bin compliance margin is necessary. [EPA-HQ-OAR-2014-0827-1269-A1 p.12]

EMA’s comments below regarding the coastdown test procedure provide extensive details on the sources and extent of variability in aerodynamic testing. As that information shows, the agencies should not finalize a rule that does not account for known sources of testing variability. Without an adequate compliance margin, OEMs will be required to move a large section of vehicles that tested in a higher Bin to a lower Bin to allow themselves the necessary compliance margin. That will result in making the Phase 2 Standards that much more infeasible. [EPA-HQ-OAR-2014-0827-1269-A1 p.14]

A compliance margin is necessary for the proposed aerodynamic certification measurements. However, proposed section 1037.401(b) does not include any compliance margin whatsoever for an audit of aerodynamic certification, despite the fact that coastdown testing includes a great deal of variability – significantly more than in Phase 1 where the agencies did include a compliance margin. If the agencies hold manufacturers to the certified CdA during an audit without providing any compliance margin, manufacturers would have to compensate for the lack of a test margin by raising their GEM CdA input by approximately one Bin to provide themselves with the necessary margin to account for the variability inherently associated with compliance testing. Such a forced increase of manufacturers’ aerodynamic CdA GEM inputs would make achieving the Proposed Phase 2 Standards, in effect, a full-Bin more difficult, which amounts to a hidden stringency increase, further exacerbating the infeasibility of the Proposed Phase 2 Standards for heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.16]

The variability of coastdown testing is on the order of +/- 5%, based on EPA's own test data under very controlled conditions (i.e., same flat test track, same vehicle and time-of-day, low wind, skilled driver, etc.). (See Daimler Trucks North America’s SAE ComVEC 2013 Presentation). If EPA expects manufacturers to certify vehicles with no compliance testing margin provided in the rules to account for that 5% variability, then manufacturers will have to certify vehicles at 5% above their true CdA. In turn, the agencies’ stringency numbers will need to be increased to reflect the fact that the agencies projected aerodynamic improvement targets – plus 5% – would be the necessary inputs into GEM. The alternative and better option is for the agencies to recognize the variability inherent in the proposed audit procedures, and to provide that a vehicle would fail an audit only if its CdA is more than 5% above the certified level. [EPA-HQ-OAR-2014-0827-1269-A1 p.16]

EPA also is proposing to allow aerodynamic audits under methods of the Agency’s choosing. For example, EPA is proposing that in auditing a vehicle’s aerodynamic performance, the Agency “may use any of the procedures specified in § 1037.525 for measuring drag area.” See Proposed § 1037.401(b). As a practical matter, this would force manufacturers to consider the variability among all of the methods referenced in section 1037.525 in order to determine the maximum CdA that the Agency might calculate with any one of them, and to include additional margins of compliance into all vehicles’ declared CdA’s to protect against the variability that may occur when a vehicle is tested using a procedure that the manufacturer did not use. This would make already-difficult aerodynamic targets that much more unachievable. [EPA-HQ-OAR-2014-0827-1269-A1 p.16]

To remedy this unreasonable result, EMA recommends as follows for any audit, whether for aerodynamics or for any engine-related or vehicle-related parameter input into GEM: the Agency should (first) inquire about the method that the manufacturer used in its certification testing, and (second) assuming that method is authorized under the Phase 2 regulations, then the Agency should use that same method for its audit. The underlying rationale is that if a manufacturer has selected a proper test method,
then the Agency should not, in effect, second-guess the manufacturer. Rather, the audit should merely be a test of whether the manufacturer’s results under that authorized method are valid. To that end, the agencies should utilize the same test methods and testing location as used by the manufacturer. The agencies also should use the same reference test tractor and trailer as used by the manufacturer to eliminate potentially significant sources of variability. Under EPA’s proposal, however, the Agency could confound natural variations arising from different test procedures with test-to-test variations, thus increasing the likelihood of the Agency erroneously concluding that the manufacturer submitted invalid or improper test results. EPA should not second-guess manufacturers or misapply the results from differing test method and measurement errors to challenge manufacturers’ otherwise proper certifications. The agencies’ proposed test methods need to be revised and improved substantially, as discussed further below. [EPA-HQ-OAR-2014-0827-1269-A1 p.16-17]

On the other hand, EPA’s proposal to conduct SEAs that involve testing two or six additional vehicles, beyond those originally planned for testing, is untenable. Testing will in all likelihood have to take place at a specific track (for example, in Cape Canaveral, Florida), given the limited number of suitable test facilities. In addition, data analysis takes time. For manufacturers to know that vehicles might fail an SEA (e.g., due to test-to-test variability inherent in the aerodynamic testing procedures) and to arrange to get two or six additional vehicles out to the test facility within a narrow test window is not reasonable. Rather, EPA should (i) assign a realistic compliance margin to SEAs, as the Agency did in Phase 1, and (ii) adopt realistic and reasonable SEA procedures, such as testing another vehicle at a later date. [EPA-HQ-OAR-2014-0827-1269-A1 p.19]

- For confirmatory tests, the agencies should use the same tractor, trailer, and wind instrumentation, at the same testing facility as used by the vehicle manufacturer
- For SEAs, use the same test method, test facility and trailer, as well as the same instrumentation, if applicable. [EPA-HQ-OAR-2014-0827-1269-A1 p.18-19]

With respect to other confirmatory testing issues, EMA agrees with the agencies’ approach in proposed section 1037.201(g). The agencies have recognized that manufacturers cannot store a large number of test vehicles for an indefinite period, nor can they guarantee that on any given day they will have exactly the configuration of vehicle that the agencies request under proposed section 1037.201(g). Rather, if EPA intends to require testing of a number of full-scale vehicles, EPA should understand that manufacturers may need to sell some of those vehicles. Consequently, EPA should agree to work with manufacturers to find acceptable test vehicles at acceptable times, which perhaps could mean that EPA’s first choice of vehicle is not available on the day the Agency requests it. The agencies have proposed that manufacturers would be able to produce similar vehicles, not necessarily the original test vehicles. EMA agrees with this approach. [EPA-HQ-OAR-2014-0827-1269-A1 p.19]

Coastdown Test Procedure

There are a number of fundamental problems with the proposed aerodynamic testing requirements. In particular, the proposed coastdown test procedures are not sufficiently defined and do not adequately address many key issues, such as yaw angle, type and number of sensors (i.e., anemometers), test speeds, and test sequence. The test procedures also fail to provide any compliance margin, which creates basic feasibility concerns given the many sources of significant testing variability. [EPA-HQ-OAR-2014-0827-1269-A1 p.4]

The proposed coastdown test procedure (see Proposed § 1037.527) will produce inherently inaccurate results. The proposed test procedure assumes 0° yaw wind conditions, a completely unrealistic assumption. When coastdown testing is conducted, there always will be some wind, which necessarily
increases the CdA. Additionally, the non-aerodynamic losses during a coastdown test (such as tire rolling resistance and driveline friction) are underestimated in the proposed test procedure, which will further increase the measured CdA. Finally, the proposed test procedure does not include a method of correction for pavement surface variability of the test track. All of those factors need to be addressed. [EPA-HQ-OAR-2014-0827-1269-A1 p.17]

Chief among those test procedure issues is the agencies’ unrealistic assumption of zero yaw conditions (= no cross-wind). EPA and NHTSA are assuming that a coastdown test will yield a 0 degree CdA value (the lowest point on the drag polar), whereas in reality manufacturers measure something that is higher up the drag polar (at a non-zero point). Theoretically, manufacturers could attempt to wait at the test track for zero-wind conditions, but EPA is authorized to conduct confirmatory coastdown tests with wind speeds up to 6 mph. Consequently, it is necessary for manufacturers and EPA to assign and account for an average yaw angle in any given coastdown test. [EPA-HQ-OAR-2014-0827-1269-A1 p.17]

With a complete drag polar determined through the alt-aero method (CFD or wind tunnel), it is possible to calculate the ratio between two values at two different yaw conditions. That way, manufacturers could measure at 2 degrees and EPA could measure at 3 degrees (depending on the wind conditions during the test) and then the manufacturers could adjust its value to EPA’s test condition (or vice versa) and actually have two comparable test values. Given the shrinking (if not disappearing) compliance margin, it is critically important to ensure as close to an “apples-to-apples” comparison as possible. Thus, including yaw angle is important to the implementation of a fair and reasonable coastdown test. [EPA-HQ-OAR-2014-0827-1269-A1 p.17]

Another problem associated with the proposed coastdown test is its failure to properly account for the various non-aero losses (driveline/axle losses, rolling resistance). The “low speed” test may not be as accurate as it needs to be due to the inaccurate estimation of axle losses/rolling resistance. Specifically, rolling resistance is known to increase significantly between the “low speed” test and the “high speed” test, but that is not accounted for in the proposed coastdown test procedure. The underestimated non-aero losses “bleed” into the aerodynamic load estimation, leading to an overestimation of the CdA. [EPA-HQ-OAR-2014-0827-1269-A1 p.17]

With respect to the actual running of a coastdown test, there are multiple sources of test-to-test variability. More specifically, all of the following variables will need to be accounted for in any final regulatory coastdown test. [EPA-HQ-OAR-2014-0827-1269-A1 p.17]

Coastdown Test Variables [EPA-HQ-OAR-2014-0827-1269-A1 p.18]
Test Conditions (up to +10% increase in CdA) [EPA-HQ-OAR-2014-0827-1269-A1 p.18]
– Wind (head, tail, yaw)
– Temperature (including tire impacts)
Track (up to 5% increase in CdA due to surface difference) [EPA-HQ-OAR-2014-0827-1269-A1 p.18]
– Grades
– Pavement surface
– Pavement temperature
Tractor (up to 5% increase in CdA due to newer truck and/or tires) [EPA-HQ-OAR-2014-0827-1269-A1 p.18]
– Tire model and wear
– Axle friction
– Vehicle speed
– Wind speed and direction
Trailer Gap [EPA-HQ-OAR-2014-0827-1269-A1 p.18]
– Many trucks cannot achieve the regulated gap due to long wheel base or short cab (especially day cabs)
– +/- 2” tolerance
– Trailer skirt location relative to tractor bogie

Trailer [EPA-HQ-OAR-2014-0827-1269-A1 p.18]
– Corners
– Skirt tolerances
– Skirt stiffness
– Tires

Since improved aerodynamic performance is a cornerstone of the Proposed Phase 2 Standards, the test methods to assess that performance need to be correct, repeatable and accurate. Otherwise, the foundation of the Phase 2 program could be subject to challenge. To strengthen and enhance the test methods at issue, and in addition to accounting for the sources of variability noted above, the agencies should implement the following improvements: [EPA-HQ-OAR-2014-0827-1269-A1 p.18]

- Tighten the wind constraints to <=2 mph crosswind (maintain the other constraints)
- Include a tire rolling resistance offset between low and high-speeds to account for the speed dependency of the rolling resistance term
- Add yaw measurement (not just air speed) and define the tolerance to +/- 0.5 degrees
- Change the location of the anemometers to at least 1.5 meters above the trailer’s leading edge
- Change the proposed test sequence to high-low, high-low in matched pairs
- Increase the required number of tests to >30 valid high-low pairs in a test day
- Determine average yaw during each high-speed coast
- Plot CdA vs. yaw, where each high-speed coast generates a data point
- Define objective data-acceptance criteria based on statistical results
- Define minimum grade and elevation survey data requirements to ensure that any change in velocity due to grade can be captured during high and low-speed runs
- Obtain an effective mean CdA at an effective mean yaw angle for the test
- “F_{alt-aero}” then should be defined at the yaw angle for the reference test
- Vehicle manufacturers should provide the yaw curve for the reference vehicle through the “alt aero” method; this could be used by the agencies to account for any differences in wind condition/yaw angle between a reference test and a confirmatory test [EPA-HQ-OAR-2014-0827-1269-A1 p.18-19]

In addition, the agencies should commit to review the current trailer-gap specification and tolerance (i.e., 45” +/- 2”; see section 1037.501(g)). In that regard, tighter trailer-gaps may be appropriate in the future for assessing aerodynamic performance, as well as compliance with the Phase 2 Standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.19]

Changes to CFD Certification

Since the highway test cycle in GEM assumes that heavy-duty vehicles spend 86% of the time traveling at 65 mph, EMA recommends that the agencies raise the test speed for Computational Fluid Dynamics (“CFD”) certification from 55 mph to 65 mph to be consistent with GEM. In addition, EMA recommends that the agencies replace the full yaw sweep, as generated through SAE J1252, with a single surrogate yaw angle of 4.5 degrees, which represents the intended (SAE J1252) wind-averaged condition. [EPA-HQ-OAR-2014-0827-1269-A1 p.19-20]
EMA recommends that these amendments be included in proposed section 1037.531. [EPA-HQ-OAR-2014-0827-1269-A1 p.20]

Aerodynamic Adjustment Factors

One core issue relates to the proposed test procedures and data assessment methods to determine a heavy-duty vehicle’s certification to and compliance with the proposed aerodynamic standards for each major tractor model. The agencies’ proposed procedures would include, among many other requirements, a requirement that vehicle manufacturers test up to six (6) vehicle models each year in both the day-cab and sleeper-cab configurations, resulting in a total of twelve (12) coastdown tests per year. [EPA-HQ-OAR-2014-0827-1269-A1 p.4]

Only one aerodynamic adjustment factor, $F_{alt-aero}$, should be required. This is confirmed by the data set forth in RIA Table 3-21 (reproduced above at page 7) which shows that the $F_{alt-aero}$ values are extremely close (1.11-1.15) among the tested vehicles. (See also Agency data, reproduced below, showing $F_{alt-aero}$ factors of 1.09 +/- 0.02 for three tested vehicles). [EPA-HQ-OAR-2014-0827-1269-A1 p.20]

Data that vehicle manufacturers have provided to the agencies also establish that the relevant $F_{alt-aero}$ values are within a range of three-tenths of 1% (0.30%). However, proposed section 1037.525(b)(3) would require determining separate adjustment factors for “a high-roof day cab and a high-roof sleeper cab corresponding to each major tractor model.” The coastdown testing needed to establish such multiple adjustment factors would be a time-consuming, costly and unreasonable burden. Additionally, there would not be any need for such multiple adjustment factors if the aerodynamic test procedure is made sufficiently robust to produce comparable results at different facilities on different days. Simply stated, the aerodynamic adjustment factor should not be vehicle dependent. [EPA-HQ-OAR-2014-0827-1269-A1 p.20]

Constant-Speed Testing

The agencies are considering the adoption of a constant-speed test for assessing aerodynamic performance in lieu of the proposed coastdown test. EMA cannot support this proposal at this juncture. There is insufficient time in this rulemaking process to properly study whether constant-speed testing is equivalent to or better than coastdown testing in determining the aerodynamic drag coefficient. The complex and time-consuming test procedure would require multiple studies to determine the reproducibility of the results and their comparison to results from coastdown tests. Accordingly, EMA recommends that the constant-speed test be included only as a potential alternative to be phased-in at a future date, if appropriate, to allow more time to study the proposed procedure. In that regard, a number of considerations will need to be studied in evaluating the potential merits of a constant-speed test, including the following: [EPA-HQ-OAR-2014-0827-1269-A1 p.70]

- There should be a requirement for either axle or wheel-end torque sensors (wheel-end torque sensors on front-drive axles with unpowered, shortened half-shafts on rear-drive axles have been shown to be effective and cost-efficient)
- There should be a requirement for equal data (time) in each direction at each speed
- Onboard anemometer calibrations ($V_r$) should be required in the SAE J2263 method with all valid 50 and 70-mph constant-speed data; zero-offset (yaw calibration) should be performed using equal 70-mph data in each direction
- Requirements should be defined for preconditioning prior to each steady-state speed and throughout the data-collection process
- Speed-dependent tire RR terms should be included (ISO or SAE tire data depending on test process precondition constraints – steady-state or transient)
- A correction should be included for non-zero inertial terms in each 10-sec segment
- Corrected force tolerance should be specified (include gravity and inertial corrections) rather than drive-torque consistency to validate data
- A minimum requirement for yaw distribution should be specified before curve-fitting to determine drag polar
- Given the error with low speed measurement in high wind conditions, a 1st order wind speed/direction force correction should be adopted [EPA-HQ-OAR-2014-0827-1269-A1 p.70]

In sum, the foregoing issues, along with many others, will need to be carefully considered before the agencies move to adopt a constant-speed test as a designated reference test method. [EPA-HQ-OAR-2014-0827-1269-A1 p.70]

4x2 Axle Configurations

The agencies should specify that any vehicle with a “4x2” axle configuration and that also is equipped with a heavy-duty powertrain should be classified as a Class 8 vehicle, regardless of GVWR. If such a vehicle has a heavy-duty certified engine, it should be treated as a Class 8 vehicle, and so should be able to generate Class 8 credits. In that regard, 4x2 tractors are typically purchased to pull multiple trailers and, as a result, normally pull heavier loads than a typical 6x4 tractor, even if the GVWR of the tractor is less than 33,000 pounds due to the reduced number of axles. [EPA-HQ-OAR-2014-0827-1269-A1 p.43]

Phase 1 Changes

The proposed changes to the Phase 1 wind-average drag aerodynamic certification calculation should not be finalized. As it stands, proposed section 1037.525(d)(2)(iii) would establish a new equation for calculating the wind-averaged drag area for model year 2018 and later vehicles. Such a Phase 1 change – in effect, a retroactive change – would require recertification of all heavy-duty tractors that utilized the alternative yaw-sweep correction factor (which alternative has been relied on by virtually all manufacturers to demonstrate compliance), and would increase the aerodynamic drag inputs into GEM starting in 2018, effectively increasing the stringency of the Phase 1 standards for model years 2018-2020. That is fundamentally unfair and, from an administrative rulemaking perspective, invalid. If EPA and NHTSA want to alter the stringency of the Phase 1 program, they will need to provide the requisite leadtime and stability periods. [EPA-HQ-OAR-2014-0827-1269-A1 p.21]

More specifically, pursuant to the equation in the current version of section 1037.525(d)(2)(iv), the corrected drag area to be used to determine the Phase 1 aerodynamic bins is calculated by multiplying the zero-yaw drag area by “CFys,” which is a yaw-sweep correction factor. Current Phase 1 regulatory section 1037.521(f)(2) provides the option to calculate wind-average drag, as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.21]

(f) Yaw sweep corrections. You may optionally apply this paragraph (f) for vehicles with aerodynamic features that are more effective at reducing wind-averaged drag than is predicted by zero-yaw drag. You may correct your zero-yaw drag area as follows if the ratio of the zero-yaw drag area divided by yaw sweep drag area for your vehicle is greater than 0.8065 (which represents the ratio expected for a typical aerodynamic Class 8 high-roof sleeper cab tractor): [EPA-HQ-OAR-2014-0827-1269-A1 p.21]
(1) Determine the zero-yaw drag area and the yaw sweep drag area for your vehicle using the same alternate method as specified in this subpart. Measure drag area for 0°, −6°, and 6°. Use the arithmetic mean of the −6° and 6° drag areas as the ±6° drag area. [EPA-HQ-OAR-2014-0827-1269-A1 p.21]

(2) Calculate your yaw sweep correction factor (CF<sub>ys</sub>) using the following equation: [EPA-HQ-OAR-2014-0827-1269-A1 p.21]

\[ CF_{ys} = (\pm 6^\circ \text{ drag area}) \times 0.8065 / (\text{Zero Yaw Drag Area}) \]

Subparagraph (5) of current section 1037.521(f) also provides as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.21]

(5) As an alternative, you may choose to calculate the wind-averaged drag area according to SAE J1252 (incorporated by reference in §1037.810) and substitute this value into the equation in paragraph (f)(2) of this section for the ±6° yaw-averaged drag area. [EPA-HQ-OAR-2014-0827-1269-A1 p.21]

This regulatory flexibility has proved to be critical to the cost-effective implementation of Phase 1, and heavy-duty vehicle manufacturers have expressly relied on the alternative set forth in section 1037.521(f) in certifying their heavy-duty tractors. However, in the proposed Phase 2 regulations, and without any proper notice or study, EPA and NHTSA are proposing to replace the option set forth in subparagraph (f)(5) with a new equation in proposed section 1037.525(d)(2), which increases the target ratio of zero-yaw drag area to wind-averaged drag area from 0.8065 to 0.8330 (when using the SAE J1252 wind-averaging) after MY 2017. [EPA-HQ-OAR-2014-0827-1269-A1 p.21-22]

The effect of this unilateral revision by the agencies is an increase in CF<sub>ys</sub> by a factor of 0.833/0.8065, which amounts to an increase of 3.3% in the CdA used for certification. This will necessarily shift tractors to lower, less aerodynamic bins, which again effectively increases the burden of compliance and the stringency of the Phase 1 standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.22]

For example, the Phase 1, Bin IV CdA range for high-roof sleepers is 5.6-6.2, but effectively will become 5.42-6.00 under EPA’s revision. Consequently, all trucks currently above 6.00 CdA will shift down to Bin III. The net result is that approximately 36% of Bin IV sleeper trucks will shift to the lower Bin. Similarly, the current Bin III CdA range for high-roof sleepers is 6.3-6.7, but will effectively become 6.1-6.48 under the agencies’ retroactive changes to the Phase 1 Standards, causing a corresponding reversion to Bin II. Additionally, since mid-and low-roof tractors can be binned based on their high-roof equivalents, and since the low- and mid-roof subcategories for both sleepers and day-cabs typically are in applications with lower penetrations of aerodynamic devices due to operational considerations, those factors also will drop many Phase 1 tractors that are in those low- and mid-roof subcategories from Bin II (which will reduce the vehicles’ FEL) into Bin I. [EPA-HQ-OAR-2014-0827-1269-A1 p.22]

EPA and NHTSA argue that since the correction factor at issue is an option, the announced regulatory change is not a stringency increase. But all manufacturers are using this “option,” and, in effect, are required to do so given the impossibility of meeting the agencies’ automatic engine shutdown (“AES”) system targets (discussed further below at page 52). Consequently, the revision at issue is, in fact, an unacceptable, essentially retroactive Phase 1 stringency increase that will significantly impact credit balances and feasibility. It is also a change with near-zero leadtime to certify MY 2018 vehicles, since those vehicles can begin production on Jan. 2, 2017. [EPA-HQ-OAR-2014-0827-1269-A1 p.22]

For its part, NHTSA is proposing to amend the stringency of its Phase 1 program, and to expand the NHTSA standards to four decimal places. The expanded precision would be required in calculating
vehicle FELs. EMA supports this amendment, since it will correct the current error in the calculation of GHG/FE credits. [EPA-HQ-OAR-2014-0827-1269-A1 p.22]

That said, EMA is concerned that there is no reference in the NPRM that the agencies will use the corrected method to recalculate the 2013 and 2014 model year credits, which manufacturers have earned based on the year-end reports that they have already submitted. The agencies should allow for those recalculations of earned credits. In addition, the agencies will need to account for this in their release of an updated version of GEM. [EPA-HQ-OAR-2014-0827-1269-A1 p.23]

In-Use Tractor Testing

A second core issue relates to the proposed requirement that vehicle manufacturers conduct chassis dynamometer testing of three sleeper-cab tractors and two day-cab tractors each year to verify the results simulated through the updated GEM Model. Simply stated, vehicle manufacturers do not have sufficient testing facilities to run all of those required verification tests, which would not be cost-effective even if sufficient facilities were available. In addition, the proposed test methods are (again) not sufficiently defined. More fundamentally, EMA questions the need for the proposed chassis dynamometer testing. If EPA and NHTSA believe that such testing is sufficiently important, the agencies are, of course, free to undertake that testing on their own. However, the agencies have not proposed any rational basis for imposing such a significant cost on manufacturers, with little or no corresponding environmental or societal benefit. [EPA-HQ-OAR-2014-0827-1269-A1 p.4]

Proposed section 1037.665 would require annual chassis dynamometer testing and reporting of emissions (including NOx, PM, CO, NMHC, CO2, CH4, and N2O emissions) from “three sleeper cabs and two day cabs” for the informational purpose of comparing “real world” test results with GEM-based results. Such annual testing would impose a very significant burden on manufacturers and could result in a shortage of available heavy-duty chassis dynamometer test facilities, all while yielding no corresponding benefit. In particular, testing five vehicles is insufficient to identify or confirm fleet trends. Moreover, testing on a chassis dynamometer would not discern “real-world” fuel efficiency improvements like those resulting from AMTs, predictive technologies or other systems that improve the way a driver drives, and that are recognized in GEM – but are impossible to recreate on a chassis dynamometer. In other words, the results would be unrepresentative of the full fleet of vehicles and further unrepresentative of real-world driving, so the results would not fully reflect a vehicle’s compliance with Phase 2 Standards. Moreover, the costs for this proposed “informational” testing would be inordinately high and have not been fully accounted for in the agencies’ cost-benefit analysis for the Proposed Phase 2 Standards. In addition, EPA lacks the legal authority to compel manufacturers to test in-use, non-new motor vehicles and engines. Accordingly, while EMA is willing to work with the agencies to explore means to assess the in-use performance of Phase 2 vehicles, the proposed chassis-dynamometer testing is not a valid, reasonable or cost-effective approach for generating such in-use data. [EPA-HQ-OAR-2014-0827-1269-A1 p.28]

There are better, less burdensome ways for the agencies to gather the Phase 2 data at issue. One option would be for EPA to do its own testing or to work with manufacturers to develop a collaborative in-use testing research program. As an additional alternative, the agencies should consider using data that manufacturers already generate as part of their ongoing development processes. Product validation engineering groups regularly run vehicles through modified fuel economy tests to verify the real-world fuel-saving potential of new technologies. Those tests are conducted in a controlled way, are documented in detail, and yield very reliable results. Those data could provide the agencies with the information they are looking for in a far more cost-effective manner. Further, the agencies could consider tracking manufacturers’ inputs into GEM as a means of monitoring improvements in GHG/FE technologies. Alternatively, if chassis dynamometer testing is utilized to develop comparative information, it should be
limited to testing only one vehicle configuration and only during model years when the underlying GHG/FE standards change. [EPA-HQ-OAR-2014-0827-1269-A1 p.28-29]

Chassis Dynamometer Testing

The agencies have asked for comment on the utilization of chassis dynamometer testing for certification instead of relying on GEM. EMA opposes any mandate for chassis dynamometer testing for medium-duty and heavy-duty vehicles. There are far too many certifiable vehicle configuration and far too few chassis dynamometer testing facilities to make it possible to implement such a dynamometer-based certification program. Furthermore, it should be recognized that a chassis dynamometer test would require separate inputs for aerodynamic performance and rolling resistance, loads that compromise over 70% of a typical vehicle’s load factors. In addition, such testing is subject to other significant variables, such as driver differences, rolling resistance on the chassis dynamometer rolls, tire temperature, and many other variable factors. [EPA-HQ-OAR-2014-0827-1269-A1 p.63]

Accordingly, given the potential variability between GEM-based certification and dynamometer-based certification, EPA needs to specify that the Agency will only utilize a chassis-dynamometer-based audit test where the underlying certification test was conducted at a chassis-dynamometer testing facility. In all other cases, the Agency’s audits should be GEM-based to match the certification method that the manufacturer has used. In that regard, EMA supports setting the cut point for chassis-based certification testing at 14,000 pounds GVWR. [EPA-HQ-OAR-2014-0827-1269-A1 p.63]

Response:

Standard Trailer

The agencies re-evaluated the proposal to include trailer skirts on the Phase 2 reference trailer with consideration of the comments. We still project that the bulk of trailers that will be in operation during the life of tractors produced early in Phase 2 will be represented by the aerodynamic performance of a trailer with skirts. Therefore, we are adopting the reference trailer as proposed. However, we also want to recognize that the trailer fleet will continue to evolve over the lifetime of tractors built and certified to Phase 2, especially from MY 2027 and later. Based on testing conducted to support the trailer portion of Phase 2, we found that on average a boat tail added to a dry van trailer with skirts reduces wind averaged $C_dA$ by 0.6 m$^2$. We recognize that if we do not account for reduced aerodynamic loads in the real world, then we may not be appropriately evaluating the tractor powertrain. We considered changing the standard trailer in MY 2027; however, this would lead to significant testing burden for the manufacturers because they would have to determine new $C_dA$ values for their entire fleet of tractors. Instead, we are adopting Phase 2 GEM that beginning in MY 2027 will take the $C_dA$ input for each vehicle and reduce it by 0.3 m$^2$ to reflect the lower aerodynamic loads that are a mix of trailers with skirts and trailers with skirts and boat tails. This change has been accounted for in both the baseline and standard setting of the CO$_2$ emissions and fuel consumption values.

Aerodynamic Compliance Margin/SEA

The agencies have refined the aerodynamic test procedures, developed a new SEA approach, revised aerodynamic bin boundaries, and adjusted aerodynamic bin adoption rates in the technology packages for the final rule. This package of changes as a whole is in response to the set of detailed comments from stakeholders. The changes to the coastdown test procedures reduce the test-to-test variability of the $C_dA$ results. The new SEA approach appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on
inaccurate testing. The high roof bin values being adopted in the HD Phase 2 final rulemaking differ from those proposed due to the coastdown and other aerodynamic test procedures changes. However, in both the NPRM and this final rulemaking, we developed the Phase 2 bins such that there is an alignment between the Phase 1 and Phase 2 aerodynamic bins after taking into consideration the changes in aerodynamic test procedures and reference trailers required in Phase 2. The Phase 2 bins were developed so that a tractor that performed as a Bin III in Phase 1 would also perform as a Bin III tractor in Phase 2.

The widths of the aerodynamic bins represent a balance between narrower bins to further differentiate the performance of aerodynamic technologies versus wider bins to allow less test burden (more tractors fall within a given bin). The range of Phase 1 aero Bin IV is 0.5 m$^2$. The agencies set the Phase 2 aerodynamic bin boundaries in the final rule with a range of 0.5 m$^2$ for Bins I through III and 0.4 m$^2$ for Bins IV through VI. The agencies held discussions with the tractor manufacturers to discuss bin widths post-proposal to help us achieve the proper balance.

Although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor $C_dA_s$ and solicited supplemental comments on it. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur. It is important to note that, although SEAs are directed by EPA, the actual testing is conducted by the manufacturer at their chosen facilities. This minimizes many potential causes of test variability, such as differences in test trailers, test tracks, or instrumentation. Thus confidence intervals need only reflect true test-to-test variability. Also, manufacturers generally rent facilities for coastdown testing as needed, which means EPA will need to provide some advance notice to allow the manufacturer to reserve the appropriate facility.

Aerodynamic compliance will be determined by comparing the certification $C_dA$ bin with the bin determined from the SEA. Variability in the coastdown tests are addressed partially through the implementation of a bin structure, as opposed to using the test result directly. However, there may be tractors whose results are near the edge of a bin for which the SEA result could be in the neighboring less aerodynamic bin. To address this issue, the agencies are finalizing a confidence interval to apply to the top of the $C_dA$ bin, within which an SEA result would be considered to be in compliance. The basis for this confidence interval, $z$, is $a\sigma x+b$, where $\sigma x$ is the standard error of the SEA result, $a$ is a t-value, and $b$ is an offset to account for testing variability. Details of this approach and the SEA process for aerodynamic performance are discussed in RIA Chapter 3.2.2.2.2 and Section III.E(2)(a)(ix) of the Preamble.

The agencies determined that a value of 1.5 was appropriate for $a$. This critical t-value for a failure of 1.5 means that, from the precision error alone, the agencies must have a confidence level of 93 percent that

---

the test results is above the boundary of the bin declared for that tractor configuration. This comes from
the (one-tailed) probability of approximately 7 percent that a result falls in the tail of a normal distribution
for a t-value of 1.5.

In addition to the precision component, the agencies are allowing an offset, b, to be applied to account for
test-to-test variability. The variability of multiple tests of the same tractor was used to consider value
b. As mentioned earlier, Sleeper Cab 3 was tested on multiple days. Wind conditions varied between
each of these tests, causing different effective yaw angles. To compare the tests with each other, the
wind-averaged CdA values were used, after adjustment to 4.5° as described in RIA Chapter 3.2.1.1.3. For
a given alternate method used for the yaw adjustment, the wind-averaged CdA values varied by a range of
0.11 m².

The coastdown testing at NRC was used to investigate site-to-site variability to inform the b value. While
the agencies anticipate that the manufacturers would use the same test facilities that they used for their
reference tractor tests, they could choose a different site based on availability or other factors. The
coastdown analysis process the agencies are finalizing could not exactly be used on the NRC data because
wind conditions were not always favorable, and an unequal numbers of runs were conducted in each
direction. A matched pair analysis (instead of a low-pair mean) was used along with the alternate method
adjustments that were performed for the SwRI data in order to compare all results in the wind-averaged
drag domain. The wind-average CdA estimated using the NRC data differed by 0.15 m² from that using
the SwRI data.

As shown in Figure 3-9 of the RIA, the standard error of test decreases as the number of runs in a test
increases. At 24 runs, the standard error is on average, approximately 0.84 percent (not the +/- 5 percent
noted by the commenter). For a given distribution, increasing the number of runs to 100 would roughly
halve the standard error to 0.42 percent, as the standard error decreases with the square root of the number
of runs. With an a value of 1.5, the contribution to the confidence interval, z, of the precision error at the
Bin III/IV boundary of 5.6 m² is approximately 0.04 m².

Since the bin boundaries are expressed to one decimal place, the SEA provision also allows for rounding,
which provides an additional 0.049 m². Finally, the agencies selected a b value of 0.03 m². Combining
the selected a and b values, the estimated standard error after 100 tests, and the rounding margin; the
estimated confidence interval for a tractor at the Bin III/IV boundary is 0.12 m². This in the 0.11-0.15 m²
range estimated by the repeat tests done on Sleeper Cab 3 at SwRI and NRC and is around 30 percent of
the width of Bin IV. The agencies are finalizing a confidence interval of z=1.5*σ/√n+0.03, which would be
applied to the SEA result when determining compliance as per SEA test procedures in 40 CFR 1037.305.

The agencies have limited the types of aerodynamic methods that would be used for SEAs in the final
rule. 40 CFR 1037.305 states that EPA would require manufacturers to use the reference method
(coastdown) or the method used by the manufacturer for certification.

40 CFR 1037.150(s) states that EPA will conduct confirmatory testing of Falt-aero using a statistical
analysis consistent with the principles of SEA testing in 40 CFR 1037.305.

With respect to the proposed language in 40 CFR 1037.401 (in-use testing), we are adopting language that
is very similar to the proposal. CAA section 206 provides EPA with broad discretion to conduct in-use
testing. EPA notes that in-use aerodynamic testing would likely be limited to full-scale testing, such as
coastdown. We believe EMA’s comment are primarily related to recall determinations. In this context,
we note that EPA’s policy has been to generally use the specified test procedures (which would be
coastdown in this case) to evaluate compliance with the standards. To the extent EPA were to use other
test procedures, they would likely to be used evaluate compliance with requirements other than the GHG standards, such as the prohibition against defeat devices.

Consistent with EMA’s comment, EPA is adopting 40 CFR 1037.201(g) language that allows manufacturers to choose to deliver another vehicle or component that is identical in all material respects to the test vehicle or component, or a different vehicle or component that we determine can appropriately serve as an emission-data vehicle for the family.

**Coastdown Test Procedures**

The agencies, after further consultation with EMA, have made a number of changes to the coastdown test procedures for the final rule (see 40 CFR 1037.528).\(^{141}\) The items below summarize the responses to EMA’s comments.

- The agencies have taken into account that the coastdown testing is typically not conducted under zero wind (zero yaw) conditions in the final rule. The Phase 2 regulations in 40 CFR 1037.525 now use the CdA at the “effective yaw angle” of the coastdown testing instead of assuming zero yaw. This provides an “apples-to-apples” comparison.
- As noted in the comments, coastdown testing measures all of the losses associated with the vehicle, including aerodynamics, rolling resistance, and driveline losses. To isolate the aerodynamic CdA, it is important to remove the losses for the driveline and tire rolling resistance. For the final Phase 2 rules, the agencies are incorporating into the coastdown procedure a modified SAE J2452 test procedure that requires manufacturers to measure the speed dependence of the tire rolling resistance for each of the steer, drive, and trailer tire models used on the article undergoing a coastdown test. The agencies are also requiring that manufacturers measure the speed dependence of the spin losses of the model of the drive axle(s) used on the article undergoing a coastdown test.
- The agencies set the recommended wind constraints to \(\leq 6\) mph. The required constraints are as proposed with one additional constraint that the wind component parallel to the direction of travel must not exceed 6 mph.
- EPA adopted regulations that require yaw measurement (not just air speed) with a tolerance of +/- 0.5 degrees.
- EPA adopted regulations that require the location of the anemometers must be at least 1.5 meters above the trailer’s leading edge. EPA requires pairs of high-low testing for coastdown, but allows some flexibility in the order that the tests are run.
- The agencies have developed a process of identifying and removing coastdown test outliers for the determination of data acceptance. First, the CdA and yaw angle data can be plotted and then the median yaw angle of the data is determined. All results differing by more than 1° from the median are removed. Then the mean CdA value of the remaining data points is determined. CdA values that differ by more than two standard deviations from this mean CdA are removed. At least 24 data points are needed after removal of outliers for the results to be valid. Finally, the mean CdA and mean effective yaw angle are calculated from the remaining points. The Falt-aero is determined at the effective yaw angle of the coastdown test. These values are then used to adjust to reflect a 4.5 degree yaw angle result based on an alternate method yaw curve results.
- EPA adopted provisions in 40 CFR 1037.528 that require if the road grade is greater than 0.02% .

over the length of the test surface, you must determine elevation as a function of distance along the length of the test surface and incorporate this into the analysis. In addition, road grade may exceed 0.5% for limited portions of the test surface as long as it does not affect coastdown results, consistent with good engineering judgment.

- EPA adopted provisions in 40 CFR 1037.525 that require vehicle manufacturers to provide the C\text{dA} results for a minimum set of yaw angles from any alternative method for the reference vehicle.
- The agencies believe that it is necessary to specify a range for the trailer gap used in aerodynamic testing. It is well-accepted that gap influences the overall C\text{dA} value, with smaller gaps producing lower C\text{dA} values. The agencies will not allow a variation in test procedure to be used to artificially lower C\text{dA} values. 40 CFR 137.501 states that the king pin located with its center 36±0.5 inches from the front of the trailer and a minimized trailer gap (no greater than 45 inches). 40 CFR 1037.525 provides an allowance for a scenario where a tractor and trailer cannot be configured to meet the gap requirements. Manufacturers are to test with the trailer positioned as close as possible to the specified gap dimension and use good engineering judgment to correct the results to be equivalent to a test configuration meeting the specified gap dimension.

Changes to CFD Certification

The agencies are adopting provisions to align the speed at which CFD is conducted in Phase 2 (65 mph) with the average of the coastdown high speed range.

Aerodynamic Adjustment Factor

The agencies determined the Falt-aero values for all of the tractors tested using different aerodynamic methods for Phase 2 using the aerodynamic test procedures and data analysis finalized for Phase 2. As shown in further detail in RIA Chapter 3.2.1, the Falt-aero values ranged between 1.13 to 1.20 for multiple sleeper and day cab tractors tested with the same CFD software. Therefore, the agencies concluded that a single Falt-aero value is not sufficient for determining the correlation of test methods for all tractors. Furthermore, based on the comments and further refinement of our selective enforcement audit (SEA) provisions in the Phase 2 final rule, we are adopting provisions that require manufacturers to determine Falt-aero for a minimum of one day cab and one sleeper cab in MYs 2021, 2024, and 2027. While this significantly reduces the test burden from the levels proposed, it also only represents a minimum requirement.

Constant Speed Testing

The agencies are not finalizing constant speed as the reference aerodynamic method. The agencies investigated the use of constant speed testing as the reference method to achieve a wind-averaged C\text{dA} result, which would have eliminated the need to rely on alternate methods for yaw curves. We received comments from manufacturers that they did not have enough experience in constant speed testing and recommended that the agencies not use it as a reference method. Though the agencies believe that the potential for a wind-averaged C\text{dA} from constant-speed testing exists, we agree with the manufacturers’ potential concerns about developing a robust constant speed test procedure as a reference method in time for the final Phase 2 rule. However, a constant speed test procedure has been developed for use as an alternate method based on significant testing conducted by EPA (see RIA Chapter 3.2). The constant

---

142 See Section III.E.2.a.ix for details on the SEA requirements.
speed test procedures are described in 40 CFR 1037.534. Below is a summary of responses to EMA’s comments.

- The procedure requires wheel torque measurements on each of the drive wheels. If some drive wheels can be disabled and unpowered, then only the powered wheels may be instrumented.
- The procedure requires testing at 50 and 70 mph in both calm and windy conditions to obtain data over a wide range of yaw angles. Testing is conducted over a sequence of test segments at constant vehicle speed as follows:
  (i) 300±30 seconds in each direction at 10 mi/hr.
  (ii) 450±30 seconds in each direction at 70 mi/hr.
  (iii) 450±30 seconds in each direction at 50 mi/hr.
  (iv) 450±30 seconds in each direction at 70 mi/hr.
  (v) 450±30 seconds in each direction at 50 mi/hr.
  (vi) 300±30 seconds in each direction at 10 mi/hr.
- An onboard anemometer is required for testing. The air speed measurement correction is based off of the roadside/trackside weather station, similar to the coastdown procedure.
- Required preconditioning is similar to the coastdown procedure.
- Speed dependence of tire rolling resistance must be determined using the modified SAE J1269 test procedure at multiple speeds.
- Corrections for inertial forces were not included because tolerances limit the speed variation allowed during testing and because the vehicle is likely to both accelerate and decelerate during the ten-second periods, which can have offsetting effects over many data points.
- The wind conditions must be such that 80 percent of the values of yaw angle, \( \gamma_a \), from the 50 mi/hr and 70 mi/hr test segments are between 4° and 10° or between −4° and −10°.
- The agencies set the drive torque validation criteria as follows - All ten of the 1 second mean torque values used to calculate a corresponding 10 second mean torque value must be within ± 50 % of that 10-second mean torque value.
- The onboard anemometer measurements for air speed are corrected using onboard measurements and measured ambient conditions as described in 40 CFR 1037.528(f).
- The output of the procedure is an average \( C_{dA} \) value at ±4.5°.

4x2 Tractors

EPA adopted language in 40 CFR 1037.106 that allows manufacturers to optionally certify 4x2 tractors with heavy heavy-duty engines to the standards and useful life for Class 8 tractors, with no restriction on generating or using emission credits within the Class 8 averaging set.

Phase 1 Changes

Phase 1 Aerodynamics Equation: EPA proposed a different equation with a ratio of 0.8330 in 40 CFR 1037.525(d) for the case of full yaw sweep measurements to determine wind-averaged drag correction as an amendment to the Phase 1 program. Some commenters argued that this change would impact stringency of the Phase 1 standard, but we disagree because manufacturers are already subject to EPA compliance using both methods (full yaw sweep and ± 6 degree measurements), and this Phase 1 flexibility was not used in setting the level of the Phase 1 standards. Nevertheless, we are adopting the final rule without amending this part of the Phase 1 rules. Commenters persuasively indicated that any such amendment to the Phase 1 rules at this date could upset compliance plans predicated on the rules remaining un-amended. These expectations and reliance are legitimate, and the agencies accordingly are not amending this aspect of the Phase 1 rules. NHTSA Standards: NHTSA is finalizing its standards and method for calculating performance values for the Phase 1 and 2 programs with increased significant
digits as the only option for compliance. Retaining the previous method would result in ongoing differences in credit plans and balances, and continue the associated burden on manufacturers. Since manufacturers already have and will continue to develop compliance strategies for the EPA GHG program, the change will enable those strategies to also directly comply with the NHTSA fuel efficiency program, creating a more aligned National Program. Compliance with the EPA GHG program is unaffected by the change. EPA will modify the single interface used by manufacturers for certification to include increased significant digits for NHTSA’s values. The new interface will apply retroactively starting in 2013 MY and will require each manufacturer’s to recalculate their credit balances using the new approach.

In-Use and Chassis Dynamometer Testing

After consideration of the comments, the agencies are requiring tractor manufacturers to annually chassis test five production vehicles over the GEM cycles to verify that relative reductions simulated in GEM are being achieved in actual production. See 40 CFR 1037.665. We do not expect absolute correlation between GEM results and chassis testing. GEM makes many simplifying assumptions that do not compromise its usefulness for certification, but do cause it to produce emission rates different from what would be measured during a chassis dynamometer test. Given the limits of correlation possible between GEM and chassis testing, we would not expect such testing to accurately reflect whether a vehicle was compliant with the GEM standards. Therefore, we are not applying compliance liability to such testing. Rather, this testing will be for informational purposes only. However, we do expect there to be correlation in a relative sense. Vehicle to vehicle differences showing a 10 percent improvement in GEM based only on the technologies that can be simulated in the chassis dynamometer (aerodynamic loads, rolling resistance loads, axle efficiency, transmission type and efficiency, engine fuel maps, axle ratio, etc.) should show a similar percent improvement with chassis dynamometer testing. Nevertheless, manufacturers will not be subject to recall or other compliance actions if chassis testing did not agree with the GEM results on a relative basis. Rather, the agencies will continue to evaluate in-use compliance by verifying GEM inputs and testing in-use engines. Note that NTE standards for criteria pollutants may apply for some portion of the test cycles.

EPA believes this chassis test program is necessary because of our experience implementing regulations for heavy-duty engines. In the past, manufacturers have designed engines that have much lower emissions on the duty cycles than occur during actual use. By using this simple test program, we hope to be able to identify such issues earlier and to dissuade any attempts to design solely to the certification test. We also expect the results of this testing to help inform the need for any further changes to GEM.

As also noted in Section II. B. (1) of the Preamble, it can be expensive to build chassis test cells for certification. However, EPA has structured this pilot-scale program to minimize the costs. First, this chassis testing will not need to comply with the same requirements as will apply for official certification testing. This will allow testing to be performed in developmental test cells with simple portable analyzers. Second, since the program will require only five tests per year, manufacturers without their own chassis testing facility will be able to contract with a third party to perform the testing. Finally, 40 CFR 1037.665(c) states that we may approve a request to perform alternative testing that will provide equivalent or better information compared to the specified testing, therefore the agencies may consider testing such as suggested by the commenter. We may also direct the manufacturers to do less testing than we specify in this section.

EPA estimates that the cost to conduct chassis testing at a third party facility would be approximately $30,000 per tractor, for a total of $150,000 per year per manufacturer. RIA Chapter 7.2.1.2 includes the compliance costs of the program, including the increased level of reporting in the tractor program.
Perplexingly, EMA states (without further discussion) that “In addition, EPA lacks the legal authority to compel manufacturers to test in-use, non-new motor vehicles and engines.” Section 207 (b) (1) of the Act authorizes EPA establish “methods and procedures” if EPA determines that “there are available testing methods and procedures to ascertain whether, when in actual use throughout its warranty period … each vehicle … to which regulations under [section 202] apply comply with the emission standards of such regulations.” That is precisely what EPA has done here. Moreover, section 207 (b)(2) provides for substantial enforcement authority if EPA determines that vehicles are not meeting section 202 standards “when in actual use.” Under EMA’s apparent theory, that authority applies to a null set since any vehicle in actual use is by definition non-new.

In its comments, Volvo slightly expanded on EMA’s argument, stating that “we do not believe EPA has the authority to compel emissions testing of non-new vehicles simply for collecting information to compare to the regulatory approach.” But EPA seeks the information as an assurance that in-use performance is adequately evaluated through the certification process. So this information is directly related to assuring that in use performance is consistent with certification, and thus is directly related to compliance with the section 202 (a) standards. (EPA, must, of course, develop standards that apply in use, see section 202 (a), and therefore can require testing designed ultimately to assure that standards are met in use).

With respect to the certification of tractors, the agencies are not adopting chassis dynamometer testing to demonstrate compliance with the Phase 2 tractor CO\textsubscript{2} and fuel consumption standards. Instead, the agencies are adopting a compliance structure that includes component testing and GEM. Therefore, the audits would be based on the components, not on chassis testing.

**Organization:** Union of Concerned Scientist

**MODEL-YEAR ALIGNMENT**

Some concerns have been raised in public by vehicle manufacturers regarding the industry’s convention of introducing vehicles of a particular model year ahead of the calendar year. In particular, it has been cited that common practice for engines is to tie them to the calendar year, thus creating a potential misalignment between engine and vehicle model year. [EPA-HQ-OAR-2014-0827-1329-A2 p.13]

Currently, EPA and NHTSA allow significant latitude for vehicle manufacturers to determine for purposes of compliance their own model year of vehicles sold—a model year may begin as early as Jan 2 of the preceding year and can extend through December 31, effectively a two-year window. If a vehicle manufacturer is concerned that its ability to comply with a regulation is dependent on the availability of a particular engine aligned with the calendar year, there is already ample flexibility for a manufacturer under this definition. It does not seem sensible to allow a common industry practice to interfere with regulations, since no single manufacturer is bound by convention and, if the standards were weakened in response, may choose to align the model years anyway. We appeal to the agencies not to adjust the stringency or timing of tractor vehicle regulations in response to these concerns, as it could lead to the unnecessary postponement of environmental benefits. [EPA-HQ-OAR-2014-0827-1329-A2 p.13]

**CALCULATION OF WIND-AVERAGED DRAG**

In the Phase 2 regulations, the agencies recognized that it is important for manufacturers to consider yaw angle when designing a vehicle, as wind can have significant effect on fuel energy lost to aerodynamics—as such, they are now requiring that wind-averaged drag be input into GEM. In Phase 1, however, the manufacturers had the flexibility to adjust the zero-yaw aerodynamic drag coefficient by a correction
factor to reflect this design characteristic (40 CFR 1037.521(f)). The agencies are now proposing an adjustment to this factor based on additional data (Draft RIA Table 3-7). [EPA-HQ-OAR-2014-0827-1329-A2 p.14]

The Phase 1 stringency did not include the use of the correction factor, which we now know based on additional data was much too low, thus giving manufacturers more credit than is appropriate for the fuel and emissions savings attained. The new data clearly show that the flexibility of being able to use the correction factor results in a 3.3 percent lower value than is appropriate. We strongly support adjusting this factor to accurately reflect real world reductions in fuel consumption and global warming emissions. [EPA-HQ-OAR-2014-0827-1329-A2 p.14]

Aerodynamic inputs into GEM are determined by which bin the manufacturers’ CdA value corresponds to. A CdA reduction of 3.3 percent corresponds to an average of 30 percent of an aerodynamic bin—on average, this could mean that about 30 percent of vehicles are being run in GEM with a higher aerodynamic bin than is justifiable. Given the effect of aerodynamic bin on the GEM model, this could mean a credit of about 4 g CO2/ton-mile per affected high-roof sleeper—that is approximately 5.5 percent of the average value that these vehicles are supposed to achieve over the Phase 1 rule. The agencies estimated that about 80 percent of all sleeper cabs are high-roof, which roughly means that these vehicles are responsible for about one-third of all HDV emissions (Phase 1 RIA, Figure 1-5). If 30 percent of those vehicles are getting an artificially inflated credit of 5.5 percent, this would mean an erosion of benefits of approximately 0.5 percent of the entire Phase 1 rule. That is the equivalent of over 100 million gallons of oil and 1 million metric tons of greenhouse gas emissions just for the model years in question. It is critical therefore that this be remedied. [EPA-HQ-OAR-2014-0827-1329-A2 p.14]

If for some reason the agencies are unable to correct this factor through a technical amendment, the stringency of the Phase 2 rule should reflect the undue credits that manufacturers would be banking entering the 2021 model year, in order to ensure that the regulations be set based on real world performance and result in the appropriate real world fuel consumption and emissions reductions. [EPA-HQ-OAR-2014-0827-1329-A2 p.14]

COMPLIANCE MARGIN FOR AERODYNAMIC TESTING

The agencies are eliminating the ability for manufacturers to “pass” a real-world compliance audit of aerodynamics as long as the confirmatory test results in measurement within the bin greater than certified (example, Bin II if certified as Bin III; see 40 CFR 1037.150(k)). This was a significant margin of error for manufacturers that could have encouraged gaming, and we agree with the agencies that this was unjustified based on the reproducibility of coastdown testing—as Table 3-8 in the Draft RIA illustrates, the typical reproducibility for coastdown testing is around 2 percent, much less than the 15- to 25-percent error for which the real world audit allowed. With the agencies’ additional changes to the testing procedure to account for environmental conditions, this is a much-needed adjustment that will make the program stronger and hold manufacturers more accountable for real world reductions in fuel use and emissions due to improvements in tractor aerodynamics. Constant speed testing, which the agencies are also considering, appears to offer an even narrower band of reproducibility (Draft RIA Table 3-9), providing further argument against a large “compliance margin.” [EPA-HQ-OAR-2014-0827-1329-A2 p.14]

THE STANDARD TRAILER AND INCENTIVIZING TRACTOR-TRAILER INTEGRATION

Tractor aerodynamics are measured while pulling a standard trailer. In Phase 1, this trailer contained no aerodynamic devices; however, the uptake of aerodynamic devices on trailers has led to the agencies
determination that tractors should be measured against a trailer with an aerodynamic skirt in Phase 2. [EPA-HQ-OAR-2014-0827-1329-A2 p.14]

Because tractors and trailers are completely interchangeable, there is no guarantee that a new tractor will be pulling the newest trailer. Therefore, we do not recommend further revising the standard trailer over the course of the rule to reflect improvements to new trailers, which some parties have called for, since tractors will generally be on-call to haul a variety of different trailers. However, we do believe it is important to recognize opportunity for innovation in cases where tractors and trailers may be more closely coupled because it can lead to significant fuel consumption reductions. [EPA-HQ-OAR-2014-0827-1329-A2 p.15]

Results of the SuperTruck program and countless aerodynamic designers over the years have shown that designing the tractor-trailer system together as an integrated system would lead to significantly more aerodynamic vehicles. While we do not anticipate the ability for this type of integration to become mainstream in the timeframe of this rule, we recommend that the agencies develop a procedure to incentivize tractor manufacturers to work with trailer manufacturers to develop vehicle systems that better optimize the aerodynamics of the tractor-trailer in order to spur the market in this direction. [EPA-HQ-OAR-2014-0827-1329-A2 p.15]

One possible way to do this is through A-to-B testing. Tractor manufacturers and trailer manufacturers already must obtain aerodynamic information relative to a standard tractor and trailer. If the system is truly integrated, there will be further reductions in CdA that are not captured when attached to a standard tractor or trailer. Consider two tractors, TRAC0 (baseline) and TRAC1 (advanced), and two trailers, TRLR0 (baseline) and TRLR1 (advanced). The manufacturer of TRAC1 already must complete a test of TRAC1 and TRLR0 ([CdA]10). Likewise, the trailer manufacturer must already prove the effectiveness of its trailer with an A-to-B comparison using a Bin III tractor or better (therefore, TRAC0 or TRAC1)—this could be measured as [CdA]x0-[CdA]x1. Finally, [CdA]00 is simply a baseline configuration that could be used repeatedly by the two manufacturers. This leaves just a single test unaccounted for in estimating the additional efficacy of the integrated tractor-trailer system. If the tractor and trailer are truly integrated, then the difference in aerodynamic drag between the baseline tractor pulling a baseline trailer and the advanced, integrated tractor trailer would be greater than the sum of the differences between the baseline and advanced tractor and baseline and advanced trailer ([CdA]00-[CdA]11 ~ ([CdA]00-[CdA]10)+([CdA]x0-[CdA]x1)). The difference between the two sides could be considered as a credit to the tractor manufacturer, applicable to the certified CdA for TRAC1. [EPA-HQ-OAR-2014-0827-1329-A2 p.15]

There are two additional considerations to address here. The first is that under the trailer regulation, trailer manufacturers can choose the tractor pulling the trailer, as long as it is Bin III or better—this means that credit for tractor-trailer integration is currently evaluated under the trailer regulation. A credit on the tractor side could therefore be seen as double-counting. However, given the relative research budgets and in light of the SuperTruck program itself, it seems much more likely that any additional investment in this opportunity would be made by tractor manufacturers, so therefore this does not provide sufficient incentive. [EPA-HQ-OAR-2014-0827-1329-A2 p.15]

The second consideration is that there is no guarantee that the tractor and trailer would always be used as an integrated system. It seems likely that the purchaser would be incentivized to use the two together due to the increased upfront investment, but that can’t be validated. [EPA-HQ-OAR-2014-0827-1329-A2 p.15]
To address both of these concerns, we recommend that the credit only be given to the tractor manufacturer upon submitted data on how these vehicles are being operated together over the lifetime of the tractor. While it is likely that fleet operators purchasing these tractors would purchase an appropriate number of integrable trailers, we believe that the burden of proof should be on the manufacturer to prove the use of these vehicles in order to avoid undercutting the environmental benefits of the regulation. This arrangement could avoid the most significant negative environmental impacts of over crediting while promoting advanced aerodynamic design. Given the impact that aerodynamics can have on the overall efficacy of the rule (see section above on the Calculation of Wind-Averaged Drag), it is important that the incentive be balanced against real world performance. [EPA-HQ-OAR-2014-0827-1329-A2 p.15]

**SUPPLEMENTAL DYNAMOMETER AND OVER-THE-ROAD TESTING**

The agencies have proposed a chassis dynamometer testing program designed to complement full vehicle standards. Due to the agencies’ reliance on GEM modeling for certification, we find this proposal entirely necessary and consistent with the goal of producing real-world benefits. Not only should this program be required of manufacturers, but the results of these tests should be shared publicly as part of an annual compliance report. It is in the public interest to ensure that any regulation is yielding the anticipated reductions in harmful emissions—therefore, it is a necessary component of that program that the public be made aware of the actual emissions of these vehicles. In order to maintain the greatest usefulness to the public, the agencies should give additional guidance to the OEMs on vehicles to select for production testing, prioritizing the testing of high-volume vehicles to inform the assessment of clear industry trends. [EPA-HQ-OAR-2014-0827-1329-A2 p.15-16]

In addition to the proposed tractor dynamometer testing, the agencies should implement a program to perform over-the-road testing of select vehicles to monitor the advancement of emissions reductions and fuel economy under real world conditions. This data could further inform any updates to dynamometer or GEM test cycles in the future along with future rulemakings on fuel economy, greenhouse gas emissions, and criteria pollution. The recent admittance by Volkswagen to circumventing laboratory testing with defeat devices harkens back to activities in the nineties by the heavy-duty truck industry and again highlighted the critical importance of not only ensuring test cycles and dynamometer testing accurately reflects real world driving as closely as possible but also the necessity of actually performing on-road testing of vehicles. [EPA-HQ-OAR-2014-0827-1329-A2 p.16]

**Response:**

*Model Year Alignment*

Phase 2 is requiring a significant number of changes that apply to both the engine and the vehicle so it is necessary for alignment of model years between the two categories. The final Phase 2 rule includes a greater impact of engine technologies than were considered in the NPRM to determine the tractor standards. By aligning the model years of the tractors with the engines, this essentially provides some additional lead time for the tractor manufacturers. This additional lead time was considered by the agencies in setting the tractor stringency levels. For example, the technology package developed by the agencies for setting the 2027 MY tractor standards included both a high adoption rate of waste heat recovery and new engine platforms that will require some modifications to the vehicle, therefore, the vehicle standard cannot take effect before the engine standards.

*Phase 1 Wind Averaged Drag Equation*
EPA proposed a different equation with a ratio of 0.8330 in 40 CFR 1037.525(d) for the case of full yaw sweep measurements to determine wind-averaged drag correction as an amendment to the Phase 1 program. Some commenters argued that this change would impact stringency of the Phase 1 standard, but we disagree because manufacturers are already subject to EPA compliance using both methods (full yaw sweep and ± 6 degree measurements), and this Phase 1 flexibility was not used in setting the level of the Phase 1 standards. Nevertheless, we are adopting the final rule without amending this part of the Phase 1 rules. Commenters persuasively indicated that any such amendment to the Phase 1 rules at this date could upset compliance plans predicated on the rules remaining un-amended. These expectations and reliance are legitimate, and the agencies accordingly are not amending this aspect of the Phase 1 rules. However, the agencies evaluated the status of Phase 1 credit balances in 2015 by sector. For tractors, we found that manufacturers are generating significant credits, and that it appears that many of the credits result from their use of an optional provision for calculating aerodynamic drag. However, we also believe that manufacturers will generate fewer credits in MY 2017 and later when the final Phase 1 standards begin. Still, the agencies believe that manufacturers will have significant credits balances available to them for MYs 2021-2023, and that much of these balances would be the result of the test procedure provisions rather than pull ahead of any technology. Therefore, we are increasing the stringency of the CO$_2$ and fuel consumption tractor standards for MYs 2021-2023 by 1 percent to reflect these credits (see Preamble Section III.D.1b.xiii).

**Aerodynamic Compliance Margin**

Although EPA sometimes provides interim compliance margins to facilitate the initial implementation of new programs, we generally do not consider such an approach to be an appropriate long-term policy. Consistent with the commenter’s suggestion, we are not adopting a fixed compliance margin for Phase 2. Nevertheless, EPA recognizes that compliance testing relying on coastdowns to evaluate aerodynamic parameters differs fundamentally from traditional compliance testing, in which test-to-test variability is normally expected to be small relative to production variability. With coastdown testing, however, test-to-test variability is expected to be larger relative to production variability. In response to comments addressing this difference, EPA developed a different structure for conducting SEAs to evaluate tractor C$_d$A$_s$ and solicited supplemental comments on it. We believe the structure being finalized appropriately balances EPA’s need to provide strong incentives for manufacturers to act in good faith with manufacturers’ need to avoid compliance actions based on inaccurate testing. Our current assessment is that, where a manufacturer acts in good faith when certifying and uses good engineering judgment throughout the process, false failures for individual vehicles would be rare and false failures for a family would not occur. As shown in Figure 3-9 of the RIA, the standard error of test decreases as the number of runs in a test increases. At 24 runs, the standard error is on average, approximately 0.84 percent (not the +/- 5 percent noted by the commenter). For a given distribution, increasing the number of runs to 100 would roughly halve the standard error to 0.42 percent, as the standard error decreases with the square root of the number of runs. Additional discussion is included in Section III.E.2.a of the Preamble to the final rule.

**Standard Trailer**

The agencies re-evaluated the proposal to include trailer skirts on the Phase 2 reference trailer with consideration of the comments. We still project that the bulk of trailers that will be in operation during the life of tractors produced early in Phase 2 will be represented by the aerodynamic performance of a trailer with skirts. Therefore, we are adopting the reference trailer as proposed. However, we also want

---

to recognize that the trailer fleet will continue to evolve over the lifetime of tractors built and certified to Phase 2, especially from MY 2027 and later. Based on testing conducted to support the trailer portion of Phase 2, we found that on average a boat tail added to a dry van trailer with skirts reduces wind averaged $C_dA$ by 0.6 $m^2$. We recognize that if we do not account for reduced aerodynamic loads in the real world, then we may not be appropriately evaluating the tractor powertrain. We considered changing the standard trailer in MY 2027; however, this would lead to significant testing burden for the manufacturers because they would have to determine new $C_dA$ values for their entire fleet of tractors. Instead, we are adopting Phase 2 GEM that beginning in MY 2027 will take the $C_dA$ input for each vehicle and reduce it by 0.3 $m^2$ to reflect the lower aerodynamic loads that are a mix of trailers with skirts and trailers with skirts and boat tails. This change has been accounted for in both the baseline and standard setting of the CO$_2$ emissions and fuel consumption values.

With respect to UCS’s recommendation for the agencies to facilitate the transition to more integrated tractor-trailers, such as those demonstrated with SuperTruck, the agencies believe this would require a significant change in tractor-trailer logistics to encourage more matching of specific tractors to specific trailers in operation. We believe that this would be most appropriately handled through the Off-Cycle Credit program.

**In-Use Chassis Testing**

The agencies are finalizing the tractor chassis test requirement largely as proposed. Past experience has shown us that including a broad range of testing discourages manufacturers from focusing their development efforts on a single narrow test procedure. Even though there will be no direct compliance liability for the GHG testing, the agencies would still be able to identify differences in performance that resulted (on purpose or inadvertently) from how the powertrain is installed in the chassis.

EPA agrees that in-use (or over-the-road) testing of engines provides a number of benefits for ensuring useful life compliance. The heavy-duty on-highway engine manufacturers are already required to conduct in-use testing under the criteria pollutant regulations. In addition, the GHG Reporting Rule required manufacturers to submit CO$_2$ data from all engine testing beginning in the 2011 MY, which we believe is equally applicable to in-use measurements. Furthermore, EPA conducts periodic in-use testing of heavy-duty engines.

**Organization:** United Parcel Service (UPS)

**Drive Cycle Weightings Need to be Re-evaluated**

UPS notes that our class 8 tractor and trailers average 54 miles per hour in part because we also deploy speed governors on all our heavy trucks. This disparity between our actual average speed and what is assumed in the proposed rule will significantly reduce the fuel efficiency potential of speed-dependent technologies such as aerodynamic devices and low rolling resistance tires. We agree in principle with the following ATA comments on this point. [EPA-HQ-OAR-2014-0827-1262-A1 p.11]

The proposed rule indicates drive cycle weightings of 5% of the transient cycle, 9% of the constant speed 55 mph cycle, and 86% of the constant speed 65 mph cycle for sleeper cabs. For day cabs, the weightings are 19% of the transient cycle, 17% of the constant speed 55 mph cycle, and 64% of the constant speed 65 mph cycle. ATA believes these weightings are not reflective of real world operations and tend to overestimate the benefits of certain technologies, such as aerodynamics and rolling resistance, and potentially discount others. [EPA-HQ-OAR-2014-0827-1262-A1 p.11]
‘As discussed in Appendix 2, using 3.6 million spot speed records collected from throughout the U. S. during the month of May 2015, trucks operated at speeds of 55 mph or greater 57% of the time. This is significantly lower that the weightings being used by EPA (95% of the time for sleeper cabs and 81% of the time for day cabs).’ [EPA-HQ-OAR-2014-0827-1262-A1 p.11]

Limited Flexibility Must be Built In to the Use of Speed Limiters

UPS deploys speed limiters on all its class 8 trucks, and we support ATA’s efforts to advocate for lower average speed of all vehicles, including the mandatory, electronic speed governing of large trucks. Such changes would yield substantial benefits in fuel efficiency, as well as in safety. We think that greater flexibility is needed in how speed limits are set in these devices and that this is easily achieved given today's ECMs. The concept of 'tamper-proof' devices is unnecessary and incompatible with modern trucks because any changes, and in fact the mere entry into the ECM software settings is trackable by authorities. Instead of ‘tamperproof devices,’ UPS would support a regulatory approach in which the fleet owner can adjust speed settings, but only if certified personnel make these changes and their activities within the ECIVIs are trackable and fully accountable to proper authorities. [EPA-HQ-OAR-2014-0827-1262-A1 p.12]

UPS notes that the proposed rule does not provide any incentive for speed limiters because, as we understand it, the test cycles are conducted at legal speed limits and therefore unless EPA and NHTSA provide some specific credit to the speed limiter, it gains nothing for the OEM. And the fleet owner gains nothing via this in the eventual rule. Traffic of course does not always honor the posted speed limit. As vehicle air drag increases as the square of velocity, the potential fuel savings with speed limiters are substantial. UPS urges EPA/NI-ITSA to consider providing some credit for inclusion of speed limiters. [EPA-HQ-OAR-2014-0827-1262-A1 p.12]

Response:

Drive Cycle Weightings

The agencies considered these comments along with the information that was used to derive the drive cycle weightings in Phase 1. The agencies believe that the study cited by ATA includes weightings of speed records, which represent the fraction of time spent at a given speed. However, our drive cycle weightings represent the fraction of vehicle miles traveled (VMT). The agencies used the vehicle speed information provided in the ATA comments and translated the weightings to VMT. Based on our assessment, their findings produce weightings that are approximately 74 percent of the vehicle miles traveled are at speeds greater than 55 mph and 26 percent less than 55 mph. In addition, the study cited by ATA represents “Class 8 trucks” which would include day cab tractors, sleeper cab tractors, and heavy heavy-duty vocational trucks. Based on this assessment, the agencies do not believe this new information is significantly different than the drive cycle weightings that were proposed. Therefore, we are adopting the drive cycle weightings for tractors that we adopted for Phase 1 and proposed for Phase 2.

Vehicle Speed Limiters

The commenter is mistaken in their assessment that the rule does not provide any incentive for speed limiters. Phase 1 and Phase 2 provide CO₂ emissions and fuel consumption reductions in GEM for vehicles with tamper-proof vehicle speed limiters (VSL) set below 65 mph. The existing Phase 1 VSL flexibilities provide opportunities for manufacturers to receive credit for VSL while still allowing the settings to change after an “expiration” time determined by the manufacturer and the agencies adopted provisions to allow for VSLs with “soft top” speeds. At this time, we believe that the Phase 1 flexibilities
sufficiently balance the desire to encourage technologies that reduce GHG emissions and fuel consumption while minimizing the compliance burden of trying to accommodate changes throughout the useful life of the vehicle. Therefore, the agencies are not adopting any new VSL provisions for Phase 2.

**Organization:** Volvo Group

**Aerodynamic Drag Determination**

While we are open to continued evaluation of alternative aerodynamic test methods, Volvo Group opposes the agencies’ proposal to shift the primary test method from coast-down to constant speed at this time, simply because there is inadequate time to fully evaluate any new test method prior to promulgation of the final rule. The agencies should not mandate Constant Speed Aerodynamic testing as the default method for CdA determination in the final rule. [EPA-HQ-OAR-2014-0827-1290-A1 p.38]

Volvo Group supports all comments from EMA on necessary changes to the processes for coast-down measurements and alternative aero certification. This issue has been extensively discussed with the agencies and the major heavy-duty tractor manufacturers have agreed on the proposal. Measurement of tractor-trailer aerodynamic drag is extremely complex and subject to many variables. Even if there are advantages to constant speed testing, there is inadequate time to evaluate and resolve the many critical details needed to ensure accurate results, maintain a level playing field, and to establish new aero bins and targets based on test results. We also believe that the expected advantages from constant speed testing could be largely gained through further refinement of the coast-down procedure. We are open to continued evaluation of constant speed testing that could be introduced as a technical amendment or in a subsequent rulemaking when and if it is found to be an improvement over coast-down and all issues are resolved. [EPA-HQ-OAR-2014-0827-1290-A1 p.38]

**EPA coast down test data**

The EPA plans to use coast down test data from a handful of tractors to set the standards for Phase II. These “standard-setting” tractors were tested under varying wind conditions, from yaw angles below 2° for some to ∼4° for others. Since Phase I procedure assumes coast down to represent 0° condition, the associated errors were larger on the trucks tested under higher crosswind condition. EPA needs to account for this in establishing the baseline. [EPA-HQ-OAR-2014-0827-1928-A1 p.16]

Although the Phase II procedure accounts for wind condition, the analysis procedure leads to a somewhat flatter yaw curve than expected (or obtained from alternate aero methods). The same truck tested under higher crosswind (yaw>2°) may produce a lower certification CdA (@4.5°) than when tested under calmer conditions. Ironically, this is the exact opposite of the problem encountered in Phase I. [EPA-HQ-OAR-2014-0827-1928-A1 p.16]

The EMA (industry consensus) proposal requested the EPA to limit crosswind during coast down tests to <2mph, which was not accepted by the compliance division. This constraint had been proposed initially to address the artificial asymmetry in the CdA vs. yaw curve, but this needs to be re-visited in the context of the flatter yaw curve generated by the Phase II coast down procedure. [EPA-HQ-OAR-2014-0827-1928-A1 p.16]

Since the initial proposal of the Phase 1 rule, the industry has been working with coastdown to understand the issues and to improve measurement and analysis methods. In Phase 1 comments, Volvo Group and the rest of the industry noted shortcomings in the coastdown procedure and provided the agencies with many suggestions on sources of errors and variability and how to correct or account for them. Few of the comments were implemented in Phase 1. Since that time the industry has gained significantly more
experience in coastdown testing and provided feedback and a full proposal to the agencies on limiting variability and improving accuracy in the Coastdown process. [EPA-HQ-OAR-2014-0827-1290-A1 p.38]

Based on the industry’s gained knowledge of the Coastdown procedure, our comments and our inputs already provided to the agencies, as well as industry's complete lack of experience with Constant Speed testing, Volvo Group requests that the agencies incorporate the industry recommendations and maintain coastdown in the Phase 2 final rule as the default procedure. We support a longer term process to continue to improve the aerodynamic procedures, which may at some point incorporate constant speed testing via subsequent rulemaking or via technical amendments to the final rule. [EPA-HQ-OAR-2014-0827-1290-A1 p.39]

**EPA constant speed test data**

At this time Volvo does not have sufficient information or experience with constant speed testing to comment on the test data collected by the EPA. Based on our experiences to date with the proposed coast down testing and analysis procedure, we should expect to unearth several issues as we look into constant speed testing in earnest. [EPA-HQ-OAR-2014-0827-1928-A1 p.16]

**Multiple Aerodynamic Adjustment Factors**

The aerodynamic adjustment factor (\(F_{\text{alt-aero}}\)) is a ratio between the test result of the full vehicle coastdown test and the alternative method (computational fluid dynamics or reduced scale model wind tunnel testing) used by a manufacturer to evaluate the multitude of truck models and aero options. The proposed rule section 1037.525(b) (3) would require determining separate adjustment factors for “a high-roof day cab and a high-roof sleeper cab corresponding to each major tractor model.” The agencies came to the conclusion that this would be required based on limited and faulty test data using the test procedure with all the flaws we have reported to the agencies and reviewed in the EMA comments. In fact, the whole aerodynamic adjustment factor concept is based on the premise that \(F_{\text{alt-aero}}\) is not vehicle dependent but only method dependent. We have shared data with EPA showing that, when the testing is done under the conditions and methods industry has recommended, \(F_{\text{alt-aero}}\) is highly consistent for widely varying truck models. As such, there is no need to repeat the full vehicle aerodynamic testing for many different vehicles as proposed. This testing is extremely time-consuming and expensive and must not be expanded without adequate quantifiable benefit. [EPA-HQ-OAR-2014-0827-1290-A1 p.39]

**EPA wind tunnel test data**

Volvo does not intend to use reduced scale wind tunnel (RSWT) as an alternate aero method for Phase II certification since it is cost prohibitive, given the diversity and complexity of its highway tractor portfolio. Nevertheless, EPA has raised concerns about variability between alternate methods (different CFD tools, various wind tunnels, etc.) especially regarding potential facility dependence of yaw curves. EPA’s own data shows a variation of ~2% (1.078 to 1.101) in terms of \(\text{CdA}(4.5°)/\text{CdA}(0°)\) comparing constant speed, two different CFD methods and one RSWT facility. EPA considers this level of variability acceptable, while Volvo does not. [EPA-HQ-OAR-2014-0827-1928-A1 p.16]

**EPA CFD simulation data**

The CFD data from two different sources (vendors) show significant discrepancy on the order of 10-15%. While this may be alarming, it is within the expected level of variation between RANS-based steady-state calculations and Lattice-Boltzmann method based transient simulations. Although such discrepancies are supposed to be absorbed into \(F_{\text{alt-aero}}\), differences in the two yaw curves could affect the certification \(\text{CdA}\). EPA’s data shows this difference to be ~0.5% on the particular truck in the NoDA. [EPA-HQ-OAR-2014-0827-1928-A1 p.16]
Aerodynamic Audits

Volvo Group fully supports EMA’s comments on reducing audit measurement variability by auditing for conformance or selective enforcement by using only the same vehicles (tractor and trailer), test facilities, and methods used by manufacturers to certify vehicle aerodynamics. In addition, we support the need to add audit margins that consider all the variables inherent in these measurements. [EPA-HQ-OAR-2014-0827-1290-A1 p.39]

Chassis Dyno Testing

Volvo Group does not support the requirement to annually test five tractors on a chassis dynamometer as proposed in NPRM section 1037.665. Chassis dyno testing requires simulated or separately measured inputs to determine road loads associated with aero drag, rolling resistance, climbing grades, and acceleration; loads that comprise around 90% of the vehicle load in the tractor cycles. Rolling resistance of the drive tires on the dynamometer rollers does not duplicate on-road rolling resistance, so applied dynamometer loading must be corrected for this as well as for dynamometer inertia. Accessory loads will not duplicate on-road utilization unless the use of power steering, compressed air, vehicle cooling, ram air, air conditioning, and electrical systems are all precisely managed. Differences in driver shifting, throttle control, and braking have large impacts. In addition, there are many other variables in the test set up and measurements. In short, chassis dyno testing introduces errors that are much worse than simply simulating vehicle efficiency. The only system actually tested in a chassis dyno test is the powertrain, which is tested much more precisely in a powertrain test. [EPA-HQ-OAR-2014-0827-1290-A1 p.41]

There are few facilities capable of running a Class 8 chassis dyno test, particularly when adding the proposed requirement to include emissions of NOX, PM, CO, NMHC, CO2, CH4, and N2O. Building such a facility is estimated to cost as much as $2M. Manufacturers could end up competing to contract testing to the few capable test sites, driving up costs. In addition, the cost to pull a vehicle out of service and provide a substitute vehicle, or to build and run-in a new vehicle add enormous cost, especially when the resulting data has little value. [EPA-HQ-OAR-2014-0827-1290-A1 p.42]

Furthermore, we do not believe EPA has the authority to compel emissions testing of non-new vehicles simply for collecting information to compare to the regulatory approach. The proposed testing has no bearing on vehicle or engine certification and is an unnecessary burden without justification. EMA has proposed alternative methods to collect data to help the agencies refine the simulation and certification protocol. We support this effort but cannot support the current NPRM proposal. [EPA-HQ-OAR-2014-0827-1290-A1 p.42]

4x2 Tractors with Class 8 Powertrains

Under the Phase 1 rule, the agencies allowed OEMs to certify vehicles into a higher service class and they propose to continue this with the Phase 2 rulemaking. No credits can be generated from vehicles certified to the higher service class, but any deficit produced must be offset by credits generated from other vehicles within the higher service class. Volvo used this flexibility to accommodate very limited volumes of Class 7 4x2 Tractors. These tractors are HHD models that only differ in axle configurations and gross vehicle weight ratings (GVWR) from other vehicles of the same model and still utilize the same HHD engines and drivelines as the Class 8 versions of the same model (>10L). [EPA-HQ-OAR-2014-0827-1290-A1 p.48]

In Volvo’s case, the Class 7 tractors have GVWRs of no less than 32,000 lbs. by utilizing a 12,000 lb. front gross axle weight rating (GAWR) with a 20,000 lbs. rear. At times the rear GAWR is 21,000 lbs.,
but this still results in a Class 7 vehicle with a GVWR of 33,000 lbs. (just 1 lb. short of being a Class 8 vehicle). Even though these 4x2 tractors have a GVWR from 32,000-33,000 lbs, and are considered by definition to be class 7, they are rated to 80,000 lbs. gross combination weight rating (GCWR) and are routinely employed to pull double trailers with the added benefit of maneuverability and improved efficiency from eliminating one axle. [EPA-HQ-OAR-2014-0827-1290-A1 p.48]

Since these Class 7 4x2 tractors are in the same (or even heavier) duty cycles as their Class 8 counterparts, are rated to 80,000 lbs. GCWR, and utilize a HHD powertrain, Volvo proposes that the agencies allow these vehicles to be certified as Class 8 with any generated credits banked in the HHD service class. [EPA-HQ-OAR-2014-0827-1290-A1 p.48-49]

Response:

Constant Speed Testing

The agencies investigated the use of constant speed testing as the reference method to achieve a wind-averaged C_dA result, which would have eliminated the need to rely on alternate methods for yaw curves. We received comments from manufacturers, including Volvo, that they did not have enough experience in constant speed testing and recommended that the agencies not use it as a reference method. Though the agencies believe that the potential for a wind-averaged C_dA from constant-speed testing exists, we did not pursue this as the reference method based on these comments. Similarly, we do not expect manufacturers to use constant speed testing as an alternate method (even though it is an option) because it requires full-scale on-road tests for all certification configurations, which is extremely burdensome and the entire reason for not requiring coastdown tests for certification of all tractor configurations in the first place.

Coastdown Testing

Please see the agencies’ response to EMA’s comments regarding aerodynamic test procedures, located in this section of the RTC.

The agencies are requiring calculation of a mean yaw angle to characterize a coastdown result in Phase 2. Thus, there will no longer be an assumption of zero yaw for a coastdown result. At least 24 runs within a certain ±1° yaw angle range and statistical criteria, as determined by the test conditions, are required to determine a mean C_dA and yaw angle. This helps to reduce the precision error from the proposed coastdown procedure. The coastdown CdA and yaw angle must then be used in conjunction with data from an alternate aerodynamic method to produce a wind-averaged drag result, using surrogate angles of ±4.5°.

The agencies coasted down the Phase 1 tractor configurations using the Phase 1 test procedures. Any data that exceeded the Phase 1 maximum, average, or cross-wind limits were considered invalid and not included in the analysis shown in RIA Chapter 3.2.1.1.1. The remaining valid data is appropriate for use to determine the Phase 1 bins.

The agencies adopted a lower low speed range (20 to 10 mph instead of 25 to 15 mph proposed) to address the issue raised by the commenter related to the fact that coastdown testing using the proposed approach produced a flatter yaw curve. Additional detail and analysis is included in RIA Chapter 3.2.1.1.2.6.

Aerodynamic Adjustment Factors
The agencies determined the Falt-aero values for all of the tractors tested using different aerodynamic methods for Phase 2 using the aerodynamic test procedures and data analysis finalized for Phase 2. As shown in further detail in RIA Chapter 3.2.1, the Falt-aero values ranged between 1.13 to 1.20 for multiple sleeper and day cab tractors tested with the same CFD software. Therefore, the agencies concluded that a single Falt-aero value is not sufficient for determining the correlation of test methods for all tractors. Furthermore, based on the comments and further refinement of our selective enforcement audit (SEA) provisions in the Phase 2 final rule, we are adopting provisions that require manufacturers to determine Falt-aero for a minimum of one day cab and one sleeper cab in MYs 2021, 2024, and 2027.\footnote{See Section III.E.2.a.ix for details on the SEA requirements.} While this significantly reduces the test burden from the levels proposed, it also only represents a minimum requirement.

**Wind Tunnel and CFD**

The agencies expect some differences between CFD simulations of the same vehicle between multiple acceptable CFD software, which is why the $F_{alt-aero}$ calculation is required.

To account for differences between yaw curves, a multiplicative, not additive, approach was finalized to adjust between the effective yaw angle and the surrogate yaw angle.

RIA Chapter 3.2.1 shows that the two CFD software in the EPA dataset in conjunction with the tractor’s coastdown result produce good agreement in the final surrogate-angle $C_dA$ values for Sleeper Cab 1 (5.96 and 5.98 m$^2$).

A spread of 2\% in the yaw increase between alternate methods is not a large amount given that $C_dA$ bin widths are set around 8\%. Not including constant speed results in the alternate method evaluation further reduces the spread of the results from Sleeper Cab 1 down to about 1\%. We should note that the agencies incorporated the use of alternate aerodynamic methods into the test procedures mainly to allow manufacturers to use tools they were already using in product development for GHG certification. Because of variability in these tools, precision error of coastdown testing, and the large number of configurations to certify, the agencies set up a bin structure for certifying aerodynamic performance instead of requiring precise test results as input into GEM.

Please see the agencies’ response to EMA’s comments regarding aerodynamic audit procedures, located in this section of the RTC.

**In-Use and Chassis Dynamometer Testing**

After consideration of the comments, the agencies are requiring tractor manufacturers to annually chassis test five production vehicles over the GEM cycles to verify that relative reductions simulated in GEM are being achieved in actual production. See 40 CFR 1037.665. We have revised 40 CFR 137.665 for the final rule to allow testing of new or used tractors. We do not expect absolute correlation between GEM results and chassis testing. GEM makes many simplifying assumptions that do not compromise its usefulness for certification, but do cause it to produce emission rates different from what would be measured during a chassis dynamometer test. Given the limits of correlation possible between GEM and chassis testing, we would not expect such testing to accurately reflect whether a vehicle was compliant with the GEM standards. Therefore, we are not applying compliance liability to such testing. The testing is ultimately related to compliance with the standards since it is used as a cross-check on GEM-based results from certification. However, we do expect there to be correlation in a relative sense. Vehicle to
vehicle differences showing a 10 percent improvement in GEM based only on the technologies that can be simulated in the chassis dynamometer (aerodynamic loads, rolling resistance loads, axle efficiency, transmission type and efficiency, engine fuel maps, axle ratio, etc.) should show a similar percent improvement with chassis dynamometer testing. Nevertheless, manufacturers will not be subject to recall or other compliance actions if chassis testing did not agree with the GEM results on a relative basis. Rather, the agencies will continue to evaluate in-use compliance by verifying GEM inputs and testing in-use engines. Note that NTE standards for criteria pollutants may apply for some portion of the test cycles.

EPA believes this chassis test program is necessary because of our experience implementing regulations for heavy-duty engines. In the past, manufacturers have designed engines that have much lower emissions on the duty cycles than occur during actual use. The recent experience with Volkswagen is an unfortunate instance. By using this simple test program, we hope to be able to identify such issues earlier and to dissuade any attempts to design solely to the certification test. We also expect the results of this testing to help inform the need for any further changes to GEM.

As also noted in Section II. B. (1) of the Preamble, it can be expensive to build chassis test cells for certification. However, EPA has structured this pilot-scale program to minimize the costs. First, this chassis testing will not need to comply with the same requirements as will apply for official certification testing. This will allow testing to be performed in developmental test cells with simple portable analyzers. Second, since the program will require only five tests per year, manufacturers without their own chassis testing facility will be able to contract with a third party to perform the testing. Finally, 40 CFR 1037.665(c) states that we may approve a request to perform alternative testing that will provide equivalent or better information compared to the specified testing, therefore the agencies may consider testing such as suggested by the commenter. We may also direct the manufacturers to do less testing than we specify in this section.

EPA estimates that the cost to conduct chassis testing at a third party facility would be approximately $30,000 per tractor, for a total of $150,000 per year per manufacturer. RIA Chapter 7.2.1.2 includes the compliance costs of the program, including the increased level of reporting in the tractor program.

In its comments, Volvo slightly expanded on EMA’s argument, stating that “we do not believe EPA has the authority to compel emissions testing of non-new vehicles simply for collecting information to compare to the regulatory approach.” But EPA seeks the information as an assurance that in-use performance is being adequately evaluated through the certification process. So this information is directly related to assuring that in use performance is consistent with certification, and thus is directly related to compliance with the section 202 (a) standards. (EPA, must, of course, develop standards that apply in use, see section 202 (a), and therefore can require testing designed ultimately to assure that standards are met in use).

4x2 Tractors

EPA adopted language in 40 CFR 1037.106 that allows manufacturers to optionally certify 4x2 tractors with heavy heavy-duty engines to the standards and useful life for Class 8 tractors, with no restriction on generating or using emission credits within the Class 8 averaging set.

4.6 PM Emissions from APUs

Organization: American Lung Association
The American Lung Association offers the following recommendations to strengthen the stringency and timing of the proposal and address several key elements of California’s commitment to protecting public health and air quality. [NHTSA-2014-0132-0087-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.143-144.]]

The American Lung Association urges strengthening changes to require that particle pollution from the increased use of Auxiliary Power Units be reduced through filter technologies. The projected increase in Auxiliary Power Units (APUs) to achieve fuel and emissions savings, and APUs’ associated particle pollution increases, must be mitigated nationwide with the use of particle filter systems as are required in California. We simply cannot afford trade-offs in this rule that would allow for increased carcinogenic, lethal diesel exhaust or climate-forcing black carbon emissions. Californians enjoy protections that should be extended to all Americans. [NHTSA-2014-0132-0087-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.146.]]

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Organization: American Trucking Associations (ATA)

New Standards for Auxiliary Power Units will Increase Cost and Discourage Use

ATA is concerned that efforts to place additional emissions controls on diesel-fired auxiliary power units (APUs) will discourage the use of this fuel efficient technology. Currently, APUs are one of several alternatives to operating the main engine for ancillary power and cab comfort. And while APUs provide year-round comfort and fuel savings, as opposed to heat- or air conditioning-only systems, they tend to be at the higher end of the cost spectrum. Requiring additional emissions control technology will further increase the cost of this technology and likely discourage its use. [EPA-HQ-OAR-2014-0827-1243-A1 p.15]

California currently requires diesel-powered APUs to be equipped with particulate filters when used on trucks with 2007 and newer engines. And while these filters are available, use has been limited primarily due to the additional cost and maintenance. Carriers who rely on APUs for fuel savings throughout the United States tend to forego their use in California in order to comply with the state’s unique filter requirements. This practice reduces the overall fuel savings benefit from an APU. ATA believes a further expansion of this type of requirement will have a negative impact on the use of idle reduction technologies and fuel efficiency. [EPA-HQ-OAR-2014-0827-1243-A1 p.15]

For example, currently battery-powered APUs are another option. However, depending on a number of factors, including period of operation, ambient temperature, power demand, etc., this option may or may not meet a carrier’s ancillary power and cab comfort requirements during federally-mandated rest periods. By increasing the cost of one of the most common idle reduction technologies, diesel-powered APUs, solutions to reduce idling will become more limited. ATA recommends that EPA fully consider the potential impacts of increasing the cost of APUs on consumer acceptance, how such a cost increase will impact the cost-benefit assumptions used in the proposed rule, and what operational limitations may exist with other idle reduction technology option. [EPA-HQ-OAR-2014-0827-1243-A1 p.15]
Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. We project that the annual impact of the final program to further control PM will lead to a reduction of PM$_{2.5}$ emissions nationwide by 927 tons in 2040 and by 1,114 tons in 2050. Our review of the costs and cost effectiveness of these standards indicate that they will be reasonable. We have also concluded that given the timing of the PM emission standards for APUs installed in new tractors and the availability of the technologies, engines for use in APUs can be designed to meet the new standards in the lead time provided. In terms of safety, EPA considered the facts that diesel particulate filters are a known technology. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Organization: Bendix Commercial Vehicle Systems, LLC

III. Class 7 and 8 Combination Tractors, C. Proposed Phase 2 Tractor Standards, (3) PM Emissions From APUs [EPA-HQ-OAR-2014-0827-1241-A1 p.5]

EPA is also seeking comment on new standards to further control emissions of particulate matter (PM) from auxiliary power units (APU) installed in tractors that would prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Bendix believes that the full vehicle emissions and fuel consumption should be considered. This means that APUs should not be excluded from the counting of CO2 emissions or the fuel consumed for their operation. Inclusion of the emissions and fuel consumption of APUs will create a more accurate comparison when considering alternatives to diesel powered APUs or APU alternatives altogether. [EPA-HQ-OAR-2014-0827-1241-A1 p.5-6]

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Organization: California Air Resources Board (CARB)

4. Address projected diesel PM increases due to the increase use of auxiliary power units

The proposal encourages manufacturers to increase the use of auxiliary power units (APUs) to reduce idling. While CARB supports reducing such unnecessary idling, U.S. EPA estimates that this action could increase diesel particulate matter emissions throughout the rest of the country by nearly 10 percent, thus exacerbating public health issues associated with exposure to toxic diesel particulate matter. This is one of the largest public health problems tackled by GARB in recent decades, and even after an extensive control program in California, diesel particulate matter remains responsible for about 60 percent of the known risk from toxic air contaminants. As such, CARB supports the development of a federal rule that requires diesel particulate filters on APUs, concurrent with the Phase 2 program, similar to requirements already in place in California. [EPA-HQ-OAR-2014-0827-1265-A1 p.4]

In the Phase 2 NPRM, U.S. EPA and NHTSA rightly note that CARB, recognizing the excess PM emissions from APUs, requires APUs that operate in California to control PM emissions by either installing a DPF that is Level 3 (85 percent filtration efficiency) verified or must have the APU exhaust routed to the truck’s exhaust system upstream of the truck’s DPF. To comply with California’s
requirements, several APU and DPF manufacturers have verified Level 3 DPFs for use with APUs. Commercially available today, verified DPFs for use with APUs include Thermo King’s Electric Regenerative DPF for use with their TriPac APU, Impco Ecotrans Technologies’ ClearSky DPF for use with their Comfort Pro APU, and Proventia’s Electronically Heated DPF for use with the Thermo King TriPac APU. APUs are typically equipped with diesel-fueled off-road engines with power ratings less than 25 hp. The verified DPFs are available as factory installed on APUs or as APU retrofits. As of December 31, 2014, approximately 7,000 APUs equipped with CARB verified DPFs have been sold nationwide. These technologies have been in use now for the last 5 to 7 years and during this period, CARB has not received any complaints from end users related to DPF performance, safety, reliability, or noise issues that would make these devices impractical to use on APUs. Thus, there are no technical feasibility issues that would hinder U.S. EPA and NHTSA from requiring additional PM controls on APUs. [EPA-HQ-OAR-2014-0827-1265-A1 p.179-180]

The health risk posed by diesel PM is one of the largest public health problems tackled by CARB in recent decades, and even after an extensive control program including a series of air toxic control measures in California (see for example the mobile source measures listed at http://www.arb.ca.gov/toxics/atcm/atcm.htm), diesel PM remains responsible for 60 percent of the known risk for air contaminants. Hence, controlling diesel PM remains a huge priority for CARB. Diesel PM also contains black carbon, which is a powerful short-lived climate pollutant, so even beyond the toxicity reasons for controlling diesel PM, there are climate reasons as well. The PM 2.5 increases projected for the Phase 2 regulation are very significant – an increase of 1,631 tons and 2,257 tons of nationwide PM 2.5 in 2035 and 2050, respectively. To put those emission increases in perspective, they are greater than the entire projected reductions of 1,058 tons statewide diesel PM in 2023 from CARB’s Truck and Bus Regulation.87 While this issue does not significantly affect California because CARB already requires DPFs on APUs, CARB staff supports adopting similar requirements at the federal level concurrent with the Phase 2 program. [EPA-HQ-OAR-2014-0827-1265-A1 p.180-181]

Based on price quotes provided by the three manufacturers, the average incremental cost of a verified DPF for an APU is approximately $2,500. This cost estimate for an APU engine rated at less than 25 hp is relatively high compared to the $580 DPF incremental cost estimate for a 150 hp off-road engine that U.S. EPA cites in the NPRM. The higher cost quoted by the three manufacturers for these DPFs is due to the low sales volume of APUs with verified DPFs since the requirements only apply to California as opposed to being a nationwide requirement. Also, since DPFs are not required on APUs installed on trucks equipped with 2006 or older MY engines, California does not prohibit the purchase and installation of non-DPF equipped APUs. It only restricts their operation within the state if installed on trucks equipped with 2007 or subsequent MY engines. Thus, many trucking companies that purchase APUs do not purchase the DPF. CARB staff expects if the requirements are applied nationally, the sales volume will increase and consequently the incremental cost will drop significantly, most likely to levels even below the $580 DPF cost estimate for a 150 hp engine that U.S. EPA and NHTSA cite in the NPRM. [EPA-HQ-OAR-2014-0827-1265-A1 p.180]

Overall, CARB staff strongly urges U.S. EPA and NHTSA to regulate PM emissions from APUs in this rulemaking since the technology is commercially available, trucking businesses are currently using it, and it is cost-effective. It does not make sense to pursue CO2 emissions reductions at the expense of increased toxic diesel PM emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.181]

---

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

As indicated in our response to Thermo King and Proventia comments below (EPA-HQ-OAR-2014-0827-1196-A1; EPA-HQ-OAR-2014-0827-0811-A1), in the NPRM, EPA discussed several sources for DPF cost estimates. The three sources included the Nonroad Diesel Tier 4 rule, ARB, and Proventia. EPA developed long-term cost projections for catalyzed diesel particulate filters (DPF) as part of the Nonroad Diesel Tier 4 rulemaking. In that rulemaking, EPA estimated the DPF costs would add $580 to the cost of 150 horsepower engines (69 FR 39126, June 29, 2004). On the other hand, ARB estimated the cost of retrofitting a diesel powered APU with a PM trap to be $2,000 in 2005. Proventia is charging customers $2,240 for electronically heated DPF for retrofitting existing APUs. EPA considered all of the comments on DPF costs and more closely evaluated NHTSA’s contracted TetraTech cost report which found the total retail price of a diesel-powered APU that includes a DPF to be $10,000. Based on all of this information, EPA is projecting the retail price increment of an actively regenerating DPF installed in an APU to be $2,000. This cost is incremental to the diesel-powered APU technology costs beginning in 2024 MY.

Organization: Center for Biological Diversity

THE EPA MUST ADOPT A PARTICULATE MATTER (“PM”) CAP THAT PROTECTS AGAINST INCREASED BLACK CARBON EMISSIONS FROM AUXILIARY POWER UNITS

As proposed, the Phase 2 standards would result in an increase in national black carbon and associated fine particulate matter (“PM”) emissions from auxiliary power units (“APUs”): this is untenable. APUs allow a tractor to maintain power during non-road hours, but the tradeoff is increased black carbon and particulate matter emissions. Black carbon is a significant short-lived climate pollutant that must be controlled to avoid undermining the climate benefits of the proposed standards. In addition, PM poses significant public health risks. [EPA-HQ-OAR-2014-0827-1460-A1 p.20]

Black carbon is a potent short-lived pollutant with climate impacts that may be second only to carbon dioxide over the next 20 years. As such, it has received international attention as an important part of short-term actions to stave off immediate climate catastrophe and avoid imminent tipping points. Black carbon, or soot, is a product of incomplete combustion. It is typically co-emitted with organic carbon; the ratio of black carbon to organic carbon is highest for fossil fuels. Both black carbon and organic carbon are components of particulate matter. [EPA-HQ-OAR-2014-0827-1460-A1 p.20]

One of the fundamental characteristics of a climate pollutant is the amount that it contributes to global warming. This is often characterized as radiative forcing. The most recent Assessment Report (“AR5”) from the Intergovernmental Panel on Climate Change estimates that the radiative forcing for black carbon is approximately 0.40 W/m². For comparison, Chung and Seinfeld recently reported observational estimates of direct radiative forcing for both black carbon and organic matter from biomass burning. They estimate direct radiative forcing for black carbon to be 0.65 W/m² and the contribution of organic carbon to be 0.0 W/m² due to the offsetting balance of absorption by brown carbon and light scattering. Thus,
the radiative forcing of black carbon is at least similar to that of methane, and potentially higher. [EPA-HQ-OAR-2014-0827-1460-A1 p.20]

Public health impacts from black carbon include both cardiovascular and respiratory effects.\textsuperscript{101} Much of the negative health effect can be attributed to ultrafine black carbon particles emitted from diesel engines and likely reflects increased inflammatory responses.\textsuperscript{102} Black carbon has also been associated with decreased memory and learning in children.\textsuperscript{103} Moreover, cancer risk is increased with exposure to diesel particulate emissions.\textsuperscript{104} Notably, these public health impacts can be avoided easily through the use of diesel particulate filters. [EPA-HQ-OAR-2014-0827-1460-A1 p.20]

The United States has reduced black carbon emissions, primarily from diesel engines, through a number of recent regulatory actions. However, allowing an increase in PM – and associated black carbon – from APUs will undermine both recent efforts to reduce US black carbon emissions and the climate benefits of the proposed standards for medium- and heavy-duty trucks. An increase in diesel PM will also result in harm to public health. Consequently, it is imperative that the agencies adopt measures to ensure that PM emissions from APUs are fully controlled. [EPA-HQ-OAR-2014-0827-1460-A1 p.21]

The EPA should take into account that California already requires PM emissions to be controlled from APUs. Thus, manufacturers of vehicles for use in that state will already be complying with such a requirement. In California, a diesel-fueled APU operated on a truck equipped with a 2007 or newer engine must either be fitted with a verified Level 3 particulate control device (85% particulate reduction efficiency), or have its exhaust plumbed into the vehicle's exhaust system upstream of the particulate matter after-treatment device.\textsuperscript{105} We urge the EPA to adopt a similar, nation-wide control requirement for PM emissions from APUs, which would level the playing field and enhance air quality in all states. [EPA-HQ-OAR-2014-0827-1460-A1 p.21]

**Response:**

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

**Organization:** Coalition for Clean Air/California Cleaner Freight Coalition

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 217-218.]

I agree with MECA, who talks about the APUs having a filter requirement nationwide, as they do here in California. EPA should adopt this regulation expeditiously.

**Response:**

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

**Organization:** Daimler Trucks North America LLC

18. PM Emissions from APUs

**Requirement to Control PM Emissions from APUs** – The agencies propose new standards to further control emissions of particulate matter (PM) from auxiliary power units (APU) installed in tractors that would prevent unintended consequence of increasing PM emissions from tractors during long duration idling. 80 FR 40211. The agencies request comment on the technical feasibility of diesel particulate filters ability to reduce PM emissions by 85 percent from non-road engines used to power APUs. We understand the direction the agencies are taking in regulating APUs to reduce the amount of PM, and we currently supply APUs that meet California ARB emission requirements. The technology is available and has been used in California for years (CARB 13 CCR § 2485(c)(3)(A)(1) as stated on page 176 of the RIA). If the EPA plans to adopt regulations on PM emissions from APUs, we recommend that the EPA adopts the CARB requirements word-for-word to reduce future complexity on APU emissions and idling requirements. This will allow for a nationwide standard which in turn will satisfy the agencies requirements. That said, we think it makes more sense to simply require that APUs meet Tier 4-final regulations. [EPA-HQ-OAR-2014-0827-1164-A1 p.134-135]

**Response:**

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Though EPA did not adopt CARB’s APU requirements directly, manufacturers should be able to meet both EPA and ARB requirements using the same engines and emission control technologies. EPA used the existing engines and effectiveness of DPFs that were developed for the ARB
program as the basis for setting the PM standards. Additional details are discussed in Section III.C.3 of the FRM Preamble.

**Organization:** Environmental Defense Fund (EDF)

**EPA should promulgate more stringent PM emission standards for APUs to protect public health**

Auxiliary power units (APUs) are among the technologies available today to reduce fuel use from sleeper cab tractors due to idling. We request the agencies adopt more protective health-based diesel particulate matter (PM) emissions standards for these units to bring them in line with the truck engines they are relieving. [EPA-HQ-OAR-2014-0827-1312-A1 p.50]

Reducing idling is an important step in reducing fuel consumption, GHG emissions and other airborne contaminants from diesel engines in sleeper cabs because they are estimated to idle 6-8 hours a day, as many as 250-300 days a year.\(^{213}\) EPA estimates that every year long-duration idling of truck and locomotive engines consumes over one billion gallons of diesel fuel and emits 11 million tons of carbon dioxide, 200,000 tons of oxides of nitrogen, and 5,000 tons of particulate matter.\(^{214}\) A truck owner can end up paying an extra $6000 or more per year in fuel costs.\(^{215}\) Also, idling can increase engine maintenance costs, shorten engine life, harm driver well-being, and elevate noise levels. [EPA-HQ-OAR-2014-0827-1312-A1 p.50]

EPA has verified dozens of cost-effective technologies that can be applied to APUs to reduce fuel consumption and CO2 emissions from these engines. EDF supports the inclusion of APUs as a technology option manufacturers can use to meet the proposed standards for sleeper cab trucks. [EPA-HQ-OAR-2014-0827-1312-A1 p.50]

However, the PM standards for diesel APUs, established under the nonroad rule, are not as protective as the truck engine standards for MY 2007 and later trucks, which require the use of diesel particulate filters (DPFs) or comparable alternative. This disparity allows diesel APUs to emit more than 5 times as much harmful diesel PM as a MY 2007 or later diesel sleeper cab engine.\(^{216}\) Indeed, EPA estimates in the proposal that without further controls on APUs, harmful particulate emissions will increase by 1,600 tons annually by 2035 and more than 2,200 tons annually in 2050. This increase in PM emissions will be particularly significant at idling “hotspots” like truck stops, travel centers, rest areas, distribution centers and port areas, creating high concentrations of harmful diesel PM, and threatening the health of drivers, area workers and neighboring communities, many of which are often low-income. In addition to the health impacts, diesel PM is made primarily of black carbon, which is a potent GHG. We therefore request that the agencies promulgate more protective PM emissions standards for these units to protect public health and the environment from the harmful impacts of diesel PM. [EPA-HQ-OAR-2014-0827-1312-A1 p.51]

To address these public health concerns, in 2008, California Air Resources Board established more protective standards for diesel APUs that require the use of diesel particulate filters or a comparable alternative, which reduce PM by as much as 85 percent and make APUs as clean as the truck engines they are attached to. CARB concluded that the technology to make these reductions is available and cost-effective.\(^{217}\) [EPA-HQ-OAR-2014-0827-1312-A1 p.51]

It is imperative that EPA follow California’s leadership and protect the health of all Americans by adopting protective particulate matter standards for APUs. Such an action will allow cost-effective APU technology to be used to reduce unnecessary fuel consumption by idling trucks without increasing harmful particulate pollution. [EPA-HQ-OAR-2014-0827-1312-A1 p.51]

**Response:**

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

**Organization:** Environmental Law and Policy Center

The proposed regulation should do more to protect children's health. Asthma hospitalization rates in Chicago are nearly double those of the national average, and that's why we're so concerned that the proposed rule would actually increase particulate pollution by encouraging the use of auxiliary power units on trucks. We urge you to amend this rule by requiring that these units be equipped with particulate filters. This would eliminate the long-term increase in particulate pollution which may occur as a result of these regulations.

**Response:**

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

**Organization:** Idle Smart

3. As proposed, implementation of Extended Idle technologies in Phase 2 rulemaking would lead to higher PM2.5 emissions, which is directly counter to the stated goals of Phase 2 to reduce GHG emissions. This fact is acknowledged and quantified in the Phase 2 draft. The Phase 2 draft explicitly states that the use of APUs results in “an increase in PM emissions” and goes on to quantify the impact using data presented in MOVES2014. Specifically, the adverse PM2.5 emissions impact of utilizing diesel APUs is 1,631 tons and 2,257 tons of PM2.5 emissions in 2035 and 2050, respectively. As noted in the rulemaking, this is because diesel APUs emit 1.8 grams PM per hour vs. 0.35 grams PM per hour for 2010 or newer model engines. Putting this in simpler terms and comparing it to Idle Smart yields the following: [EPA-HQ-OAR-2014-0827-1128-A1 p.3]
Said another way, utilizing a diesel APU to offload 2000 Extended Idle hours a year generates 3600 PM grams/year, which is nearly 20 times that which is produced when utilizing Idle Smart’s automatic start/stop solution. [EPA-HQ-OAR-2014-0827-1128-A1 p.4]

12 Exhaust Emission Rates for Heavy-Duty On-road Vehicles in MOVES 2014, September, 2015

13 Idle Smart performance metrics (2014)

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Organization: Manufacturers of Emission Controls Association (MECA)

Control of Black Carbon with Particulate Filters

Black carbon is a major component of particulate matter emissions from mobile sources and is believed to have a significant net atmospheric warming effect by enhancing the absorption of sunlight. Black carbon is a mix of elemental and organic carbon, in the form of soot, emitted by fossil fuel combustion, bio-mass burning, and bio-fuel cooking. Black carbon is a dominant absorber of visible solar radiation in the atmosphere. Anthropogenic sources of black carbon are transported over long distances and are most concentrated in the tropics where solar irradiance is highest. Because of the combination of high absorption, a regional distribution roughly aligned with solar irradiance, and the capacity to form widespread atmospheric brown clouds in a mixture with other aerosols, emissions of black carbon are thought to be the second strongest contribution to current climate change, after CO2 emissions. The glacier retreat has accelerated since the 1970s and several scientists have speculated that solar heating by soot in atmospheric brown clouds and deposition of dark soot over bright snow surfaces may be an important contributing factor for the acceleration of glacier retreat. A study published in a 2009 issue of Nature Geoscience (vol. 2, 2009) by researchers from the NASA Goddard Institute and Columbia University found that black carbon is responsible for 50% of the total Arctic warming observed from 1890 to 2007 (most of the observed Arctic warming over this timeframe occurred from 1976 to 2007). [EPA-HQ-OAR-2014-0827-1210-A3 p.10]

It is estimated that 70% of the black carbon emissions from mobile sources are from diesel-fueled vehicles, with the assumption that 40% of gasoline PM is black carbon and 60% of diesel PM is black carbon. The black carbon concentration and its global heating will decrease almost immediately after reduction of its emission. Black carbon from diesel vehicles can be significantly reduced through emission control technology that has been required on every U.S. heavy-duty diesel truck manufactured since 2007. The basis for the design of wall-flow particulate filters is a ceramic honeycomb structure with alternate channels plugged at opposite ends. As the gases pass into the open end of a channel, the plug at the opposite end forces the gases through the porous wall of the honeycomb channel and out through the neighboring channel. The porous wall and the filter cake of particulate matter that forms within and on the surface of the wall serve as the filter media for particulates. Since the filter can fill up over time by developing a layer of retained particles on the inside surface of the porous wall, the accumulated particles...
must be burned off or removed to regenerate the filter. This regeneration process can be accomplished with a variety of methods including both active strategies that rely on generating external sources of heat (e.g., fuel burners, fuel dosing strategies that utilize fuel combustion over a catalyst, electrical elements, intake air throttling) and passive strategies that utilize catalysts that are displayed directly on the filter element or upstream of the filter. During the regeneration of DPFs, captured carbon is oxidized to CO\textsubscript{2} but this filter regeneration still results in a net climate change benefit since the global warming potential of black carbon has been estimated to be as high as 2,200 times higher than that of CO\textsubscript{2} on a per gram of emission basis. It is estimated that the installation of DPFs has reduced PM emissions from U.S. heavy-duty diesel vehicles by 110,000 tons per year. The ACES Phase 2 study that evaluated the PM emissions from 2010 technology heavy-duty engines showed that DPF equipped engines emit PM at one to two orders of magnitude below the current standard of 0.01 g/bhp-hr and deliver over 99% PM capture efficiency over their lifetime. MECA encourages EPA to develop policies and/or incentives that reward vehicle and engine manufacturers for employing technologies such as particulate filters that provide significant reductions in mobile source black carbon emissions. [EPA-HQ-OAR-2014-0827-1210-A3 p.10-11]

Control of PM from Auxiliary Power Units

Auxiliary power units or APUs are used on heavy-duty trucks during “hoteling” at truck stops or other suitable rest areas. During long periods of idling, the APU provides power to auxiliary systems such as cabin electricity and air conditioning so that the main truck engine can be turned off. Because APUs have diesel engines less than 10 horsepower, they burn less fuel than the main engine and thus reduce CO\textsubscript{2} emissions. Under Tier 4 standards, the small displacement of these engines allows them to operate without exhaust emission controls such as diesel particulate filters and as a result they emit 5-10 times more PM emissions than the much larger displacement but filter-equipped main truck engine idling for the same amount of time. The California Air Resources Board recognized this fact and in 2008, included as part of their anti-idling regulations for heavy-duty trucks, a requirement that APUs must be retrofit with a particulate filter capable of achieving at least an 85% reduction in PM or have the APU exhaust diverted through the main DPF in the exhaust system of the truck. To achieve an 85% PM reduction, the particulate filter must be a wall flow device, or similar. ARB has verified four of these retrofit devices, made by third-party manufactures, for installation on existing APU engines. Due to the relatively cold exhaust temperatures of these small engines, the DPF filters installed on APUs must use either all active or a combination of passive and active regeneration to periodically clean the soot from the filter. Active regeneration can be accomplished through the use of a fuel burner or electrical heater upstream of the filter element that can be activated if the back pressure is too high. [EPA-HQ-OAR-2014-0827-1210-A3 p.11]

California’s APU Air Toxics Control Measure (ATCM) regulation demonstrates that it is feasible to control PM from small APU engines and several companies are supporting this market. The technology is commercially available and has been implemented on APUs since 2008 as part of the state’s Diesel Risk Reduction Plan (DRRP). In the Phase 2 proposal, EPA estimates the potential PM reduction impacts from installing DPFs on APUs as approximately 3,000 tons in 2035. Because these engines operate for many hours in a single location, the health impact from PM exposure to people that work, stop or live near rest areas and truck stops may be of greater concern than might be indicated by a simple mass-based inventory. Groups of trucks operating their APUs at a truck stop are similar to a stationary point source. California based their requirements for using PM controls on stationary sources on the health-based cancer risk of PM exposure around a point source exceeding one in a million. To better quantify the emissions impacts of installing emission controls on small diesel engines, such as APUs, TRUs and other small off-road engines, CARB is funding a demonstration program at UC-Riverside. MECA is supporting this effort with technology and expertise and we encourage EPA to seriously consider requiring DPF
technology on APU engines as part of this regulation. We agree with EPA’s cost estimates for a DPF retrofit on an existing APU, that cost includes the expense of verifying the device and the need for a separate control unit to monitor and regenerate the filter. We believe that the cost would be significantly lower if the filter could be integrated onto the APU engine at the time of manufacture or the APU exhaust is routed into the truck exhaust, upstream of the DPF, at the time of vehicle manufacture and incorporates economies of scale that an OEM can achieve with larger numbers of engines. [EPA-HQ-OAR-2014-0827-1210-A3 p.11-12] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.212-213.]]

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Organization: Moving Forward Network

Eliminate loophole for Auxiliary Power Units (APUs), which will increase harmful Particulate Matter Emissions – As the California Air Resources Board has pointed out, a regulation that will increase the use of APUs more extensively throughout the nation will result in increased PM2.5 emissions unless these APUs are equipped with diesel particulate filters. We cannot sacrifice public health protections as we seek to battle climate pollution. We represent groups on the front lines battling deadly pollution from the freight industry. This approach that increase PM2.5 emissions is even more problematic given at least one state, California, has shown that diesel particulate filters can be required on APUs. The final rule should require the use of diesel particulate filters on APUs. [EPA-HQ-OAR-2014-0827-1130-A2 p.2]

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Organization: National Association of Clean Air Agencies (NACAA)

Next, EPA projects an increase in the use of auxiliary power units (APUs) under the Phase 2 proposal and an associated 10-percent increase in PM emissions. The agency seeks comment on this, but proposes nothing to address the unacceptable and unnecessary expected rise in PM pollution. Exposure to diesel PM is one of the greatest public health challenges of our time. In California, for example, diesel PM was identified as a toxic air contaminant in 1998. However, even after implementation by the state of extensive control programs, diesel PM remains responsible for 60 percent of the known risk from toxic air contaminants. Therefore, NACAA recommends that, concurrent with the final Phase 2 rule, EPA adopt national requirements to equip APUs with diesel particulate filters, similar to CARB’s requirements. [EPA-HQ-OAR-2014-0827-1157-A1 p.4-5]

Additionally, while MOVES modeling points to other air quality benefits of APU usage, there remains a significant difference between the emission standards for Tier 4 smaller nonroad diesel engines typically used in APUs when compared to the emission rates of a modern long-haul truck at idle. To prevent any potential backsliding from air quality benefits appreciated from the newest onroad engine standards, we recommend adding provisions to ensure that there are no increases in emissions of NOx or PM as a result
of increased use of APUs on all affected vehicles. We also encourage EPA to ensure against overestimation of the potential NOx benefits associated with APU use. [EPA-HQ-OAR-2014-0827-1157-A1 p.5]

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Furthermore, the MOVES emission rates for extended idle were lowered significantly for criteria pollutants based on the analyses of the latest test programs that reflect the current prevalence of clean idle certified engines. The extended idle rate for NOx was changed from 203 g/hr to 42.6 g/hr for model year 2013 and later. This change resulted in smaller differences between emission rates for extended idle and APUs for all criteria pollutants. Therefore, the emissions benefits of using APUs during extended idle, instead of the main engine, are lower for non-GHGs in the final rulemaking than at proposal.

Organization: Natural Resources Defense Council (NRDC)

Prevent increases in diesel particulate matter (PM) pollution from greater use of diesel-powered auxiliary power units (APU) by establishing appropriate APU PM emission requirements. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

Prevent Increases in Diesel Particulate Matter from Diesel APUs

Auxiliary power units (APUs) offer significant fuel savings and CO2 emissions benefits compared to main engine idling. However, the agencies note that the proposed rule results in a net increase in PM emissions from the increased use of diesel APUs (Table III-2 of Proposed Rule). Non-road diesel engines used to power APUs do not meet the same criteria pollutant emission standards as the main engine. [EPA-HQ-OAR-2014-0827-1220-A1 p.9]

Short- and long-term exposure to particulate matter pollution can have severe negative health impacts. Communities close to diesel vehicle and equipment operation suffer from high health risks due to PM exposure. To address this issue, the California Air Resources Board (CARB) requires diesel powered APUs to obtain equivalent or better particulate matter emissions than the main engine through the use of a diesel particulate filter or alternative means. There are three manufacturers offering particulate matter filters for diesel fuel APUs.\(^\text{21}\) [EPA-HQ-OAR-2014-0827-1220-A1 p.9]

Given the availability of technology to control PM emission from diesel powered APUs, the potential health impact to communities from elevated levels of PM emission from truck idling, and the existence of preventative measures already in place in California, the EPA should require diesel powered APUs to achieve the maximum technically feasible and cost-effective reductions in PM emissions. [EPA-HQ-OAR-2014-0827-1220-A1 p.9]

\(^{21}\) See CARB verified devices listed at [http://www.arb.ca.gov/msprog/cabcomfort/cabcomfort.htm](http://www.arb.ca.gov/msprog/cabcomfort/cabcomfort.htm)
Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from new tractors during long duration idling. The 2018 provision is a compliance constraint, simply not allowing credit for APUs installed in MY 2018 tractors unless the APU engine meets specified PM standards. Additional details are discussed in Section III.C.3 of the FRM Preamble.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

There should be no backsliding on fine particulate matter (PM2.5) and NOx from increased use of auxiliary power units (APUs).

We also urge the agencies to ensure that there are no increases in emissions of either PM2.5 or NOx as a result of the proposed rule. We note that the agencies project an increase in PM2.5 as a result of increased APU use. While idle reduction represents an important opportunity for fuel savings, any increase in this harmful pollutant is unacceptable, particularly given that appropriate PM control technology for APUs is already in the marketplace and currently required by CARB. EPA should adopt similar requirements to CARB’s for PM control on APUs, and should do so concurrently with this proposed Phase 2 rulemaking. Similarly the agencies should ensure there is no backsliding on NOx emissions as a result of increased use of APUs. [EPA-HQ-OAR-2014-0827-1221-A1 p.3 [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.139.]]

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

The agencies do not expect backsliding of NOx emissions due to the use of APUs. EPA conducted a new analysis of the emission rates for extended idle for the final rule. The NOx extended idle rate for main engine idling was lowered in the MOVES analysis from 203 g/hr to 42.6 g/hr for model year 2013 and later to reflect new analysis of test results, but the extended idling NOx emission rate of APUs is 15.6 g/hr which is still significantly lower than main engine idling.145

Organization: Ozone Transport Commission (OTC)

Auxiliary Power Units

In the Regulatory Impact Analysis (RIA) for the Heavy-Duty Greenhouse Gas proposal USEPA cites a reduction in NOx emissions of around 7% in 2025 due to the implementation of the rule, primarily from an expansion of the use of Auxiliary Power Units (APUs). Although this reduction is commendable, it is not nearly enough to achieve the NOx reductions necessary for the states in the OTR to meet their clean ozone obligations, and leaves a great amount of potential for emission reductions unrealized. There are

also concerns as to whether the 7% reductions will be achieved given that USEPA has reduced its estimate of the emission benefits from the use of APUs cited in the first Heavy-Duty Greenhouse Gas Rule. [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Lastly, while MOVES modeling points to the air quality benefits derived from APU usage, there remains a significant difference between the emission standards for the Tier 4 smaller nonroad diesel engines typically used in APUs as compared to the emission rates of a modern long haul truck at idle. To prevent any potential backsliding from air quality benefits appreciated from the newest on-road engine standards, we recommend adding language to ensure that there are no increases in emissions from either NOx or fine particulate matter as a result of increased use of APUs on all affected vehicles. [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Response:

EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of increasing PM emissions from tractors during long duration idling. Additional details are discussed in Section III.C.3 of the FRM Preamble.

The agencies do not expect backsliding of NOx emissions due to the use of APUs. EPA conducted a new analysis of MOVES emission rates for extended idle for the final rule. The NOx extended idle rate for main engine idling was changed from 203 g/hr to 42.6 g/hr for model year 2013 and later, but the extended idling NOx emission rate of APUs at 15.6 g/hr is still significantly lower than main engine idling.

Organization: Proventia Emission Control

Proventia received ARB approval (Executive Order DE-13-003) for their level 3 (85 percent PM reduction) actively regenerating DPF to fit the Thermo King Tripac APU and has been manufacturing and selling it since 2012. Due to the very low exhaust temperatures of the APU (110 to 260C), the DPF systems need to be actively regenerating. This technology is proven, reliable, and commercially available. [EPA-HQ-OAR-2014-0827-0811-A1 p.1]

The EPA technology cost estimate of $580 added to the cost of 150 hp engines is accurate, if it is defined as the OEM cost of materials and manufacturing cost in production quantity exceeding 10,000+ annually. [EPA-HQ-OAR-2014-0827-0811-A1 p.1]

The $2,240 cost estimate cited for Proventia for the electrically heated DPF is an end-user price for an aftermarket retrofit device, not an OEM cost for an OEM device. Proventia estimates that a comparable OEM cost of materials and manufacturing cost for production quantity exceeding 10,000+ annually would be $975 for the actively regenerating DPF for APU. The basis for this estimate is that current Proventia production cost in quantity of 50 units is $1069. [EPA-HQ-OAR-2014-0827-0811-A1 p.1]

It should be noted that the $580 added cost for 150 hp engines is likely to be for a catalyzed passively regenerating DPF due to the higher exhaust temperatures for this class of engine. In comparison, the APU’s, due to their low exhaust operating temperatures, always need an actively regenerating DPF and the cost of actively regenerating devices is significantly higher than passively regenerating devices. [EPA-HQ-OAR-2014-0827-0811-A1 p.1]
Response:

In the NPRM, EPA discussed several sources for DPF cost estimates. The three sources included the Nonroad Diesel Tier 4 rule, ARB, and Proventia. EPA developed long-term cost projections for catalyzed diesel particulate filters (DPF) as part of the Nonroad Diesel Tier 4 rulemaking. In that rulemaking, EPA estimated the DPF costs would add $580 to the cost of 150 horsepower engines (69 FR 39126, June 29, 2004). On the other hand, ARB estimated the cost of retrofitting a diesel powered APU with a PM trap to be $2,000 in 2005. Proventia is charging customers $2,240 for electronically heated DPF for retrofitting existing APUs. EPA considered all of the comments on DPF costs and more closely evaluated NHTSA’s contracted TetraTech cost report which found the total retail price of a diesel-powered APU that includes a DPF to be $10,000. Based on all of this information, EPA is projecting the retail price increment of an actively regenerating DPF installed in an APU to be $2,000. This cost is incremental to the diesel-powered APU technology costs beginning in 2024 MY.

Organization: Thermo King

Technical Feasibility of Diesel Particulate Filter (DPF) Requirements in Auxiliary Power Unit (APU) Applications [§III.C(3)]

Section III.C(3) of the Proposed rule requests comment on the technical feasibility of requiring the use of DPFs for diesel-powered APUs, as is required by the California Air Resources Board (CARB), and on the assumptions made by EPA in its preliminary analysis. Ingersoll Rand has significant concerns with regards to a nationwide requirement for use of DPFs in diesel-powered APUs, and strongly urges EPA not to impose such a burden on the trucking industry. [EPA-HQ-OAR-2014-0827-1196-A1 p.1]

Thermo King currently offers a DPF option on its line of diesel-powered APUs in order to help the trucking industry comply with CARB requirements. However, the incremental cost of the DPF option can be as high as $3,500 – considerably higher than the cost estimated by EPA in this section of the proposed rule – and often the deciding factor in removing the cost-effectiveness justification for the installation of an APU at all. [EPA-HQ-OAR-2014-0827-1196-A1 p.1-2]

If diesel-powered APUs were to no longer be cost-effective on a nationwide basis, Ingersoll Rand believes the consequences on the trucking industry would be significant. Currently, the only alternatives available to diesel-powered APUs are battery-powered options. While battery-powered APUs may be commercially available, the technology is not yet mature enough to adequately serve as a replacement for diesel. A typical battery-powered APU provides half the air conditioning cooling capacity of a diesel-powered model, and often is unable sustain a charge for the entire driver rest period. Drivers are already under constant pressure to meet mandated rest times regardless of factors such as traffic or weather; having to sacrifice comfort during these periods by relying on battery-powered APUs would be an added detriment to their ability to get quality rest, which could ultimately decrease highway safety. According to the Federal Motor Carrier Safety Administration\(^1\), 33.6% of large truck accidents in 2013 cited at least one driver-related factor, and of those accidents 11.4% were determined to be the result of driver impairment, which includes fatigue. [EPA-HQ-OAR-2014-0827-1196-A1 p.2]

Ingersoll Rand believes that high-capacity battery-powered APUs will eventually become a commercially available and cost-effective alternative to diesel-powered APUs, and Thermo King has been dedicating resources to research and development in this area for some time. However, mandating this technology today would significantly decrease consumer choice, competitiveness in the APU marketplace, and driver comfort and safety. Ingersoll Rand would welcome additional research, development, and deployment of
high-capacity battery technologies available to APUs supported by or in collaboration with EPA. [EPA-HQ-OAR-2014-0827-1196-A1 p.2]

**Response:**

The agencies have adopted CO₂ emissions and fuel consumption standards based on our analysis of one technology pathway for each level of stringency, but manufacturers will be free to use any combination of technology to meet the standards, as well as the flexibility of averaging, banking and trading, to meet the standards on average. In addition to diesel powered APUs, tractor manufacturers have several other idle reduction technology options in addition to other vehicle technologies such as aerodynamic designs, lower rolling resistance tires, and powertrain improvements. In addition, the idle reduction technology package in the final rule actually has an overall lower cost (even after increasing the diesel APU technology cost for the final rule) than would have been developed for the final rule due to the reduced penetration rate of diesel APUs. The stringency of the tractor standards are not affected because of the higher penetration rate of other idle reduction technologies. The increased use of these other idle reduction technologies offsets the difference in APU use, even though these other technologies are not quite as effective as APUs from a GHG standpoint.

In the NPRM, EPA discussed several sources for DPF cost estimates. The three sources included the Nonroad Diesel Tier 4 rule, ARB, and Proventia. EPA developed long-term cost projections for catalyzed diesel particulate filters (DPF) as part of the Nonroad Diesel Tier 4 rulemaking. In that rulemaking, EPA estimated the DPF costs would add $580 to the cost of 150 horsepower engines (69 FR 39126, June 29, 2004). On the other hand, ARB estimated the cost of retrofitting a diesel powered APU with a PM trap to be $2,000 in 2005. Proventia is charging customers $2,240 for electronically heated DPF for retrofitting existing APUs. EPA considered all of the comments on DPF costs and more closely evaluated NHTSA’s contracted TetraTech cost report which found the total retail price of a diesel-powered APU that includes a DPF to be $10,000. Based on all of this information, EPA is projecting the retail price increment of an actively regenerating DPF installed in an APU to be $2,000. This cost is incremental to the diesel-powered APU technology costs beginning in 2024 MY.

**Organization:** Truck & Engine Manufacturers Association (EMA)

**APU Requirements**

The agencies should not impose any new emission requirements on APUs as a part of the Phase 2 program. APUs already meet the Tier 4 nonroad standards, and so are in compliance with technology-forcing emission limits. This rulemaking is not the proper forum for amending the Tier 4 nonroad engine standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.64]

**Response:**

As explained in Preamble section III.C.3, EPA is adopting new PM standards that apply exclusively to APUs installed in MY 2018 and later new tractors that will prevent an unintended consequence of
increasing PM emissions from tractors during long duration idling.\textsuperscript{146} We project that the annual impact of the final program to further control PM will lead to a reduction of PM$_{2.5}$ emissions nationwide (i.e. prevent emissions that would otherwise occur) by 927 tons in 2040 and by 1,114 tons in 2050. As explained at the conclusion of this response, EPA considers the costs of achieving these emission reductions (more precisely, preventing their occurrence) to be reasonable.

EPA has carefully considered the adequacy of lead time. With respect to the constraint that takes effect in 2018, EPA acknowledges that it is acting relatively aggressively to forestall potential increases in APU-related diesel exhaust PM emissions. However, this 2018 provision is a compliance constraint which prevents tractors from obtaining any credit for use of an APU unless the APU is certified to a given standard which is already being achieved within the industry. APUs not meeting that standard can be used for other purposes. This provision thus can be implemented expeditiously, and it is appropriate to do so given that diesel exhaust PM is a likely human carcinogen. See Preamble Section VIII.A.6. The MY 2021 standard, which is essentially the same type of provision as the 2018 provision except that any APU installed in a MY 2021 tractor would have to meet the given PM standard, has adequate leadtime for the same reason as the 2018 provision. The MY 2024 and 2027 standards are predicated on use of diesel particulate filters, a known technology which can be designed into these engines within that amount of lead time.\textsuperscript{147} In addition, APUs and their engines do not have to meet these standards; they only must do so if the APUs are to be used in new MY 2024 and later tractors.

In terms of safety, EPA considered the fact that diesel particulate filters are a known technology with no known adverse safety implications.

EPA regards any costs associated with these provisions to be reasonable. First, none of these costs need be incurred, and so the standard can be viewed as cost free to both tractor manufacturers and manufacturers of APUs and APU engines. Tractor manufacturers can use other types of idle reducing technologies, or choose a Phase 2 compliance path not involving idle control. The agencies have developed technology packages for determining the final Phase 2 tractor GHG and fuel consumption standards that are predicated on lower penetration rates of diesel APUs than in the NPRM and have included several additional idle reducing technologies, making it more likely that alternative compliance paths are readily available. See RIA 2.8.3.5 indicating that APUs are not projected to be a critical part of the compliance pathway for achieving either the MY 2024 and MY 2027 standards. APU manufacturers (and manufacturers of APU engines) also can market their product to any entities other than MY 2024 and later new tractors without meeting the DPF-based PM standard.

In addition, the PM standard is necessary to avoid an unintended consequence of GHG idle control. The standard adopted is also appropriate for APUs used in on-highway applications, since it is comparable to the heavy-duty on-highway standard after considering rounding conventions (the PM standard for a tractor’s main engine is 0.01 g/hp-hr as specified in 40 CFR 86.007-11(a)(1)(iv)); cf. CAA section 213

\textsuperscript{146} As noted in the final Preamble, this standard can be expressed and justified as either a tractor vehicle standard or as a standard for the non-road engine powering the APU. The standard can be a vehicle standard because engines of any age can be placed in motor vehicles and the vehicle remains a new motor vehicle. See CAA section 216(3) (definition of new motor vehicle engine, which includes “an engine in a new motor vehicle” and so is not limited to engines of the same model year as the vehicle).

\textsuperscript{147} Cf, CAA section 213 (a)(3) which directs the Administrator to consider standards equivalent in stringency to the comparable on-highway standard. Here, the MY 2024 and 2027 PM standards for APU engines used in new tractors will be identical to the on-highway engine standard for comparably sized engines. Although CAA section 213(a)(3) is not applicable here (it does not apply to PM), the provision is nonetheless suggestive of Congressional intent to provide parity between on-road and non-road engine standards where feasible and otherwise reasonable to do so.
(a)(3) (in considering what standards for non-road engines are “available,” EPA “shall first consider” emission standards equivalent in stringency to on-highway standard for comparable engines). The emissions in question also are of diesel exhaust PM, which is a likely human carcinogen. See Preamble Section VIII.A.6.b. In the agency’s view, the toxicity of the pollutant in question further supports that the costs of this standard, which costs need not be incurred, are reasonable.

A final reason we regard the costs as reasonable is that the costs of APUs equipped with a diesel particulate filter are included as part of the agencies’ cost assessment of the tractor vehicle standard. See RIA Chapter 2.11.6.3. The agencies have explained why the costs of that vehicle standard are reasonable. EPA further noted in Section III.C.3 of the Preamble that the quantified benefits of the filter-based PM standard are greater than potential costs, but EPA’s determination that the costs of the APU provisions are reasonable is not based on that information.
5 Trailers

5.1 General Comments

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Inclusion of trailers. The addition of trailers to the program is crucial, because known, affordable trailer aerodynamic and tire technologies can deliver almost 10% fuel savings for tractor-trailers. [EPA-HQ-OAR-2014-0827-1280-A1 p.5] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p.55.]]

Response:

The agencies agree and are adopting a trailer program as part of the final Phase 2 rulemaking.

Organization: American Trucking Associations (ATA)

NHTSA Should be Aware of Potential Weight Implications of Regulating Under-Ride and Over-Ride Guards

In July 2015, NHTSA issued an Advanced Notice of Proposed Rulemaking pertaining to rear impact (under-ride) guards and other safety strategies for single unit trucks. NHTSA also indicated that it will issue a Notice of Proposed Rulemaking focusing on rear under-ride guards on trailers. Further, NHTSA noted that it is still evaluating a petition request to improve side under-ride and front override guards for all trucks and will issue a separate decision on those issues at a later date. [EPA-HQ-OAR-2014-0827-1243-A1 p.22]

A measure included under Phase 2 to advance trailer fuel efficiency promotes the use of lighter weight materials in their construction (i.e., decreasing trailer weight will allow for the substitution of additional freight weight). NHTSA must remain aware that if the pending petition on side under-ride and front over-ride guards is granted, such new standards will increase tractor, trailer, and straight truck weights. While NHTSA and EPA give OEMs credit for selling new, light-weight equipment under Phase 2, lightweighting gains could be quickly overcome by the added weight attributed to the addition of new side under-ride and front over-ride guards. Likewise, new requirements for rear under-ride guards will likely result in increased weights attributed to the use of stronger materials used in their construction. [EPA-HQ-OAR-2014-0827-1243-A1 p.22]

Response:

The agencies recognize the interrelatedness of this regulation to other federal regulations. The subject of a possible side guard requirement is in a research stage. As discussed in a July 2015 document, NHTSA is in the process of evaluating issues relating to side guards and will issue a decision on them at a later date. In December 2015, NHTSA issued a notice of proposed rulemaking proposing to adopt requirements of Transport Canada’s standard for underride guards. NHTSA is currently assessing next steps on that proposal, and includes as part of its analysis consideration of impacts of any decisions on the fuel efficiency of the vehicles.

We cannot predict how the performance of future aerodynamic devices may be impacted if such requirements were in place, though we do expect both trailer and device manufacturers will be mindful...
of the performance of both features in their future designs. The additional weight of the any future safety-related components would have the potential to increase vehicle weight, but EPA and NHTSA will not adjust their CO\textsubscript{2} or fuel consumption standards to account for the weight increase. Customers that expect their trailers to “weigh-out” can request that the trailer manufacturer adopt some of the agencies’ lightweight components or other weight reduction measures, which could keep their trailers within the weight limits, improve their CO\textsubscript{2} emissions and fuel consumption, and assist in the trailer manufacturer’s Phase 2 compliance.

**Organization:** American Trucking Associations (ATA)

**Trailer Concerns**

While ATA recognizes the potential for fuel-efficiency gains from improved trailer design, ATA commends the agencies in affording trailer OEMs flexibility in achieving new trailer efficiency targets. The trailer manufacturing industry is far different from the engine and truck manufacturing sectors. Whereas there are only a handful of truck and engine manufacturers, there are well over 100 trailer manufacturers in the U.S. with the vast majority being designated as small businesses. The top 10 trailer manufacturers account for over 75% of total sales. Unlike the business relationships between engine and truck manufacturers, trailer manufacturers remain separate and unique entities. [EPA-HQ-OAR-2014-0827-1243-A1 p.23]

Trailers come in a variety of different styles including dry vans, refrigerated, tank, flat bed, and specialized to name a few. The ratio of trailers to tractors is 3:1 or more and tractors are often paired with a variety of different trailer types depending on a company’s operations. Adding another level of complexity to the equation, the useful life of a trailer can exceed 20 years with proper maintenance and even be remanufactured to provide many more years of useful life. [EPA-HQ-OAR-2014-0827-1243-A1 p.23-24]

Having just surpassed the 100-year anniversary of the semi-trailer, ATA agrees that it is time to reassess trailer design elements including use of LRRTs, aerodynamic devices, tire pressure technologies, and light-weighting. Trailer regulation should be nationally harmonized and not done in a piecemeal manner such as CARB has done. As a key stakeholder, ATA desires to work with the agencies in developing a logical and cost-effective approach in developing a national trailer efficiency improvement program. [EPA-HQ-OAR-2014-0827-1243-A1 p.24]

**Response:**

The agencies designed this program to be a national program. The agencies recognize the unique characteristics of the trailer industry and we developed the Phase 2 trailer standards and compliance regime with this in mind. We are confident these standards can be achieved and that compliance with the standards can be successfully demonstrated, including by manufacturers that lack prior experience implementing such standards. We are adopting many of the proposed flexibilities that are meant to reduce the compliance burden for this newly regulated industry. Compared to the proposal, the final program also reduces the number of regulated trailer types by limiting the non-box trailer program to tanks, flatbeds and container chassis only, which removes more than 70 small business trailer manufacturers from the program.

**Organization:** Corwin, Michael
I currently work for a small trucking company that has 26 trucks running the US & Canada. … I have no problem with mandating fuel efficient tires but they should be for everyone regardless of the type of trailer. The easier way to accomplish this would be to put the regulations on the tire manufacturers which would get rid of the inefficient ones altogether making the cost better for the end user. I purchased a used trailer a number of years ago in California that had brand new tires on it but as it turned out they weren’t on any rolling resistance list that I could find. I was unable to get the dealer to switch them and couldn’t afford to do it myself at the time. If the rules said that to be sold in the US they had to meet minimum rolling resistance standards this would help both the manufacturer and the end user. It would also have off road heavy equipment using them as well which should improve their efficiency as well. [EPA-HQ-OAR-2014-0827-0730-A1 p.1]

Response:

EPA’s regulatory authority is limited to vehicle manufacturers; we cannot set emissions-related standards for suppliers, including tire manufacturers. However, under the trailer program, trailer manufacturers will be equipping new trailers covered by the program with tires that meet the LRR specifications needed for each of those trailers to comply with the performance standards or design standards of this rule. We expect this increased market demand from trailer manufacturers will encourage tire manufacturers to make appropriate LRR tires available.

Also, although tires are not specifically regulated as part of FMVSS No. 121, tires (including the LRR tires that trailer manufacturers will be installing for compliance with the Phase 2 trailer program) are part of the braking system that must meet the performance requirements outlined in FMVSS No. 121.

Organization: Corwin, Michael

On the issue of aerodynamics, the truck can be made aerodynamic, regardless of the trailer it is pulling, so the regulations should be separate for the tractor and for the trailer. This would allow regulators to take into account the different types of trailers regardless of the truck that is pulling it and no matter what truck pulled it the aerodynamics would be good. The vast majority of companies pull one type of trailer vs multiple types but one truck lease operator may switch companies several times and pull a different type of trailer each time. By having the requirements separate the long term effects would be better. [EPA-HQ-OAR-2014-0827-0730-A1 p.1]

Response:

The agencies are setting GHG emissions and fuel consumption standards separately for the tractor and trailer. We designed our trailer program such that box vans are tested and evaluated with relatively aerodynamic high roof tractors (Bin III or better) that are likely to be in widespread use in the timeframe of the program. In the tractor program, high roof tractors are paired with box vans that include aerodynamic skirts. By evaluating tractors and trailers that are likely to be paired in-use, including the expected aerodynamic improvements, OEMs will be better equipped to design their tractor and trailer aerodynamic improvements to work synergistically with the other half of the vehicle.

Organization: Great Dane

We at Great Dane support reductions in Greenhouse Gas emissions and improved energy efficiencies in transportation. The issue of Greenhouse Gas (GHG) regulations affecting semi-truck trailers is a complex matter. Trailer designs and specifications vary widely from customer to customer and even
within a given customer’s fleet based on their operational needs. [EPA-HQ-OAR-2014-0827-1219-A1 p.1]

In conversations with the EPA we have shared our concerns with staff as to the potential consequences of deployment of certain types of devices that we believe will significantly increase the likelihood of adverse effects on trailers such as water leaks due to mechanical damage, corrosion due to accumulation of road chemicals (one of the most extensive problems the transportation industry faces) or unplanned device damage as a result of operation of the trailer. We believe that the trailer OEM and fleet together are best qualified to determine the practicality of the use of a particular device and hope that the agencies agree with our viewpoint. [EPA-HQ-OAR-2014-0827-1219-A1 p.3]

We appreciate the agencies study of multiple alternatives as detailed in the NPRM and believe that for many reasons a regulatory approach with a more aggressive adoption of stringencies than the proposed approach (Alternative 3) increases the probability of negative effects on stakeholders considerably. Thus we suggest that the agencies consider devising an incentive based approach that could benefit all stakeholders to augment the proposed approach and assist in the deployment and adoption of advanced technologies as opposed to adoption of the more stringent Alternative 4 being considered. [EPA-HQ-OAR-2014-0827-1219-A1 p.4]

Great Dane looks forward to continuing to work with both EPA and NHTSA to further shape and refine the proposed rule and help develop the most appropriate regulations for the industry. We appreciate your consideration of these matters. [EPA-HQ-OAR-2014-0827-1219-A1 p.5]

Response:

The agencies are adopting standards based on the proposed Alternative 3 and essentially agree with the commenter that the three-year pull ahead reflected in Alternative 4 raises issues of adequacy of lead time, including reliability of the technology. We designed our program such that manufacturers can gradually introduce technologies that are generally familiar to their customers.

Organization:  Institute for Policy Integrity at NYU School of Law

The agencies have made several changes to the Phase 2 rule that are consistent with our previous comments. Notably, the Phase 2 proposal includes standards for trailers. For more on Policy Integrity’s views on heavy-duty vehicle regulation, see our comments on the Phase 1 rulemaking.6 [EPA-HQ-OAR-2014-0827-1195-A1 p.3]

Organization:  Sierra Club

Finalize proposed trailer standards

We applaud the agencies for proposing to include trailers in the standards. This is a critical part of the proposed standards, as we know that existing trailer aerodynamic and tire technologies can deliver more than 10 percent fuel savings for tractor-trailers. [EPA-HQ-OAR-2014-0827-1277-A1 p.3]
Response:

In response to The Institute for Policy Integrity at NYU School of Law, National Association of Clean Air Agencies, and Sierra Club, we appreciate your support of our proposed trailer program. The agencies are including standards for trailers in the final Phase 2 program.

Organization: STEMCO

We support the EPA and NHTSA’s effort to reduce greenhouse gas emissions in the transportation industry while at the same time recognizing the complexity of implementing this nationwide regulation, especially when trailers are included for the first time. Because our products related to this regulation are primarily installed on trailers, our comments will apply only to that portion (section IV) of the EPA and NHTSA’s proposal. In general, we believe that this proposal combines an appropriate standard for achieving the goal of significant environmental improvements with an implementation strategy that aims to minimize negative impacts on industry stakeholders. We specifically support: [EPA-HQ-OAR-2014-0827-1259-A1 p.2]

Response:

We appreciate the commenter’s support for our proposed trailer program. The trailer manufacturers unanimously opposed the accelerated timeline of the proposed Alternative 4 in their public comments, citing lead time concerns. The agencies agree that the accelerated timeline of that alternative raises serious concerns regarding adequacy of lead time, including reliability concerns. To afford adequate lead time, the agencies are adopting standards based on the four-stage implementation schedule of Alternative 3, with some changes to our projected technology adoption rates, including strengthened standards for the full-aero van program that includes greater adoption of advanced aerodynamics in the final (MY 2027) stage.

We are finalizing an aerodynamic device testing compliance path that provides for trailer aerodynamic device manufacturers to seek preliminary approval of the performance of their devices (or combinations of devices). Trailer manufacturers could then choose to use these devices and apply the approved performance levels in the certification application for their trailer families.

Organization: Stoughton Trailers

Continue voluntary implementation of technological advances:

The trucking transportation industry has and is very interested in all aspects of fuel saving technology and has through programs such as SmartWay made advances in fuel conservation. The driving force behind such implementations has been the financial bottom line. Some of the innovations employed include increases to interior volume while maintaining exterior size, reduction in weight, decking systems for multi-layer cargo transportation; along with some of the technologies the EPA regulation is basing its reductions on, such as aerodynamic devices, low rolling resistant tires, and automatic tire inflation systems. These advances have been employed as the industry has seen and realized value supported by evidence. The current proposal for a regulation will indeed claim a difference which would likely have been accomplished through the voluntary adoption of systems proven as functional. An
unintended side-effect will be the increased creation of CO\textsubscript{2} due to the additional fuel expended on those “regulated units” that do not operate in a manner which causes the added options to provide for a realized and effective performance (i.e. the added weight will cause additional fuel usage and additional trips due to the inability to maximize the cargo potential: not to mention the increase to potential safety issues and the cost of maintaining the components and the fact that shipping the components will result in added miles traveled due to additional loads being generated). [EPA-HQ-OAR-2014-0827-1212-A2 p.1-2]

When push comes to shove the industry is very resourceful and may take action which actually detracts from the overall purpose of reducing CO\textsubscript{2} creation: one such scenario has been experienced in the CARB regulating of the state of California; some shipments have found their way to a container/chassis combination as an over-the-road mode of transportation. The combined weight effect of 5,000lb increase to the empty weigh of the unit of transference. [EPA-HQ-OAR-2014-0827-1212-A1 p.2]

Request 3: Maintain voluntary program without mandated regulations. [EPA-HQ-OAR-2014-0827-1212-A2 p.2]

Request 4: do not regulate non-CO\textsubscript{2} producing transportation equipment. [EPA-HQ-OAR-2014-0827-1212-A2 p.2]

Response:

The agencies believe the majority of box vans will experience CO\textsubscript{2} and fuel consumption reductions with use of the technologies that we expect trailer manufacturers to utilize to achieve the standards. The agencies have tailored the standards in part to avoid the problem raised by this commenter; adding technologies under circumstances where they do not provide CO\textsubscript{2} or fuel savings benefit. Thus, the final rule has separate standards for partial- and non-aero trailers. We believe that many of the box vans that operate at lower speeds will have work-performing equipment (e.g., side platforms, rear lift gates) that will allow manufacturers to designate these trailers as partial-aero or non-aero vans. Partial-aero standards are based on adoption of a single aerodynamic device, and non-aero vans have design standards that require installation of tire technologies only with no aerodynamic requirements. A small fraction of the box van industry may not qualify for a partial- or non-aero designation, yet still operate at lower speeds. These vans may not achieve the real-world benefits that their compliance results would suggest or that similar vans experience because they frequently travel at higher speeds. However, in RIA Chapter 2.10.2.1.1, we show that even trailers operating under 100\% transient conditions will experience a small benefit from use of trailer skirts, and trailers that spend any time at speeds of 55-mph or greater will achieve benefits of at least 1\% during that time, compared to operating without skirts.

The agencies are establishing GHG emissions and fuel consumption standards that provide appropriate and maximum feasible reductions under their respective statutory authorities. We do not believe a voluntary trailer program will produce sufficient emissions and fuel consumption reductions to meet our regulatory obligations. The agencies’ baseline accounts for improvements already present in the trailer fleet due to participation in the voluntary SmartWay program or other factors. The agencies project that very significant and cost-effective reductions over that baseline are available, largely through further utilization of already-available tire and aerodynamic technologies that are not presently deployed on significant portions of the trailer fleet. Thus, reliance on further voluntary efforts will not achieve reductions which are readily feasible in the lead time provided, cost-effective, and which indeed, will
pay for themselves in fuel savings. See RIA Chapter 7 and our memo to the docket for more information on our cost calculations.\textsuperscript{148}

**Organization:** Truck Trailer Manufacturers Association (TTMA)

9 - Ways to simplify/streamline

When and if legal authority is given to regulate trailers, there are certain ways that the program could be streamlined. One example would be to require trailer tires to be low rolling resistance and/or trailers to have ATIS as part of NHTSA only, so that compliance can be within the manufacturer’s certification label to remove unneeded compliance burden. That way, the regulated classes of trailers goes down and the EPA can focus its priorities where they will do the most good, while manufacturers of non-aero- and non-box-trailers will have a minimum of compliance burden while maximizing the available CO2 reductions/fuel savings. [EPA-HQ-OAR-2014-0827-1172-A1 p.14-15]

Moreover, there are far more effective methods to reduce fuel consumption and improve the freight sector’s carbon footprint. Recent proposals to lengthen combination trailers to 33’ would have a tremendous impact. This can be seen in the agencies’ own data and proposed CO2 standards for trailers, where longer trailers have substantially lower CO2 emissions per ton-mile\textsuperscript{22}. Similarly, an increase in permissible weights would be met with improvements in fuel economy and carbon footprint. Also, a slight reduction in speed limits for HD vehicles would be most effective\textsuperscript{21}. Any and all of these would have to be done carefully so as to give due consideration to all aspects including safety concerns, but they would work better than the proposal as written. [EPA-HQ-OAR-2014-0827-1172-A1 p.15]

Regardless of exemption levels and classification schemes, requiring reporting on every individual trailer produced and each device fitted as the proposal envisions is overly capricious, unreasonably burdensome and is not supportive of the goal of reducing greenhouse gas emissions or saving fuel. Individual trailer manufacturers can certify that they have complied with the regulations and that should be sufficient. If the agencies elect to regulate end users as we suggested in our authority objections sections, we could see adding a panel/label that clearly spells out the characteristics of the trailer in terms that work with that regulation. [EPA-HQ-OAR-2014-0827-1172-A1 p.15]

**Response:**

Each agency has an independent obligation here to develop standards. See *State of Massachusetts v. EPA*, 549 U.S. at 532 (“But that DOT sets mileage standards in no way licenses EPA to shirk its environmental responsibilities. EPA has been charged with protecting the public’s "health" and "welfare," 42 U.S.C. § 7521(a)(1), a statutory obligation wholly independent of DOT’s mandate to promote energy efficiency. See Energy Policy and Conservation Act, § 2(5), 89 Stat. 874, 42 U.S.C. § 6201(5). The two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency”). The agencies have worked diligently to develop a single national program so that compliance with the standards of either agency assures compliance with the other agency’s standards, and with standards of the State of California as well. The agencies have also developed a compliance regime for trailer manufacturers designed to minimize regulatory burden and complexity. Examples are design standards for non-aero trailers, and (for the other regulated trailers) certification via use of an equation rather than needing to run the full GEM model.

We expect trailer manufacturers to produce their range of trailer models with a relatively small number of certified configurations. The regulation also generally allows manufacturers to group their trailer models into one or two emission families. The application for certification requires data submission for at most three different configurations. The annual production report would require configuration information for each trailer produced, but trailers with like configurations could be grouped together.

Size and weight restrictions for tractor-trailers are under the jurisdiction of the Federal Highway Administration (FHWA), and are largely controlled by the weight limits established by Congress in 1956 and 1974, the size limits established in the Surface Transportation Assistance Act (STAA) of 1982, and the size and weight limits established in the Intermodal Surface Transportation Efficiency Act of 1991. Changes to these restrictions would require a broader process involving Congress and Federal and State agencies, and is beyond the scope of the Phase 2 trailer program.

**Organization:**  
Truck Trailer Manufacturers Association (TTMA)

**Costing**

Anti-Trust issues prevent us from gathering cost of goods data. Our members have commented that the costs of certain components in the RIA seem quite low. We will encourage members to submit specific examples directly to the agencies as confidential business information. [EPA-HQ-OAR-2014-0827-1172-A1 p.18]

**Response:**

We did not receive comments specifically indicating technology costs that differ from those in the proposal. General comments that imply costs are too high or too low are not sufficient to direct the agencies to make appropriate changes, particularly when the agencies have presented a documented component-by-component cost assessment. As a result, the cost of our projected technology packages remain unchanged from the proposal.

**Organization:**  
Truck Trailer Manufacturers Association (TTMA)

**12 - Conclusion**

If rules must be crafted, they should be done so reasonably, and not arbitrarily, so as to avoid these sorts of deleterious effects. We have pointed out certain areas that the agencies have overlooked for both exclusion from the rule and for changing the ways that box trailers are counted to account for the ways that they are used. We also encourage regulators to refrain from unnecessarily harming the trailer manufacturing industry by being sensitive to its small-business, produce-to-order nature and to craft any such regulation with the realization that there is no “average” trailer manufacturer. Putting a manufacturer out of business by forcing it to make what it cannot sell or exclusively absorb costs that it cannot pass on will save no fuel and reduces no emissions. There are methods in use today that accomplish regulation of the industry without such an arbitrarily heavy hand as the agencies are proposing here. We have detailed a few such ways that the agencies should consider that would reduce the unreasonable burden while still accomplishing the agencies goals. [EPA-HQ-OAR-2014-0827-1172-A1 p.19]

Once again, we appreciate the agencies’ outreach to us and pledge to continue dialog to help the agencies craft the best regulations possible. We will continue to gather data and may submit further
information as it becomes available, and welcome inquiries from the agencies. [EPA-HQ-OAR-2014-0827-1172-A1 p.20]

Response:

The agencies recognize that the trailer industry is differently situated when compared to many other light- and heavy-duty vehicle sectors. The final standards acknowledge and account for those differences, where it is legitimately possible to do so. We have significantly reduced the number of regulated trailers in the final program. The non-box trailer subcategory is now limited to tanks, flatbeds, and container chassis. All other non-box trailers -- about half of the non-box trailers produced -- are excluded from the Phase 2 trailer program, with no regulatory requirements. We offer reduced standards for trailers with work-performing equipment that would impede installation of aerodynamic technologies. We are adopting the same list of work-performing equipment that can be used to qualify box vans for partial- or non-aero designations, and are including roll-up doors as work-performing equipment through MY 2023. Additionally, in response to many comments from entities representing both small and large trailer companies, we are limiting averaging as a compliance mechanism to MY 2027 and later, and offering a set allowance of trailers from each manufacturer that do not have to meet the standards in the years without averaging (i.e., prior to MY 2027). These are a few of the provisions the agencies are adopting to ensure these standards are reasonable for this newly regulated industry.

We appreciate TTMA’s participation in pre-proposal meetings, including our small business discussions, and its comments on the proposed rulemaking.

Organization:  Utility Trailer Manufacturing Company

Market Forces Will Achieve Most of the Benefits of the Proposed Rules with Few of the Costs

The semi-trailer industry is a mature, extremely competitive, cyclical, low-margin industry. Utility Trailer and the other large manufacturers do not dictate specifications to their customers. Rather, their customers are often large trucking fleets who design their trailers to meet specific needs and then seek to have the manufacturers produce them on a semi-custom basis. The customers are overwhelmingly interested in a trailer that meets their respective specific needs in the most cost-effective way, as the transportation industry too is a mature, low-margin industry. [EPA-HQ-OAR-2014-0827-1183-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.219.]]

What this means is that if technological advances exist that will permit the transporters to move their goods more efficiently at lower costs, they will require the manufacturers to supply those advances. The Agencies justify the Proposed Rules by touting its cost-benefit payback to the trailer owner, claiming that there is a two-year payback on the mandated technologies.1 As mentioned later, Utility Trailer believes the Agencies have understated substantially the cost of the mandated technologies. But accepting as accurate for now the Agencies’ estimates on which it based its Proposed Rules, the owners have every incentive to require that their trailers have these technologies in place and to buy them. [EPA-HQ-OAR-2014-0827-1183-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.219.]]

What possible justification is there for the Agencies to substitute their judgment and mandate for free-market forces, which operate very efficiently in the trailer industry? The Proposed Rule does not provide any; it does not explain why the operators, left to their own devices and the free-market, would not adopt these technologies. [EPA-HQ-OAR-2014-0827-1183-A1 p.2]
One justification, of course, is that the technologies simply don’t provide the savings touted by the Agencies in all applications. As discussed later, all real efficiencies from the aerodynamic devices (trailer skirts, trailer tails, and similar devices) mandated by the Agencies come at higher speeds – not a surprising conclusion since elementary physics tells us that aerodynamic drag is proportional to velocity squared, and power (and thus fuel) required to overcome this drag force is proportional to velocity cubed. Those transportation applications that operate at the lower speeds – such as urban delivery, food service, and many short-haul operations – will not achieve significant fuel savings (which, of course, correlates directly to reduced CO2 emissions) from the aerodynamic devices. Those users have no need for the devices, and requiring installation for those applications accomplishes little if anything. [EPA-HQ-OAR-2014-0827-1183-A1 p.2-3]

In other words, the free market efficiently self-selects which applications should install the aerodynamic devices on trailers – the Agencies themselves note that operators have every incentive to do just this. As discussed later, the Proposed Rule imposes substantial regulatory and administrative burden on the trailer-manufacturing industry. There is neither a need nor justification for adding layers of mandates and regulations where the market has every incentive to achieve the same results through voluntary compliance. The Proposed Rule is silent on this topic. [EPA-HQ-OAR-2014-0827-1183-A1 p.3]

Response:

As noted in our response to Stoughton in this Section 5.1 on page 965, we do not believe a voluntary trailer program will produce sufficient emissions and fuel consumption reductions to meet our statutory mandates. Additionally, most box vans that exclusively travel at low speeds will qualify for designation as partial- or non-aero vans. For those without work performing equipment, our results from RIA Chapter 2.10.2.1.1 indicate that the technologies will provide some savings to those trailers, even if they spend a large portion of their time at lower speeds.

Organization: Utility Trailer Manufacturing Company

The Proposed Rule fails to account for the increases in greenhouse gases that will result from the Rules; they do not measure net greenhouse gas effects of the devices.

A proper analysis of the greenhouse-gas reduction resulting from implementing the Proposed Rule would speak of the net effect on greenhouse gases by accounting from increases in emissions resulting from the Proposed Rule. The Proposed Rule largely fails to do this, even though the Rule will result in activities that will increase greenhouse gases. [EPA-HQ-OAR-2014-0827-1183-A1 p.12]

First, manufacturing the devices results in unwanted greenhouse gas emissions. The aerodynamic devices typically are constructed from lightweight metal, plastic, and – particularly for the skirts – polymers and glass fiber. Many of these materials require extreme heat and significant quantities of petrochemicals to produce, as well as the energy expended in the mining or manufacturing process. The materials also must be transported to the factory and repair shops, and additional fuel is required, of course, to move a trailer with the additional weight of the devices attached. [EPA-HQ-OAR-2014-0827-1183-A1 p.12-13]

It is not easy to determine the amount of greenhouse gases or CO2 emitted from these trailer devices; it certainly is not negligible, and the Agencies should not ignore it or assume it is negligible. But as written, the Proposed Rule neglects the fuel costs and greenhouse-gas emissions associated outside of operations on the trailer. The Proposed Rule needs to account for the greenhouse gases and energy consumption of various devices during the entire lifetime of the component’s construction, delivery, use
and disposal, rather than just highway use as it does now. It would be pointless to require the use of devices whose greenhouse-gas savings in use are small compared to the greenhouse-gas emissions resulting from production, delivery, maintenance, retreading, disposal, and the like. [EPA-HQ-OAR-2014-0827-1183-A1 p.13]

Additionally, any computation of the additional greenhouse-gas emissions associated with manufacturing and repairing the aerodynamic devices must account for the fact that there is not a 1-to-1 ratio of tractors to trailers. The GHG-2 Impact Analysis acknowledges that there are typically two long-refrigerated box trailers per tractor and three (and sometimes up to six) long-dry-van box trailers per tractor. The fuel savings analysis ignores this reality. When these multipliers are included, the number of trailer aerodynamic devices required to achieve the savings is basically doubled or tripled, and by extension, the amount of GHG (CO2) emissions reductions required to make up for the total the GHG emissions caused by their fabrication, installation, and maintenance. [EPA-HQ-OAR-2014-0827-1183-A1 p.13]

Response:

The agencies cannot precisely calculate the upstream emissions/fuel consumption associated with producing and delivering the devices, a simple back-of-the-envelope, worst-case analysis can show that they would be much less than the projected fuel savings. For example, assuming that energy consumption represents 25 percent of the cost of a $1,500 aerodynamic package, it would be equivalent to about 100 to 150 gallons of diesel fuel.\(^{149}\) Even this worst case cost estimate would be offset by a mere one percent savings after the 100,000 miles of operation.

Regarding the comment about accounting for the ratio of tractors to trailers, the agencies calculate overall GHG emissions based on our MOVES model. In MOVES, tractors and trailers are modeled together, such that we are only considering active tractors and trailers, not trailers that are parked and waiting to be used. If we assume an average tractor-trailer ratio of 1:3, the GHG reductions projected by MOVES as a result of trailer improvements would not account for 2/3 of the trailers produced. Consequently, our published GHG reductions are lower than what could be expected if we accounted for all trailers produced.

Organization: Utility Trailer Manufacturing Company

Second, the Proposed Rule ignores that the aerodynamic devices are not one-time purchases; rather, they are unlikely to survive more than a fraction of the trailer’s expected life and therefore must be replaced multiple times. Our freight trailers are expected to last 15 years on average. There is no data to suggest that the aerodynamic devices will last nearly that long. The aerodynamic trailer devices have only been available since 2010. Early-adopter fleets (having approximately 5,300 trailers with skirts) have reported spending $1.2 million over 5 years repairing or replacing damaged skirts and trailer tails on their long-box trailers. [EPA-HQ-OAR-2014-0827-1183-A1 p.13]

Skirts, for example, dwell in space beneath the trailer where objects regularly intrude. Whether it is railroad tracks, inclines on loading docks, or road debris, the skirts will be abused. Utility Trailer and the other manufacturers know this from real-world use, as shown by the following two photographs that reflect a frequent result when the skirts encounter real-world intrusions into their space. [EPA-HQ-OAR-2014-0827-1183-A1 p.13]

\(^{149}\) Assuming $2.50 to $3.50 per gallon of fuel.
Tails encounter similar problems. As noted, the driver cannot see the tail when it is deployed, and drivers often forget to retract the tail and then back into a fence or dock, damaging the trailer. Additionally, because the tail causes the door when fully opened to rest further away from the side of the trailer, drivers catch the door on another trailer when backing in or pulling out, as shown by the following photograph. Such damage requires repairing or replacing the doors, as well as the devices themselves. [EPA-HQ-OAR-2014-0827-1183-A1 p.14]

Response:

Aerodynamic device and tire pressure system suppliers indicated that their products could be expected to last the life of the trailer with proper maintenance. The agencies recognize that some fraction of the CO\(_2\)- and fuel consumption reducing technologies installed on trailers for compliance with this program will experience damage in their lifetime. Our analysis of these technologies indicates that even trailers traveling in mostly urban conditions will experience benefits from these technologies. See RIA chapter 2.10.2.1.1. Because of this, we expect customers will have sufficient incentive to make any necessary repairs. And because of their relatively simple designs, we can assume that the repaired technologies will usually perform as well as the original and our trailer program benefits will be maintained. With proper maintenance, which can include replacement of worn subcomponents, we are aware of no reason that these systems would be unable to meet the durability requirements of the trailer program to last the full 10 year useful life of the trailer.

We note the durability requirements included in the regulations. Utility cites marginal impacts for “early-adopters”, but these do not accurately represent the devices that we expect will be used to comply with the trailer program. The regulations require that devices be durable for 10 years, and thus, we expect them to be more durable than the devices used by early adopters. We acknowledge that improved durability may not cover all damage due to accidents or misuse, but we expect manufacturers and customers will increasingly select devices that remain effective in common trailer operations.

Organization: Utility Trailer Manufacturing Company

Third, the aerodynamic devices add weight to the trailers. A typical combination of skirt and tail adds between 300 and 350 pounds to a trailer. This is a problem for all trailers, since added weight means added fuel usage. But it also presents additional problems for that high percentage of trailers (often but certainly not exclusively refrigerated trailers) that weigh out rather than cube out. Adding the weight of trailer aerodynamics will typically displace hundreds of pounds of payload per trip and thus cause additional trips to be made to deliver the same amount of product. This not only negates the fuel savings of the trailer aerodynamic device, but also adds to traffic congestion and increases carbon emissions for all vehicles on the road. [EPA-HQ-OAR-2014-0827-1183-A1 p.14]

Response:

The agencies evaluated the effect of additional aerodynamic device weight on CO\(_2\) emissions using our GEM vehicle simulation tool. For both short and long box vans in the model, the additional weight of
aerodynamic devices was found to increase the gCO₂/ton-mile results by less than 1 percent. See our memo to the docket for more information on these calculations.150

Additionally, the potential positive implications of weight reduction efforts could partially or fully offset concerns from added weight of aerodynamic devices, including fuel use, GHG emissions, and safety. We discuss this issue, including NHTSA’s associated safety analysis in our response to the Utility comment regarding the “cost-benefit calculation” below.

**Organization:** Utility Trailer Manufacturing Company

Requiring the trailer industry to affix trailer skirts and tails to all trailers in the hopes of achieving questionable aerodynamic efficiencies is not a wise policy choice. The Agencies have not done a satisfactory job of determining the savings that will result from the aerodynamic-device requirements. What is known is that the projected efficiencies depend on assumptions that are demonstrably unrealistic, and that when real-world data is used to perform the efficiency calculations, the projected efficiencies – even in an ideal environment – drop dramatically. Additionally, the savings even then are overstated because they do not account for the net decrease in emissions, ignoring emissions caused in manufacturing and transporting the devices, in replacing the devices, and in the added weight affixed to the trailers. The better option is to allow the industry to continue its practice of voluntarily adopting these technologies in those uses where it makes sense to do so. This is a proven approach. Accordingly, Utility Trailer requests that the aerodynamic device requirement be removed from the proposed EPA Phase 2 Rule. In other words, the term “C3*(ΔCDA)” should be removed from the equation, and the maximum “eCO2” grams per ton-mile should be adjusted downward to compensate equivalently. [EPA-HQ-OAR-2014-0827-1183-A1 p.14-15]

**Response:**

The agencies are not requiring trailer manufacturers to install any particular device to their trailers (with the exception of the design standards for non-box and non-aero trailers). The standards for box vans are performance standards, and manufacturers can choose to install any combination of aerodynamic, tire, and weight-reduction technologies, or make changes to the trailer design to achieve the desired performance. Trailer manufacturers can evaluate and choose which devices to offer to their customers and install on their trailers. Our primary box van standards are based on adoption of aerodynamic technologies, and we are finalizing a program that includes these technologies as a compliance option for box van manufacturers. However, a manufacturer can offset reduced aerodynamic performance by incorporating a significant weight reduction. Manufacturers can also fine-tune their trailer designs to improve their aerodynamic properties without the addition of bolt-on technologies. Additionally, manufacturers have the option to use our off-cycle provisions that can account for innovative technologies or strategies that cannot be captured adequately by our GEM-based compliance equation.

The per-vehicle reductions based on the performance standards (ranging from 3% to 9% for the different trailer subcategories) are representative of performance under specific conditions that we established to reasonably compare different trailers and technologies from multiple manufacturers. The individual performance of each trailer in a given subcategory will differ based on their use, and we do not claim that every trailer in the real world will achieve the reductions suggested by their performance in testing.

---

Our own testing demonstrated the potential improvements with use of these technologies for both long and short trailers. While the testing was performed at high-speed conditions, our analysis in Chapter 2.10.2.1.1 of the RIA indicates that some improvements are seen at much lower speeds. Since most trailers spend at least some of their time at speeds of 55-mph or greater, they can experience even greater emission and fuel consumption reductions during that time.

The agency responded to Utility’s comment about “manufacturing and transporting” emissions the agencies’ analytical assumptions with a sample upstream emissions calculation on page 970.

**Organization:** Utility Trailer Manufacturing Company

**The cost-benefit calculation is flawed because it fails to give safety adequate consideration and weight.**

The aerodynamic devices specified by the EPA are relative newcomers to the market. Manufactured of plastic, fiberglass, and light metal, they are easily damaged as the trailers travel over the road and railroad crossings, or – in the case of trailer tails – as drivers routinely back into docks, fences, and other trailers. Some number of these devices will become detached in over-the-road operations, resulting in some number of increased accidents. [EPA-HQ-OAR-2014-0827-1183-A1 p.17]

The additional technologies are also likely to increase accidents and the injuries and fatalities associated with them. As noted previously, adding the aerodynamic technologies to trailers that otherwise would run at full permitted weight will mean that cargo equal to the weight of the devices will have to be transported on additional trips. There is a correlation – some would say direct – between miles driven and accidents/injuries/fatalities. The Agencies have not accounted for this important societal cost in performing their cost-benefit analysis. [EPA-HQ-OAR-2014-0827-1183-A1 p.17]

Finally, the effect of implementing a combination of technologies on a large scale is not yet sufficiently evaluated to be certain that there will not be unintended consequences. Other than its own side skirt, Utility Trailer does not know of any other aerodynamic device that has been certified to meet or exceed relevant DOT regulations. For example, some vendors market devices to cover the ends of axles, claiming they will reduce drag. But covering the wheel end may reduce airflow, causing the components to run hotter. Before installing such devices, a prudent manufacturer would require approval from the axle supplier, the bearing supplier, the hub supplier, the oil-seal and hubcap supplier, the lubricant supplier, the brake supplier, the wheel supplier, and the tire supplier. [EPA-HQ-OAR-2014-0827-1183-A1 p.17-18]

**Response:**

We emphasize that the agencies do not require trailer manufacturers to install any specific technologies to meet the standards (with the exception of design standards for non-aero box vans and non-box trailers, for which specific tire technologies are required). The performance standards for most box vans are designed to be met with a variety of technologies. Trailer manufacturers can evaluate and choose which devices to offer to their customers and install on their trailers.

Regarding the comment about potential accidents from debris from damaged aerodynamic devices, we refer to this excerpt from a recent DOT study:

*Damage from road debris, or detachment of aerodynamic skirts and tails in normal vehicle operation are a potential safety issue for aerodynamic features, particularly for underbody devices. However, no*
reported incidents of aerodynamic component detachment or structural failure while en route could be found in the literature. Trailer skirt developers have prioritized the design of components that are resilient against road damage. Various aerodynamic skirts have been in continuous use on MD/HDVs in European and certain Asian countries for over two decades, where regulatory and economic factors promote both fuel efficiency and the provision of vulnerable road user (VRU) underride protection. Newer skirts are typically constructed of fiber-reinforced plastic and appear to resist damage when repeatedly impacted by curbs, loading dock ramps, railroad crossings, and snow. Some designs have full-flex struts that allow them to bend up to 90 degrees rather than snap, as in older monolithic designs, and they weight as little as 190 pounds.. (Excerpt from “Review and Analysis of Potential Safety Impacts of and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles,” U.S. DOT, June 2015. DOT HS 812 159).

This study’s conclusions are reinforced by anecdotal experience with these technologies. The primary technologies that the agencies expect manufacturers to use for compliance, especially in the early years of the program, are trailer skirts, LRR tires, and tire pressure systems. All of these technologies, although far from universal, have significant in-use experience, often in combination with each other. As with the DOT investigators, the agencies are aware of no large-scale concern in the industry about unintended consequences of the use of these technologies. We expect that with the implementation of the trailer program and its durability requirements, such concerns will generally be addressed as manufacturers and suppliers respond to the new program in their new technologies and designs.

Regarding Utility’s comments about unintended consequences, we leave it to manufacturers to determine what appropriate approvals need to be obtained before accepting a technology to install on its trailers. EPA is adopting durability requirements for all CO_2- and fuel consumption-reducing technologies applied to meet the rules, and technologies that fail to remain durable are subject to our recall provisions in 40 CFR 1068 Subpart F. We also note that to the extent that manufacturers install devices using pre-approved data submitted by device manufacturers, these device manufacturers are subject to the same recall provisions as vehicle manufacturers. NHTSA evaluated the potential safety impact suggested by TTMA and noted by Utility. NHTSA recognizes that regulatory and market factors that result in changes in trailer weight can potentially have safety ramifications, both positive and negative, as discussed in response to the similar TTMA comment on page 1019.

Organization:  Wabash National Corporation

The Final Rule Should Be Consistent with Overlapping Government Policies to Promote Technological Advancements and Innovation in the Trailer Manufacturing Industry

EPA should work with other agencies to ensure that its trailer regulations harmonize with other requirements being applied to trailers and trailer manufacturers. At least five such opportunities for complementary policies and regulations currently exist, with respect to: (1) NHTSA RIG, (2) twin 33s, (3) the federal excise tax (“FET”), (4) weight exemptions for aerodynamic devices, and (5) harmonized rules with CARB. [EPA-HQ-OAR-2014-0827-1242-A2 p.20]

- NHTSA continues to analyze the cost-benefit and feasibility of new RIG standards and installation of side crash underride guards. The ability to integrate these side guards with aerodynamic skirt devices is unknown, but at a minimum, both types of devices would add significant weight to trailers and potentially could interfere with the performance of the other.
- Allowing twin 33-foot trailers would improve freight efficiency, and freight efficiency is a prime way to improve fuel efficiency. With fewer trucks on the road, GHG emissions are reduced.
• Installation of aerodynamic devices adds to the overall cost of a new trailer, which is subject to the FET. Exemption of aerodynamic devices from the FET, similar to the exemption provided for auxiliary power units, would incentivize their installation.

• Similarly, providing a weight exemption for aerodynamic devices would incentivize their installation by removing the inherent conflict between payload capacity and trailer devices imposed by regulatory weight constraints.

• To reduce compliance complexity, the agencies should ensure that there is a nationally harmonized 50-state program for trailers. Any federal requirements should be aligned and harmonized with existing and potential future CARB regulations. In Phase 1 of this rule, the agencies recognized the importance of cooperating with CARB and stakeholders to craft a consistent set of rules in the HD National Program. Wabash has significant concerns that the Phase 2 Proposal contains little, if any, discussion of the importance of national standards for trailer manufacturers. As EPA acknowledges, this is the first rule regulating trailer manufacturers under Title II of the Clean Air Act. Harmonized and consistent national standards are even more important to Wabash and other trailer manufacturers. [EPA-HQ-OAR-2014-0827-1242-A2 p.20]

Whenever possible, EPA should proactively engage with other agencies imposing requirements on trailers to align those requirements and ensure a cost-effective and smooth glide path to regulation under Title II of the Clean Air Act. [EPA-HQ-OAR-2014-0827-1242-A2 p.20]

Response:

The agencies recognize the interrelatedness of this regulation to other federal regulations. As noted in our response to ATA previously on page 960, the subject of a possible side guard requirement from NHTSA is in a research stage. We cannot predict how the performance of future aerodynamic devices may be impacted if such requirements were in place, though we do expect both trailer and device manufacturers will be mindful of the performance of both features in their future designs.

Size and weight restrictions for tractor-trailers are under the jurisdiction of the Federal Highway Administration (FHWA), and are largely controlled by the weight limits established by congress in 1956 and 1974, the size limits established in the Surface Transportation Assistance Act (STAA) of 1982, and the size and weight limits established in the Intermodal Surface Transportation Efficiency Act of 1991. Changes to these restrictions would require a broader process involving Congress and federal and state agencies, and is beyond the scope of the Phase 2 trailer program. Similarly, Federal Excise Taxes are managed by the Internal Revenue Service (IRS) and beyond the scope this program. The comment does not suggest that our regulations conflict with current size, weight or safety requirements in other agencies; simply that these suggestions would complement our Phase 2 rulemaking.

The agencies designed the Phase 2 GHG and fuel efficiency rules to be a national program: identical standards and compliance mechanisms at the federal level. The agencies consulted with CARB prior to the NPRM and we are adopting the set of standards that we believe are the maximum feasible and appropriate under the EPA’s and NHTSA’s respective authorities, considering lead time, cost, and other factors, such as small business considerations. California has adopted the Phase 1 program, and the agencies hope that the same will be true for these maximum feasible and appropriate Phase 2 standards.

Organization:  XL Specialized Trailers

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 205-206.]
The truck/trailer industry is a very innovative industry that embraces new technologies and standards that enhances the efficient operation of our equipment as well as leading to a safer product. Mandating the implementations of this type of regulation across the board creates a counter-productive environment that leads to subpar products that end up costing consumers more and not achieving the goals set out by the regulatory agencies.

Response:

The trailer program was designed with standards tailored to specific trailer types. The agencies proposed and are adopting performance standards for box vans and do not require the use of specific technologies. Instead, manufacturers can decide which combinations of aerodynamic, tire, and weight reduction technologies to apply. To limit the compliance burden for non-box trailers, we proposed design standards requiring use of lower resistance (LRR) tires and automatic tire inflation systems (ATIS). The final trailer program further reduces that burden by limiting the regulated non-box trailers to tanks, flatbeds and container chassis only, and basing the design standards on use of LRR tires and less expensive tire pressure monitoring systems (TPMS). We believe a majority of the trailers that would find limited benefits from this these technologies are among the excluded trailer types.

5.2 Trailer Designs Covered By This Proposed Rule

Organization: STEMCO

STEMCO recommends equal treatment under the regulation for long van roll-door trailers. We believe the fuel savings and emissions reductions can be significant given the number of medium and long haul trailers in this category, and including them creates an incentive for innovation. [EPA-HQ-OAR-2014-0827-1259-A1 p.2]

Response:

The agencies recognize there may currently be limited availability of rear aerodynamic technologies for roll-up door trailers, yet, as the commenter suggests, we also understand that innovations and improvements continue for all trailer aerodynamic technologies. For this reason, the final trailer program includes an interim provision – through MY 2023 – for box vans with roll-up doors to qualify for non-aero and partial-aero standards (as defined immediately below), by treating such doors as work-performing devices equivalent to rear lift gates. For MY 2024 and later, roll-up doors will not qualify as a work-performing device in this way; however, we expect that manufacturers of trailers with roll-up doors will comply with the 2024 and later MY standards using combinations of new rear aerodynamic technologies, in conjunction with improved trailer side and gap-reducing technologies as appropriate.

Organization: Union of Concerned Scientists (UCS)

SHORT VAN TRAILERS

Short, “pup” van trailers are utilized in a significantly different manner than long van trailer, often in tandem. This means that for 28’ trailers, they may fall either fall in lead directly behind the tractor or at the end. Thus, reducing aerodynamic drag for short van trailers is more complex and devices must therefore not only be effective in either position but deployable. [EPA-HQ-OAR-2014-0827-1329-A2 p.17]
The agencies’ definition of “short” trailers extends beyond pups to include trailers up to 48’ in length. While California’s trailer regulations are applicable to 53’ and longer van trailers, the aerodynamic technology being moved to market today for long van trailers is applicable to trailers of shorter length, and we recommend that the agencies’ definition of a “short” trailer be restricted to only those most likely to be utilized in a tandem configuration. Therefore, we recommend that the agencies shift the cut-off length between a long and short van trailer from 52’ down to at least 47’. [EPA-HQ-OAR-2014-0827-1329-A2 p.17]

Response:

The agencies agree that 48-foot vans are aerodynamically similar to longer vans and that 28-foot trailers are often used in tandem, reducing the opportunity for rear aerodynamic features. However, the agencies believe that the use of 48-foot vans is more similar to that of shorter trailers than to that of the long-haul vans that make up most the long box subcategory. Trailer manufacturers have indicated that 48-foot vans are mostly used in short-haul operations (e.g., local food service delivery) and consequently they travel less frequently at speeds at which aerodynamic technologies can be most beneficial. Also, 48-foot vans make up a relatively small fraction of box vans. The agencies thus do not believe that standards predicated on the use of more effective aerodynamic technologies on 48-foot vans will provide a substantial enough additional reduction in CO\textsubscript{2} emissions and fuel consumption to justify more stringent standards for those trailers. For these reasons, the agencies are maintaining the proposed 50-foot demarcation between long and short box vans and are basing the standards for each van size category accordingly. Please see our memo to the docket with our complete analysis of the 50-foot demarcation.

5.3 Proposed Trailer Standards for CO\textsubscript{2} and Fuel Consumption

Organization: American Trucking Associations (ATA)

In-Use Trailers Should be Used in Establishing Compliance Baseline The trailer efficiency improvements use a baseline 2017 SmartWay trailer. In-use trailers at the time would be a more representative baseline figure. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

Response:

The agencies used the available data to project a baseline trailer for evaluating trailer improvements. We did not use a “baseline 2017 SmartWay trailer”, but did refer to our baseline by the bin in which we expected SmartWay-verified technologies to fall. In a letter from TTMA, the association stated that, as of 2014, 35% of their members’ 53-foot van sales included skirts. We assume these skirts performed similarly and would fall into our final trailer aerodynamic Bin III. Our long box van baselines for the final standards assume skirt adoption will rise to 40% by 2018, with an additional 5% in Bin IV. TTMA also noted that under 2% of their members’ short trailers included skirts and we project that there will be a modest increase by 2018 so that the value adopted in our (2018) baseline is 5% for trailers less than 50-feet in length. See also RIA chapter 2.10.3.2.

Because the agencies cannot be certain about future trends, we also considered a second baseline. This “dynamic baseline” reflects the possibility that, absent a Phase 2 regulation, there would be continuing

adoption of aerodynamic technologies in the long box trailer market after 2018 that reduce fuel consumption and CO₂ emissions. This case assumes the research funded and conducted by the federal government, industry, academia and other organizations would, after 2018, result in the adoption of additional aerodynamic technologies beyond the levels required to comply with existing regulatory and voluntary programs. In this second baseline, adoption of trailer side skirts on long box vans increases beyond 2018 at a rate of 5% every three years, until the adoption rates of the technologies reach 75% of long box vans in MY 2040. See Section IV.D.2.b of the Preamble for a description of our baselines. As noted in that section, the dynamic baseline mainly impacts long-term, overall Phase 2 program projections of benefits beyond MY 2027. When calculating the relative CO₂ reduction due to our trailer standards in this program, we use the flat baseline. However, the reduction values are relatively insensitive to the choice of trailer baseline throughout the timeframe of the rules. The 35% difference in skirt adoption between flat and dynamic baselines in MY 2040 results in just a 1 gCO₂/ton-mile difference in emissions for long dry vans and long refrigerated vans.

**Organization:** Bay Area Air Quality Management District (BAAQMD)

The proposed EPA/DOT Phase 2 rule-making can help us pursue both our air quality and GHG emission reduction goals. To ensure the maximum benefits are achieved from this joint-rule-making effort, we would like to offer the following suggestions.

Collaborate with the ARB to set uniform truck/trailer standards that would apply throughout the nation’s truck fleet. [EPA-HQ-OAR-2014-0827-1136-A1 p. 2]

**Response:**

The agencies consulted with ARB prior to the NPRM and considered ARB comment on the NPRM. We are adopting the set of standards that we believe are the maximum feasible and appropriate under the agencies’ respective authorities, considering lead time, cost, and other factors, such as small business impact considerations.

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Stringency of trailer standard, alternative 4 recommended**

The NPRM also requests comments on whether Alternative 3 or Alternative 4 should be the preferred alternative. Both alternatives provide a gradual increase in the adoption rates of aerodynamic technologies, leading to the same final stringency, except that Alternative 4 arrives at the final stringency three years earlier. The main difference in the implementation of the two alternatives is the second phase of standards, which occurs during the 2021 MY. Under Alternative 4, the adoption rates specified in Alternative 3’s second phase is skipped so that Alternative 3’s 2024 standards take effect in 2021, and Alternative 3’s 2027 standards take effect in 2024. [EPA-HQ-OAR-2014-0827-1265-A1 p.72]

Since most of the requirements for trailer aerodynamic equipment can be met with technology that is already available, the difference in cost from accelerating the adoption of these technologies by three years would be low. Table I-11 in the NPRM provides the costs of the technology needed on a baseline trailer to comply with the Phase 2 regulation, under Alternatives 3 and 4 and is provided here for reference. [EPA-HQ-OAR-2014-0827-1265-A1 p.72]
As indicated in the table, the added cost per trailer to meet Alternative 3 MY 2024 standards is $1010 (2012 dollars); whereas the cost to meet the Alternative 4 MY 2021 standards (the equivalent of the MY 2024 Alternative 3 standards) is $1080 (2012 dollars), a difference of $70, or 6.9 percent. Similarly, the difference in cost to meet the final stringency requirements of the two alternatives is $60, or 5.1 percent. [EPA-HQ-OAR-2014-0827-1265-A1 p.72]

The differences in compliance cost should then be viewed in terms of their effect on the payback period, since the adoption of Alternative 4 requires more aerodynamic trailers sooner, leading to greater fuel savings earlier. The NPRM provides the results of analyzing the payback periods of the two alternatives, and have determined that choosing Alternative 4 over Alternative 3 results in negligible impacts on the payback periods, with both alternatives having payback periods of 2 years, as shown below in the NPRM’s Table I-12. [EPA-HQ-OAR-2014-0827-1265-A1 p.73]

While Tables I-11 and I-12 show that there is a negligible impact on the economics of fleets that operate trailers, it is also important to compare the impacts of the two alternatives in terms of the overall costs and benefits of the regulation as well. Table X1 and X-3 in the NPRM provide a comparison of the net costs and benefits of the two alternatives for the tractor-trailer vehicle as a whole, in which trailer benefits play a major part. Under both the 3 percent discount rate and the 7 percent discount rate assumptions, Alternative 4 provides a greater net benefit, after subtracting out the costs, over the 2018 to 2029 timeframe. [EPA-HQ-OAR-2014-0827-1265-A1 p.73]

Upon examining the cost-benefit analysis provided in the NPRM and differences in stringency between the two alternatives, and drawing upon CARB’s experience in implementing its Tractor Trailer GHG Regulation, CARB staff recommends Alternative 4. Under Alternative 4, by 2021, 65 percent of long box van trailers (defined in the NPRM as those over 50 feet) would employ Bin V aerodynamic technology, which is equivalent to SmartWay Elite levels, which became effective in 2014. CARB staff believes it is reasonable to assume 65 percent penetration of such technology by 2021, which will be five years after the adoption of the proposed Phase 2 regulation and seven years after SmartWay Elite levels became effective. In addition to recommending Alternative 4, CARB staff also recommends two modifications to the stringency levels. First, given that Bins I through VII can all be attained using existing technology, CARB staff believes that the final phase of standards should incorporate some adoption of Bin VIII, which represents as yet undeveloped technology. Having seen how quickly aerodynamic technology has evolved since the SmartWay's launch in 2004, CARB staff believes that these technologies will continue to evolve at a rapid pace for the next nine years, when the final phase of standards in Alternative 4 takes effect. As such, CARB staff recommends that the stringencies of Alternative 4 for long box dry van trailers should be modified to include some adoption of Bin VIII technology trailers, such as 10 percent Bin V, 45 percent Bin VI, 40 percent Bin VII, and 5 percent Bin VIII, by 2024. Using the compliance equation given in the proposed 40 CFR 1037.515 in the redline version of the regulation, this modification reduces the final standard by a further 0.24 grams of CO₂ per ton-mile. CARB staff believes that it is important to include at least a nominal adoption rate of Bin VIII technologies in order to move beyond off-the-shelf technology and push for further development of aerodynamic technologies. In the event that such technology is still unavailable by the 2024 MY, the 5 percent adoption rate is low enough such that manufacturers would still be able to meet the stringency...
Another recommended modification relates to the final stringencies of long box refrigerated van trailers. From the RIA, the trailer-to-tractor ratio of refrigerated vans (2:1) is lower than that of dry vans (3:1), which means that a refrigerated van trailer is typically used on the road more than dry van trailers. Because of the higher use experienced by refrigerated van trailers, investments in aerodynamic equipment for refrigerated trailers can generate faster, and larger, returns on investment. In addition, because of the higher base cost of a refrigerated trailer (roughly twice as much as a dry van trailer\(^{34}\)), the incremental cost of the required aerodynamic equipment would be a much smaller percentage of the base cost of a refrigerated van trailer than it would be for a dry van trailer. For these reasons, CARB staff believes that the final stringency level (applicable to MY 2024 under Alternative 4) of long box refrigerated van trailers should be adjusted so that the combined adoption of Bins VI and VII should match or exceed that of long box dry van trailers. For example, the Alternative 4 MY 2024 long box refrigerated van trailer adoption rates should be as follows: 10 percent Bin V, 60 percent Bin VI, and 30 percent Bin VII. Using the compliance equation from the proposed 40 CFR 1037.515 in the redline version of the regulation, this modification reduces the final standard by a further 0.41 grams of CO\(_2\) per ton-mile. [EPA-HQ-OAR-2014-0827-1265-A1 p.74-75]

**Response:**

In determining “maximum feasible” and “appropriate” under the agencies’ respective authorities, we must consider more than just the cost and availability of technologies that could be used to meet the standards. We must also consider lead time, cost of compliance, and may consider factors such as disproportionate impacts on small businesses. We do not believe the accelerated timeline of Alternative 4 provides sufficient lead time for all manufacturers to test, evaluate, market and adopt today’s most advanced technologies by MY 2024. While Alternative 5 does provide an additional three years to adopt more advanced technologies, the proposed stringency of that alternative would require nearly 100% adoption of technologies with performance the agencies did not observe in testing. These factors alone justify not adopting this alternative. Additionally, Alternative 5 would include aerodynamic improvements for some non-box trailers, but we expect these relatively new and untried technologies would result in relatively little emission and fuel consumption benefit at relatively high cost. Furthermore, non-box trailers are predominately manufactured by small businesses. We believe these small businesses would be unable to compete with the few large manufacturers to meet those standards, which could result in significant economic impacts for these companies. See our response to UCS on page 1026 for a more complete explanation of our decision to adopt design standards for non-box trailers.

We are adopting a set of trailer standards based on the implementation schedule of Alternative 3. The agencies adjusted their baseline adoption rates, and made several changes to our projected adoption rates that made the standards more stringent than those proposed for certain of the trailer subcategories, and thus address some of the issues raised in this comment. The standards for all box vans are now based on nearly 100% adoption of SW-level tires in MY 2018, and CRR of 4.7 kg/ton in MY 2021 (at proposal, the MY 2024 standard was predicated on these penetration rates). Additionally, the full-aero van program is predicated on greater adoption than at proposal of advanced aerodynamics in the MY 2027 standard.
The proposed aerodynamic bins were adjusted to account for wind-averaging and additional test data obtained since the NPRM. A majority of the combinations of skirts and tail or skirts, tails and gap reducer, including several technologies that are designated “SmartWay-Elite,” were found to fall within the new Bin V. The agencies observed one device combination that presently meets Bin VI, suggesting that this bin can be met with combinations of existing aerodynamic technologies. However, no technology combinations tested met our new Bin VII. Our MY 2027 standards for full-aero long vans are based on significant but not universal adoption of technologies in our new performance Bin VI; full-aero short van standards for MY 2027 are based on some adoption of Bin IV-type technologies. These two bins represent future, optimized combinations of aerodynamic technologies for these lengths. Trailer and device manufacturers continue to develop more effective individual aerodynamic technologies, and combinations of technologies, which is a trend that we expect to continue as the requirements of the trailer program are implemented. By the 2027 time frame, we expect that there is ample lead time for existing commercial long van and short van technologies and technology combinations to be optimized such that they can meet Bin VI and Bin IV performance levels respectively, and that these technologies will be broadly, but probably not universally, used. See Chapter 2.10.2.1.3 of the RIA.

Thus, in response to the commenter’s suggestion that the agencies adopt the proposed Alternative 4 standards, the agencies note that features of the proposal that we think are possible are in fact reflected in the final standards. While we believe the standards can largely be met by optimizing use of existing aerodynamic technologies, the optimization process will require greater lead time. As trailer and device designers approach the higher technologically feasible levels of aerodynamic performance, the engineering challenges of developing devices that individually and synergistically perform at these levels becomes greater. Technology costs may not be extreme, but we do not see cost as the key concern during this process. While we are optimistic that these performance levels will in time be achieved on a broad commercial basis, we are not prepared to assume that this can happen before MY 2027. Further, the advent of commercial technologies capable of exceeding these performance levels similar to the more stringent standards of the proposed Alternative 5 is even more uncertain and would require advances that may well not be technologically achievable, even with fundamental changes to the industry. On the basis of what we know today, the agencies are unable to show a pathway for the industry to achieve such additional improvements in the time frame of this program, at least without the potential for major disruptions to the industry due to requiring, for example, fundamental changes to trailer design and construction, or impractical levels of tractor-trailer integration.

Based on our analyses and as informed by the comments, we believe that the final standards in the program, slightly revised from the proposed Alternative 3 standards, are appropriate and represent the maximum feasible standards.

In response to the comment about refrigerated long box vans, we have reassessed the relative stringencies of the dry and refrigerated van categories. Our test results show that gap reducers have a relatively small impact on aerodynamic performance, and several technology combinations that did not include a gap reducer were able to achieve our higher aerodynamic bins. The proposed MY 2027 standards for dry vans were predicated on the use of gap reducers, but refrigerated vans are unable to use gap reducers due to the TRU. We are confident that sufficient technology combinations exist that could meet our dry van stringencies without the use of a gap reducer. Consequently, our final refrigerated van standards in MY 2027 are predicated on stringencies that match the dry van stringencies. Note that the numerical standards for dry and refrigerated vans only differ due to the difference in default vehicle weight within GEM, which is reflected in the GEM-based compliance equation for trailers.
**Organization:** Environmental Defense Fund (EDF)

**EDF supports the inclusion of standards for trailers**

EDF fully supports the agencies proposal to establish standards for trailers. Trailers are the primary vehicles for moving freight in the U.S.\(^70\) In 2010, there were nearly 5.8 million commercial trailers registered in the U.S.,\(^71\) and production of trailers by the top 25 manufacturers was up 9.4 percent in 2012, over the year before.\(^72\) Trailers impact the fuel efficiency of trucks through aerodynamic drag, tire rolling resistance and additional weight. Trailer efficiency measures would garner much-needed additional GHG and fuel consumption reductions in the tractor-trailer fleet by promoting the development and deployment of new trailer technologies. Such measures would also address market barriers like split incentives and consumers’ lack of confidence in technology performance. The technologies needed to make significant efficiency improvements are incredibly cost-effective, well-tested and on trailers today. We request that the agencies finalize robust standards for all trailers that reflect the leading efficiency technology for each trailer type. See Section VI below for specific recommendations on strengthening the trailer program. [EPA-HQ-OAR-2014-0827-1312-A1 p.15-16]

**Trailer standards can be strengthened and achieved earlier**

Trailers used with Class 7 and 8 tractors contribute significantly to the heavy-duty vehicle sector’s total CO\(_2\) emissions and fuel consumption. We commend the Agencies for following through on their commitment in the Phase 1 rule to address trailers and proposing the first ever trailer standards. We support the Agencies’ proposed framework, which will provide important GHG reductions. [EPA-HQ-OAR-2014-0827-1312-A1 p.35]

We also encourage the Agencies to strengthen the standards by accelerating the compliance timelines and encouraging technology innovation. The proposed standards are based on off-the-shelf technologies that are in use on trailers today. In fact, there is already a significant market demand for these technologies in part because of California’s existing trailer regulations, the SmartWay voluntary program and because of the very short payback periods for all of the trailer technologies being considered.\(^155\) Consequently, we believe the trailer program could be improved by accelerating the implementation schedule and requiring the broader deployment of more advanced aerodynamics and tire technologies. The Agencies themselves indicated in the Preamble that Alternative 4, which accelerates the program to 2024, “has the potential to be the maximum feasible alternative within the meaning of section 32902(k) of EISA, and appropriate under EPA’s CAA authority.” Additionally, Alternative 5 indicates that there are other efficiency technologies the Agencies could include and additional types of trailers the program could be applied to. We encourage the Agencies to consider the stringency levels in Alternative 5 applied to the timeline suggested in Alternative 4. [EPA-HQ-OAR-2014-0827-1312-A1 p.35-36]

---

Response:

See our previous response to CARB on page 980, which includes our justification for adopting standards based on Alternative 3. Also, in response to the comment about the effect of the existing California program, the SmartWay program, and favorable payback, we have accounted for all of these factors in our estimates of technology adoption and effectiveness in our reassessment for the final program, based on information we have developed and drawn from the comments. (Chapter 2.10 of the RIA). The commenter correctly points to important drivers of future technological improvement in the early stages of the program. However, consistent with our latest aerodynamic test results, reaching the higher performance levels for the later years will be very challenging for the industry and will require time. This is the key factor limiting the time frame and the degree of aerodynamic performance that is appropriate and feasible in the later years of the program’s phase-in.

Organization:  Great Dane

We appreciate the agencies’ study of multiple alternatives as detailed in the NPRM and believe that for many reasons a regulatory approach with a more aggressive adoption of stringencies than the proposed approach (Alternative 3) increases the probability of negative effects on stakeholders considerably. Thus we suggest that the agencies consider devising an incentive based approach that could benefit all stakeholders to augment the proposed approach and assist in the deployment and adoption of advanced technologies as opposed to adoption of the more stringent Alternative 4 being considered. [EPA-HQ-OAR-2014-0827-1219-A1 p.4]

Response:

The agencies are adopting a set of trailer standards based on the implementation schedule of Alternative 3, and have concluded that the significant emission and fuel consumption reduction of the final trailer program based on Alternative 3 are appropriate. We do offer an off-cycle testing option for manufacturers to evaluate innovative strategies for meeting the standards. Trailer configurations that exceed the standards will not receive credit in the early years of the program, but these trailers can be used to off-set lower performing trailers if manufacturers opt to participate in averaging in the MY 2027 or later.

Organization:  International Council on Clean Transportation (ICCT)

*Trailers* – The trailer technologies upon which the stringency is determined embrace the already commercialized technologies that have been spurred by EPA’s SmartWay program and California’s in-use regulation. These technologies are already being adopted in increasing numbers by leading SmartWay Elite fleets and as part of the California regulation (Sharpe and Roeth, 2014). Asking trailer manufacturers and tractor fleets to move toward 2015’s leading technologies by 2024 provides sufficient lead time. [EPA-HQ-OAR-2014-0827-1180-A4 p.5] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.39.]}
Response:

See response to CARB earlier in this section on page 980. As we discuss in that response, we acknowledge that technology development is proceeding, but also recognize that the significant additional engineering and development and the widespread commercial adoption of technologies and technology combinations capable of meeting or exceeding the performance of the best available technologies today requires the degree of lead time that the final program provides.

Organization:  Natural Resources Defense Council (NRDC)

NRDC strongly supports the inclusion of trailer standards in the rule and urges the agencies to adjust the standards so that the proposed 2027 stringency is achieved by 2024. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

Set Standards for Trailers

NRDC strongly supports the agencies’ proposal to adopt CO\textsubscript{2} emission and fuel consumption standards for new trailers designed for use in combination tractor-trailer configurations. The agencies note that they “expect that the MY 2027 standards would be met with high-performing aerodynamic and tire technologies largely available in the marketplace today.” NRDC believes that the current availability of technology supports the proposal to start standards no later than 2018 (as proposed by EPA) and that the 2027 standards can be achieved by 2024. [EPA-HQ-OAR-2014-0827-1220-A1 p.6-7]

NRDC recognizes that the trailer industry is being regulated for the first time. However, the prospect of regulatory requirements on the industry is not new. In 2011, NRDC urged the agencies to adopt trailer requirements in Phase 1. Although the agencies declined to include trailer standards in the Phase 1 rule, the agencies amassed information and signaled a likely future standard stating that “[t]he agencies broadly solicited comments on controlling fuel efficiency and GHG emissions through eventual trailer regulations as we described in the notice of proposed rulemaking which could set the foundation of a future rulemaking for trailers.” [EPA-HQ-OAR-2014-0827-1220-A1 p.7]

While trailer manufacturers have not previously been under federal regulation for CO\textsubscript{2} and fuel consumption, the agencies note that the manufacturers are familiar with applying and proving the effectiveness of technologies. As justification for the program starting in 2018, the agencies note that “box trailer manufacturers have been gaining experience with CO\textsubscript{2} and fuel consumption-reducing technologies over the past several years, and the agencies expect that trend to continue, due in part to EPA’s SmartWay program and California’s Tractor-Trailer Greenhouse Gas Regulation.” The agencies appropriately expect that trailer manufacturers will be familiar with necessary technology and the regulatory process in time for 2018 compliance. The agencies also expect the standard levels proposed for 2027 could be met with existing technology. For these reasons, combined with the fact that standards will establish new certainty for investment in the trailer marketplace, NRDC believes that trailer manufacturers could cost-effectively meet the proposed 2027 stringency levels by 2024. [EPA-HQ-OAR-2014-0827-1220-A1 p.7]

Response:

See response to CARB and EDF comments earlier in this section, starting on page 980.
Organization: Rubber Manufacturers Association (RMA)

The Agencies Should Adjust the Tire Limit Values for Non-Aero Vans and Non-Box Trailers

The NPRM proposes the requirements of LRR tires on “non-box” and “non-aero vans” of RRc < 4.7 kg/t. Such trailers may instead use tires with RRc < 5.1 kg/t through MY 2023. The application of low rolling resistance trailer tires to “non-box” and “non-aero” trailers may present conflicts in the ultimate service and application of these and similar non-box trailers. [EPA-HQ-OAR-2014-0827-1304-A1 p.23]

Variable terrain use of such trailers often demand tread designs, e.g. deeper tread depths, tread rubber, sidewall scuffing resistance, use on different axle configurations, etc., such that typical highway-type low rolling resistance tires may not provide optimal service performance. [EPA-HQ-OAR-2014-0827-1304-A1 p.24]

Typical examples of tread depths for such non-box and non-aero trailer tires would be: [EPA-HQ-OAR-2014-0827-1304-A1 p.24]

- 14 – 18/32” for 15, 17.5, 19.5 rim diameters
- 16 – 22/32” for 22.5 and 24.5 rim diameters

Comparing to line haul trailer tire tread depths, typical examples would be: [EPA-HQ-OAR-2014-0827-1304-A1 p.24]

- 13 – 16/32” for 17.5, 19.5 rim diameter tires
- 11-13/32” for 22.5, 24.5 rim diameter tires

Mandatory use of the proposed 5.1 kg/t (current SmartWay™ verification threshold) and 4.7 kg/t will challenge the balance of performance in non-aero van and non-box trailer applications. Since tires for non-aero vans and non-box trailers are significantly different in construction and desired performance from trailer tires such as those verified by the SmartWay™ program, it is inappropriate to use the SmartWay™ target values as near-term limit values for these tire applications. [EPA-HQ-OAR-2014-0827-1304-A1 p.24]

i. The Proposed Lead Time is Insufficient to Redesign Tires to Meet the Proposed Tire Rolling Resistance Limit Values for Non-Aero and Non-Box Trailer Applications

By the time this regulation is final, 2018 trailers will be nearing production, and original equipment contracts may already be in place. There is simply not enough time to design and fully execute a product development program within a tire company with the intent of designing tires for non-aero vans or non-box trailers that would meet the proposed limit values. RMA requests that the Agencies adjust the limit values for tires for these two trailer subcategories to reflect actual tire rolling resistance performance in this tire market segment. [EPA-HQ-OAR-2014-0827-1304-A1 p.24]

Regarding lead time, the NPRM states that because “most manufacturers of long box trailers have some experience installing these [SmartWay] tire technologies for customers,” it is appropriate to truncate lead time for compliance with low rolling resistance requirements. This may be true of line haul-type applications, but it is not true of non-aero vans and non-box trailers. RMA challenges the assertion that
the MY 2018 CO2 emission standards “thus could be met by adopting off-the-shelf aerodynamic and
tire technologies available today” in the case of non-aero vans and non-box trailers, since SmartWay
verified tires are not appropriate for these trailers. [EPA-HQ-OAR-2014-0827-1304-A1 p.24-25]

RMA also challenges the assertion that “the technologies [manufacturers of trailers other than long
boxes] would need are fairly simple and can be incorporated into trailer production lines without
significant process changes.” While it is certainly true that for a trailer manufacturer, installing one tire
on a trailer is the same as installing another tire type, the technology required to redesign tires for non-
aero vans and non-box to meet the proposed targets is not similarly “fairly simple.” EPA should
consider not only “the burdens of installing and marketing” low rolling resistance technologies but also
the research and development, testing and commercialization costs associated with developing new tires
to meet the proposed requirements for non-aero vans and non-box trailers. The lead time analysis is
based on the faulty assumption that SmartWay-type tires are appropriate for all other types of trailers.

ii. RMA Data Collection and Analysis

RMA collected rolling resistance data from its member companies to assess the typical rolling resistance
of tires appropriate for installation on non-aero vans and non-box trailers. As seen in Figure 12 and
Figure 13 below, most of the tires studied do not meet the SmartWay™ threshold of 5.1, which is
identified as the limit values for 2018 and 2021, since these tire types are not within the scope of the
SmartWay™ program, which focuses on tires for line haul applications. This rolling resistance level
would be very challenging to meet for tires appropriate for non-aero vans or non-box trailers,
particularly since the first trailer model year of applicability is 2018, and would require the development

[Figure 12, 'Distribution of Rolling Resistance of Tires for Non-Aero Vans and Non-Box Trailers', can
be found on p.26 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

[Figure 13, 'Analysis of Rolling Resistance of Tires for Non-Aero Vans and Non-Box Trailers', can be
found on p.27 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

iii. RMA Proposal for Revised Tire RRc Limit Values for Non-Aero Vans and Non-Box Trailers

RMA has evaluated the data it collected to develop a proposal for a revised baseline and targets for non-
aero vans and non-box trailer tires. RMA assessed what percentage of current products are performing
at or below the 2017 baseline proposed in the NPRM and what percentage would meet the maximum
values for model years 2018, 2021, 2024 and 2027 (Figure 14). As is shown in Figure 14, only 55
percent of the products surveyed would achieve the 2017 baseline, while only 21 percent would achieve
the 2018 value. As discussed above, redesigning nearly 80 percent of products for non-aero vans and
non-box trailers in time for the 2018 model year simply is unrealistic, particularly given that these
products are not within the scope of the SmartWay verification program and in order to achieve
satisfactory performance require deeper and more aggressive tread to achieve satisfactory performance
compared to their Class 8 line haul counterparts. [EPA-HQ-OAR-2014-0827-1304-A1 p.27-28]

In Figure 14, RMA proposes an alternative 2017 baseline and model year targets for the Agencies’
consideration. This proposal balances incremental improvement with required technology changes and
considers the percent of products that would have to be redesigned to meet the maximum values for
each model year. [EPA-HQ-OAR-2014-0827-1304-A1 p.28]
For Non-Aero Vans and Non-Box Trailers, the Agencies Should Modify the Limit Values in order to assure that the maximum values reflect current technology and achievable improvements since SmartWay-type data collected by the Agencies may not be sufficient to characterize these tire segments. [EPA-HQ-OAR-2014-0827-1304-A1 p.35]

II. The Agencies Should Adjust the Limit Values and GEM Inputs for Non-Aero Vans and Non-Box Trailers

In its October 1, 2015 comments, RMA stated that mandatory use of the proposed 5.1 kg/t (current SmartWay® verification threshold) and 4.7 kg/t will challenge the balance of performance in non-aero van and non-box trailer applications. After review of the documents made available in the NODA, including the GEM P2v2.1 summary, RMA continues to support this view. Since tires for non-aero vans and non-box trailers are significantly different in construction and desired performance from trailer tires such as those verified by the SmartWay® program, it is inappropriate to use the SmartWay® target values as near--term limit values for these tire applications. [EPA-HQ-OAR-2014-0827-1933-A1 p.3-4]

RMA refers the agencies to its October 1, 2015 comments for a detailed discussion of these issues and data to support RMA’s views. [EPA-HQ-OAR-2014-0827-1933-A1 p.4]

Response:

We agree that many non-box trailers are used on “variable terrain” and that the SmartWay-based tire rolling resistance levels on which the proposed design standards for these trailers were based are appropriate for line-haul trailers, but may be ill-suited for off-road applications. The agencies made several revisions to our non-box trailer program based on these and similar comments. First, we are limiting the type of non-box trailers in the program to tank trailers, flatbed trailers, and container chassis. In general, these trailers are more likely to be used in on-road applications compared to many specialty non-box trailers. Limiting the regulated non-box trailers to this narrow range of trailer types reduces number of trailers that would need tires with large tread depths and high rolling resistances.

We appreciate the tire information the commenter shared with the agencies. While we know tread depth can be related to rolling resistance, the comment does did not include a correlation or indicate how the agencies should use the provided information to adjust our proposed values. We did, however, revise tire rolling resistance baselines for these three non-box trailers by increasing the rolling resistance by 0.5 kg/ton. Absent regulation, we project that the baseline rolling resistance of the regulated tank trailers, flatbed trailers and container chassis would be 6.5 kg/ton. The revised MY 2018 design standard for these non-box trailers now require use of tire pressure systems and LRR tires meeting a CRR of 6.0 kg/ton. Beginning in MY 2021, the non-box trailer design standards would be based on tire pressure systems and LRR tires with a CRR of 5.1 kg/ton, which is the current SmartWay threshold limit for box vans and met by 55% of the tires in Figure 14 of the comment. Non-box trailers standards no longer would require rolling resistances below 5.1 kg/ton, whereas the NPRM proposed these trailers be equipped with tires meeting a 4.7 kg/ton CRR.

Box vans may be designated “non-aero” vans if they have certain work-performing equipment installed. These work-performing equipment (e.g., lift gates) are expected to indicate urban, low-speed delivery and not “variable terrain.” While customers may not currently be requesting these tires on their local delivery trailers, the comment does not indicate a reasonable technological barrier to non-aero box vans.
adopting tires similar to those used on other box vans. Nor did the commenter provide information about why the development of tires for the non-aero subset of box vans would be different than for other box vans. Therefore, the agencies did not adjust the CRR level for non-aero box van design standards.

In response to the comment about tire development lead time, we agree with the commenter that manufacturers of non-box trailer tires intended primarily for off-road use may require longer to develop LRR tires for these applications. However, because our final trailer program excludes such trailers, lead time required to develop LRR tires for these trailers is not an issue for the program. According to the information provided in Figure 14 of the comment, 76% of the surveyed tires would achieve or exceed the MY 2018 non-box trailer rolling resistance, and 21% would achieve the MY 2021 rolling resistance, suggesting that the tires are available today and less lead time would be required to achieve similar levels of performance for the remaining tires.

We note that non-aero box vans and non-box trailers have design standards and do not use GEM. While the agencies did change the baseline tire rolling resistance and tire rolling resistance requirements for non-box trailer standards, there are no changes needed to the GEM vehicle simulation tool.

**Organization:**  Truck Trailer Manufacturers Association (TTMA)

Outside of regulating direct use, the agencies should continue voluntary implementation of technological advances. The trucking transportation industry has been and still is very interested in all aspects of fuel-saving technology, and has, through programs such as SmartWay, made great strides in fuel conservation. The driving force behind such implementations has been the financial bottom line of the motor carriers. Some of the innovations employed include increases to interior volume while maintaining exterior size, reduction in weight, decking systems for multi-layer cargo transportation; along with some of the technologies the EPA regulation is basing its reductions on, such as aerodynamic devices, low rolling resistance tires, and automatic tire inflation systems. These advances have been employed as the industry has seen and realized value supported by evidence. The current proposal for a regulation will indeed claim a difference which would likely have been accomplished through the voluntary adoption of systems proven as functional. An unintended side-effect will be the increased creation of CO₂ due to the additional fuel expended on those “regulated units” that do not operate in a manner which causes the added options to provide for a realized and effective performance.

**Response:**

See our response to Stoughton in Section 5.1 on page 965 related to a non-mandatory program. See also our response to Utility’s comments relating to “upstream” or manufacturing emissions on page 970 and our general response in Section 1.

According to ACT Research, only 30% of long dry vans in 2011 were equipped with side skirts and automatic tire inflation. Aerodynamic testing and modeling conducted by the agencies indicates that fuel consumption could be significantly reduced by greater adoption of aerodynamic and tire improving technologies in the dry and refrigerated van population. The same technologies can reduce fuel consumption in trailers that travel shorter distances and at slower average speeds than trailers on long haul cycles, as shown in RIA Chapter 2.10.2.1.1 and discussed in our response to Stoughton on page 965. Lack of information and other factors may be hindering greater adoption of the technologies by fleets. The regulation will address the slow uptake of the technologies by industry by promoting widespread adoption of aerodynamic and other technologies while creating a level playing field for regulated entities.

**Organization:**  Union of Concerned Scientists (UCS)
Trailer Standards

The inclusion of trailers in the Phase 2 regulations is an important step forward. California’s regulations as well as EPA’s SmartWay program have helped to significantly reduce fuel use through improvements to trailers as well as identify and incentivize further technology development. [EPA-HQ-OAR-2014-0827-1329-A2 p.16]

However, the agencies’ assumptions on aerodynamics underestimates the feasible reductions from trailers in this timeframe. We recommend that the agencies adopt the More Stringent Trailer Alternative out to 2024, with a stringency target in 2027 that will lead to approximately 1% additional benefit in fuel consumption. Furthermore, the agencies should identify opportunities to encourage innovation for improvements to non-box trailers as well as tractor and trailer integration. [EPA-HQ-OAR-2014-0827-1329-A2 p.16]

Response:

See response to CARB in this section on page 980. As discussed in that response, we do not believe that a more stringent program is feasible, and we do not agree that more emission and fuel consumption benefit is available through this program.

We did not propose, nor does the commenter specifically suggest, a regulatory mechanism that would encourage innovative improvements for non-box trailers or tractor-trailer integration in this program. In both of these cases, the agencies concluded that much more information would be needed to have proposed such technologies that are in their infancy, but we will continue to consider them as a part of potential future action.

Organization: Utility Trailer Manufacturing Company

The Proposed Rule’s warranty provisions are unworkable.

The Proposed Rule requires that all drag-reducing devices added to trailers be warranted for five years (one year for tires) to ensure that “these components and systems are designed to remain functional for the warranty period.” Putting aside any issues concerning the Agencies’ authority to prescribe warranties offered by manufacturers, the proposal is flawed. To the extent a warranty is provided, the warranty should be a pass-through warranty from the manufacturer of the device; the trailer manufacturer should not be required to offer a separate warranty, as it does not control the manufacture of many of those products. [EPA-HQ-OAR-2014-0827-1183-A1 p.23]

Utility Trailer also has the following specific warranty concerns:

Tires: some users will wear through tires in less than a year. This hazard is magnified by the anticipated overinflation problems associated with widespread adoption of automatic tire-inflation systems, as described previously. Tire wear and road-hazard damage must not be covered under any warranty. [EPA-HQ-OAR-2014-0827-1183-A1 p.23]

Skirts and trailer tails: As noted previously, these devices are damaged in routine operations. Manufacturers must have clear protections against turning normal wear and tear, collisions, or abuse into a warranty claim. [EPA-HQ-OAR-2014-0827-1183-A1 p.23]
Tire-inflation systems: A 5-year warranty is excessive. Utility Trailer is not aware of any system that has a baseline warranty of more than 3 years. The proposed warranty period for these devices should be reduced. [EPA-HQ-OAR-2014-0827-1183-A1 p.23]

Response:

Manufacturers of motor vehicle parts “may certify that use of such part will not result in a failure of the vehicle … to comply with emission standards.” CAA section 207 (a)(2). We are adopting an emission-related warranty period for trailers of five years for any technologies that may affect trailer CO₂ emissions, except for tires. For trailer tires, the rules specify a warranty period of one year. An emission-related warranty does not apply to components that are damaged in collisions or through abuse, nor does it cover components that experience wear with normal use. The emission-related warranty is meant to apply to defects in the product or to improper installation by the manufacturer. Trailer manufacturers are free to stipulate what is and is not covered under their 5-year emission-related warranties. A copy of a manufacturer’s emission-related warranty statement must be provided to EPA at the time of certification, and customers must have clear access to the terms of this warranty, the repair network, and the process for obtaining emission-related warranty service.

The agencies view the emission-related warranty period offered by many component manufacturers as a business decision, rather than as a reflection of the actual durability of the systems. With proper maintenance, which can include replacement of warn subcomponents, we are aware of no reason that these systems would be unable to meet the durability requirements of the trailer program. We believe these components should be designed to last the full useful life of the trailer if properly maintained and a five year emission-related warranty is justified. We do note that trailer manufacturers can specify that the emission-related warranty depends on the proper maintenance of components.

Organization: Utility Trailer Manufacturing Company

The Agencies should modify the Rule to encourage customers to voluntarily adopt the technologies, and to encourage manufacturers to continue to develop new technologies.

Customers will understandably be concerned about the effect of the required technologies on their operations and bottom line. The Agencies could ameliorate these concerns somewhat by adding provisions to the Proposed Rule that would encourage customers to accept the new requirements. For example, exempting the required devices from excise taxes attributed to those devices, or permitting weight limits on trailers to increase by the weight of the added devices would make the technologies more attractive to the customers and mitigate some of the additional costs imposed by the regulations in the form of additional trips due to displaced cargo. [EPA-HQ-OAR-2014-0827-1183-A1 p.23] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.219-220.]]

Additionally, the Agencies should consider modifying trailer width, length, and height limitations to accommodate required devices and to encourage new, more efficient aerodynamic configurations. For example, permitting trailer sidewalls and roof to expand in width and height, respectively, would allow potential future designs with rounding of the front and rear box-van corners in a more aerodynamic configuration. And measuring overall length at the allowed extreme width or height would permit manufacturers to consider rounding the front of the trailers without sacrificing capacity. [EPA-HQ-OAR-2014-0827-1183-A1 p.23-24]
Response:

Please see our response to Wabash in Section 5.1 on page 975 regarding exemptions for federal excise tax, and trailer size and weight. Such actions outside the authority of our agencies and are beyond the scope this program. The commenter does not suggest that our regulations conflict with current size, weight or safety requirements in other agencies, simply that these suggestions would complement our Phase 2 rulemaking.

Organization: Wabash National Corporation

Wabash Opposes Alternative #4

EPA is requesting comment on whether its Alternative #4, which would accelerate the 2027 standards to 2024, is more appropriate than its current proposal. Wabash has significant concerns regarding whether this accelerated timeline, with respect to the trailer industry, would be achievable with demonstrated technologies, whether such technologies would have demonstrated reliability, and what the associated costs would be. Wabash believes that such accelerated standards would not be feasible for every application. EPA might consider adopting Alternative #4 for some regulatory categories (e.g., engines), and not others (e.g., trailers). [EPA-HQ-OAR-2014-0827-1242-A2 p.19]

Response:

The agencies are adopting standards based on the implementation schedule of Alternative 3.

5.4 Projected Trailer Technologies, Effectiveness, and Cost

Organization: Aluminum Association

Trailer Floor Crossmembers

Table 3 in Section 1037.515 Weight Reduction for Trailers indicates that aluminum floor crossmembers achieve a 203 pound credit for the GEM calculations. The 2015 NACFE Lightweighting Confidence Study as well as aluminum industry data support that the best value for use in the weight credit for aluminum floor crossmembers is 250 pounds. In view of this differential, the Association asks that EPA revise the table to reflect 250 pounds. [EPA-HQ-OAR-2014-0827-1260-A1 p.5-6]

Wheel Lightweighting

Table 7 of 1035.520 Wheel-Related Weight Reductions (80 FR 40630) indicates that a dual wide aluminum wheel is eligible for a weight reduction credit of 21 pounds. Based on information previously submitted to EPA by the Aluminum Association, the Association notes that given current wheel manufacturing technology that the correct value for this credit is 25 pounds and requests that the entry in the table be changed accordingly. This can be seen in the difference between the Accuride 50408 22” x 8.5” steel wheel at 70 lbs and the Alcoa 88367 LvL ONE 22” x 8.5” aluminum wheel at 45 lbs (70 lbs – 45 lbs). The credit value of 30 lbs as noted for a lightweight aluminum wheel in the table remains correct based on the 40 lb weight of the Alcoa ULTRAx Ultra-ONE lightweight aluminum alloy wheel previously noted (70 lbs – 40 lbs). [EPA-HQ-OAR-2014-0827-1260-A1 p.6]

Also in Table 7, the heading of the right hand column is “Weight Reduction (lb per tire or wheel).” Because the table applies to both dual width and wide base wheels, this nomenclature is unclear.
Association suggests that the column heading remain “Weight Reduction” but that the units be specific to each row in the table indicating that for wide-base the weight reduction is “lbs per wheel/tire set” and for dual width that the weight reduction is “lbs per wheel.” This clarification is important because wide-base wheels have a corresponding additional weight reduction in the tire weight (one wide base tire weighs less than the sum of the two tires that it replaces on a dual width wheel set) in addition to the reductions in wheel weight. [EPA-HQ-OAR-2014-0827-1260-A1 p.6]

The Association also proposes changes to the Table 7 of 1037.520 as follows – Consolidate the categories of wide base ‘Aluminum Wheel’ and ‘Light-Weight Aluminum Alloy Wheel’ into a single category as there is no weight differentiator in wide base wheels similar to what there is in dual width wheel sets (between the Alcoa Lvl-ONE and Ultra-One, for example). Subsequently, based on calculations made by the Aluminum Association and its member companies, the weight credits for wide base drive wheel/tire sets should be 159 lbs and for wide base trailer wheel/tire sets should be 131 lbs. Corresponding changes should therefore be made to the table. Supporting calculations for these values are shown below. Recognize that the 159 lbs and 131 lbs are based on a wide base wheel/tire set which replaces two dual width wheel/tire sets. If these values were to be recognized in the GEM on a pre-replacement basis they would be input as half those amounts. [EPA-HQ-OAR-2014-0827-1260-A1 p.6-7]

[Tables of weight calculations can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1260-A1]

Response:

The agencies updated the weight reduction assigned to trailer crossmembers in our respective regulations to reflect these comments, which are persuasive. Also, we agree with the commenter’s assessment that aluminum and aluminum alloy wheels provide about the same weight reduction for wide-base tires, and we conservatively apply the same values to both of these wheel technologies for dual-wide tires as well.

The commenter provides specific values for trailer wheel weight reductions that are reasonable. The final Phase 2 program uses the Aluminum Association weight-reduction value for both aluminum and aluminum alloy wide-base single trailer wheels and tires (131 lb). We have also accepted the commenter’s weight-reduction value for aluminum dual-wide wheels and tires (25 lb), which has mentioned above, we apply to both aluminum and aluminum alloy dual-wide wheels, including trailer wheels. The aluminum and light-weight aluminum alloy wide-base single drive wheels for vocational and tractors were similarly combined into a single value for Phase 2. However, we are maintaining the more conservative Phase 1 light-weight aluminum alloy value of 147 lb per wheel instead of adopting the 159 lb per wheel value recommended in the comment. Manufacturers that wish to receive additional weight reduction have the option to use our off-cycle provisions to determine appropriate values for their specific applications.

The agencies agree with the commenter that it may be unclear that the units for the wide-base tire weight reduction includes the reduced weight of the wheel and the tire. We are changing the units to “(lb per wheel)” and adding a footnote to the table indicating that the wide-base reductions also include reduced tire weight.

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Van trailer aerodynamics
For 53’ van trailers, we find the proposed standards to be well within the technical capabilities of the industry. The required average reduction in drag in 2027 is delta CdA = 1.1, only marginally higher than the Bin VI (SmartWay Elite) value of delta CdA=1.0. The agencies state: “To date, SmartWay has verified over 70 technologies, including nine packages from five manufacturers that have received the Elite designation.” (p.40254) Whether or not the mix of bins will include more advanced trailers as the agencies assume in their compliance packages, reaching an average aerodynamic performance twelve years hence that matches that of multiple packages being produced today is a reasonable, and perhaps overly lenient, requirement of the industry. [EPA-HQ-OAR-2014-0827-1280-A1 p.18]

To put the agencies’ overall aerodynamic targets for long-haul combination trucks with dry vans in perspective, Daimler reported a 54% reduction in drag for its SuperTruck.15 By comparison, the agencies’ compliance package for 2027 contains tractor and trailer aerodynamic parameters resulting in a 41% reduction in drag (CdA =4.2) from the (adjusted) 2010 baseline level of CdA=7.4. Thus, the 2027 targets do not even require the industry to match levels of improvement being demonstrated today. [EPA-HQ-OAR-2014-0827-1280-A1 p.18]

Response:

See our response to CARB in Section 5.3 above page 980 for our justification for adopting standards based on Alternative 3.

Also, the agencies caution against comparing reported performance from device manufacturers and programs such as SmartWay and SuperTruck to the performance we project in this rulemaking. In terms of aerodynamics, most device (and device combination) testing, including SmartWay verification, is performed at one constant speed. EPA’s GEM model, which is the basis of our trailer program compliance as well as our determination of the stringency of the standards, uses a drive cycle-weighting of 86% (long box vans) or 64% (short box vans) of the miles at 65-mph. As seen in Chapter 2.10.2.1.1 of the RIA to these rules, device combinations with performance similar to SmartWay-Elite technologies will produce CO\(_2\) reductions that are 1% and 2% lower for these long- and short-box van weightings, respectively. Additionally, in contrast to the reductions reported under SmartWay and comparable programs, the agencies report our reductions relative to a baseline adoption rate we project would be in place without regulation. For long box vans, this includes over 50% of the industry performing at an aerodynamic Bin III (i.e., skirts), almost 50% adoption of ATIS, and a high adoption of SmartWay-level LRR tires. In total, this long box van baseline is a 3% improvement over a no-control long van. This 3% difference, in addition to the 1%-2% difference due to drive cycle, must be taken into account when comparing to published performance data. EPA obtained additional aerodynamic test data since the NPRM and updated the trailer program’s aerodynamic bins accordingly, as described in Chapter 2.10 of the RIA and summarized in our response to CARB on page 980. This new data, which includes many SmartWay-Elite combinations, provides a more complete assessment of the performance capabilities of today’s box vans, and was used to update our baseline trailers and adoption rates for the new standards.

Organization: American Iron and Steel Institute
Specifically, for trailers, the agencies identified several components and associated weight savings, ranging from 50 to 430 lbs. The basis of these weight savings, however, is not adequately supported in the record for this rulemaking. [EPA-HQ-OAR-2014-0827-1275-A1 p.15]

In the Regulatory Impact Analysis (‘RIA’) for the Proposed Rule,\(^\text{45}\) barely one page is devoted to the description of the information on which the associated weight reduction options were calculated. The agencies identified 11 common trailer components but referenced only unidentified, confidential data for this information.\(^\text{46}\) Therefore, the Proposed Rule does not allow for informed comment on these values since the source of the data and how the values were calculated is unknown. [EPA-HQ-OAR-2014-0827-1275-A1 p.15]

It is furthermore impossible to determine how much weight is saved based on the vague descriptions of the components listed in Table 2-73 of the RIA and the inability to verify the listed weight reductions. Calculating a weight 'savings' necessitates identification of a specific replaced component; but these are also unknown. Therefore, pursuant to CAA Section 307, EPA cannot finalize the proposed values. [EPA-HQ-OAR-2014-0827-1275-A1 p.15]

---

\(^{46}\) RIA at 2-166.

Response:

The agencies referred to four sources for trailer weight reduction information in the Draft RIA, as listed below. Although the name of the source was confidential in one case, the key information from that source, as well as from the other three, has been available in the public docket from the time of the NRPM.

The four references, as noted in our Draft RIA for the Proposed Rule, are listed below with their original reference numbers included in parentheses for convenience. We concluded that these four sources provided sufficient support for our proposed trailer weigh-reduction values. For the final program, we have incorporated additional information into our assessments of trailer weight reduction.

- (157) Memo to docket regarding confidential weight reduction information obtained during SBREFA Panel, June 4, 2015 (The name of this source is confidential, however, the memo includes the components, materials, and weights.

We also received comments on our proposed weight-reduction table from the Aluminum Association, Meritor, Utility Trailer, and Wabash National in addition to American Iron and Steel Institute. These
parties had a wide range of comments about our proposed weight-reduction values, but none of them identified problems with the public availability of our data sources for comment.

Meritor and the Aluminum Association did not express disagreement with the general approach the agencies took with regard to the weight table, but stated some of the weight reduction values in the table were incorrect. The groups proposed specific weight changes to some components in the weight table based on their products, such as wheels and cross members. Utility Trailers and Wabash National stated the substitution of aluminum or high strength steel in trailers should not be the only way manufacturers can associate weight reduction with fuel savings. Utility said trailer manufacturers should also be able to use redesign as a means of apply weight savings to their compliance calculations or substitution of materials not included in the weight reduction table, such as plastic. Wabash National stated that rather than relying on an exclusive list of eligible technologies, the agencies should develop a process for adding to the list either by specifying criteria by which additional materials could be used for compliance, or by establishing a petition process for including additional components and materials on the list.

For the final trailer program, we note that the list of weight reduction values is not a manufacturer’s exclusive means of applying weight reduction for compliance. The agencies have included the option for trailer manufacturers to use the existing Phase 1 process to demonstrate off-cycle technologies. (See Preamble Section IV.F.5.d). In the case of general lightweighting of a trailer, a manufacturer could measure the difference in trailer weight and use this value in the weight component of the compliance equation.

Organization: American Trucking Associations (ATA)

Tire Pressure Monitoring Systems Should be Given Credit Under the Rule

TPMS have not historically been included in the EPA’s SmartWay program since the agency had no way to determine the effect these systems have on fuel economy unless each requesting fleet provided a clear description of how it would respond to alerts. This information was necessary so that the EPA could calculate the resulting fuel savings. However, much has transpired since the inception of the SmartWay Program. The Federal Motor Carrier Safety Administration ("FMCSA") has studied TPMS since 2006. It found that these systems accurately reported inflation pressure values within 2 to 3 psi of the measured value and accurately warned of low pressure within 2 to 3 psi of the expected threshold. In 2007, the performance and durability of TPMS was examined in a field test using transit buses. This study found that TPMS-equipped buses did not experience increased average tire pressure due to diligent tire pressure maintenance and the location of the TPMS display is essential to impact tire maintenance practices, fuel economy, and tire life. [EPA-HQ-OAR-2014-0827-1243-A1 p.14]

In late 2011, the FMCSA published the results of a field test it conducted over the previous 24 months of tire pressure monitoring and ATIS on two fleets that were considered to have good tire maintenance. The test revealed that both TPMS and ATIS delivered a 1.4% improvement in fuel economy. [EPA-HQ-OAR-2014-0827-1243-A1 p.14]

Technology has greatly advanced since the tests that FMCSA conducted. Today, TPMS is much more advanced than the first generation of TPMS that was tested by FMCSA which just delivers alerts to the driver in the cab through an in-cab display. Second generation TPMS (TPMS 2.0 systems) are integrated with telematics and GPS so that the tire data and alerts are sent from vehicles and delivered to a fleet’s operations and maintenance department. By providing the fleet with the location and visibility of its tire problems, dispatch can provide instructions to the driver to handle developing tire problems.
immediately and maintenance is aware of the exact nature of these issues when the vehicle arrives at the fleet’s location. With the reports these systems provide the fleet, problem tires are attended to before the vehicle sets out on its next trip, thereby dramatically reducing in-route breakdowns and optimizing the percentage of time tires are run properly inflated. In essence, a fleet is able to build its entire tire maintenance program around this technology and drastically improve its ongoing tire inflation maintenance. Therefore this technology has an even greater effect on fuel consumption and greenhouse gas emissions than the TPMS 1.0 systems which were proven to deliver 1.4% improvement in fuel economy by the FMCSA. [EPA-HQ-OAR-2014-0827-1243-A1 p.14-15]

Due to the advances that have been made in TPMS 2.0 systems and the impact they have on fuel economy and greenhouse gas emissions, the Tire & Wheel (S.2) Study Group of ATA’s Technology and Maintenance Council (“TMC”) requests that TPMS 2.0 systems, tire pressure monitoring systems that are integrated with telematics, be included in the technology options provided under Phase 2. Without inclusion of this technology, there will be no system available in the TMC standard to address tire inflation pressure for powered vehicles since ATISs that are plumbed inside an axle (a market requirement by US fleets) are currently only available for trailers and an advanced technology that can seriously impact GHG emissions will be overlooked. [EPA-HQ-OAR-2014-0827-1243-A1 p.15]

**Light-Weighting Must Account for Additional Weight and Impacts on Durability** Light-weighting is included as an efficiency improvement option for trailers. Whether the additional weight attributed to add-on trailer technologies — such as aerodynamic skirts — is accounted for in the fuel savings estimate figures needs clarification. In addition, any consideration to further expand current menu technology credits for trailer light-weighting should assess and disclose how such measures impact trailer durability and useful life. [EPA-HQ-OAR-2014-0827-1243-A1 p.24]

**Drop-Floor Trailers Should be Afforded Efficiency Credit** It remains unclear whether the agencies have considered the aerodynamic benefits of drop-floor trailers in their menu options. If such credits are not presently accounted for, ATA asks that such credits be added for all box-trailer categories. [EPA-HQ-OAR-2014-0827-1243-A1 p.24]

**Fleets Should not be Forced to Invest in Inefficient Trailer Technologies** Fleets should not be forced to purchase specific technologies only in the name of OEM compliance if such technologies do not add benefit to a fleet’s operations. To pigeon-hole fleets into making financial investments on equipment that is ill-suited to their operations is not a good business model or good government. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

**Consideration Should be Given to Exempt Certain Trailers from Using ATISs** Certain tires loads, especially on heavy-hauls, have working tire pressures exceeding the capabilities of on-board compressors. Additional on-board compressor tanks can cost $800 and add an additional 150 pounds of weight. Consideration should be given to exempt certain trailers from using ATIS and instead allow the use of TPMS as previously discussed. [EPA-HQ-OAR-2014-0827-1243-A1 p.24]

**Response:**

The agencies agree that TPMS generally promote proper tire inflation and that including these lower-cost systems as a compliance option will increase acceptance of the technologies. The final trailer program provides for manufacturers to install either TPMS or ATIS as a part of compliance. The performance standards provide ATIS a slightly greater credit in the GEM-based equation than it does for TPMS to account for the greater uncertainty about TPMS effectiveness due to the inherent user-interaction required. The effectiveness values adopted for ATIS (1.2%) and TPMS (1.0%) in the trailer
program are consistent with those in the tractor and vocational vehicle programs. For non-aero box vans and non-box trailers design standards, manufacturers can install either a TPMS or an ATIS with their lower rolling resistance tires to comply.

The component substitutions provided in our trailer weight reduction tables are not meant to indicate a specific make or model of component. The intent of these tables is to provide a generic weight reduction value for manufacturers that optionally choose to install these components on their trailers. We expect manufacturers will only install components that meet their individual durability standards. We do not anticipate the weight of these components to significantly change over the useful life of the vehicle and, therefore, any CO₂ or fuel consumption reductions observed from use of these components will likely be maintained throughout the full useful life. We accounted for some additional vehicle weight due to aerodynamic devices in our MOVES inventory analysis, such that our overall program benefits include the small fuel consumption increase. However, as noted in our response to Utility in Section 5.1 on page 971, the per-vehicle weight increase had a small relatively impact. We did not include additional weight within our GEM vehicle simulation tool and it is not reflected in the GEM-based compliance equation for trailers.

The agencies proposed and are finalizing provisions that consider a drop-deck design for box vans to be “work performing equipment” that inhibits the use of aerodynamic technologies. The agencies are not providing any “credits” to these trailers, but they can be designated “partial-aero” box vans and meet less stringent performance-based standards based on use of a single aerodynamic device. Box vans with a drop-deck design in addition to rear work-performing equipment, such as a lift gate, can be designated “non-aero” box vans that have tire-based design standards with no aerodynamic requirements.

The performance standards for full-aero and partial-aero box vans do not require any specific technologies to be used. Trailer manufacturers can work with their customers to identify the appropriate aerodynamic, low rolling resistance tire, tire pressure monitoring and weight reduction technologies that are most likely to benefit the customer’s operations. In the years that we do not offer averaging flexibilities, manufacturers can specify a small portion of their production that does not need to meet the standards. In MY 2027 and later, when averaging provisions are in place, manufacturers can offer trailers with fewer technologies to some customers if they make up the difference in performance with other trailer sales.

In response to the comment about ATIS not being suitable for some trailers, the final program addresses this concern to some extent by allowing manufacturers to use either ATIS or TPMS at their discretion. In addition, by excluding many trailers designed for heavy-haul and off-road use, the final program is, in effect, more focused on trailer applications where ATIS is a viable option.

**Organization:** California Air Resources Board (CARB)

The proposed rule requires the use of LRR tires for all trailer types. The LRR tire requirement for short and long box type trailers begins with an 85 percent adoption rate of Level 1 tires, which have a coefficient rolling resistance of 5.1 (kilograms per ton) kg/ton, equivalent to today’s SmartWay-verified tire models, with the remaining 15 percent using the baseline tires with a coefficient of rolling resistance of 6.0 kg/ton. CARB staff believes that the adoption rate for Level 1 tires can be increased to at least 95 percent given that industry has already had years of experience with U.S. EPA’s SmartWay program.

---

and that the Truck Trailer Manufacturers Association stated in a October 16, 2014 letter to U.S. EPA informing them that SmartWay-verified LRR tires are now standard with new trailers. Furthermore, U.S. EPA and NHTSA propose a 100 percent Level 1 tire adoption rate for non-box trailers and non-aero trailers, indicating that it should be possible for box-type trailers to meet a higher adoption rate as well. [EPA-HQ-OAR-2014-0827-1265-A1 p.71]

Response:

The agencies adjusted our baseline adoption rate of LRR tires for box vans based on more recent information. In addition, the standards for all box vans are now based on nearly 100% adoption of SW-level tires in MY 2018, and CRR of 4.7 kg/ton in MY 2021 (one stage earlier than proposed). However, with the exception of the standards for non-aero/non-box trailers, the standards are performance standards and so do not mandate use of LRR tires (or any other particular technology).

Organization:  FedEx Corporation

1. Trailer Aerodynamics and Rear Roll-up Doors: When the proposed rule is fully implemented it will establish a trailer aerodynamic efficiency requirement that includes the use of “Bo-Tails.” The operating companies of FedEx utilize rear roll-up doors on their trailers for a number of reasons we will expound on in the Addendum portion of this commentary (just below). Simply said, the operators of trailers utilizing rear roll-up doors request that roll-up doors be covered as acceptable “Partial Aero” or be given a “Qualified Exemption” to the mandate of Bo-Tail use until an effective, durable and cost efficient product is available which is compatible with the rear frame design utilized by rear roll-up doors. The “To Be” created technology efficiency should be verified by EPA. [EPA-HQ-OAR-2014-0827-1302-A1 p.3]

Rear Rollup Benefits:

A. Driver safety - Roll-up doors allow the trailer to be positioned against a dock without requiring the driver to approach a dock, stop, fold the Bo-Tail, swing open the doors and then reenter the tractor to complete the parking maneuver. Roll-up doors prevent the extra process steps and contribute to process efficiency. [EPA-HQ-OAR-2014-0827-1302-A1 p.3-4]

B. Dock worker safety - The roll-up door allows a worker to approach the door latches on a solid surface, unlatch the door and using their legs to lift the door properly. [EPA-HQ-OAR-2014-0827-1302-A1 p.4]

C. Less space is required between parked trailers with roll-up doors [EPA-HQ-OAR-2014-0827-1302-A1 p.4]

4. Components Ratings: While the proposal currently states that it is the responsibility of manufacturers to document the contributive benefit of the components installed on the Tractor and or Trailer; fleets such as FedEx need the verified efficiency of the available components separately, and/or when used in combination. There should be a government-provided rating of components to assist a fleet in its deliberation as to which components are the most effective and should be included in future purchases. Implementation would be inhibited if fleets were required to conduct their own evaluations of individual components. [EPA-HQ-OAR-2014-0827-1302-A1 p.4]
Response:

The agencies recognize the benefits of roll-up doors for some operations and it is not the intent of the Phase 2 trailer program to restrict the use of roll-up doors. We are aware of some technologies that will provide small-scale improvements to the rear of trailers with roll-up doors, but are not aware of any existing technologies that match the performance of current boat tails designed for use with outswinging doors. Current boat tail technologies are designed to conveniently fold when rear doors are opened. We expect that any future designs intended to work with roll-up doors will be designed with similar convenience in mind, including features that address the accessibility and safety concerns raised by the commenter.

While we expect many box vans with roll-up doors will include additional features (e.g., drop decks, side platforms) that would qualify these trailers for a partial-aero designation, we understand that some trailers equipped with these features may not be able to find suitable technologies to meet even the partial-aero standards. Because of the current limited availability of rear aerodynamic technologies for roll-up door trailers, the final trailer program includes an interim provision – through MY 2023 – that treats roll-up doors as work-performing devices equivalent to rear lift gates. We understand that innovations and improvements continue for all trailer aerodynamic technologies, and this provision is limited to the early years of the program to provide a degree of incentive for device manufacturers to continue to develop and improve aerodynamic technologies that are appropriate for roll-up doors. For MY 2024 and later, roll-up doors will not qualify as a work-performing device. We intend for this interim provision to allow trailer manufacturers time to obtain, become familiar with, and prepare to market these technologies to their customers.

For trailers, the agencies are not adopting a program to provide a rating of components to the fleets or public. We do not expect fleets will need to conduct their own testing to evaluate technologies. While some trailer manufacturers may choose to perform their own testing, we are adopting provisions for device manufacturers to submit aerodynamic test data to EPA to be pre-approved for use by trailer manufacturers, and we expect most trailer manufacturers to take advantage of this option to obtain performance information. The agencies are not committing to make this information public at this time. However, trailer or device manufacturers may make this information available to their customers to promote adoption of these technologies. The agencies cannot ensure that any fleet’s individual trailer will experience the same performance in-use as suggested by the aerodynamic test results used for compliance, but our program will provide a relative basis from which fleets can compare performance. In general, aerodynamic technologies in higher bins will have better performance than others at most speeds.

Organization: Great Dane

Great Dane supports the use of tire technologies that save fuel and reduce emissions, but as previously stated, many factors come into play as far as the practicality of employing that approach. Not being our primary focus and since we don’t directly operate trailers in revenue service we cannot offer firsthand information on the tradeoffs associated with these technologies. However, we do note that we have customers who have stated to us that low rolling resistance (LRR) tires and/or automatic tire inflation systems (ATIS) do not meet their expectations and thus they do not specify those components. Our sales records support that fact. [EPA-HQ-OAR-2014-0827-1219-A1 p.1-2]

Trailer Aerodynamics
Great Dane believes that trailer aerodynamics, generally referred to as trailer aero or trailer aero treatments, plays an important role in reducing fuel consumption and resultant emissions. We recognize that fleets operate a variety of equipment in both “long haul” and “short haul” operations which would include both high and low speed operations and “transient” conditions as stated in the Notice of Proposed Rulemaking. A variety of trailer aerodynamic solutions have emerged and become commercially available since approximately the year 2000. As is widely recognized, all of these devices and systems are more effective as to reducing drag forces as vehicle speed increases. [EPA-HQ-OAR-2014-0827-1219-A1 p.2]

Aerodynamic treatments are widely available in the marketplace today for box (dry and refrigerated van) type trailers. We believe that market penetration to date of successful trailer aero technologies depends on many factors, with device return on investment and regulations in California (CARB), tempered by economics, being the principal drivers. [EPA-HQ-OAR-2014-0827-1219-A1 p.2]

We believe that the growth in adoption of aero for box type trailers since approximately the year 2000 is largely a result of skirt use on trailers used in long haul or in some cases regional operations where highway speeds for extended distances allow sufficient payback of the devices to justify their cost (both initial costs and maintenance). We note that adoption rates of other aero technologies such as gap reducers, underbelly devices and rear devices has been much lower over the same time period, likely a result of their relative performance and resulting return on investment or incompatibility with a fleet’s operational constraints or both. [EPA-HQ-OAR-2014-0827-1219-A1 p.2]

As per our conversations with the Environmental Protection Agency (EPA), we note an absence of competition in the availability of rear aero solutions and we further note and believe that the reason that these technologies markedly lag the growth in use of trailer side skirts is due to the potential for damage of these rear devices during docking operations. This is exacerbated by the challenges that fleets face with equipment and personnel, and the great variation of facilities that shippers and receivers expect carriers to service. While we understand the intent of the proposed regulations, we do not believe that an approach to force technology and to require the use of rear devices via large technology penetration rates is appropriate due to the challenges many fleets face in docking operations. We do not believe that the operation of trailers at loading docks will change to a substantial degree over the period of proposed regulation. Therefore we believe that a technology forcing regulatory approach for rear devices will not result in cost effective deployment of rear devices at high penetration rates as anticipated by the agencies. [EPA-HQ-OAR-2014-0827-1219-A1 p.3]

Under the proposed regulations Great Dane and our customers will experience increased costs. The agencies believe that the fleets will recoup those costs in an acceptable timeframe thru fuel savings. Great Dane’s additional costs in complying with the rule will be passed onto our customers, although we are already taking measures to minimize this effect. [EPA-HQ-OAR-2014-0827-1219-A1 p.3]

Response:

The agencies developed our Phase 2 trailer standards using specific technology packages for each phase of the program. Our standards for full-aero long box vans (dry and refrigerated) are based on the performance of trailer configurations that include bolt-on aerodynamic technologies, ATIS, and LRR tires. In practice, however, trailer manufacturers have the option to comply with these standards using any combination of aerodynamic improvements, LRR tires, tire pressure systems (including TPMS), and weight reduction that best meets the needs of their customers.
It is possible that manufacturers could meet the standards by installing higher performing aerodynamics and substituting several light-weight components for heavier ones to avoid the use of LRR tires and tire pressure systems if customers do not have confidence in tire technologies. Similarly, it is possible that a different combination of existing or future aerodynamic devices would have comparable performance to skirts and a tail, and manufacturers could offer an aerodynamic package that does not involve a rear device. It is likely that the trailer industry, including both trailer manufacturers and aerodynamic device manufacturers, will continue to develop new technologies that will improve the aerodynamic performance of box vans over the next ten years, providing additional compliance avenues over time. Regarding the costs of the new technologies, we acknowledge and quantify the costs manufacturers will incur that will, in most cases, be passed on to customers, and the program accounts for these costs as well as the cost savings that end users will experience.

Trailer and device manufacturers have an incentive to develop innovative, high-performing designs that also account for their customers’ varying preferences and operational characteristics. In addition, operators’ experience and familiarity with these evolving technologies will grow as their use becomes more widespread. For example, driver experience with trailer tails is limited today, since only a small fraction of trailers use them. We expect these technologies will continue to evolve and increased market demand will lead to designs that address any deployment or collapsing concerns at loading docks. Additionally, the growing direct and indirect experience among operators will reduce the instances of damage and inefficiencies raised by the commenter.

Organization: International Council on Clean Transportation (ICCT)

Trailers

The ICCT supports the agencies integration of trailers into the Phase 2 regulation. We believe that this proposal builds on the successes of the SmartWay program and California’s in-use GHG regulation and will both promote the adoption of existing cost-effective technologies as well as spur new innovation. In designing standards for a tremendously diverse market, the agencies have developed a sound program that limits testing and compliance complexity in order to minimize the burden on trailer manufacturers. We support the agencies’ high-level regulatory decisions, as they are congruent with previous ICCT recommendations (Sharpe et al, 2013; Sharpe, 2014) in key areas: trailer manufacturers are the regulated entity; the standards for trailers are expressed in grams (and gallons) per ton-mile; the classification framework facilitates improvements in aerodynamics, tire technologies, and lightweighting in box trailers, while for non-box trailer types, improvements are focused on tire technologies; aerodynamic testing procedures for tractors and trailers are closely aligned; and trailer aerodynamic testing utilizes an “A-to-B” approach in which the same tractor model is used to test a baseline and an ‘enhanced’ trailer in order to certify the enhanced trailer model’s aerodynamic performance. [EPA-HQ-OAR-2014-0827-1180-A4 p.10]

The agencies largely incorporated the portfolio of commercializable trailer efficiency technology. With a rulemaking timeframe of 2027, we would encourage the agencies to consider greater penetration of higher aerodynamic bins for all box trailers, as well as ways to promote more aerodynamic improvement in non-box trailers. The agencies’ analysis of technology adoption rates for trailers is firmly rooted in a fact-based assessment of the current baseline and target levels of penetration that are reasonable. Given the rapid acceleration of uptake of fuel-saving technologies over the past five years as a result of the SmartWay program, California’s in-use tractor-trailer GHG regulation, and attractive returns on investment for many technologies, the agencies could consider advancing the proposed timing of the required technology penetration by several years and greater final penetration of technology in 2027. [EPA-HQ-OAR-2014-0827-1180-A4 p.10]
Response:

We appreciate the commenter’s support for the proposed Phase 2 trailer program. See response to CARB in section 5.3 on page 980 regarding our preferred alternative, and our response to UCS in Section 5.4 on page 1026 regarding aerodynamic technologies on non-box trailers.

Organization: Meritor, Inc.

Improve Automatic Tire Inflation Definition and Correct Misstatements about the Market.

The definition of automatic tire inflation systems (ATIS) listed in Subpart 1, Definitions & Other Reference Information, is not consistent with the historical industry definitions. The Technology Maintenance Council, (TMC), of the American Trucking Association, in their Recommended Practice, RP239A (most recently updated in 2014) uses the following widely accepted definition of ATIS:

Automatic Tire Inflation Systems maintain tire pressure at a single preset level and are pneumatically or electronically activated. These systems eliminate the need to manually inflate tires.

The current definition included in the rulemaking states:

ATIS means a system installed on a vehicle to keep each tire inflated to within 10% of the target value with no operator input.

Assigning an arbitrary number of 10 percent is not consistent with the manner in which these systems are used in practice. Tire pressure increases by 15 – 20 percent when the tire is hot and running on a fully loaded vehicle at 75 mph on asphalt roads on a sunny day. Tires cool back down to the specified tire pressure after a few hours. The reduced fuel economy and increased greenhouse gas emissions are due to tire underinflation. ATIS systems assure that tires will always be running at the recommended cold tire inflation pressure.

Response:

The commenter is essentially correct. The agencies accordingly updated the definition of ATIS and removed the reference to 10% of a target value.

Organization: Meritor, Inc.

Page 40612, § Section 1037.107 Emission standards for trailers of the proposed rulemaking, discusses the use of low rolling resistance tires and that “qualified” automatic tire inflation systems are required on non-box trailers effective MY 2018. It is our recommendation that the term “qualified” be expanded. SAE Recommended Practice (RP) J2848-2, dated June 2011, is a RP on the subject of ATIS. It is the industry standard that details the basic operational requirements for any ATIS. This RP should be
referenced in the proposed rulemaking when “qualified” automatic tire inflation systems are discussed. [EPA-HQ-OAR-2014-0827-1254-A1 p.16]

Response:

The use of the term “qualified” was intended to refer to the definitions of ATIS in our respective regulations.

Organization: Meritor, Inc.

“Most trailer SERs have experience installing ATI systems on some of their trailers, but ATI systems are not installed as a standard feature on any of the SERs’ current products. The non-box trailer manufacturers have installed tire inflation systems on some trailers, but indicate that the customers are reluctant to purchase the systems because of the added cost. In addition, the manufacturers noted that inflation systems are often tied to a particular suspension system and they cannot be applied universally.” [EPA-HQ-OAR-2014-0827-1254-A1 p.16]

In fact, all ATIS in the marketplace today can be universally applicable to all hollow tube trailer axles, regardless of the manufacturer or the suspension type to which they are affixed. [EPA-HQ-OAR-2014-0827-1254-A1 p.16]

Page 40285 (IV.F.(6)(d)) of the NPR states:

“We request that trailer manufacturers as well as tire and aerodynamic technology manufacturers provide information regarding the current projected availability of the technologies that trailer manufacturers can use to meet our proposed standards.” [EPA-HQ-OAR-2014-0827-1254-A1 p.16] In this regard, it should be noted that ATIS are universally applicable to ALL trailer types contemplated in these regulations, and that while some suspension and axle manufacturers attempt to commercially limit the application of only their ATIS to their suspensions and axles, this is not a technical limitation of commercially available ATIS. [EPA-HQ-OAR-2014-0827-1254-A1 p.16]

Response:

The Panel Report that the commenter points to is referring to a comment made by a trailer manufacturer and we cannot change the contents of that report. The agencies did not refer to any technical limitations of connecting ATIS to particular trailer types in the Preamble or RIA of the final rulemaking. Our request for comment was intended to gather information on production capabilities of tire technology suppliers, since trailer manufacturers expressed concern that there would not be sufficient availability for the volume of trailers requesting the technologies.

Organization: National Association of Clean Air Agencies (NACAA)

NACAA commends EPA for including requirements to regulate GHG emissions associated with trailers for the first time at the national level. While we support the proposal as a first step by requiring nearly all trailer types designed for on-highway use to use low rolling resistance (LRR) tires and automatic tire inflation systems, we believe the proposed trailer provisions miss several opportunities to maximize fuel efficiency technologies in the heavy-duty trailer sector. [EPA-HQ-OAR-2014-0827-1157-A1 p.4]
Based on manufacturers’ and fleets’ experiences with EPA’s SmartWay program and CARB’s experience in implementing its Tractor Trailer Greenhouse Gas Regulation, we urge EPA to 1) consider expanding the proposed requirements for aerodynamic technologies on box type trailers to include other trailer types, such as tanker and flatbed trailers; 2) increase the proposed penetration rate for Level 1 LRR tires to at least 95 percent for short and long box type trailers; 3) adopt Alternative 4 augmented with revisions to include a nominal adoption rate in Bin VIII technologies (which represent as yet undeveloped technology) in order to further advance aerodynamic technology development; and 4) increase the final Alternative 4 stringency (applicable to MY 2024) for long box refrigerated van trailers so that the combined adoption of Bins VI and VII match or exceed that of long box dry van trailers. [EPA-HQ-OAR-2014-0827-1157-A1 p.4]

Response:

The agencies appreciate the commenter’s support for the trailer program. In response to the comments about the stringency of the program, see the response to CARB in section 5.3 on page 980. We are not adopting performance standards for non-box trailers that would require the use of aerodynamic technologies. Of the tank, flatbed, and container chassis manufacturers that at the time of our analysis would be covered by the Phase 2 trailer standards, about 75% qualify as small businesses. We believe tire technology-based design standards achieve a balance between the most consistent CO₂ and fuel consumption benefit across this subset of trailers, and our desire to reduce the compliance burden for this newly regulated industry that is largely made up of small businesses. Also, see our response to USC regarding non-box aerodynamics on page 1026 of this section.

Organization:  Owner-Operator Independent Drivers Association (OOIDA)

Aerodynamic Devices

It should be understood that whenever an aerodynamic device is used, the benefit of the other devices will be affected. For example, installing a gap fairing will affect the aerodynamic drag of the side skirts. Therefore, the benefits gained by combining aerodynamic technologies cannot be summed by adding the individual estimated fuel savings. Combining all the various aerodynamic devices, such as side skirts, front gap fairings, and rear fairings, which individually are estimated to produce 4 to 7 percent, 1 to 2 percent, and 1 to 5.1% in fuel savings respectively, will not result in a grand total of 6 to 14 percent in fuel savings. [EPA-HQ-OAR-2014-0827-1244-A1 p.19-20]

The benefits of aerodynamic technology fluctuate greatly depending on the trailer type and cargo. For instance, as stated above, front trailer fairings are not designed for refrigerated-vans, and are most effective when installed on tractor-trailers with a gap greater than 36 inches. [EPA-HQ-OAR-2014-0827-1244-A1 p.20]

While aerodynamic technologies sound good academically, they often do not make sense in the real world. In some instances aerodynamic technology can actually cost fuel rather than save fuel. For example, a sleeper cab tractor with a full-height air deflector that is pulling a flatbed trailer will decrease fuel efficiency because the high roof sleeper increases the frontal area of the truck beyond what the trailer requires.²⁰ [EPA-HQ-OAR-2014-0827-1244-A1 p.20]

Trucking operations not only vary by types of cargo, but also by geographic region and length of haul, which greatly affects the benefits of aerodynamic technology. Truck drivers in costal and urban areas run very different routes than those who operate on the great plains of the Midwest. Short-haul
operations primarily use day cab tractors, which constitute approximately one-third of Class 8 trucks. [EPA-HQ-OAR-2014-0827-1244-A1 p.20]

In an article published in the Brow Beat, Susan King, a spokesperson for the American Trucking Associations, stated that aerodynamic technology does not make sense for every truck. The drag on a vehicle increases with the square velocity, so reducing drag becomes much more important as the average speed of a truck increases. Ms. King pointed out that this technology does not start to be effective until the truck is averaging 60 to 65 mph. “So you wouldn’t see these panels on trucks that handle local deliveries.” [EPA-HQ-OAR-2014-0827-1244-A1 p.21]

Therefore, unless an owner-operator is running long-haul where they average 60 to 65 mph, these aerodynamic technologies would have little to no effect on fuel savings, and it would be difficult for owner-operators to see a return-on-investment. For example, in California, the speed limit for heavy-duty vehicles is 55 mph, thus these technologies would not be able to reach their maximum effect. Additionally, tens of thousands of owner-operators service our nation’s ports, and many never exceed 45 mph. [EPA-HQ-OAR-2014-0827-1244-A1 p.21]

20 Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles, National Academies Press (2010), pg. 98.

Response:

The agencies recognize the possibility of dissynergies when aerodynamic devices are combined. We are accounting for these dissynergies by applying a correction to any individually pre-approved aerodynamic data that manufacturers intend to use in combination. Manufacturers would be able to claim 100% of the pre-approved effectiveness value for the highest performing device, 90% for the second-highest performing device, and 80% for any additional devices. See 40 CFR 1037.526(c). Device manufacturers and trailer manufacturers maintain the option to test combinations of devices and claim the effectiveness observed in their testing. It is possible that some device combinations will perform better in combination than the sum of their individual effectiveness values, but manufacturers will have to test those devices in combinations to claim those values.

The agencies also recognize that some aerodynamic devices may not be appropriate for all box vans. We are maintaining the performance standards for box vans that allow a manufacturer to install a variety of devices with similar performance that can meet a specific customer’s need. Gap reducers and other front fairing technologies are never required to meet the standards. Our aerodynamic testing described in Chapter 2.10 of the RIA indicates that the performance of these devices can be made up with other technologies. Especially in the early years of the program, manufacturers may be able to substitute large weight reductions to achieve the same performance as aerodynamic technologies. We expect refrigerated vans that are unable to use aerodynamic devices on the front of the trailer will have sufficient technology options to meet the standards. Additionally, the agencies are adopting provisions that provide manufacturers the option of designating box vans with work performing equipment (WPE) as “partial-“ and “non-aero”, which reduces or eliminates the need to use aerodynamic technologies to meet the standards. The agencies believe a large fraction of short-haul box vans would have WPE to qualify for these reduced standards.
The agencies designed our trailer program to achieve CO\textsubscript{2} and fuel consumption reductions for the majority of regulated trailers. Our standards are based on consistent pairing of appropriate tractors and trailers. We cannot control tractor-trailer pairings in use, and understand that there may be situations where a high roof tractor operator may be asked to transport equipment using a flatbed or other mismatched trailer. However, our experience shows that most trailers are matched with an appropriate tractor and we can expect consistent reductions in the real world.\textsuperscript{154}

The agencies recognize that the performance of aerodynamic devices improves with increased vehicle speed. However, our evaluation in Chapter 2.10.2.1.1 of the RIA indicates that even a trailer that travels exclusively in transient conditions would experience a non-zero benefit by reducing drag. A long dry van pulled by a sleeper cab tractor may achieve 9\% CO\textsubscript{2} reduction for a SmartWay-Elite combination of devices when traveling at 65-mph, and closer to 7\% at a speed of 55-mph. While the CO\textsubscript{2} reduction decreases to about 1\% under completely transient driving conditions, there is still a slight benefit for these trailers. The relatively few box vans that travel exclusively in transient conditions, but do not qualify for partial- or non-aero designation, may see a longer return on investment than their high-speed counterparts, but they will still benefit.

The majority of the drayage traffic at ports involves transport of containers using container chassis, and, in some cases, specialty trailers such as auto haulers and flatbeds to transport “breakbulk” cargo that will not fit in containers, or tanks to transport liquids. Container chassis, flatbed, and tank trailers fall under our non-box trailer design standards that require the use of tire technologies only. Many other specialty trailers are completely excluded from the program. We are not establishing standards for these trailers commonly used in port operations that would necessitate the use of aerodynamic technologies to comply. The drayage tractors pulling these trailers may be classified as vocational vehicles (see 40 CFR 1037.630 for these optional custom chassis standards). See the Preamble, Sections III.C.4.b, V.b.2.b, and V.B.3.b.

**Organization:** Owner-Operator Independent Drivers Association (OOIDA)

**Automatic Tire Inflation**

Automatic tire inflation technology is among the agencies’ list of approved technologies in order for OEMs to achieve compliance goals. The agencies have projected as part of the NPRM that 50\% of dry van and refrigerated trailers will have automatic tire inflation (ATI) systems installed to maintain optimal tire pressure by MY 2018. This penetration rate is far too high, as many owner-operators would prefer to purchase tire pressure monitoring (TPM) systems rather than ATI systems because of the reduced cost and complexity while achieving similar savings. It is important that ATI systems are not forced onto consumers by assuming such high adoption rates. [EPA-HQ-OAR-2014-0827-1244-A1 p.23]

**Response:**

The MY 2018 adoption rates referred to in this comment are the Alternative 1 baseline adoption rates the agencies projected would be in place without a regulatory program for trailers. We have adjusted those adoption rates for the FRM, based on an informal survey conducted by TTMA and provided in a

\textsuperscript{154} Memorandum to Docket EPA-HQ-OAR-2010-0162-0045. “Truck and Trailer Roof Height Match Analysis”, August 9, 2010.
TTMA’s members observed an average ATIS market penetration of 40% for 53-foot vans, 26% for shorter vans and 3-20% for several non-box trailer types. Our new MY 2018 baseline adoption rates are 45% for long vans and 30% for short vans based on this information.

The agencies did not propose, but are adopting provisions to accept TPMS as a means of complying with the Phase 2 trailer standards. Design standards for non-aero box vans and non-box trailers (i.e., flatbed, tank, and container chassis) now require LRR tires and either TPMS or ATIS. Performance standards for full- and partial-aero box vans are based on the use of ATIS, but manufacturers have the option of installing TPMS and claiming a slightly reduced effectiveness. As with all performance standards, we do not require any specific technology be installed on full- and partial-aero box vans. Customers can work with their trailer manufacturer to determine an appropriate combination of aerodynamic technologies, LRR tire, tire pressure systems, or weight reduction options to apply to meet the standards for a given model year.

Organization: Pressure Systems International (PSI)

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 206-210.]

My interest in presenting at this hearing is to address the definition of an automatic tire inflation system and the requirements of a ‘qualified ATIS system.’

Today we estimate that approximately half of the commercial trailers being produced in North America have some type of tire solution with the overwhelming majority being ATIS. We also estimate that over one million trailers are currently running with ATIS today.

The benefits of ATIS include increasing fuel economy, reducing greenhouse gas emissions, and significantly reducing tire and safety related roadside service calls. It also dramatically reduces road debris from tire casings and better utilization of casings for retreads for lower oil consumption by the tire manufacturers. A typical return on investment is well under 12 months.

The basic principle of ATIS is to ensure that tires maintain a minimum specified tire pressure as determined by the fleet. However, there are numerous tire solutions in the market today, and there are operational characteristics between some of those that classify themselves under the ATIS heading. With most ATIS systems, air is automatically added whenever an individual tire pressure below the system setting either while the trailer is in a static or dynamic state.

I wish to clarify two very important items in the proposed rulemaking: the definition of ‘automatic tire inflation system’ listed in Subpart I. Definitions and other reference information is not consistent with the historical industry definitions. TMC, the Technology Maintenance Council of the American Trucking Association, in their recommended practice, RP-239(a), most recently updated in 2014, uses the following widely-accepted definition of ATIS, and I quote: ‘Automatic tire inflation system maintain tire pressure at a single preset level, and are pneumatically or electronically activated. A warning indicates to the driver that the system has been activated, and air is being added to a tire. These systems eliminate the need to manually inflate tires.’

The current definition included in the proposed rulemaking states, and again, I quote, 'ATIS means a system installed on a vehicle to keep each tire inflated to within 10 percent of the target value with no operator input.' Assigning an arbitrary number of 10 percent is not consistent with the laws of tire physics. Tire pressures increase by 15 to 20 percent when the tire is hot and running on a fully loaded vehicle at 75 miles an hour on an asphalt road on a sunny day. Tires will cool back down to the specified tire pressure after several hours depending on the size type tire.

The issue with tires and reduced fuel economy and increased greenhouse gas emissions is because of tire under inflation. ATIS systems assure that tires will always be running at the recommended cold tire inflation pressure.

The second issue to address is a clarification regarding 'qualified automatic tire inflation systems.' Section 1037.107, Emissions Standards for Trailers, of the proposed rulemaking, discusses the use of low rolling resistance tires, and that qualified automatic tire inflation systems are required on non-box trailers effective model year 2018. It is our recommendation that the term 'qualified' be expanded.

SAE Recommended Practice J2848-2, dated June 2011, is an RP on the subject of automatic tire inflation systems. It is the industry standard that details the basic operational requirements for any automatic tire inflation system. This RP should be referenced in the proposed rulemaking when qualified automatic tire inflation systems are discussed.

Response:

The agencies updated our definition of ATIS and removed the reference to 10% of a target value. The use of the term “qualified” was intended to refer to the definitions of ATIS in our respective regulations.

Organization: Schneider

Trailer Aerodynamic Devices. Trailer aero devices are most beneficial at speeds above 45 MPH and most truckload fleets operate less than 60% of the time and miles above this speed. Many trailers are operated as a warehouse on wheels, consequently, low miles per year. The low miles per year at slow speeds limit the benefits of aero devices on trailers. In addition, certain applications cause the trailer and aero devices to be susceptible to damage. Any device which must be deployed by the driver, if trailer tail, is susceptible to not being deployed and not producing a benefit. Any device which protrudes from the vehicle (ice trailer tail) creates a risk of contact with, and damage to, fixed objects in the operating environment if the driver forgets about the presence of the device (i.e. trailer tails hitting light poles in parking areas, trailer tails hitting dock doors). [EPA-HQ-OAR-2014-0827-1201-A1 p.3]

Response:

See our response to Stoughton in Section 5.1 on page 965 for a comparison of the benefits we expect over the range of operation a trailer may experience. Also, see our responses to Utility in Section 5.1 (page 971) and Great Dane in this section (page 1000) for our assessment of the use of and potential damage to current and future rear aerodynamic devices.

The agencies believe it is in the best interest of fleets and owner-operators to be aware of technologies that will improve CO₂ emissions and fuel consumption. Aerodynamic devices must be designed to last the full useful life of the vehicle. While device manufacturers are not responsible for damage caused in-use, we believe they have an incentive to ensure their products can withstand typical driving conditions of those using their products. Problems with inadvertent damage and damage from environmental
conditions will decrease as new products are introduced to improve on previous designs, and the industry becomes more familiar with the available technologies.

**Organization:** STEMCO

STEMCO supports higher fuel efficiency standards in tractor trailers and has shown it is possible to gain an additional 5% fuel efficiency by using a TrailerTail® rear drag mitigation device. [EPA-HQ-OAR-2014-0827-1259-A1 p.1]

STEMCO believes requiring automatic deployment or “always deployed” technology puts undue burden on fleets, who have a variety of operating models and driver profiles. We feel it is best to give fleets choices and leave enforcement to the various safety agencies. [EPA-HQ-OAR-2014-0827-1259-A1 p.1]

**Available Technologies**

**Automatically deploying boat tails**

STEMCO believes that this regulation should not require boat tails to automatically deploy when the vehicle is in motion. Our company commercially sells both manual and AutoDeployTM versions of our TrailerTail® product line and has found that both offerings are needed to satisfy industry demand. Smaller fleets, fleets with lower driver turn-over, and fleets with established driver training and/or MPG incentive programs typically prefer the lower-cost manual TrailerTail® option, whereas other fleets are willing to pay a premium to guarantee deployed TrailerTails® without driver interaction. Because manual boat tails are already deployed during the vast majority of their highway travel (and we see this percentage continuing to increase as boat tails become more commonplace with drivers) and because fleets who purchase boat tails are already financially incentivized to deploy them (free fuel savings at that point!), we think natural market forces are sufficient to ensure that boat tails are deployed frequently enough to meet the environmental goals of this regulation. We also believe that it would be unfair and unwarranted to force fleets who are already successfully deploying manual boat tails to spend additional capital on a redundant automatically deploying option when they purchase new trailers. [EPA-HQ-OAR-2014-0827-1259-A1 p.3]

STEMCO instead suggests including a stipulation in the final regulation requiring all aerodynamic devices (boat tails, side skirts, etc.) to be designed such that they can be easily positioned into their EPA approved aerodynamic shape before or during vehicle motion, and that they can properly maintain their EPA approved aerodynamic shape during vehicle motion. A more specific requirement could be that a manually deploying boat tail must take a single driver less than 10 seconds to unfold into the fuel-saving shape. We believe that this matches the spirit of the regulation and may close an unforeseen loophole if an inexpensive, but difficult to unfold, boat tail is commercialized with the intent of achieving compliance but rarely being deployed while in-service. [EPA-HQ-OAR-2014-0827-1259-A1 p.3]

**Response:**

The agencies see value in rear trailer devices that automatically deploy to ensure proper positioning in-use. However, we are not requiring auto-deployment as a criteria for rear devices in order to provide additional selection for customers, including possible use of less-expensive options. In response to the comment suggesting that boat tail technologies be required to demonstrate a specific degree of ease of deployment and that they maintain their shape in use, we did not propose, and the final program does
not include, such requirements. We expect that commercial factors will tend to result in designs that indeed achieve promised fuel savings benefits through effective aerodynamics and reasonable ease in deployment. In their application for certification, trailer manufacturers will provide basic information about devices used on their trailers. Where there may be some question on the performance values submitted, the agencies maintain the ability to test devices using our full-scale test procedures to ensure the actual production devices perform as claimed.

**Organization:** Stoughton Trailers

Unintended consequence: brake/wheel end warming;

Over the history of design of a wheel end for usage on trailers a continued goal is to provide for the safest, longest lasting, and cost sensitive components possible. The industry continues to reconfigure the brake drum toward these ends. Consequently the weight of a brake drum has been reduced approximately 18% over the past 30+ years (resulting in reduced fuel consumption and therefore reduce CO2 creation). The proposal may reverse this design due to the need to dissipate heat. The heat being created due to braking action, which up until now was cooled via air flow. The concern with the proposal is that with added side skirts and wheel deflectors for Aero purposes the air flow across the drum area is minimized resulting in an allowance of temperature increase. One way to manage the temperature would be to add mass to the brake drum, resulting in additional weight. Thus conflicting with the intended potential advantages of fuel conservation. If temperature is allowed to build it will affect bearings, lubricant, seals, brake lining, heat treatment of drum......in extreme conditions the tire bead could break seal from the rim or the tire could actually ignite and burn the unit to the ground. [EPA-HQ-OAR-2014-0827-1212-A2 p.1]

Request 1: Provide direction to aero manufacturers to negate the potential hazards listed above or remove requirement for aero all together. [EPA-HQ-OAR-2014-0827-1212-A2 p.1]

**Response:**

Many trailers are using trailer skirts today and we do not have data to suggest that trailer brake overheating is a widespread problem (nor did the commenter provide any). We agree that skirts have the potential to reduce airflow to the wheels, but the agencies do not have sufficient information to determine the trailer design, operational characteristics, or environmental conditions that may lead to overheating, or the role of maintenance in preventing occurrences. Further, a study group (S.11 Sustainability and Environmental Technology) at the American Trucking Association’s Technology & Maintenance Council (TMC) examined this potential issue. The study group interviewed several fleets that used trailer aerodynamic devices and found no evidence that use of these devices resulted in increased maintenance or component failures. As a result, the study group did not pursue the study. Additionally, we expect that manufacturers will continue to evaluate all aspects of their trailers’ performance, and suppliers will have an incentive to create components that meet their customers’ durability and performance standards while accommodating future trailer designs.

**Organization:** Stoughton Trailers

**EPA-HDGHG2: Reduction of GHG, Targeted vs projected Target:** Defined by joint consideration of US-EPA and DOT’s NHTSA

- Projected to reduce GHG emissions by 270 MMT (530 million barrels of oil) over the life of the regulated vehicles [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
**Trailer Industry discussion:**

- Considering dry van production for a 5 year period and the life cycle of those units [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
  - Cost of devices employed to comply (see page 5): $1,398,097,750.00 (this does not take into account any proof testing of performance see page 8) [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
    - Realized fuel savings: (see page 6) 85.34 million barrels (i.e. 164 barrels per full aero type unit) -- 16.1% of Target
  - Effect on purchase price: 7.4% increase (range 2.14 to 9.8% see page 5) [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
    - For an industry which operates in a single digit profit margin
  - Note break even payback period from 52 to 66 months not considering upkeep and maintenance (this is 2x to 3x acceptable timeframe) [EPA-HQ-OAR-2014-0827-1212-A2 p.3]

Request 7: Continue with voluntary program

- Components detracting from target: reduces to <16% of Target [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
  - Weight of aero devices added to equipment causes 1.03% more truckloads to deliver current payload amounts: consumes an additional (12,500 truckloads based on a 500 mile length of load trip) see page 7 76,401 barrels oil [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
  - Delivery of aero devices: 4,200 truckloads: 25,641 barrels oil (see page 7) [EPA-HQ-OAR-2014-0827-

Request 8: Continue with voluntary program (eliminates > 16,000 trips: safety?)1212-A2 p.3

- Alternative consideration: Rail usage 6.6% of Target [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
- For every 30% reduction in Highway miles for 30% of the fleet (i.e. 173 barrels per unit) see page 7 35.05 million barrels of oil [EPA-HQ-OAR-2014-0827-1212-A2 p.3]

Request 9: Exclude rail use equipment from aero regulation: usage exceeds over the road full aero benefit.

- 33ft doubles legislation: 50.9% of Target [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
  - Saves 18% of miles traveled: see page 8 270 million barrels of oil [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
  - This savings accomplishes more than 50% of the program goals without installation of defined components and subsequent cost to the industry. [EPA-HQ-OAR-2014-0827-1212-A2 p.3]
  - Number of tractors on the road is reduced and therefore the # of potential accidents and deaths due to those accidents are diminished. [EPA-HQ-OAR-2014-0827-1212-A2 p.3]

Request 10: Exclude 33ft equipment from aero regulation: usage exceeds over the road full aero benefit by a factor of 3x. Recommend 33ft unit adoption.

Assumptions for consideration: provided by EPA presentation to TTMA
Target savings of 530 million barrels of oil during lifecycle of units 2014 thru 2018
equals (=) 6.36 billion gals of diesel (i.e. 270MMT GHG)

EPA presentation to TTMA (1 gal equates to 93.6 lbs GHG)
Units built in 2013 (135k) as avg/yr: 675k total units in program (2013 ACT report)
Average unit price: $28,000 (Industry pricing)
Fuel cost: $2.50 per gallon (current at pump)
Average fuel economy (w/o program): 6.5 miles per gallon (mpg) (Stoughton Trucking fleet data)

Fuel Savings:
- Full Aero: 5% Fuel savings yields: 6.825 mpg (calculated based on above)
- Partial Aero: 2.5% savings: 6.6625 mpg
- Non-Aero: 1.25% savings: 6.58125 mpg

Price of components for full aero: $896 (Sideskirt OEM installed with FET) + $1904 (boat tail) + $795 (Tire inflation system) + Unknown tire differential = $3595
Assume $2750 (volume price reduction)
Mileage traveled per unit annually: 45,000 miles (Large trucking fleet: top 3: data)
Number of Units in time (2014-2018): 135,000 per year; therefore 675,000 units

Cost to Install fuel saving devices:
- Full Aero: 60% of fleet: 0.6 x 675,000 units x $2750 per unit
  first year: $222,750,000.00 (9.8% of sales)
  program units (5 years): $1,113,750,000.00 (9.8% of sales)

- Partial Aero: 25% of fleet: 0.25 x 675,000 units x $1325 per unit (omit boat tail)
  first year: $44,718,750.00 (4.7% of sales)
  program units (5 years): $223,597,750.00 (4.7% of sales)

- Non-Aero: 15% of fleet: 0.15 x 675,000 units x $600 per unit (include no aero)
  first year: $12,150,000.00 (2.14% of sales)
  program units (5 years): $60,750,000.00 (2.14% of sales)

Total Fleet: first year: $279,618,750.00 (7.4% of sales)
program units (5 years): $1,398,097,750.00 (7.4% of sales)

**Fuel Savings:**

**Full Aero @ 5% efficiency @ highway speeds (60% distance):**
60% of miles considered to be effective as highway speed, 60% of fleet
First year: $135,000 units x 45,000 miles x 60% x 60% @ (6.825 vs 6.5) mpg
16,021,978 gal i.e. $40,054,945.00 avg payback 66 months
1.34 million barrels oil
Full program period i.e. 675,000 units @ 10 year unit life (i.e. 15 year program)
801,098,901 gal i.e. $2,002,747,252.00
66.76 million barrels of oil

**Partial Aero @ 2.5% efficiency @ highway speeds (60% distance):**
60% of miles considered to be effective as highway speed, 25% of fleet
First year: $135,000 units x 45,000 miles x 60% x 25% @ (6.6625 vs 6.5) mpg
3,419,325 gal i.e. $8,548,114.00 avg payback 52 months
0.285 million barrels oil
Full program period i.e. 675,000 units @ 10 year unit life (i.e. 15 year program)
170,966,229 gal i.e. $427,415,572.00
14.25 million barrels of oil

**Non-Aero @ 1.25% efficiency @ highway speeds (60% distance):**
60% of miles considered to be effective as highway speed, 15% of fleet
First year: $135,000 units x 45,000 miles x 60% x 15% @ (6.58125 vs 6.5) mpg
1,038,462 gal i.e. $2,596,154.00 avg payback 56 months
0.086 million barrels oil
Full program period i.e. 675,000 units @ 10 year unit life (i.e. 15 year program)
51,923,077 gal i.e. $129,876,692.00
4.33 million barrels of oil

**Cumulative Fleet:**
First year: 20,479,765 gal i.e. $51,199,412.00
1.71 million barrels oil
Full program period 1,023,988,207 gal i.e. $2,559,970,518.00
85.34 million barrels of oil

**Effect of delivery of aero devices:**
- Approximately 160 understructure aero kits/load and 170 boat tails/load (average due to weight/space limitations)
- Equates to 4200 loads @ 500 miles delivery (proximity of supplier to OEM)
  - 2,100,000 miles traveled
  - 307,692 gallons used @ cost of $769,231 (based on increased MPG)
  - 25,641 barrels oil
- Production of aero device adds approximately ??????? MT GHG, to consider

**Added Trailer loads due to aero device weight:**
• Average weight of aero device equals: 300lbs (skirts) + 165lbs (boat tails)
• Average payload in trailer 45,000 lbs
• For each 97 loads (1) additional load will be required
  o 1.03% increase in overall mileage required to deliver same amount of payload: 6,257,250 miles @ 6.825 mpg
  916,813 gallons used @ cost of $2,292,033
  76,401 barrels oil

Rail service discussion: (30% used as number which provides for equivalent fuel savings; actual number is approximately 3 times if rail service were to be fully utilized)
  • Consider mile reduction at a rate of 30% (i.e. 13,500 miles repurposed)
    o 13,500 x (30% of fleet)675000 units @ 6.5 mpg
  saves 420,576,923 gallons of fuel (35.05 million barrels oil)
  saves $1,051,442,307 of fuel
  39.37 billion lbs GHG (17.86MMT)
  • General fuel consumption: locomotive moves 200 truckloads while consuming the same volume of fuel as a tractor over the highway for a single unit. i.e. 0.5%
    Therefore fuel savings would be: 35.05 million barrels oil
  • These units need not be considered in the over the road fleet and should therefore be exempt from all of the requirements of the proposed regulation.

33ft doubles proposed legislation:

  o Assume 20,000 units per year (15 year affect); Represents 5% of the fleet (i.e. 20 year life cycle) and is therefore extremely conservative for the present calculation.
  o Saves 18% of miles traveled:
    0.18x[(20000 x 45000 x 15)+(20000 x 45000 x 14)+(20000 x 45000 x 13)+…………..(20000 x 45000 x 1)]=19,440,000,000 miles @ 6 mpg
    =3,240,000,000 gal (270 million barrels oil)
  • Note mileage reduced (6 mpg vs 6.5) to compensate for increased coefficient of drag due to longer (combination) units.

Units to be Tested for compliance
In order to establish a coefficient of drag each model would need to be tested in a wind-tunnel to assure accuracy. Furthermore a subsequent test is required to record the percentage of drag reduction which can be assumed for each potential aerodynamic device. For accuracies consideration a corresponding track test would be required to correlate the drag reduction to the actual fuel savings. The following only considers the wind tunnel portion of the cost associated with Cd establishment.
  • Considering multiple side (12), roof(6), understructure (7), height (6), width(2), length (5), and limited misc. options (3), the number of possible combinations would exceed 90,000 variations.
    o Assuming an average order size of approximately 50 units per specification yields a requirement for establishing over 2700 (first year) base lines for coefficient of drag for the industry.

Cost to Establish Coefficient of Drag (Cd): number of models to be tested based on a declining percentage due to repeat business
Year 1: 2700 models x $19000/model = $51,000,000.00 (1.4% of sales)
Year 2: 1620 models x $19000/model = $30,780,000.00 (60% of models)
Year 3: 1080 models x $19000/model = $20,520,000.00 (40% of models)
Year 4: 810 models x $19000/model = $15,390,000.00 (30% of models)
Year 5: 675 models x $19000/model = $12,825,000.00 (25% of models)
Response:

The agencies considered the calculations provided by Stoughton. The values assumed for barrels of oil and MMT of GHG saved were noted to be taken from an EPA presentation to TTMA. Any numbers presented to TTMA would be referencing Phase 1 results. Since trailers were not considered in Phase 1, we cannot speak directly to these values, but we will address the theme of the calculations. Note that additional details regarding the agencies’ calculations in response to this comment are provided in a memo to the docket.156

To start, Stoughton calculates the cost to install devices and relates it to the total sales of the industry, then estimates the fuel savings by adopting those technologies. The comment indicated that a 7.4% increase in purchase price was unacceptable, due to the “single digit profit margin” of the trailer industry. The agencies recognize that trailer manufacturers have very low profit margins. However, we expect a majority of these costs will impact the overall cost of trailers across the industry and should not be isolated to individual trailer manufacturers.

We repeated Stoughton’s calculations to address the concerns with payback. These calculations indicate there is an average payback across the industry of 66 months (5.5 years). However, the agencies’ technology costs take into account a baseline adoption rate of technologies that we believe the industry would be applying if there were no Phase 2 trailer regulations. This market-driven adoption cannot be counted against the program. In the case of long box vans, we expect 45% of the trailers sold would have skirts or better in 2018 (TTMA indicated 35% of new long box vans have skirts today). To account for this, we applied a factor of 0.55 to the calculation for full-aero cost and the 5% benefit to 45% of the baseline, which resulted in a small reduction in payback to 65 months.

Additionally, these calculations assume that aero devices are only effective during 60% of trailer mileage, but the agencies make the more reasonable assumption that the effectiveness of the technologies is not zero for the remaining 40% of the miles. See RIA 10.2.1.1. Assuming these lower-speed miles are, on average, 25% of the high speed benefit gives 6.58 mpg, 6.54 mpg, and 6.52 mpg for the remaining 40% of the miles for full-, partial- and non-aero trailers, respectively. Applying these values in the calculation reduces the payback to 55 months. The agencies also disagree with the effectiveness that Stoughton applied. The full- and partial-aero effectiveness values appear to only account for aerodynamic improvements. If we add 1.25% (the value applied to the non-aero trailers) to the full-aero and partial-aero trailers to account for tire improvements, the new effectiveness values reduce the payback to 43 months (3.5 years).

Finally, most skirts are SmartWay-verified to achieve 5% reduced fuel consumption, yet these calculations apply a 5% reduction to the full-aero trailers that are assumed to include skirts and tails, and a 2.5% reduction to the partial-aero trailers that will likely include skirts. Applying an improvement of 9.25% to the full-aero trailers (a conservative 8% for skirt and tail aero and 1.25% for tires) and 6.25% to the partial-aero trailers (5% for skirts and 1.25% for tires) reduces the payback to 29 months; under 2.5 years. The agencies rely on EPA’s MOVES model for a much more sophisticated analysis that applies the average effectiveness of technologies for each trailer subcategory over each year of the program with decreasing VMT over the trailers’ lifetime. However, even the simplified calculation

performed here with more closely-aligned assumptions, results in a 2.5 year payback that is close to the agencies’ estimate.\textsuperscript{157}

The agencies address Stoughton’s safety concerns with the addition of weight due to aerodynamic devices in our response to TTMA on page 1019 of this section. Please see our response below. We conclude that the additional weight from aerodynamic technologies can easily be offset by substituting light weight components to accommodate manufacturers that believe their customers will frequently weigh-out. These components can then be applied in the Phase 2 program to offset use of some aerodynamic technologies for these trailers.

The agencies agree that intermodal trailers that spend some time traveling by rail have the potential to reduce fuel consumption and CO\textsubscript{2}. However, we do not have sufficient data to estimate the savings across the industry in order to quantify an appropriate credit value. Additionally, we would have to identify the characteristics of trailers that would indicate intermodal use, as well as the impact of the additional weight added to those trailers that may offset some portion of the rail benefits when they are on-road. The agencies are not adopting a credit for rail usage in this rulemaking, but could consider it in future rulemakings with additional data.

The agencies recognize the benefit of tandem trailers in reducing VMT and improving freight efficiency. However, we cannot guarantee that any short trailers, including 28-foot and 33-foot trailers, will be used in tandem when they are introduced into commerce. We are not adopting provisions to exempt any length of tandem trailer.

\textbf{Organization:} Thermo King

\textbf{Aerodynamic Packages available for Reducing CO2 Emissions and Fuel Consumption as Calculated by the Greenhouse Gas Emissions Model (GEM) for Trailers [§IV.D(2)(a)]}

Section IV.D of the Proposed Rule sets new requirements for CO2 emissions and fuel consumption in long and short trailers, and discusses the technology packages available to meet these standards. [EPA-HQ-OAR-2014-0827-1196-A1 p.2]

However, due to the size and performance requirements of today’s transport refrigeration units (TRUs), some of the technologies discussed would not be possible to implement in a refrigerated trailer, especially those which seek to make aerodynamic improvements. Ingersoll Rand is supportive of EPA’s recognition of these exceptions, which are reflected by the distinction of dry vans and refrigerated vans into separate classes with different consumption requirements. That said, since GEM is ultimately a performance-based metric using “binned” sets of technologies, it is difficult for Thermo King to analyze specifically which technologies EPA considers inapplicable to refrigerated vans. [EPA-HQ-OAR-2014-0827-1196-A1 p.2]

Ingersoll Rand requests that EPA specify those technologies which are not applicable to refrigerated vans due to TRU requirements, or otherwise provide clarification to truck manufacturers on the matter. As an example, most gap reducer technologies cannot be implemented in refrigerated vans, as this

\textsuperscript{157} The 2 year payback the agencies reference in our preamble and RIA to this rulemaking is a result of the combined tractor and trailer program costs and benefits. The calculations performed in response to this comment are for the trailer program only, based on the assumptions provided by Stoughton with modifications noted in our response.
would block the required airflow to the heat exchanger surfaces contained within the TRU, which is necessary to provide adequate refrigeration to the trailer’s contents efficiently. Ingersoll Rand believes that added guidance from EPA on the specific technologies for reducing emissions and fuel consumption that are applicable to refrigerated vans, as well suggested approaches to meeting these new GEM requirements in refrigerated vans while only using applicable technologies, will go a long way toward ensuring that trucks with refrigerated trailers operate efficiently as a system. [EPA-HQ-OAR-2014-0827-1196-A1 p.2-3]

Response:

The agencies are adopting standards with the same stringency between dry and refrigerated vans in each length subcategory. We recognize that most current gap reducers would not be appropriate for refrigerated vans with TRUs, yet several technology combinations exist that can compensate for no gap reducer (see our response to CARB in Section 5.3 on page 980). We designed our standards with example technology packages, but we do not restrict our box van performance standards to any given set of technologies. Manufacturers can choose from many combinations of aerodynamic devices, tire rolling resistance levels, weight reduction options, and tire pressure systems to achieve their desired performance. The agencies cannot create a comprehensive list of technologies that may or may not apply for each trailer design. Instead, we rely on the judgment of trailer manufacturers in coordination with their customers to choose the most effective designs that will meet the requirements of the standards as well as the needs of the customers’ applications.

Organization:  Truck Renting and Leasing Association

We also support: (3) equal focus on the potential fuel economy savings from improvements in the design and aerodynamics of trailers. [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

Response:

The agencies designed the box trailer program to be based on performance standards. As long as a manufacturer can demonstrate improved aerodynamic performance through aerodynamic testing, it does not matter if the improvements were made to the trailer design or achieved with the use of third-party bolt-on devices. The agencies did not have the resources to evaluate trailer design changes in their analysis, but that does not preclude manufacturers from pursuing design changes as part of their compliance plan.

Organization:  Truck Trailer Manufacturers Association (TTMA)

TTMA is highly concerned with creating and maintaining a safe environment on and off the nation’s roadways when it comes to the use of truck trailers. The current voluntary model of Federal GHG & fuel conservation relies on payback to incentivize end users to adopt technologies like aerodynamic features. Such a payback-based feature causes users to avoid the technology in end-use situations where either speeds or loads preclude payback; e.g. if a user needs to leave a pallet off their trailer because the aero devices put them over the weight limit, they will choose not to use them. The proposed rule will, of necessity, force aero devices on end users who otherwise would be avoiding them. For low speed users, this is simply a waste of resources, but for users operating at or near weigh-out conditions, the weight of the aero devices forces more trips as freight has to be hauled on a second load. Those extra trips pose a safety risk which must be accounted for. [EPA-HQ-OAR-2014-0827-1172-A1 p.7]

Estimate of Safety Impact of Deadweight Load of Aerodynamic Devices
Using a 250 lb. weight of aerodynamic devices per trailer, and a cargo load of 50,000 lb. when tractor-trailer is in Weigh-out mode means that the 250 lb. for extra devices will have to be hauled on an additional trip. [EPA-HQ-OAR-2014-0827-1172-A1 p.7]

250 lb add'1 / 50,000 lb cargo per Weigh—out Trip = 0.5% increase in Weigh—out Trips

Approximately 30% of tractor-trailers are operating at or near weigh-out conditions.\(^\text{13}\)

0.5% increase in Weigh—out Trips x 30% VMT in Weigh—out Conditions = 0.15% increase in Vehicle Miles Traveled (VMT) [EPA-HQ-OAR-2014-0827-1172-A1 p.7]

Annual VMT for tractor-trailers is 122,705 M VMT/year.\(^\text{14}\)

0.15% Increase in VMT x 122,705 M VMT/year = increase of 184 M VMT/Year [EPA-HQ-OAR-2014-0827-1172-A1 p.7]

Collision rate for Tractor-trailers is 134/100 M VMT.\(^\text{15}\)

Increase of 184 M VMT/Yr x 134 Collisions/100 M VMT = Increase of 246 collisions/year [EPA-HQ-OAR-2014-0827-1172-A1 p.8]

Approximately 3% of Tractor-trailer Collisions involve fatalities.\(^\text{16}\)

Increase of 246 collisions/year x 3% Fatality Involvement/Collision = 7 extra fatal accidents per year [EPA-HQ-OAR-2014-0827-1172-A1 p.8]

In general, the safety impact of additional weight on trailers is 1 extra collision per year for every pound of added trailer weight, and one additional fatality-involved crash per year for every 35 pounds additional trailer weight. [EPA-HQ-OAR-2014-0827-1172-A1 p.8]

Note that since the proposal relies heavily on EPA methodology that favors “technology-forcing” regulation, where regulations are formulated to require devices that do not currently exist, the proposal goes beyond NHTSA’s mandate to reduce deaths, injuries and economic losses resulting from motor vehicle crashes. Some of these devices don’t yet exist in a form that would satisfy the proposal, and those that do have potential safety risks that have not been fully explored. [EPA-HQ-OAR-2014-0827-1172-A1 p.8]

Weight:

As described in our Safety Impact section, increased tare weight contributes to increased VMT. While the safety concerns associated with this are our first concern, we ought to consider the fuel consumption and GHG emission effects of these extra trips. This will serve to reduce benefit from applied devices. Similarly, light-weighting trailers will allow more cargo to be carried and thus result in a reduction in VMT and a corresponding reduction in Fuel consumption and GHG emissions. Based on our reading of the EPA documents, the factors applied to weight reduction strategies do not include this effect and most certainly should. [EPA-HQ-OAR-2014-0827-1172-A1 p.17]
Response:

NHTSA evaluated TTMA’s safety impact analysis. NHTSA recognizes that regulatory and market factors that result in changes in trailer weight can potentially have safety ramifications, both positive and negative. NHTSA believes that the appropriate perspective is to evaluate the regulation and market factors in their entirety. One such factor is that incentives in the Phase 2 regulation could result in an average decrease in trailer weight. Since removing weight from trailers allows more cargo to be carried, fewer trips are needed to move the same amount of cargo, and fewer crashes – including fatal crashes – could occur. Fleets and other customers have a natural incentive to request lighter-weight trailers. From the trailer owners’ perspective, reducing trailer weight not only allows them to increase cargo when they are near capacity, but also reduces fuel consumption whether the trailer is fully loaded or not. In pre-proposal meetings with trailer manufacturers, companies said that customers are requesting lighter-weight components when possible and manufacturers are installing them.

To further incentivize a shift to lighter weight materials, the Phase 2 program provides two compliance mechanisms, both of which are discussed in the Preamble (Section IV.D(1)(d) and Section IV.F(5)(d), respectively). The first is a list of weight reductions from which manufacturers can select. The list identifies specific lighter-weight components, such as side posts, roof bows, and flooring. Manufacturers using these lighter-weight components achieve fuel consumption and GHG reductions that count toward their compliance calculations. The NPRM identified twelve components, ranging from lighter-weight landing gear (which receives credit for 50 pounds of weight reduction) to aluminum upper coupler assemblies (which receive credit for 430 pounds). See proposed section 1037.515 at 80 FR 40627. The final program includes additional lighter-weight components. In addition, for a lighter-weight component or technology that is not on the list of specific components, the program provides for manufacturers to use the “off-cycle” process to recognize the weight reduction (Section IV.F(5)(d)). Through these mechanisms, the program provides significant flexibility and incentives for trailer lightweighting.

NHTSA also recognizes that the aerodynamic devices we believe may be adopted to meet the Phase 2 trailer standards inherently add weight to trailers. In comments on the NPRM, TTMA stated that they believe that this weight increase will result in added trips and increased numbers of fatal crashes. By its analysis, this additional weight – which TTMA estimates to be 250 pounds per trailer, will cause some trucks to exceed the trailer weight limits, necessitating additional truck trips to transport freight that could not be moved by the “weighed-out” trucks. By TTMA’s analysis, these added trips would cause an additional 184 million truck miles per year and would result in 246 accidents and 7 extra fatal crashes, using an assumed accident rate of 134 collisions per 100 million VMT and a 3 percent fatality rate per accident. The agencies evaluated TTMA’s estimate of additional fatalities and disagree with some of the assumptions made in the analysis. For example, the fatality rate used was developed in a study conducted for Idaho and is higher than the national average. According to FMCSA’s 2014 annual report for “Large Truck and Bus Crash Facts” indicates there are less than 1.67 fatalities per 100 million vehicle miles traveled (VMT) by combination trucks in the U.S. for 2014. When multiplied by an estimated 184 million additional truck miles due to weighed-out trucks, the result is an increase of about 3 fatalities, or 2.7 fatal crashes.

Overall, the potential positive safety implications of weight reduction efforts could partially or fully offset safety concerns from added weight of aerodynamic devices. In fact, we believe that the Phase 2 trailer program could produce a net safety benefit in the long run due to the potentially greater amount of cargo that could be carried on each truck as a result of trailer weight reduction.

Organization: Truck Trailer Manufacturers Association (TTMA)
For the purposes of trailer manufacture and end use, the EPA’s SmartWay program coupled with voluntary adoption bring the optimal solution to reducing greenhouse gas emissions and fuel consumption in the heavy duty freight sector. [EPA-HQ-OAR-2014-0827-1172-A1 p.8]

Unlike the private car market, heavy duty trailers are used almost exclusively in a very competitive commercial market where fuel costs are second only to labor costs. As such, there is a huge financial incentive for end users to reduce the amount of fuel consumed and incidentally reduce greenhouse gas emissions released during operations. Innovators have been coming up with devices, methods and strategies to accomplish this for decades. These innovations often had varying degrees of actual effect compared to the claimed effect as each innovator would tout their product only in its best light. To complicate matters, not every innovation would be appropriate for every end user’s operation. This double level of confusion created a barrier to new products coming into use. [EPA-HQ-OAR-2014-0827-1172-A1 p.8]

SmartWay, when it came on the scene, removed one side of the confusion. By setting a standard to test products against, it allowed end users to remove one layer of variables to be evaluated before selecting a new approach to control fuel consumption. End users could now consider how well their operations would respond to SmartWay verified technologies when making their decisions. In doing so, the adoption of workable fuel savings technologies in areas where they will actually perform was accelerated. [EPA-HQ-OAR-2014-0827-1172-A1 p.8-9]

SmartWay is not perfect. For example, it lacks ability to account for possible savings from tire inflation control strategies, and it’s still limited in the types of trailers it considers, only recently expanding into refrigerated trailers. However, a voluntary program manages to get the maximum feasible improvement in fuel economy and greenhouse gas emission reduction without the unintended side effects of inappropriately pushing strategies into areas where they do not have an actual gain. [EPA-HQ-OAR-2014-0827-1172-A1 p.9]

We urge all parties concerned with creating an actual reduction in fuel consumption and greenhouse gas emissions to adopt Alternative 1 with respect to trailers. If the agencies feel the need to regulate, they should direct their regulations at end users who are selecting particular trailers to use with particular tractors for a given cargo and route. While California’s blanket requirement for trailers to be SmartWay certified was poorly thought out as to which end users might actually see benefit and which wouldn’t and had a host of unintended effects as a result, it was at least aimed at the correct market to effect change. [EPA-HQ-OAR-2014-0827-1172-A1 p.9]

We also note that in the current environment outside of California, end users that could benefit from SmartWay verified aero technologies are already using it. The proposal’s cost benefit analysis seems to overlook this important factor. As such, it both undervalues the work that has been done, by failing to note that aero-device adoption is disproportionately adopted in long haul operations and overvalues the proposal by assuming that new devices fitted to trailers that currently don’t have them would be used at fleet-average speeds, when that group of trailers are actually running at below average speeds. [EPA-HQ-OAR-2014-0827-1172-A1 p.9]

As we will describe below, any steps to pursue the agencies’ goals of improving fuel economy and reducing greenhouse gas emissions must carefully consider areas to exclude and/or exempt from regulation to avoid unintended effects. [EPA-HQ-OAR-2014-0827-1172-A1 p.9]
Response:

See our response to Stoughton in Section 5.1 on page 965 regarding non-mandatory standards. See also our response to the TTMA comment in Chapter 1 of this RTC, relating to the statutory authority for the trailer program to focus on trailer manufacturers as the regulated parties.

Organization: Truck Trailer Manufacturers Association (TTMA)

11 - Miscellaneous Points:

Automatic Tire Inflation Systems:

The definition of ATIS describes a system that does not exist. “Automatic tire inflation system means a system installed on a vehicle to keep each tire inflated to within 10 percent of the target value with no operator input.” State of the art systems only add air to underinflated tires. While overinflated tires do not have a detriment in terms of rolling resistance, they do have problems with accelerated tread wear. As stated earlier, this proposal overlooks the full carbon footprint of the things it’s proposing to regulate. For tires, CO2 emitted outside of use is 16% of the amount emitted during use. An ATIS system is slated to give a 1.5% reduction in emissions, but if that results in a substantial reduction in tread life, the relative fraction of emissions will balloon to eclipse the savings.

Response:

The agencies updated our definition of ATIS and removed the reference to 10% of a target value. In general, manufacturers and users will adjust their ATIS to an appropriate value for their applications and these systems will maintain proper tire pressure. We are not aware of evidence, and the commenter did not provide any, that overinflated tires are a significant problem with use of ATIS and thus that excessive tread wear broadly occurs with these systems.

Organization: Truck Trailer Manufacturers Association (TTMA)

Warranty Problems:

The proposal requires that all devices added to trailers be warranted for a period of five years, one year for tires. Such a warranty would be required “to warrant that these components and systems are designed to remain functional for the warranty period.” This has a few significant problems. For tires, some users will wear through their tires in less than a year’s period. With the overinflation problems expected with the widespread adoption of ATIS, we would expect that number to grow. Tire wear must not be covered under any warranty. Speaking of ATIS, the useful life for these systems is on the order of 5 years alone and we are not aware of any system that has a baseline warranty of more than 3 years. The proposed warranty period for ATIS needs to be reduced. Further, the most common problem with aero-devices is with collisions with infrastructure and other road hazards. Any warranty requirement must also exempt collisions and other non-routine use. [EPA-HQ-OAR-2014-0827-1172-A1 p.17]

Response:

See our response to the Utility comment in Section 5.1 (page 971) related to damage to aerodynamic devices. See also our response to the emission-related warranty comment from Utility in Section 5.3 (page 990). Finally, see our response to the tire over-inflation comment immediately above on page 1021.
**Organization:** Truck Trailer Manufacturers Association (TTMA)

Unintended consequence: brake/wheel end warming:

Over the history of design of a wheel end for usage on trailers, a continued goal has been to provide for the safest, longest lasting, and cost sensitive components possible. The industry continues to reconfigure the brake drum toward these ends. Consequently the weight of a brake drum has been reduced approximately 18% over the past 30+ years (resulting in reduced fuel consumption and therefore reduce CO2 creation). The proposal may reverse this design due to the need to dissipate heat. The heat is created due to braking action, which up until now was cooled via air flow. The concern with the proposal is that, with added side skirts and wheel deflectors for aero purposes, the air flow across the drum area is minimized resulting in an allowance of temperature increase. One way to manage the temperature would be to add mass to the brake drum, resulting in additional weight, thus conflicting with the intended potential advantages of fuel conservation. If temperature is allowed to build it will affect bearings, lubricant, seals, brake lining, heat treatment of drum in extreme conditions the tire bead could break seal from the rim or the tire could actually ignite and burn the unit to the ground. [EPA-HQ-OAR-2014-0827-1172-A1 p.17]

**Response:**

See our response to the Stoughton comment in this section (page 1010) relating to warming of brakes and wheel ends.

**Organization:** Truck Trailer Manufacturers Association (TTMA)

**DOE Super Truck Program**

In the DOE Super Truck Program, a truck and trailer were paired together and optimized together as a pair for aerodynamic performance. At the end of this optimization, neither the trailer nor the tractor could be said to be interchangeable with other trucks or trailers. There are truck aerodynamic design specifications or characteristics that can counteract and negate the trailer aerodynamic device fuel savings. The trailer OEM should not be regulated to add aero devices to trailers because the truck, trucks, or variety of trucks, to be used to tow the trailer is not known and such an understanding of the effects of truck aero design and how it affects the aerodynamic characteristics of the trailer is mostly not well understood nor have been shown to be constant or changing over time. [EPA-HQ-OAR-2014-0827-1172-A1 p.18]

**Response:**

The agencies understand that there can be interaction between aerodynamic features of a tractor and those aerodynamic features on the trailer it is towing. We did not base our trailer program on the advanced integrated technologies demonstrated in the SuperTruck program (see our response to UCS on page 1026 regarding SuperTruck). However, the characteristics of the tractors that we assumed in developing the trailer standards, and that we specify for compliance testing, are meant to recognize a reasonable degree of tractor and trailer aerodynamic interaction that typically occurs with real-world tractor-trailers (see also our response to OOIDA on page 1005).

**Organization:** Truck Trailer Manufacturers Association (TTMA)
When push comes to shove, the motor carrier industry is very resourceful and may take action which actually detracts from the overall purpose of reducing CO₂ creation. One such scenario has been experienced in the CARB trailer regulations in the state of California; many shipments have found their way to container/chassis combinations as an over-the-road mode of transportation which will not be required under the current proposal to be equipped with any of the aerodynamic features that trailer manufacturers will have to install on trailers. Cargo containers are also, by common design, inherently less aerodynamic given their ribbed sides and square edges. The combined weight effect of this diversion is a 5,000 lb. increase per container-chassis shipment to the empty weight of the unit of transference. Thus the proposed regulations will create an arbitrary and unreasonable outcome by diverting substantial cargo on a nationwide basis to far less efficient container chassis modes of transportation, and this will significantly undermine the desired goals of the proposal. Container and chassis manufacturers will be unreasonably favored in the marketplace by exclusion from the regulations, while their unregulated products will continue to produce less efficient aerodynamic outcomes than trailers currently in production today. [EPA-HQ-OAR-2014-0827-1172-A1 p.19]

12 Draft RIA, p2-155 “It can also be seen that very little benefit is seen for tractor trailers driving under highly transient conditions.”

13 “...weigh-in-motion data for 3-S2s indicate that over 70 percent operate at 70,000 pounds gross vehicle weight or less.” (Comprehensive Truck Size and Weight Limits Study, November 2013, Modal Shift Analysis, p8.).

14 Base Case for VMT total: 122,705,589,552. Ibid. Table 1, p12.

15 “The rate for tractor-semitrailers was 42/100 million VKT (134/100 million vmt)” (Comprehensive Truck Size and Weight Limits Study, November 2013, Highway Safety and Truck Crash Comparative Analysis, p16.).

16 “For example, in Idaho, about 3% of crash involvements for each involved a fatality, about 30-33% included an injury, and the remainder involved only property damage (PDO).” Ibid. p17.

25 TIRE PRESSURE MONITORING AND INFLATION MAINTENACE Developed by the Technology & Maintenance Council’s (TMC) S.2 Tire & Wheel Study Group; Study Group Information Report: 2010-2. ”...10 percent overinflation will reduce tread wear by five percent. ... Overinflated tires are more vulnerable to tread surface cutting, impact breaks, punctures, and shock damage which also shortens tire life.”

26 http://www.bridgestone.com/responsibilities/environment/mission/emissions.html Total Lifecycle CO₂ emissions for a tire are 86.4% during use.

28 80 FR 40282

Response:

The agencies recognize the potential for carriers to shift to use of containers in a situation where container chassis were completely unregulated. However, the agencies are adopting design standards for non-box trailers that require adoption of lower rolling resistance tires and tire pressure systems on all lengths of container chassis. While these non-box standards are not based on adoption of aerodynamic technologies, container chassis manufacturers will have appropriate regulatory requirements and we expect that this will help to limit the shift away from the lighter and more fuel-efficient box vans.

Organization: Union of Concerned Scientists (UCS)

LONG DRY VAN AND REFRIGERATED VAN TRAILERS

The EPA has recognized the benefits of trailer aerodynamics for many years through its SmartWay certification program. Most recently, it has created a new category in this voluntary program, SmartWay Elite, which can achieve 9 percent or more savings in fuel through a combination of aerodynamics and...
additional savings from low-rolling resistance tires. In fact, the agencies even note that five manufacturers now offer a total of nine aerodynamic technology packages that meet SmartWay Elite certification. Therefore, it is surprising that the agencies’ trailer regulation for van trailers in 2027 does not even achieve, on average, the same level of aerodynamic improvement as these SmartWay Elite packages offer today. [EPA-HQ-OAR-2014-0827-1329-A2 p.16]

In addition to EPA’s own work outlined in the RIA on the effectiveness of different trailer packages on the market today, other resources further confirm the conservative nature of the agencies’ trailer package. TIAX noted numerous trailer packages that yielded more than 20-percent reduction in CdA (2009). The National Research Council looked at what was already available on the market and anticipated that trailers could achieve as much as a 12.1-percent reduction in fuel in the 2015-2020 timeframe through efficient trailer aero packages (NRC 2010). And the agencies themselves have identified synergistic effects of different trailer technology combinations, suggesting that there is further room for improvement well beyond the first advanced packages certified as SmartWay Elite (Waltzer et al. 2015). [EPA-HQ-OAR-2014-0827-1329-A2 p.16]

As one would suspect, industry is not standing still in light of this potential. Modeling by Navistar’s SuperTruck team shows possible reductions in fuel use up to 16 percent from the static aerodynamic package and an additional 2- to 3-percent reduction from dynamic pitch control (Zukowski 2015). Daimler showed a 39 percent reduction in the drag coefficient from trailer technology alone. Peterbilt’s advanced trailer led to a 9% reduction in fuel consumption compared to the full SmartWay package, well exceeding SmartWay Elite levels (Damon 2013). A Freight Wing package based on work for the Volvo SuperTruck is being commercially developed and will offer between 12 and 14 percent savings in fuel (Amar 2015). Those are exactly the levels of innovation one would expect from industry when looking out at a longer time horizon, as the preferred alternative does. [EPA-HQ-OAR-2014-0827-1329-A2 p.16]

Further innovation could be developed in a move towards full-vehicle optimization. While this exceeds what is likely to be widely deployed in the timeframe of this rule, moving towards a fully integrated vehicle could lead to even further reductions in aerodynamic drag. Volvo was able to reduce the aerodynamic drag of their SuperTruck by 20 percent through trailer devices alone and 4 percent further by applying modifications to the tractor; however, through even further optimization, they have achieved a 30-percent total reduction in aerodynamic drag and have modeled a path to a 42-percent reduction (Amar 2014). We recommend that the agencies incentivize this approach by crediting tractor manufacturers for tractor-trailer integration, as noted in the section on tractor vehicle standards. [EPA-HQ-OAR-2014-0827-1329-A2 p.17]

All of this evidence speaks to the possibility of a much more ambitious standard for long van trailers. The product cycle for trailers can be much shorter than the tractors that pull them, and there are technologies already available today that can meet the standard the agencies have set for 2027. At a minimum, the More Stringent Trailer Alternative that is part of Alternative 4 is more appropriate, pulling these targets forward to 2024. Furthermore, with 2027 yielding the adoption of many SuperTruck technologies on the tractor side, we would expect SuperTruck trailers to see an even broader adoption in that timeframe, with a target that pushes innovation. A reasonable estimate of the market shift would be to have only 5 percent of the industry as laggards, while 10 percent of the industry could move toward a more fully optimized design (Table 4). This would result in an additional improvement of 0.14 ΔCdA, up to 1.27 in 2027 for long vans, yielding additional fuel consumption reductions of 1.5 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.17]

Refrigerated long van trailers would see less adoption of the most advanced levels of aerodynamic improvement because of their design but would nonetheless improve up to a ΔCdA of 1.13 in 2027 as the market shifted to more advanced designs. However, the agencies should further consider crediting
technologies to improve the efficiency of refrigeration, which results in significant consumption of fuel. [EPA-HQ-OAR-2014-0827-1329-A2 p.17]

However, we think there is further room for advancement beyond the agencies’ deployment of a standard skirt and gap reducer. For example, aerodynamic wheel covers are simply deployed and can improve aerodynamics on short and long van trailers alike (e.g., Deflecktor, RealWheels). Rear fairings can also be designed in a way that would not prevent their deployment on a middle trailer (e.g., Smart Truck Systems). This suggests that there is still further room for technology development beyond the levels achieved under the More Stringent Trailer Alternative. [EPA-HQ-OAR-2014-0827-1329-A2 p.18]

EPA’s SmartWay program is also considering the development of a SmartWay certification for pup trailers. Such a program would further incentivize the development of technologies for short van trailers, which again indicates that additional innovation can be found in this sector. [EPA-HQ-OAR-2014-0827-1329-A2 p.18]

Given the improvements that will be made to trailer aerodynamic technology for long vans in the time period of the rule, we would again expect levels of improvement in 2024 according to the More Stringent Trailer Alternative, yielding ΔCdA values of 0.26 and 0.20 for short dry van and short refrigerated van trailers, respectively. Incremental improvements to aerodynamic devices can improve these values to 0.30 and 0.24 by 2027. [EPA-HQ-OAR-2014-0827-1329-A2 p.18]

NON-BOX TRAILERS

The non-box trailer market is much more complex than van trailers due to the much greater rate of customization for specific applications. Furthermore, many of these trailers spend a significant amount of time at lower speed due to either heavy loads or off-road duty cycles. However, that should not preclude the agencies from incentivizing innovative approaches to reducing fuel use by vehicles pulling these trailers. [EPA-HQ-OAR-2014-0827-1329-A2 p.18]

The agency’s current approach does not provide a path for capturing aerodynamic improvements to non-box trailers, despite ongoing demonstration of its effectiveness. For example, Prime Inc., a for-hire carrier, has designed custom trailer skirts to improve the fuel economy of its flatbed fleet (photo). Freight Wing has tested its aerodynamic devices on flatbed, chassis, and tanker trailers as well, leading to fuel savings of 3 to 6 percent (Freight Wing n.d.). [EPA-HQ-OAR-2014-0827-1329-A2 p.18]

Because the adoption of these technologies is so dependent on duty cycle and still at the nascent stages of development, the agencies should encourage the continued testing and development of such promising technologies. Currently, the agencies have set only a “design standard” for non-box trailers, which means that technology implemented beyond the threshold design is not currently captured, and non-box trailers are excluded from averaging. [EPA-HQ-OAR-2014-0827-1329-A2 p.18]

While we recognize that this approach may make sense from a regulatory perspective for the small businesses that manufacture many of these custom trailers, we recommend that the agencies provide an option for manufacturers to include them in the averaging set. Furthermore, aerodynamic devices could be considered as an innovative technology for non-box or non-aero trailers, so an additional incentive to such as a 1.5X or 2.0X multiplier in the Phase 2 timeframe could help bring these technologies to market sooner without significant detriment to the overall environmental benefits of the rule. [EPA-HQ-OAR-2014-0827-1329-A2 p.18]

Response:

The agencies caution against comparing reported performance from device manufacturers and programs such as SmartWay to the performance we project in this rulemaking. In terms of aerodynamics, most device (and device combination) testing, including SmartWay verification, is performed at one constant speed. EPA’s GEM model, which is the basis of our trailer program compliance as well as determination of standard stringency, uses a drive cycle-weighting of 86% (long box vans) or 64% (short box vans) of the miles at 65-mph. As seen in Chapter 2.10.2.1.1 of the RIA to these rules, device combinations with performance similar to SmartWay-Elite technologies will produce CO\textsubscript{2} reductions that are 1% and 2% lower for these long- and short-box van weightings, respectively. Additionally, in contrast to the reductions reported under SmartWay and comparable programs, the agencies report our reductions here relative to a baseline adoption rate we project would be in place without regulation. For long box vans, this includes over 50% of the industry performing at an aerodynamic Bin III (i.e., skirts), almost 50% adoption of ATIS, and a high adoption of SmartWay-level LRR tires. In total, this long box van baseline is a 3% improvement over a no-control long van. This 3% difference, in addition to the 1%-2% difference due to drive cycle, must be taken into account when comparing to published performance data. EPA obtained additional aerodynamic test data since the NPRM and updated the trailer program’s aerodynamic bins accordingly. This new data, which includes many SmartWay-Elite combinations, provides a more complete assessment of the performance capabilities of today’s box vans.

The agencies value the work accomplished in the SuperTruck program, but it is difficult to separate the combined improvements for these tractor-trailer combinations into the individual tractor and trailer vehicles considered in the Phase 2 program. Tractors and trailers are manufactured by separate companies and the industries are distinctly different. We recognize that each vehicle plays an important role in the performance of the overall tractor-trailer and the performance (or lack of performance) of one can impact the potential improvements of the other. By specifying the characteristics of the tractors that we assumed in developing the trailer standards, and that we specify for compliance testing, the program recognizes a reasonable degree of tractor and trailer aerodynamic interaction that typically occurs with real-world tractor-trailers. However, we did not develop a formal incentive program for manufacturers to address tractor-trailer integration. Instead, manufacturers can petition EPA through off-cycle provisions and may be eligible for credit for innovative strategies that they may develop.

For non-box trailers, the final trailer program does not predicate its standards on the expectation that manufacturers will incorporate aerodynamic technologies on non-box trailers. The agencies are aware that some side skirts have been adapted for the non-box trailers considered in this rule (e.g., tank trailers, flatbed trailers, and container chassis), as noted by the commenter. However, there is currently insufficient information to develop aerodynamic performance standards on these relatively new and untried technologies. We did not receive data to allow us to sufficiently assess the degree of CO\textsubscript{2} and fuel consumption improvement that could generally be achieved across this segment of the industry, the associated costs of these technologies, and especially the likely disproportionate impact on small businesses. In the case of each of the general non-box trailer types included in the trailer program, the range of physical trailer designs is great, including the areas where aerodynamic devices would be installed, and technologies to date tend to be designed for narrow applications. The lack of basic information about the applicability of future technologies for these trailer types also inhibits our ability to estimate costs, either of the specific future designs themselves or of the size of the market for any particular product. As a result, only low adoption rates would be appropriate, and we expect that standards predicated on such low levels of adoption for these trailer types could result in relatively little emission and fuel consumption improvement at relatively high costs.
Moreover, a majority of the non-box trailer manufacturers are small businesses. The agencies have concluded that design standards for these trailers are the only way to ensure we achieve CO\textsubscript{2} emissions and fuel consumption reductions without disproportionately impacting that large fraction of the industry. Consequently, we are adopting tire-technology-based design standards for non-box trailers, as proposed. These design standards may not provide a direct incentive to develop aerodynamic technologies for non-box trailers, but it does not preclude customers from requesting these devices on their trailers.

Non-box trailer manufacturers may include aerodynamic improvements in their future trailer designs, but non-box trailer aerodynamic devices cannot be used for compliance at any point in the Phase 2 program. We do not provide an option for non-box trailer manufacturers to use our off-cycle provisions for innovative technologies, because it is likely that only the largest manufacturers would have the resources to do so. More importantly, we do not have a mechanism to provide additional credit to trailers in a program based on design standards. We will continue to monitor this segment of the trailer industry in this regard and may consider further action in the future.

**Organization:** United Parcel Service (UPS)

**Trailer Concerns**

UPS is not so much concerned about the technical challenges for trailers as the unrealistic cost and adoption rates on components. We anticipate generally an adoption rate of about half what EPA projects and a cost of about twice what EPA foresees. [EPA-HQ-OAR-2014-0827-1262-A1 p.13]

**Response:**

The agencies adjusted our compliance costs based on specific information provided by Wabash in their public comments (see our response in Section 5.6 on page 1092) and adoption rates based on a letter from TTMA.\textsuperscript{158} However, we cannot justify a sweeping reduction in technology costs without specific information about the technologies the commenter considered. We continue to stand by our estimates, as described in Section IV of the Preamble, which are based on the references cited in Section IV.D and available in the full public record.

**Organization:** Utility Trailer Manufacturing Company

**The Proposed Rules’ Projected Greenhouse-Gas Reductions Are Based on Unrealistic Assumptions that Fail to Account for Real-World Conditions and that Ignore Increases in Greenhouse Gases Cause by the Proposed Rules**

The Agencies project a 2.35\% (2018) to 9.4\% (2027) decrease in CO\textsubscript{2} emissions from tractor-trailers by adopting the required technologies. Those technologies yield benefits in two ways: decreasing road friction (through low-rolling-resistance tires; automatic tire-inflation systems; and weight reductions), and decreasing aerodynamic drag (through side skirts, trailer tails, and other air-deflection devices). [EPA-HQ-OAR-2014-0827-1183-A1 p.3]

The Agencies will never achieve their projected savings attributable to aerodynamic devices. This is because the projected reductions are based on assumptions that are completely unrealistic, do not account for actual conditions operators encounter every day, and ignore the increases in greenhouse gases caused by adopting the Proposed Rules. The net savings attributed to aerodynamic devices will be marginal, at best. [EPA-HQ-OAR-2014-0827-1183-A1 p.3]

**Response:**

It is not the agencies’ intent or responsibility to project the actual savings for individual vehicles in use. The 2% to 9% emissions decreases are industry-average projected reductions based on our test procedures and driving conditions represented in our model. The assumptions we have built into our projections have incorporated the information available in the public docket for this action, including public comments, for the effectiveness of the likely technologies and their industry-wide adoption rates, as well as accounting for average operational characteristics.

We recognize that the values we projected through this process will not match those of each trailer on the road under their varying technology choices and operating conditions. The values obtained in compliance are meant to provide a relative apples-to-apples comparison between trailers. The majority of the trailers in each of the covered trailer subcategories will experience benefits from these technologies, though the level of the improvement will vary, and the overall fleet-wide benefits should be in the range that we have projected.

In response to the comment about net savings, see also our general response to comments relating to “upstream” or manufacturing emissions in Section 1 and in our previous response on page 970.

**Organization:** Utility Trailer Manufacturing Company

**The Agencies employ unrealistic speed assumptions.**

The Agencies premise their projected aerodynamic savings on a computation concerning how much those aerodynamic devices will reduce drag. Drag reduction, of course, is determined both by how much more efficient the particular device is, and – more significantly – the trailer’s speed. As mentioned earlier, because aerodynamic drag is a function of velocity squared, aerodynamic drag forces are not relevant at speeds much below cruising speeds. [EPA-HQ-OAR-2014-0827-1183-A1 p.4]

The Agencies’ GEM model, however, computes savings based on the completely unrealistic assumption that trailers travel at the following speeds for the following percentage of time: [EPA-HQ-OAR-2014-0827-1183-A1 p.4]

- 65 mph cruise — 86%
- 55 mph cruise — 9%
- “Transient” — 5%

On their face, these assumptions bear no relationship to how tractors and trailers operate on America’s highways. Nor should they, because in reaching these speed assumptions the Agencies decided to ignore the significant amount of time the tractor/trailers spend idling, thus artificially boosting the percentages of time at higher-speed. [EPA-HQ-OAR-2014-0827-1183-A1 p.4]
It is both meaningless and misleading to compute projected fuel savings (and thus greenhouse-gas reductions) based on this unrealistic speed distribution, particularly when real-world data shows a dramatically different speed profile among trailer fleets. Utility Trailer obtained real-world speed data from four fleets showing the percent of time the fleet’s tractor spent at each speed; two of the fleets are long-haul, nationwide carriers traveling both in the United States as well as Mexico and Canada; two are regional fleets for food-service customers. All operate long-box trailers and use a mix of refrigerated and dry-van trailers. Data recorders logged the percentage of time the tractor/trailer was operating at each speed between 0 mph and 70 mph. One of the fleets recorded data for 4,000 tractors operating over a 6-month period; another (with the highest average speed) randomly sampled 15 tractors; and a third provided data for 26 randomly sampled tractors. The fourth fleet did not provide detailed speed data recorded by data recorders; instead, it provided its calculations of the amount of fuel saved at various speeds. This was based on data from 342 tractors, which ran between 69,457 and 2,496 miles, with most travelling roughly 30,000 miles during the time records were kept. [EPA-HQ-OAR-2014-0827-1183-A1 p.4-5]

The real-world speed data the fleets provided to Utility Trailer (denominated Fleet 1, Fleet 2, and Fleet 3) differ dramatically from that the EPA used in its GEM model in generating the assumed savings. The following spreadsheet (and graph) shows the difference. The Agencies based their definition of “transient” on that employed by the California Air Resources Board, which defined “transient” as speeds between 0 mph and 47 mph, with an average speed of approximately 15 mph. For purposes of the speed chart, “transient” is listed in the nearest speed category, 17.5 mph. [EPA-HQ-OAR-2014-0827-1183-A1 p.5]

[Table, '% of Time at Speed-EPA vs. Real-World Data', can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1183-A1, and a graph displaying the data can be found on p.6 of the same docket]

What is plain from the spreadsheet and graph is that the GEM assumption concerning the percent of time the tractor-trailers spend at higher speed dramatically exceeds what the real-world data shows. In fact, the weighted average speed of the GEM model equates to 62 mph and the average speed for these three fleets varies from 30 mph to 45 mph. [EPA-HQ-OAR-2014-0827-1183-A1 p.6]

To demonstrate further how far removed the EPA’s GEM model speed assumptions are from the real world, one can focus only on Fleet 2, the Fleet that had the highest average speed of the three fleets. As shown in the following graph, the differences persist even with these assumptions favorable to the EPA’s GEM model. Even in this fastest fleet, the single fastest tractor sampled was Truck 65000, which spent just 33.18% of the time at 65 mph, compared to 86% for the GEM model. Its average speed was 49 mph compared to the GEM average speed of 62 mph. And the slowest was Truck 651007 at 39 mph. [EPA-HQ-OAR-2014-0827-1183-A1 p.6]

[Graph, showing percentage of time individual trucks in Fleet 2 spent at each speed, can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1183-A1]

In addition to the information from the three fleets just summarized, Utility Trailer obtained information from a fourth fleet. This fleet’s data did not show amount of time the tractor-trailer operated at each speed. Rather, the data showed the amount of fuel that fleet’s tractors burned at various speeds. Tracking data over a total of 68 weeks encompassing 9.47 million miles, that data showed that 93.8% of the fuel consumed by the fleet was consumed at speeds lower than 55 mph. This confirms the relatively small gains available from tractors operating at higher speeds. [EPA-HQ-OAR-2014-0827-1183-A1 p.7]
The vast difference between the GEM assumptions and what happens in the real world is crucial to assessing the validity of the Agencies’ projected CO2 reductions. Tractor/trailers with lower average speeds will benefit less from trailer aerodynamic devices. Additionally, to produce valid data, projected speeds must also account for the routes typically driven by a given fleet. Routes in rural areas are likely to be different from urban routes, and routes along the plains will have a higher average speed than mountainous routes. Differences in state speed limits and typical weather conditions also must be factored in. The Agencies’ GEM model accounts for none of these factors. [EPA-HQ-OAR-2014-0827-1183 p.7]

Failure to use real-world speed data overstates the benefits of the Proposed Rule.

As noted earlier, the calculated emission benefits are based on speed assumptions that are radically different from those exhibited day-to-day on America’s highways. By significantly overstating the amount of time spent at high-speed operations, the speed at which aerodynamic devices actually may provide a real benefit as aerodynamic drag at that point is roughly equivalent to the drag from non-aerodynamic friction, the estimates describe benefits that never will be achieved in the real world. [EPA-HQ-OAR-2014-0827-1183-A1 p.15]

Response:

The agencies have considered these comments from Utility, along with the information that we used to derive the drive cycle weightings in Phase 1. For the Phase 1 program, we developed the sleeper cab cycle weightings (which are also used for long box van trailers in Phase 2) based on three studies that characterized the operation of line haul trucks: An evaluation using the EPA MOVES model, a study conducted by University of California Riverside, and a tire test on line haul trucks conducted by Oak Ridge National Lab.

The following discussion, excerpted from the Phase 1 RIA, Chapter 3.4.3, provides more background on the analysis:

_The distribution of vehicle miles travelled (VMT) among different speed bins was developed for the EPA MOVES model from analysis of the Federal Highway Administration data. The data is based on highway vehicle monitoring data from FHWA used to develop the distribution of VMT among road types from 1999. The information on speed distributions on the different type of roads at different times of day came from traffic modeling of urban locations and chase car data in rural California. This data was used to characterize the fraction of VMT spent in high speed cruise versus transient operation._

_The University of California Riverside and California Air Resource Board evaluated engine control module data from 270 trucks which travelled over one million miles to develop the heavy-duty diesel truck activity report in 2006. The study found that line haul trucks spend approximately 50% of the time cruising at speeds greater than 45 mph, 10% of time in transient stop-and-go driving, and 40% in extended idle operation. After removing the idle portion to establish weightings of only the motive operation, the breakdown looks like 82% of the time cruising at speeds greater than 45 mph and 18% in transient operation._

_Oak Ridge National Laboratory evaluated the fuel efficiency effect of tires on Class 8 heavy trucks. The study collected fleet data related to real-world highway environments over a period of two years. The fleet consisted of six trucks which operate widely across the United States. In the Transportation Energy Data Book (2009) Table 5.11 was analyzed and found on average that the line haul trucks spent 5% of_
the miles at speeds less than 50 mph, 17% between 50 and 60 mph, and 78% of the miles at speeds
greater than 60 mph. The table below summarizes the studies used to develop the weightings.

The fleet data cited by Utility includes weightings of speed records, which represent the fraction of *time* spent at a given speed, as opposed to EPA’s drive cycle weightings based on the fraction of vehicle miles traveled (VMT). Heavy-duty vehicle standards, including trailer standards, are expressed on a ton-mile basis (in contrast to a time basis, such as miles per hour) and, as a result, miles traveled is a more appropriate metric to consider than time traveled. For comparison, the agencies used the vehicle speed information provided in the Utility comments and translated the weightings to a VMT basis. Based on our assessment, when converted to the same metric, Utility’s findings produce weightings that are closer to those we used in developing the standards, showing 80% or more of the vehicle miles traveled by these three fleets are at speeds of 55 mph or higher, with 12% to 20% at speeds lower than 55 mph. We attribute at least some of the difference to the more limited sample represented by the three fleets Utility examined compared to the broader Phase 1 analyses. See our memo to the docket with more information on our drive cycle comparison.\(^{159}\)

While our proposed drive cycle weightings place a somewhat larger percentage of operation at 65-mph than does the more limited Utility analysis, trailers traveling at speeds of 55 mph will still experience a significant benefit with aerodynamic improvements regardless of the exact weighting. See Chapter 2.10.2.1.1 (including Figures 2-56 and 2-57). Without additional data representative of the range of national fleets, we continue to conclude that the proposed drive cycle weightings (originally developed for tractor-trailers in Phase 1), are appropriate for the Phase 2 program for trailers.

**Organization:** Utility Trailer Manufacturing Company

**The GEM model significantly overstates anticipated aerodynamic savings.**

To estimate accurately the cruise-speed fuel savings of a specific trailer aerodynamic device, first the aerodynamic fuel savings attained at each speed must be multiplied by the average percent of time the

\(^{159}\) Memorandum to Docket EPA-HQ-OAR-2014-0827, “Comparison of GEM Drive Cycle Weightings and Fleet Data Provided by Utility Trailer Manufacturing Co. in Public Comments”. July 2016.
tractor in a fleet travels at that specific speed. Then, the individual speed savings must be summed to an expected average fuel savings. The Agencies have failed to provide such a study using real-world speed data from in use tractors and trailers. Rather, by using the far-too-high GEM assumed speeds, the Agencies have significantly overstated the anticipated fuel savings from the aerodynamic devices. [EPA-HQ-OAR-2014-0827-1183-A1 p.7-8]

Appendix 1 to this submission describes in detail how the efficiency results were calculated. Using that Appendix, it is easy to track the conclusions stated in Sections 2.2.1 and 2.2.2. [Appendix 1 can be found on p.27 of docket number EPA-HQ-OAR-2014-0827-1183-A1]

**Real-world savings from side skirts are substantially less than projected in the GEM model.**

Table 1-1 in Appendix 1 shows the drag force associated with the trailer, and the reduction in drag – projected fuel savings – achievable with side skirts at 19 specific speeds between 0 and 70 mph. That table also shows the minimal savings skirts provide at lower speeds – less than 1% at speeds below roughly 35 mph. [EPA-HQ-OAR-2014-0827-1183-A1 p.8]

Using this projected fuel savings at each speed, it is possible to calculate the weighted average of fuel savings from skirts from the EPA’s GEM model, and for each of the three fleets for which we have real-world speed data. As noted previously, the EPA’s GEM study assumes only three speeds: 65 mph (86% of the time); 55 mph (9% of the time); and “transient” (assumed 17.5 mph – 5% of the time). The weighted average of the fuel savings at each of these speeds is 1.99%, as shown in Table 1-6 in Appendix 1. [EPA-HQ-OAR-2014-0827-1183-A1 p.8]

In contrast, when real-world speed data from the three fleets is used to compute the efficiencies of side skirts, the weighted average savings range between 0.95% (Fleet 1) and 1.43% (Fleet 2), depending on the speed profile of the fleet. See Table 1-6 in Appendix 1. [EPA-HQ-OAR-2014-0827-1183-A1 p.8]

If cruising speeds below 55 mph are ignored, the GEM model fuel savings is reduced slightly compared to the fleet’s fuel savings because the GEM model assumes (9% @ 55 mph + 86% @ 65 mph)≈95% of the time from 55 mph to 65 mph. At 65 mph and above, the cruise speed fuel savings for the GEM model is (1.79%), for Fleet 1 is (0.03%), for Fleet 2 is (0.21%), and for Fleet 3 is (0.54%). So, at this level, Fleet 3 provides greater savings than does Fleet 2. [EPA-HQ-OAR-2014-0827-1183-A1 p.8]

The following table and graph summarizes these comparisons. [EPA-HQ-OAR-2014-0827-1183-A1 p.8]

[Table, ’% Fuel Savings - Side Skirts’, and Graph, ’% Fuel Savings At Cruise Speeds’, can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1183-A1]

The percentages of time at each speed for each fleet are averages for the entire fleet. Within the fleets, the tractor speeds exhibit substantial variation. As noted earlier, Fleet 2 shows the highest average speed. But even within that Fleet 2, the fuel savings for both the fastest and the slowest tractors are well below the EPA GEM assumptions: [EPA-HQ-OAR-2014-0827-1183-A1 p.9]

[Table, comparing fuel savings from side skirts between fastest and slowest trucks studied and EPA GEM, can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1183-A1]
Even for the tractor that had the highest average speed in the fleet that itself had the highest average speed, the fuel savings nowhere approximate those of the GEM model. [EPA-HQ-OAR-2014-0827-1183-A1 p.10]

**Real-world savings from side skirts combined with trailer tails are substantially less than projected in the GEM model.**

The EPA’s model assumes that combining side skirts with trailer tails yields the most significant aerodynamic savings. According to the EPA, the skirt/tail combination produces a fuel savings of 5.56%. Again, this conclusion depends upon the GEM model’s assumption that the tractor-trailer travels at 65 mph 86% of the time, and at 55 mph another 9% of the time. [EPA-HQ-OAR-2014-0827-1183-A1 p.10]

The following table shows the fuel reductions as calculated by the EPA and as determined using real-world data. When actual speed data from the three fleets is used, the efficiency savings attributed to the skirt/tail combination drops by 28%, 35%, or 52% from the EPA estimates for 0–70 mph, depending on which fleet is used for comparison to the EPA’s GEM-model projections. In addition, they are all less than 3.5% at 55–70 mph, and less than 1.25% at greater than 65 mph, all under ideal conditions. [EPA-HQ-OAR-2014-0827-1183-A1 p.10]

The fuel savings generated from the combination trailer skirt and trailer tail, even under ideal cruising speed conditions, are very likely too small to be measurable in the field. [EPA-HQ-OAR-2014-0827-1183-A1 p.11]

But even these extremely modest fuel-efficiency gains overstate the results that will occur when the technology is actually mounted on trailers. Putting aside the fact that the estimates assume, unrealistically, that all trailers operate at optimum cruise conditions – level roads, no speed changes caused by traffic fluctuations, perfect weather, and the like – these estimates fail to account for human behavior: drivers do not want to deploy the trailer tails. [EPA-HQ-OAR-2014-0827-1183-A1 p.11]

Fleet 1 and Fleet 2 recently have installed trailer tails on many of the trailers in their fleet; one of the fleets has used auto deploy. But in both instances, the tails are not routinely deployed. A survey recently completed reported that the trailer tails were not deployed 58% of the time, even with auto deploy. This means that the drivers may be disabling the auto deploy feature and or the feature is still not reliable. A different fleet with trailer tails without auto deploy reported that the tails were not deployed over 20% of the time. [EPA-HQ-OAR-2014-0827-1183-A1 p.11]

The reason for the significant incidence of nonuse is that drivers consider deploying the tail to be a nuisance. Even with the auto-deploy feature, retracting the tail remains a chore for the driver since retraction is not automatic. More importantly, fleets often hold the drivers responsible for any damage to the tractor or trailer; drivers cannot see the tails when deployed, and the tails are easily damaged by both the trailer they are attached to and by the trailers parked adjacent to them. [EPA-HQ-OAR-2014-0827-1183-A1 p.11]

When other real-world factors are to be included, like the percentage of time that tractors accelerate or drive on significant road grades, in traffic, poor road conditions, etc.; the amount of fuel used for only ideal cruising conditions would diminish and so would the fuel savings and GHG emissions for a given
trailer aerodynamic device. Because of these varying factors and a small predicted fuel savings under ideal conditions that are not measurable, it would be better for the Agency to continue its voluntary program in regards to trailer aerodynamic devices. [EPA-HQ-OAR-2014-0827-1183-A1 p.11-12]

Response:

As discussed above in our drive cycle speed comparison, we converted the Utility data to a common metric and have concluded that the Phase 1 tractor-trailer analyses of average drive cycle weightings remain sufficiently robust to use for the Phase 2 trailer analyses. The three individual fleets that Utility analyzes are probably not atypical, but their experience does not disprove the agencies’ overall conclusions about average tractor-trailer operation. For this reason, the subsequent analyses that Utility performed and presents in this comment, premised as they are on this limited sample, do not provide a meaningful counter to the agencies’ broader analyses.

Further, the Phase 2 trailer compliance equation (which is based on GEM) is not a test for aerodynamic performance. Aerodynamic performance (as delta C_d A) is measured using wind tunnel, coastdown or CFD test procedures. Users submit aerodynamic performance data as an input to the equation, and the overall performance of the vehicle is calculated.

Within GEM, the simulated vehicle is driven over three drive cycles: 65-mph cruise, 55-mph cruise, and a transient drive cycle. As discussed in RIA Chapter 3.4.2.1, the two cruise speeds account for grade changes, and the transient cycle involves stops and starts with accelerations and decelerations to several different speeds. The commenter is consequently mistaken in asserting that these phenomena are unaccounted for in GEM.

In response to the comment about frequency of deployment of current trailer tails, we observe that trailer tails are used on a very small fraction of box vans today, and that experience by fleets and drivers is limited at this point. However, we expect that the growing direct and indirect experience with these devices across the industry, as well as likely design improvements that ease deployment for operation as well as ease the collapsing of the devices at loading docks, and will tend to increase proper use of these devices in order for the fuel saving benefits to be achieved.

Organization: Utility Trailer Manufacturing Company

Failure to consider the need to replace and repair the drag-reduction technologies overstates the benefits of the Proposed Rule.

The Agencies’ estimates underestimate the costs by failing to account for the emissions associated with replacing the items and repairing damaged trailers. At the more micro level, the touted cost-benefit calculation for the owner – savings in two years will pay for the devices – also is inaccurate in that the calculation does not account for the cost of replacing items or repairing trailer damage. Moreover, virtually none of those operators will see the fuel-reduction benefits described in the Proposed Rule for the reasons described previously. [EPA-HQ-OAR-2014-0827-1183-A1 p.16]

Additionally, the Proposed Rule fails to account for the costs associated with increased tire wear for low-rolling-resistance tires. Because low-rolling-resistance trailer tires are stiffer, they wear faster due to tire scrubbing, curbing, and other wear and tear. Scrubbing is a particular problem for the long-box trailers, as the “long wheel base” provides sufficient mechanical advantage, or leverage, to the tractor to easily scrub the trailer tires with a standard 49-inch axle spread and even an optional 121”-axle spread. Also, urban routes with tighter maneuvers are more susceptible to scrubbing. The stiffer low-rolling-
Resistance trailer tires are likely to be more vulnerable to wear under these conditions. The TMC, the maintenance council division of the American Trucking Association recently published their findings on LRR tire wear for tractors and trailers where they report that low-rolling-resistance trailer tires are wearing sooner than conventional standard tires.\textsuperscript{11} [EPA-HQ-OAR-2014-0827-1183-A1 p.16]

[Graph, 'Trailer Tire Mileage', can be found on p.17 of docket number EPA-HQ-OAR-2014-0827-1183-A1]

Standard trailer tires outperformed low-rolling-resistance trailer tires by an average of 4,000 miles. Increased tire replacement or retreading and replacement will contribute to greenhouse-gas emissions and mitigate the emission reduction from claimed from using low-rolling-resistance trailer tires. The Agencies have failed to consider this in their GEM Model and Proposed Rule. [EPA-HQ-OAR-2014-0827-1183-A1 p.17]

Response:

EPA has not included maintenance costs associated with aero treatments on trailers due to lack of data that could be used to support the estimates. Some commenters provided estimated annual values, but did not provide data to support their estimates. It is possible that their estimates are based on anecdotal evidence of a small number of problem installations rather than an average of all trailers equipped with aero treatments. Without such more robust information, we continue to conclude that overall maintenance costs are negligible. Our understanding is that the majority of routine maintenance includes, at most, minor actions like tightening of bolts, and that any additional costs would be minimal.

The agencies are familiar with the TMC reference cited by Utility and recognize that this report showed that standard tires outperformed LRR tires for trailers.\textsuperscript{160} However, we have two concerns with the report’s results. First, the fleets were asked to indicate mile ranges in 50,000 mile increments, which makes it difficult to see how an average of 4,000 miles was obtained and whether this is a significant difference. Second, the report did not provide any indication of maintenance that may or may not have been performed. It is possible that properly maintained tires would show no difference.

The agencies agree that trailers with large axle spreads are more susceptible to scrubbing and we are adopting provisions to exclude trailers with axle spreads greater than 120 inches (see 40 CFR 1037.5(h)).

Organization: Utility Trailer Manufacturing Company

AUTOMATIC TIRE INFLATION IS UNNECESSARY.

Even with an automatic tire-inflation system, a prudent operator should check tire pressure manually. This is because systems become damaged, because the systems are not foolproof, and because at times the systems add pressure to cold tires, but the pressure increases beyond the recommended maximum level as the tires heat during normal operation. Only by checking the tires manually can the operator be sure that the tires are actually at optimal pressure. [EPA-HQ-OAR-2014-0827-1183-A1 p.18]

Of course, many trucking fleets already have incorporated ATI systems in their trailer fleets, and they have invested the facilities and expertise to manage them properly. They believe that it is easier on drivers and saves tire wear. But this is not a reason to foist the system on all operators, particularly when prudent operators will check pressure manually in any instance. [EPA-HQ-OAR-2014-0827-1183-A1 p.18]

Additionally, most of the automatic-tire-inflation systems on the market only add air to the tires; they do not remove the air when the tires are overinflated. But as noted, overinflation is a concern when air is added to tires that are cold. Overinflation, however, increases the rate of tire wear, which increases net greenhouse-gas emissions. [EPA-HQ-OAR-2014-0827-1183-A1 p.18]

The Agencies have not demonstrated that the tire-inflation systems will generate sufficient savings versus the manual method to justify their adoption, nor have they considered the erosion of any benefits that will occur as the systems overinflate tires and decrease tire life, resulting in increased greenhouse-gas emissions. For this reason, Utility Trailer urges the Agencies to remove automatic tire inflation system from the proposed EPA Phase 2 Rules. In other words, the term “• C5” at the end of the equation should be removed, and the maximum “eC02” grams per ton-mile should be adjusted up to compensate equivalently. [EPA-HQ-OAR-2014-0827-1183-A1 p.18]

Response:

The performance standards for box vans are based on use of ATIS, but do not require any specific technology be applied. Manufacturers have the option to install any combination of aerodynamic, LRR tires, tire pressure systems, or weight reduction to meet the standards. The agencies are including ATIS as an option for compliance in our Phase 2 program as a means to ensure proper inflation and rolling resistance.

Regarding the potential for tire over-inflation with ATIS and possible consequences, please see our response to the comment from TTMA on this subject earlier in this section 5.4 (page 1021). Additionally, the final trailer program provides for manufacturers to install either TPMS or ATIS as a part of compliance. Manufacturers can offer box van customers that are confident in their drivers’ tire maintenance the option to choose no tire inflation or TPMS instead of ATIS. The final design standards for non-box trailers do require the use of LRR tires and a tire inflation system, but they can choose either TPMS or ATIS, and the trailer program does not require a specific make or model for these systems; manufacturers can already choose from several options on the market today, and these choices may expand as the program phases in.

Organization: Utility Trailer Manufacturing Company

Manufacturers should be given credit for net weight reductions, regardless of whether the weight reductions are attributable to switching to aluminum components.

The Regulatory Impact Analysis focuses on weight savings in trailers by substituting aluminum for steel components, although other portions of the Analysis recognize that weight savings are possible with high-strength steel or other materials. Aluminum, though lighter than steel, often is not the best material for a given application, since it only has approximately one-third the stiffness and lower yield strengths than steel. Manufacturers are in an excellent position to determine the best materials for their trailers and the stresses those trailers will encounter. They should be encouraged to reduce the weight of their trailers, while maintaining strength and longevity. Accordingly, since the Agency associates weight reduction with fuel-efficiency savings, manufacturers should be given credit for any weight savings in
their trailers, regardless of whether the savings come from redesign or substitution of materials, and if from substitution of materials, regardless of whether the previous material was steel, or whether the new material is aluminum, high-strength steel, plastic, or any other weight-savings material. [EPA-HQ-OAR-2014-0827-1183-A1 p.24]

5 These calculations are described in Appendix 1 – using real-world speed data from the three fleets – at various speeds.
6 Utility Trailer developed this information in the same way as it developed the statistics for efficiency of trailer skirts, but it reduced the drag coefficient to 0.423, the appropriate number with 0-degree yaw as determined by the computational fluid dynamic analysis performed by Exa Corporation.

Response:

We did not propose, but after further consideration in response to similar comments, we are finalizing a provision that makes the existing off-cycle process available to trailer manufacturers that wish to demonstrate design improvements by means not currently available in GEM (or the GEM equation). We have outlined steps for evaluating lightweight components or designs that are not listed in our current lightweighting tables. (See Preamble Section IV.F.5.d). Additionally, manufacturers have the option to use a different test procedure, with advance EPA approval, that they believe will effectively capture the benefits of their new design. See 40 CFR 1037.61

Organization: Wabash National Corporation

Wabash Supports EPA’s Proposed Bins for Trailer Aerodynamic Technologies, But Adjustments Are Needed for Bin VIII

To evaluate performance and cost of certain aerodynamic technologies, EPA and NHTSA identified “packages” of individual or combined technologies that are being sold today on box trailers. The agencies also identified distinct performance levels, or “bins,” for these technologies based on EPA’s aerodynamic testing. Table IV-4 in the Phase 2 Proposed Rule illustrates the bin structure that EPA and NHTSA are proposing for trailer compliance. Sample technologies for a 53-foot dry van in each bin include: (1) Bin I – No Aero Devices; (2) Bin II – Gap Reducer; (3) Bin III – Basic Skirt or Basic Tail; (4) Bin IV – Advanced Skirt or Tail; (5) Bin V – Basic Combinations; (6) Bin VI – Advanced Combinations (including SmartWay Elite); (7) Bin VII– Optimized Combinations; and (8) Bin VIII– Changes to Trailer Construction. [EPA-HQ-OAR-2014-0827-1242-A2 p.14]

With respect to Bin VIII, EPA must recognize that potential changes to trailer construction are limited by other regulatory requirements, including NHTSA safety standards and Department of Transportation (“DOT”) length and height requirements. Trailer manufacturers’ design innovations are limited both by regulatory requirements and by the market demand that payload capacity not be reduced. On the other hand, trailer manufacturers are able to introduce some innovations within those constraints and should be rewarded for doing so. Manufacturers should have the option to demonstrate their improved designs and be able to enter different inputs into GEM accordingly. [EPA-HQ-OAR-2014-0827-1242-A2 p.14]

Response:

The agencies have reevaluated our proposed aerodynamic bin structure for trailers based on the use of wind-averaged CdA and new test results obtained following the publication of the NPRM. The most notable difference is that we expanded the width of the lower bins. The NPRM Bins III, IV and V were reduced to two bins. Bins V, VI, and VII are identical to the highest bins from the NPRM (NPRM bins
VI, VII, and VIII). See Chapter 2.10.2.1.3 of the RIA. See our response to CARB in Section 5.3 on page 980 for an expanded description of our bin adjustments. In adjusting the bins, we have also better aligned the technologies we expect will fit in those bins based on our test results.

We are maintaining a “future” aerodynamic bin (Bin VII), but we are not aware of any current technology packages that can achieve the performance of such future designs. These designs may be changes to construction, within the limits of existing regulations, or could be newly designed components. The final trailer standards are not predicated on the use of any such future aerodynamic design changes. We did not propose, but are finalizing an off-cycle option for trailer manufacturers that wish to demonstrate design improvements by means not currently available in GEM. We have outlined steps for evaluating lightweight components or designs that are not listed in our current lightweighting tables. Additionally, manufacturers have the option to use a different test procedure, with advance EPA approval, that they believe will effectively capture the benefits of any new designs. See 40 CFR 1037.610.

5.5 Exclusions and Less-Stringent Standards

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)

Short and non-box trailers

The proposal requires 4.8% and 4.6% fuel consumption reduction in 2027 from short dry vans and short reefers, respectively. The agencies projected 2027 adoption of 95% Level II tires and automatic tire inflation (ATI) can provide almost 3% fuel savings, more than half of the 2027 target. At the same time, based on industry effectiveness estimates and the agencies’ bin adoption assumptions (30%, 60% and 10% for Bin II, III, and IV, respectively), these short trailers can achieve 4.4% fuel savings in 2027. Thus the 2027 requirements can be nearly met with aero technologies alone. Hence the total potential for fuel consumption from improvements in short trailers exceeds the proposed standard by more than 50%, and we would encourage the agencies to strengthen the 2027 requirements in order to drive advanced aero technologies for these trailers. With regard to non-box trailers, the proposed standards for 2027 would require improvement only in tires. We urge the agencies to consider adopting basic aero devices for non-box trailers in this timeframe. [EPA-HQ-OAR-2014-0827-1280-A1 p.18]

16 [http://www.arb.ca.gov/msprog/tech/techreport/epdo ve tech report.pdf](http://www.arb.ca.gov/msprog/tech/techreport/epdo ve tech report.pdf) (P. III-4)

**Response:**

See our response to CARB’s comment on the updated bin structure in Section 5.3 on page 980 and Chapter 2.10.2.1.3 of the RIA. It is important to clarify that the projections of adoption rates on which we base our performance standards are not “requirements” for box vans. The standards are designed to give manufacturers the flexibility to choose from multiple technology combination options to comply. It is possible that, in some model years, a manufacturer will be able to meet the required performance standard without certain technologies (i.e., large amounts of weight reduction, tires with very low rolling resistance, and ATIS could make up for use of aerodynamic improvements). See our memo to
the docket outlining possible combinations that can be used to meet the MY 2018 and MY 2027 standards.\footnote{Memorandum to Docket EPA-HQ-OAR-2014-0827. “Example Compliance Scenarios for the Final HD GHG Phase 2 Trailer Program” August 2016.}

The agencies adjusted our short trailer aerodynamic technology adoption rates based on test data obtained following the NPRM. Our final MY 2027 standards for short box vans are based on 60% adoption of technologies in the new Bin IV, which is equivalent to NPRM Bin V and a significant strengthening of the stringency from that proposed. While we did not observe any technology combinations that meet this bin in our testing, we note that our short box van results are based on a limited number of data points. We believe that additional technology combinations already exist in the market, beyond what we evaluated in our testing, that perform close to Bin IV and it would only be a matter of optimizing those combinations to fully achieve Bin IV. Since many of the current technologies are simply modified from versions of those made for 53-foot vans, we are confident that, over the next 10 years, this program will provide an incentive for trailer and aerodynamic device manufacturers to develop new technologies specific to short box vans that can achieve Bin IV. We also reiterate that the adoption rates projected by the agencies are only one option manufacturers can use to meet these performance standards. Weight reduction, which is more effective on short box vans, can be used in place of aerodynamic improvements, or that less aerodynamic improvement than projected could be used with weight reduction making up the difference. See Chapter 2.10.2.5 of the RIA.

We did not propose standards predicated on aerodynamic technologies for non-box trailers. The agencies concluded that much more information would be needed to have proposed such technologies that are in their infancy, but we will continue to consider them as a part of potential future action. See our response to UCS in Section 5.4 on page 1026.

**Organization:** American Trucking Associations (ATA)

**Additional Trailer Exclusions are Needed for:**

**Jeep, Dolly, and Load Divider:** A trailer composed of a trailer chassis and one or more axles, with no solid bed, body, or container attached, and which is designed exclusively to support a portion of the load on a trailer or truck. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

**Heavy-Haul:** Any trailer that has a gross vehicle weight rating (“GVWR”) of more than 120,000 pounds or any trailer equipped with an axle that has a gross axle weight rating (“GAWR”) of 29,000 pounds or more. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

**Expandable:** Any trailer that has a width of more than 102.36 inches with extendable equipment in the fully retracted position and is equipped with two short track axles in a line across the width of the trailer. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

**Extendable:** Any trailer that has air lines designed to allow extension of the vehicle frame or load deck. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

**Modular:** Any trailer that has air lines designed to allow separation and removal of deck sections or insertion of deck sections to create longer or shorter load carrying areas. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]
Sliding: Any trailer that has an undercarriage system designed to move forward or back to allow the load deck to tilt, slide, or adjust into a position that facilitates the loading or unloading of equipment but must return to original position for transport. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

Multi-Axle: Any trailer that has two or more permanently attached axles (including lift axles) and designed to accept additional removable axles, flip axles, and/or load transferring boosters; both mechanical, hydraulic, or air (or other gas). [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

Dump: An open-topped trailer having a load-bearing container body structure with a hydraulic cylinder that allows the container to be tilted to discharge its contents through an open tailgate that is used in short-haul transport of construction, paving, demolition and other bulk materials such as sand, gravel, asphalt, sludge, scrap metal, farm products etc., from off-road mine/pit loading sites to off-road construction unloading sites. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

Refuse Transfer: A usually open-topped trailer having a load-bearing container body structure that can be tilted on an external hydraulic tipping platform or equipped with a self-unloading floor to discharge its contents through an open tailgate that is used in short-haul transport of refuse material (garbage) from off-road transfer station loading sites to off-road landfill unloading sites. [EPA-HQ-OAR-2014-0827-1243-A1 p.25]

Lift Gate Equipped: Rail lift and lift gate equipped trailers operate at low speeds and perform local deliveries. As such, they ought to be classified as “non-aero” based solely on the inclusion of a lift. [EPA-HQ-OAR-2014-0827-1243-A1 p.26]

Multi-Temp Food Service: Typically has a compartment in the nose of the trailer that takes up the full width with two narrow compartments behind it. The two narrow compartments can be unloaded through the rear door but the front compartment requires unloading through a side door. [EPA-HQ-OAR-2014-0827-1243-A1 p.26]

Roll-Up Doors: Trailers utilizing rear roll-up doors should be given a partial or qualified exclusion from the aerodynamic requirements until an effective, durable and cost efficient product is available which is compatible with these types of rear frame designs [EPA-HQ-OAR-2014-0827-1243-A1 p.26]

Response:

We recognize that many trailers in the proposed non-box subcategory have unique physical characteristics for specialized operations that may make use of lower rolling resistance (LRR) tires and/or tire pressure systems difficult or infeasible. Instead of focusing on trailer characteristics that indicated off-highway use, the agencies have identified three specific types of non-box trailers that represent the majority of non-box trailers that we believe are designed for and mostly used in on-road applications: tanks, flatbeds, and container chassis. We believe that customers purchasing tanks, flatbeds, and container chassis will see an in-use benefit from using these tire technologies. Consequently, the final program as it applies to non-box trailers is limited to tanks, flatbeds, and container chassis. All other non-box trailers, about half of the non-box trailers produced, are excluded from the Phase 2 trailer program, with no regulatory requirements.

Most of the trailer examples provided in the commenter’s list would be excluded under these final provisions. However, the comment did not include sufficient information to justify a blanket exclusion of trailers with GAWR of 29,000 lbs, lift gates, multi-temp compartments, or roll-up doors. We do not know an average axle weight rating of different trailer types or the fraction of the industry that exceed
29,000 lbs today to determine whether customers would simply ask for a greater weight rating to avoid standards. Similarly, the comment did not provide data to support the claim that lift gates and multi-temp compartments indicate trailers commonly used at lower speeds where no technologies would be useful.

As noted in our responses to STEMCO in Section 5.2 (page 976) and FedEx in Section 5.4 (page 999), we are adopting an interim provision to recognize roll-up doors as work-performing equipment until MY 2024. We expect this provision will provide an incentive for device manufacturers to continue to develop and improve aerodynamic technologies that are appropriate for roll-up doors, but will allow manufacturers time to obtain, become familiar with, and prepare to market these technologies to their customers.

Organization: Environmental Defense Fund (EDF)

We are also concerned that the decision to exempt container trailers from the standards would create a potential loophole that could erode the overall benefits of the trailer program. The number of container trailers is growing and becoming a larger percentage of total trailer miles, with containers being used for longer delivery routes, displacing the use of traditional trailers. We understand the challenges of including containers under the standards, but we encourage the Agencies to develop a workable solution to this problem. [EPA-HQ-OAR-2014-0827-1312-A1 p.36]

Response:

The agencies are adopting design standards for non-box trailers, which include container chassis of all lengths, based on adoption of LRR tires and tire pressure systems. See also our response to the TTMA comment relating to container chassis in Section 5.4 on page 1023.

Organization: Great Dane

While we recognize that many fleets successfully employ skirts, we agree with the agencies that certain fleet specifications lead to the use of “work performing devices” (WPD’s) such as sidedoor steps, platforms, ramps and liftgates that preclude the use of skirts, and this does not afford those operators the opportunity to utilize skirts for fuel savings. We further note a high correlation of trailers with these specific WPD’s in the population of trailers used in “foodservice” applications delivering to restaurants, schools, hospitals and other commercial establishments. These food service trailers are generally built to allow transportation of goods at multiple temperatures. This usually requires side doors and other associated WPD’s to operate efficiently and avoid delivery by multiple single temperature trailers. Our records indicate that there is a high correlation between trailers utilizing multiple refrigeration evaporators and side doors, and those specific WPD’s to allow “multi temp” food service operations involving the delivery and unloading of goods thru the trailers’ side door or side doors from the trailers’ interior compartments. [EPA-HQ-OAR-2014-0827-1219-A1 p.2]

We note that most food service fleets specify trailers with overhead or “roll up” rear doors as opposed to the more common swinging type doors. We believe that these fleets purchase and maintain these rear doors at a premium over swing type doors in order to be able to deliver goods thru the rear door opening, typically via a “walk ramp” used by the driver or assistant when the trailer is in tight confines such as alleyways and parking lots. Such trailer specifications do not lend themselves to the use of rear aero devices or treatments, and we believe that food service fleets operate their trailers in local or at longest regional and then local delivery modes at generally lower speeds than traveled by longhaul fleets. Thus, we believe that food service trailers as characterized by multiple refrigeration system
evaporators should be exempted from any trailer aero requirements, as the WPD’s generally present on both the sides and rear of these trailers in addition to the roll-up doors and low speed operations we believe to be typical in those fleets hinder or preclude cost effective aero use. [EPA-HQ-OAR-2014-0827-1219-A1 p.3]

We agree with language in the proposed regulations that states there is consideration by the agencies of trailers “that have work-performing devices in two locations such that they inhibit the use of all (emphasis added) practical aerodynamic devices be considered “non-aero” box trailers.” We note that these WPD’s, whether installed by the trailer OEM, the customer or a third party, are there to increase the efficiency of the trailer and agree that such trailers should be exempted from aero requirements. [EPA-HQ-OAR-2014-0827-1219-A1 p.3]

The agencies have calculated and analyzed the impact on the industry based their understanding of the costs of the technologies, expected market penetrations and the fleet operational parameters such as speeds and distances traveled. As noted above we believe that certain trailers operate in regional or local delivery modes and thus we do not believe that such trailers benefit substantially from trailer aero, negating those fleets’ abilities to achieve sufficient return on those investments. We note that some trailers are equipped with rear mounted lift devices, installed by the trailer OEM, a third party or by the customer, to allow loading or unloading of freight independent of a loading dock. We believe that such trailers operate primarily in lower speed operations than fleet long haul operations and we believe that such trailers should be exempted from any trailer aero requirements. [EPA-HQ-OAR-2014-0827-1219-A1 p.3-4]

Response:

The trailer program recognizes the potential for trailer WPDs to interfere with or prevent the use of some aerodynamic devices, and provides for trailers with WPDs to be designated as partial-aero or non-aero and be subject to less stringent standards. The agencies expect many box vans with roll-up doors will include additional features that would quality these trailers for a partial- or non-aero designation. However, as noted in our responses to STEMCO in Section 5.2 (page 976) and FedEx in Section 5.4 (page 999), we are adopting an interim provision to recognize roll-up doors as work-performing equipment until MY 2024. We expect this provision will provide an incentive for device manufacturers to continue to develop and improve aerodynamic technologies that are appropriate for roll-up doors, but will allow manufacturers time to obtain, become familiar with, and prepare to market these technologies to their customers.

Organization:  International Council on Clean Transportation (ICCT)

Compliance and real-world validation

Per agency discussion within the proposed rulemaking, there appear to be some discrepancies across various companies regarding the precise times when model years fall within a given calendar year (e.g., engines within tractors could have differing model years). Importantly, the agencies’ analysis is based on a thorough investigation of the ability to introduce, and deploy in larger percentages, technologies in future years. We support the agencies approach to technology implementation timing, without including any delay in implementation due to industry-adopted convention for model years that differs across various regulated vehicle and engine manufacturers. Especially considering companies’ latitude in selling products of given model years, that are independent of calendar year, any delay in technology deployment or stringency determination due to how companies’ decisions about naming and marketing products by model year would be unwarranted. [EPA-HQ-OAR-2014-0827-1180-A4]
Response:

Consistent with Clean Air Act requirements and implementing rules\textsuperscript{162} EPA’s vehicle certification is an annual process. EPA CO$_2$ emissions standards start to apply for trailers built on or after January 1, 2018, with later standards being introduced by model year. Under the Clean Air Act, the term “model year” refers to a manufacturer’s annual production period. Manufacturers may use the calendar year as the model year, or may choose a different period of production that includes January 1 of that year. Thus, manufacturers have the option to choose any year-long period of production that begins on or before January 1 of the named model year, but no sooner than January 2 of the previous calendar year. For example, at certification, a manufacturer could specify the 2021 model year production period to be July 1, 2020 through June 30, 2021. We believe this definition provides manufacturers some flexibility in the release date of their new trailers, but ensures a level of consistency between manufacturers for regulatory purposes.

Organization: SABIC Innovative Plastics US LLC

Likewise, the agencies propose using several yaw angles to better approximate highway and wind conditions that introduce drag on the side areas of the vehicle. It is particularly important to account for lateral yaw in this rulemaking because of the relatively large lateral areas of a tractor-trailer combination. As Exa Corporation testified at the Long Beach public hearing: [EPA-HQ-OAR-2014-0827-1207-A1 p.3]

Because of the significant impact to real world efficiencies due to wind yaw effects; we feel it is imperative that wind effects be part of the standard …\textsuperscript{4} [EPA-HQ-OAR-2014-0827-1207-A1 p.3]

The agencies note that a ‘wind averaged drag coefficient is about 15 percent higher than the zero degree coefficient of drag.’ This is directionally consistent with findings from SABIC’s work with Exa to model the aerodynamic benefits of the optimized Class 8 Day Cab roof fairing.\textsuperscript{6} That research showed an 8-10 percent higher wind-averaged drag coefficient, based on the use of both zero degree and 6 degree yaw in CFD modelling.\textsuperscript{7} We believe the proposal to include yaw effects in CFD modelling for Phase 2 will result in more realistic estimates of on-road aerodynamic performance. [EPA-HQ-OAR-2014-0827-1207-A1 p.3-4]

\textsuperscript{6} Pereira, C. et al., Drag Reduction through Optimization of an Aerodynamic Day Cab Roof Fairing, SAE 2015 Commercial Vehicle Engineering Congress, October 6-8, 2015, 15CVA-0026 2015-012892 PPRES.

\textsuperscript{162} See, e.g. CAA section 206 (a) requiring certification for section 202 standards; since the standards here apply model year by model year, annual certification is required.
Response:

The agencies evaluated the aerodynamic test data for our trailer program and concluded (consistent with this comment) that wind-averaging is able to better capture aerodynamic improvements from many devices, including several small-scale devices. We are adopting a wind-averaged approach for aerodynamic testing in the trailer program. See RIA Chapter 2.10.2.1.2.3.

Organization: STEMCO

STEMCO supports excluding trailers with work-performing devices from a portion of the compliance requirements as long as those devices are purchased primarily for their work performing purpose. [EPA-HQ-OAR-2014-0827-1259-A1 p.2]

Work-performing devices

STEMCO agrees that work-performing devices such as rear-mounted lift gates and drop-deck trailer designs should qualify a trailer for a reduced “partial aero” compliance level. In addition to “partially interfering with the installation and effectiveness of some aerodynamic devices,” trailers with work-performing devices typically travel fewer highway miles each year and are therefore not as suited to receive aerodynamic devices. [EPA-HQ-OAR-2014-0827-1259-A1 p.9]

We have a small concern that a reduced “partial aero” compliance level could allow an unneeded work-performing device to be purchased specifically to reduce the aerodynamic device compliance standard in that region of the trailer. This scenario is highly unlikely because work-performing devices are generally more expensive and fleets do not want to pay more for zero (or substantially reduced) fuel savings, but there could be an example where steps for side-door access are purchased, but not used, by a fleet as a compliance alternative to sideskirts or another approved underbody aerodynamic device. It may not be necessary, but to mitigate this potential loophole, we simply suggest adding wording to the final regulation saying work-performing devices should be intended for work-performing purposes in that specific trailer’s application. [EPA-HQ-OAR-2014-0827-1259-A1 p.9-10]

Long van trailers with roll-up doors

STEMCO asks EPA and NHTSA to confirm in the final regulation that long van trailers with roll-up doors are subject to the “full aero” compliance level. We believe that the long van roll-up door subset of the industry contributes significant potential to the environmental goals sought by this regulation, with a conservative estimate of 23% of long van trailer highway miles being driven by trailers with roll-up doors each year. We also believe that maintaining long roll-up door trailers in the “full aero” compliance level will spur additional research and development and have a significant effect on bringing aerodynamic technology advances to market in the coming years. [EPA-HQ-OAR-2014-0827-1259-A1 p.10]

Response:

The agencies are adopting reduced standards for box vans designated as partial- or non-aero box vans. Because the types of work-performing equipment identified generally add significant cost and weight to a trailer, we believe that the reduced standards available for trailers using this equipment are unlikely to provide an incentive for manufacturers to install them simply as a way to avoid the full aero standards.
As noted in our previous STEMCO response in Section 5.2 (page 976) and our response to FedEx in Section 5.4 (page 999), we are adopting an interim provision to recognize roll-up doors as work-performing equipment until MY 2024. We expect this provision will provide an incentive for device manufacturers to continue to develop and improve aerodynamic technologies that are appropriate for roll-up doors, but will allow manufacturers time to obtain, become familiar with, and prepare to market these technologies to their customers.

Organization: Stoughton Trailers

2. Exempt portion of production Volume:
Official request for consideration of a graduated level of production volume subject to the regulation. The trailer industry has historically never been subject to regulation to the extent the GHG2 proposal of topic. The schedule is a declining progression from 20% to 5% over the period defined within the regulation. [EPA-HQ-OAR-2014-0827-1212-A2 p.1]

25% 2018-2020
20% 2021-2023
15% 2024-2027
10% 2027...............

Request 2: direct this type of graduation to allow for experience within the regulatory realm, in order to minimize potential non-compliance levels. [EPA-HQ-OAR-2014-0827-1212-A2 p.1]

Response:

The agencies are not finalizing the proposed provisions that would have allowed manufacturers to comply with the trailer standards using averaging before MY 2027. As a result, in the absence of mitigating provisions, manufacturers would need to comply with the applicable standards for all of their trailers. The agencies received comment, primarily from trailer manufacturers, that, without the flexibility of averaging, trailer manufacturers should be allowed to “carve-out” a set percentage of their sales that would not be required to meet the standards. In this comment, Stoughton Trailers suggests an up-to-20 percent carve-out.

The agencies considered this concept and this final program provides each manufacturer with a limited “allowance” of trailers that do not need to meet the standards. In determining an appropriate value for this allowance, the agencies sought to balance the need for some degree of flexibility in the absence of averaging while minimizing changes in the competitive relationships among larger and smaller trailer manufacturers. An allowance of 20 percent, as suggested by Stoughton, is problematic, since the annual production for individual trailer manufacturers varies so widely. An allowance of 20 percent for a very large manufacturer could very well represent the same volume of trailers as an entire year’s sales for a small manufacturer. This in turn could result in a situation where a large number of non-complying trailers would be on the market, potentially attracting customers away from smaller manufacturers that needed to market complying trailers.

Because of this, the agencies estimated a representative volume of trailers based on the 2015 Trailer Production Figures published by Trailer-BodyBuilders.com. The smallest box van manufacturer in the list produced 1800 dry freight vans in 2015. Twenty percent of that production is 360 trailers. Based on
this calculation, the trailer program includes an interim provision providing box van manufacturers an allowance of 20 percent of their production, up to a maximum of 350 units (i.e., rounding to the nearest 50 trailers) that are not required to meet the standards for model years 2018 through 2026, when the program does not include averaging and manufacturers are becoming familiar with the technologies and the program in general. All lengths of box vans, including both dry and refrigerated, produced by a given manufacturer count toward the allowance.

While averaging does not apply for partial- and non-aero box vans at any point in the program, the agencies recognize that manufacturers could also benefit from the ability to exempt some trailers from these subcategories in the early years as they transition into the full program. For this reason, for MY 2018 through 2026, the trailer program provides for manufacturers to choose to include partial- and non-aero box trailers in their 350 box-van allowance. By MY 2027, we expect that manufacturers of partial- and non-aero box vans will be able to meet the reduced standards for all vans in their given subcategories, and thus the program ends the allowance provision at that time.

Non-box trailers have design-based tire standards and averaging does not apply for this subcategory at any point in the program. Similar to the case of the partial- and non-aero box vans, we also conclude that non-box manufacturers can benefit from a transitional exemption allowance. For this reason, the trailer program also includes a separate allowance for non-box trailers, but a separate one because their production volumes differ and many non-box trailer manufacturers do not build box vans. Using the same trailer production figures referenced above, we found that the smallest non-box trailer manufacturer in the list produced 1325 trailers in 2015, and twenty percent of that production is 265 trailers. Accordingly, from MY 2018 through 2026, non-box trailer manufacturers can exempt 20 percent or 250 trailers (again, rounded to the nearest 50 trailers) from the applicable tire standards. By MY 2027, we expect that all non-box trailers will be able to incorporate the tire technologies required by the design standards.

Organization: Truck Trailer Manufacturers Association (TTMA)

6 - Further Areas Requiring Exclusion/Exemption

The proposal asks for input on the merits of exclusion versus exemption of various trailer types. Our objections to the agencies’ authority notwithstanding, we feel that all regulations should be crafted in such a way as to minimize unnecessary negative impact on manufacturers. Tracking and reporting burdens are very real costs, and should only be used by the agencies when there is a definite social gain to be had. There is no gain to be had by requiring reporting and tracking for classes of trailers that are not the subject of this proposal, so we encourage the agencies to maximize the use of exclusions wherever practicable. [EPA-HQ-OAR-2014-0827-1172-A1 p.9]

TTMA recognizes that the agencies have made great strides in gaining an understanding of the trailer industry and have laid forth certain types of trailers which should be excluded from the proposal. There are certain problems with the classification of some trailers and other types that also ought to be excluded. [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

Heavy Haul Exclusion

The proposal intended to exclude trailers designed for heavy-haul applications, but apparently used a simplistic combination of length and axle count to define a heavy-haul trailer. While such a metric is a useful test, it omits several other design characteristics that define certain heavy-haul trailers that
otherwise would not pass the proposal’s “Trailers shorter than 35 feet in length with three axles, and all trailers with four or more axles (including any lift axles).” [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

Heavy-haul style trailers are designed to carry equipment used for construction, agricultural, mining, logging, power generation and other industries, specialized loads generally not transported on a regular basis, high center of gravity loads, and over-sized (length, width, height, and/or weight) loads. Most of these trailers operate in either very small fleets (two to three trailers) or are owner-operated where requirements for specific tire and equipment types would cause a larger financial burden than the perceived benefit of reduced fuel use. [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

The following recommendations for exclusion are based on specific physical characteristics that are designed into each trailer type in order for it to perform its intended function. These trailers are not intended for nor are they used for over-the-highway long haul operations or at highway speeds for extended periods of time. These trailers will operate both on and off road, at various speeds, and in various terrains. There are not specific design characteristics that indicate that this trailer should operate at low speeds or on a specific type of terrain, but, these are physical characteristics that can distinguish heavy-haul style trailers from other trailer types. [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

“Jeep; Dolly, Load Divider”

As defined in 49 CFR 571.121 S4, a load divider dolly means a trailer composed of a trailer chassis and one or more axles, with no solid bed, body, or container attached, and which is designed exclusively to support a portion of the load on a trailer or truck excluded from all the requirements of this standard. [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

“Heavy Haul”

Any trailer that has a gross vehicle weight rating (GVWR) of more than 120,000 pounds or any trailer equipped with an axle that has a gross axle weight rating (GAWR) of 29,000 pounds or more. [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

“Expandable”

As defined in 49 CFR 571.121 S3.(a), any trailer that has a width of more than 102.36 inches with extendable equipment in the fully retracted position and is equipped with two short track axles in a line across the width of the trailer. [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

“Extendable”

Any trailer that has air lines designed to allow extension of the vehicle frame or load deck. [EPA-HQ-OAR-2014-0827-1172-A1 p.10]

“Modular”

Any trailer that has air lines designed to allow separation and removal of deck sections or insertion of deck sections to create longer or shorter load carrying areas. [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

“Sliding”
Any trailer that has an undercarriage system designed to move forward or back to allow the load deck to tilt, slide, or adjust into a position that facilitates the loading or unloading of equipment but must return to original position for transport. [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

“Multi-Axle”

Any trailer that has two or more permanently attached axles (including lift axles) and designed to accept additional removable axles, flip axles, and/or load transferring boosters; both mechanical, hydraulic, or air (or other gas). [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

Dump Trailer Exclusion:

There are a variety of trailer designs that nominally appear to be simple box trailers, but due to the design being used for in-field operations and short haul/low speed operations almost exclusively, should be excluded from the proposal. [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

“Dump trailer”

An open-topped trailer having a load-bearing container body structure with a hydraulic cylinder that allows the container to be tilted to discharge its contents through an open tailgate or equipped with special doors/gates to allow discharge of contents by gravity that is used in short-haul transport of construction, paving, demolition and other bulk materials such as sand, gravel, asphalt, sludge, scrap metal, farm products etcetera from off-road mine/pit loading sites to off-road construction unloading sites. [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

“Refuse transfer trailer”

A usually open-topped trailer having a load-bearing container body structure that can be tilted on an external hydraulic tipping platform or equipped with a self-unloading floor to discharge its contents through an open tailgate that is used in short-haul transport of refuse material (garbage) from off-road transfer station loading sites to off-road landfill unloading sites. [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

ATIS Exemption:

Certain tires/loads have working pressures is excess of what tractors can provide. These trailers should be exempt from the ATIS requirement. [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

Lift Gate Equipped Trailers:

Rail Lift & Lift Gate equipped trailers operate at low speeds and perform local deliveries. As such, they ought to be classified as “non-aero” based solely on the inclusion of a lift, however a better approach non-aero trailer classification will be discussed below. [EPA-HQ-OAR-2014-0827-1172-A1 p.11]

Response:

The trailer program includes provisions that exclude a large fraction of non-box trailers, as discussed in our response to the similar comment from ATA at the beginning of this Section 5.5 on page 1040. Similar to the list provided by ATA, many of the trailer examples in this TTMA’s list are now excluded
from the Phase 2 trailer program, with exceptions noted in the ATA response. In terms of TTMA’s additional ATIS exemption request, the comment did not include sufficient information on which to base an exemption, such as an appropriate working pressure threshold, or the number or type of trailers that would require these pressures. However, this concern should be largely addressed by the provision in the final trailer program allowing manufacturers to choose to comply with TPMS, and for manufacturers of box vans subject to performance standards to choose to comply with no tire pressure systems at all if offset by higher-performing aerodynamic or LRR tire technologies.

**Organization:** Truck Trailer Manufacturers Association (TTMA)

7 - Non-Aero Box Trailers

TTMA recognizes that the agencies have tried to account for the variety of trailer designs and the various sorts of service they are put in by creating a “non-aero box” category of trailer that is defined by the deployment of certain equipment or design features similar to our call for a “work performing equipment” exclusion in our October 16, 2014 letter. Unfortunately, the way that the proposal crafts this, it fails to capture the full extent of trailers that are operated at low speeds and for short trips. [EPA-HQ-OAR-2014-0827-1172-A1 p.12]

Consulting Figure 1-5 from the draft RIA, a significant fraction of the trailers are used on short trips and are therefore predominantly operated according to what the Agencies term “transiently.” [EPA-HQ-OAR-2014-0827-1172-A1 p.12]

[Figure 1-5 'Tractor-Trailer Primary Trip Length’ can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1172-A1]

As written, the proposal neglects the fuel costs and greenhouse gas emissions associated outside of operations on the trailer. The rule needs to account for the GHG and energy consumption of various devices during the entire lifetime of the component; construction, delivery, use and disposal, rather than just highway use as they do now. Although not required by statute, it would be foolish to require the use of devices whose GHG savings in use are small compared to the GHG emissions used during production, delivery, disposal, and necessary uses outside of running down the highway such as maintenance, retreading, etc. [EPA-HQ-OAR-2014-0827-1172-A1 p.12]

For aero-devices, estimating the carbon footprint of manufacture, distribution, service and disposal is difficult. One approach is to use a simplified cost of goods calculation based on the carbon footprint of the general automobile industry. This gives a rate of 460 kgCO2/$1,00021 Therefore, for a van trailer operated in a transient mode but still required to have $900 of aero-devices fitted, there will be a CO2 penalty of $900*(460/$1000) = 414 kg CO2 over the useful life of the aero-device. Additionally, this device will need to be hauled itself, its 250lb or 1/8th ton, would lend an additional 11g per mile (baseline emissions of 85 per ton mile times .125 ton, this would be higher on short trailers with their higher baseline). This in addition to the .15% decrease in performance from the effect of displaced cargo when operating at or near weigh-out conditions as described under “Safety Impact.” [EPA-HQ-OAR-2014-0827-1172-A1 p.12-13]

For these transiently operated trailers, what benefit is available would come from LRR Tires and ATIS. As described above, applying aero treatments to these trailers will result in an increase of GHG emissions/fuel consumption relative to an untreated trailer with LRR tires and ATIS rather than the desired reduction. The appropriate solution here is to recognize that trailers operated in transient service are more appropriately categorized as “non-aero box trailers.” The agencies can and should recognize
some fraction of the annual tractor-trailer combinations of each category as non-aero. End users eager to reap the rewards of aero-treatment payback, if it is realistic for their uses, can be counted on to select the correct type for their particular trip use. [EPA-HQ-OAR-2014-0827-1172-A1 p.13]

While we recognize the steps the proposal made to define a non-aero box trailer by certain devices fitted to it, by focusing solely on these items rather than on usage, you could create a situation where the market drives increased adoption of features to move trailers intended to be used transiently into the non-aero box category despite those devices not otherwise being needed to complete the job. An unneeded rear lift gate or side-mounted pull-out platform would have all the negative consequences of an unneeded skirt in terms of weight impact creating both a safety hazard and increased emissions described above. By allowing a fraction of tractor-trailer combinations with applicable trailers (Long vs Short/Dry vs Refrigerated) to be designated as “non-aero,” you eliminate these perversities that would arise between the proposed regulation and market forces and instead allow regulators and industry to focus on maximizing improvement. By removing the fraction of trailers that are used transiently, the standards that are set for the remaining trailers could possibly be raised from the proposed values and on a faster timetable. But this would only be possible with reasonable levels of non-aero box van classification. [EPA-HQ-OAR-2014-0827-1172-A1 p.13]

18 80 FR 40259: “(5) Exclusions and Less-Stringent Standards”

19 EPA-HQ-OAR-2014-0827-0146

20 EPA-HQ-OAR-2014-0827-0243

21 How Bad Are Bananas? The Carbon Footprint of Everything: puts the carbon emission of automobile manufacture at 720 kgCO₂/£1,000. Converting to dollars gets the quoted figure.

Response:

The agencies did not include a separate lifecycle analysis for trailer technologies in this rulemaking. However, we disagree with the lifecycle calculations provided in this comment. First, TTMA suggests that the carbon footprint of a relatively simple aerodynamic device is on the same order as a much more complex automobile with a rate of 460 kgCO₂/$1000. Considering a typical device may be constructed of 10 separate components, while an automobile consists of hundreds of components, an aerodynamic device may be 10% of this value. But even if we apply the 414 kgCO₂ calculated as the CO₂ produced by a device, we are confident that a trailer that applies this device will save more CO₂ during its use. The rule estimates that a full-aero trailer would save 4.8 g CO₂/ton-mi with a skirt and tire technologies in MY 2018 compared to a no-control trailer. If a trailer travels just 20,000 miles/year carrying 10 tons of payload, this trailer would save 960 kgCO₂/year, more than double the lifecycle CO₂. If we assume that the technology is half as effective for this particular trailer (2.4 gCO₂/ton-mi) and factor in that the trailer must carry 250 lb less payload because of the device (payload is now 9.875 tons), the trailer will still save 474 kgCO₂/year and the lifecycle CO₂ would be made up in the first year of very limited operation. Trailers with additional devices in later years of the program will arguably be more effective, and overcome the CO₂ generated in the devices’ production sooner.

In terms of the comment suggesting a program based on usage, EPA’s authority is limited to the manufacture of new vehicles. We do not have the authority to regulate the use of vehicles. Because of this, we can only establish criteria for reduced standards or exemptions based on characteristics of the
trailer that can be determined at the time of manufacture. While we expect that most trailers exclusively performing local deliveries will have work-performing devices that will qualify them for partial- or non-aero designation, we recognize that some local delivery trailers will not have these features. Because the types of work-performing equipment identified generally add significant cost and weight to a trailer (beyond the cost and weight of the aerodynamic devices themselves), we believe that the reduced standards available for trailers using this equipment are unlikely to provide an incentive for manufacturers to install them simply as a way to avoid the full aero standards.

See also our response to Utility in Section 5.1 (page 973) for our estimate of the CO\textsubscript{2} impact of additional weight of aerodynamic devices, and our response to the TTMA comment about potential safety implications of the weight addition of aerodynamic devices in Section 5.4 on page 1019.

**Organization:** Utility Trailer Manufacturing Company

**The Agencies should develop clear use and category exemptions.**

The Agencies’ Proposed Rule recognized that the proposed aerodynamic modifications are incompatible with certain trailer designs. For example, trailer tails are not designed to work on roll-up doors, and skirts are often incompatible with storage boxes and tire carriers mounted under the trailers. [EPA-HQ-OAR-2014-0827-1183-A1 p.19]

In addition to exempting such trailers from the Proposed Rule, Utility Trailer urges the Agencies to establish clear exemptions for trailers that would be used in certain operations. In these operations, the technologies are either incompatible with the options most often selected for that use, or the anticipated benefit from the technologies is extremely low due to the environment in which the trailers will operate. The trailer manufacturer would install a label on every manufactured trailer within this category, which would certify both the customer’s representation as to the use of the trailer and as permanent identification that the trailer is exempt. If the trailer’s use changed, or the customer sold the trailer to another user, the label would be removed. [EPA-HQ-OAR-2014-0827-1183-A1 p.19]

Specifically, the following categories / uses of trailers should be exempted: [EPA-HQ-OAR-2014-0827-1183-A1 p.20]

- Short-haul trailers that will travel fewer than 100 miles per day. Even California recognizes that aerodynamic regulation of such trailers is not cost-beneficial, as it exempts them from the side-skirt requirement in California. A similar exemption from the Proposed Rule’s requirements is appropriate.
- Local delivery operations, particularly those in urban environments. A significant number of these trailers are outfitted with devices – such as roll-up doors, liftgates, or side ramps – incompatible with the aerodynamic technologies. Additionally, these trailers usually operate at lower average speeds, negating any anticipated aerodynamic savings. Finally, as noted earlier, low-rolling-resistance tires are not a good fit for these applications, as they lead to increased scrubbing and damage.
- Trailers with greater than 121” axle spreads should avoid low-rolling-resistance tires, as the large axle spread causes increased scrubbing, particularly with the stiffer tread formulations in those tires. [EPA-HQ-OAR-2014-0827-1183-A1 p.20]

**Response:**
The EPA’s authority is limited to the manufacture of new vehicles. We do not have the authority to regulate the use of vehicles. California has its own authority under the CAA and they are able to regulate in-use vehicles. We do not have a means of determining or ensuring the number of miles per day a vehicle may travel, and we rely on physical characteristics of a trailer at manufacture to identify those that are likely to be used in urban or low-speed operations. This is part of the reason why the final trailer program completely excludes large numbers of non-box trailers that are not designed for primary use in highway applications. Also, the program provides reduced standards for trailers with certain work-performing equipment (either partial- or non-aero designation) and we expect many trailers that frequently operate in urban environments will qualify for these designations.

While some box vans may be operated transiently without work-performing equipment that would qualify them for partial- or non-aero designation, we expect these trailer will spend at least some time at speeds above 55 mph where trailers will see considerable benefit from aerodynamic improvements. See RIA Chapter 10.2.1.1. As noted in our response to Stoughton in Section 5.1 (page 965) and RIA Chapter 2.10.2.1.1, long box vans with skirts are expected to see reductions of 4% or more and short trailers with skirts could see 1% or more at speeds of 55 mph.

The agencies recognize that axle spread can indicate higher potential for scrubbing, but it is our understanding that axle spread can be a variable setting. The program excludes trailers from our regulations if their axle spreads cannot be set below 120-inches. However, trailers that have the ability to change their axle spread below 120-inches are included in the program. See 40 CFR 1037.5(h).

Organization: Wabash National Corporation

Wabash supports improvements in fuel efficiency as part of an overarching goal of improving overall freight efficiency. Wabash believes in two core principles with respect to the proposed regulations: (1) maximum compliance flexibility and (2) simplicity in compliance. The agencies should offer opportunities for compliance flexibility, including allowing for exemptions when the proposed measures are not economically feasible, and thus will not contribute to freight efficiency. Such exemptions are valid, and do not suggest that the industry is trying to avoid compliance, but instead represent common-sense and cost-effective regulation. Given that the composition and operation of the trailer industry is quite different from the engine and vehicle manufacturing industries, simplicity of regulation is essential. History has shown that the trailer industry has proactively and voluntarily embraced innovations when the fuel economy benefits are demonstrated, even without regulatory pressures. [EPA-HQ-OAR-2014-0827-1242-A2 p.8]

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, pp. 89-90.]

Two, not all trailer types or freight carriers will benefit from adopting fuel efficiency technologies. For example, tank trailers, flatbed trailers, and other specialty trailer types will not necessarily see benefits from the addition of aerodynamic devices, and for that, Wabash supports the EPA and NHTSA decision to exempt these trailers from aero requirements.

In addition, even some fleets operating nothing but van semi-trailers will not see benefits from the adoption of aerodynamic devices. This is because these types of trailers and fleets might operate in different duty cycles created by variations in operating locations and geographies, they may haul locally or regionally, and infrequently reach highway speeds, which is where aerodynamic devices provide payback. And they may have unique freight hauling requirements or operate off road for portions of the time.
The reality is some fleets and some trailer types simply will never demonstrate fuel savings through the use of aerodynamic devices. Thus, sensible final regulations should include exemptions for particular types of trailers or fleets whether through a fleet exception approval process or by including an extensive list of trailer characteristics that would define an aerodynamic exemption.

Response:

The trailer program is designed with a number of provisions that provide the kinds of compliance flexibility and simplification advocated by the commenter. For example, the agencies are adopting design standards for non-box trailer (tanks, flatbeds and container chassis) that are based on tire technologies only. The agencies also proposed a list of work-performing equipment (WPE) that we concluded impeded use of aerodynamic technologies and also indicated that they are more likely to be driven in short-haul operations. Trailers with these WPE can be designated partial-aero with reduced standards that are now based on adoption of a single aerodynamic device in the final program or non-aero with design standards based on tire technologies only. We are also offering a set allowance of trailers from each manufacturer that do not have to meet the standards in the years without averaging prior to MY 2027. Trailer manufacturers will determine which of their trailers would be included in this allowance. In MY 2027 and later, manufacturers can take advantage of our averaging provisions to allow some trailers in their production to meet lower standards.

The agencies are not adopting a provision for case-by-case exemption based on economic impact, as suggested by the commenter. Among other things, such an exemption leads to procedural complications, uncertainty (‘am I exempt or not’), and delay, at odds with the commenter’s (desirable) goal of simplicity and flexibility. In addition, the agencies have carefully considered costs in developing the final standards (including costs to small businesses) and have documented why the costs of the standard are reasonable. See Section IV.D.3 of the Preamble. As we describe above, we have also tailored the rules, via exemptions, simplified compliance procedures, and tire-based design standards, to reduce cost impacts on trailer manufacturers.

Organization: XL Specialized Trailers

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 203-205.]

As the current proposed regulations are presented, a very small list of exclusions and less stringent standards are laid out. We appreciate the regulatory agencies’ proposal allowing of this list, but we ask the agencies to also consider a much broader breakdown to a specific characteristic of what defines a heavy haul trailer. Most of these trailers are not intended nor are they used for over the highway long haul operations or at highway speeds for extended periods of time.

These trailers will operate both on and off road at various speeds and in various terrains. There is not specific design characteristics that indicate that this trailer should operate at low speeds on a specific type of train, but there are physical characteristics that can distinguish heavy haul style trailers from other trailer types.

Heavy haul style trailers are designed to carry equipment used for construction, agriculture, mining, logging, power generation, and other industries, specialized loads generally not transported on a regular basis, high center gravity loads, and oversized length, width, height, and/or weight loads. Generally speaking, the trailer is a tool to move the primary pieces of equipment which is then used as a primary revenue generator for the end user.
Most of these trailers operate in very small fleets of a few trailers for a single tractor, or are owner operated where requirements for specific mandatory design standards for tires and specialty equipment types would cause a larger financial burden than the perceived benefit of reduced fuel use. This definition list will be submitted as a written comment, and we are asking the agencies to seriously consider this while developing the language for this regulation.

Response:

As the commenter observes, the proposed program was designed to include nearly all trailer types, with a limited number of exemptions or exclusions. We recognize that many trailers in the proposed non-box subcategory have unique physical characteristics for specialized operations that may make use of lower rolling resistance (LRR) tires and/or tire pressure systems difficult or infeasible. Instead of focusing on trailer characteristics that indicated off-highway use, the agencies have identified three specific types of non-box trailers that represent the majority of non-box trailers that we believe are designed for and mostly used in on-road applications: tanks, flatbeds, and container chassis. Based on this additional consideration and comments like this one, the final program as it applies to non-box trailers is limited to tanks, flatbeds, and container chassis. All other non-box trailers, about half of the non-box trailers produced, are excluded from the Phase 2 trailer program, with no regulatory requirements.

Tank trailers are defined for the trailer program as enclosed trailers designed to transport liquids or gases. For example, DOT 406, DOT 407, and DOT 412 tanks would fit this definition. These non-box trailers can be pressurized or designed for atmospheric pressure. Tanks that are infrequently used in transport and primarily function as storage vessels for liquids or gases (e.g., frac tanks) are not included in our definition of tank trailers and are excluded from the program.

Flatbed trailers for purposes of the trailer program are platform trailers with a single, continuous load-bearing surface that runs from the rear of the trailer to at least the trailer’s kingpin. Flatbed trailers are designed to accommodate side-loading cargo, and this definition includes trailers that use bulkheads, one or more walls, curtains, straps or other devices to restrain or protect cargo while underway. Note that drop deck and lowboy platform trailers are not considered continuous load-bearing surfaces.

Finally, in the trailer program, container chassis are trailers designed to transport temporary containers. The standards apply to all lengths of container chassis, including expandable versions. The regulations do not apply to the containers being transported, unless they are permanently mounted on the chassis.

All non-box trailers that do not meet the definitions above are excluded and have no regulatory requirements. In addition, the rule excludes trailers intended to haul very heavy loads, as indicated by the number of axles. Specifically, the rules exclude all trailers with four or more axles, and trailers less than 35 feet long with three axles. We also exclude trailers with axle spreads that are set to be greater than 120 inches, and trailers intended for temporary or permanent residence, office space, or other work space, such as campers, mobile homes, and carnival trailers.

5.6 Compliance Provisions and Flexibilities for Trailer Standards

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Standard tractor for trailer certification

The Phase 2 proposal would permit manufacturers to test their trailers with tractors meeting Phase 2 Bin III or better (p. 40280). This will allow trailer manufacturers to gain credit for integration with tractors as both tractor and trailer aerodynamics evolve. Above we recommend that tractor manufacturers be given a comparable flexibility in their choice of test trailer while noting that a trailer already certified to
a higher delta CdA by virtue of such integration would negate any integration benefits on the tractor side. This is appropriate, since double counted of integration benefits cannot be permitted. However, tractor manufacturers may be far more likely than trailer manufacturers to pursue the development of integrated tractor-trailer aerodynamic designs, so the availability of an integration credit on the trailer side does not diminish the need for such a credit on the tractor side. [EPA-HQ-OAR-2014-0827-1280-A1 p.18-19]

Recommendations: Trailers

Consider strengthening the trailer standards for 2027 in order to increase the adoption of advanced aero technologies for both long and short dry vans and reefers. [EPA-HQ-OAR-2014-0827-1280-A1 p.19]

Promote aero technologies for non-box trailers by revising the 2027 standards. [EPA-HQ-OAR-2014-0827-1280-A1 p.19]

Response:

Tractor and trailer manufacturers that wish to include tractor-trailer integration strategies for compliance can use our off-cycle provisions to evaluate their performance. The individual tractor and trailer test programs are designed to maintain consistency between tests and be representative of tractor-trailers in use. The trailer program requires use of a standard tractor with minimum aerodynamic performance (Bin III) to ensure a poor performing tractor is not used to exaggerate the aerodynamic benefits of trailer devices (and to mirror real world conditions, where some effort is made to pair suitable tractors and trailers). We are not requiring that tractors of the same performance be used throughout the program, because we cannot guarantee that they will be available in the future.

Regarding the stringency of the trailer standards, based on the analyses for this final rule, we believe that the final standards in the program, as informed by all of the comments and slightly revised from the proposed Alternative 3 standards, are appropriate and represent the maximum feasible standards. Our final MY 2027 standards do include a small increase in adoption of high-performing aerodynamic technologies for the full-aero short and long box vans. For example, we proposed MY 2027 long box van standards based on 40% adoption of aerodynamic technologies that performed one bin higher than those we tested (Bin VII of the NPRM). The final MY 2027 full-aero long box van standards are based on 70% adoption of this level of performance (Bin VI in the updated FRM bins). Similarly, the final MY 2027 standards for full-aero short box vans are predicated on 60% adoption of technologies that perform in a bin higher than those we tested (Bin IV in the updated FRM bins). The agencies cannot predict the future technologies or trailer design changes that may be used to meet these standards. However, we are confident that the trailer industry has sufficient incentive to improve existing trailer performance in the timeframe of this rulemaking.

As explained in our response to UCS on page 1026, the final trailer program does not predicate the standards on the expectation that manufacturers will incorporate aerodynamic technologies on non-box trailers and we are adopting design-based tire technology standards for non-box trailers, as proposed.

Organization: American Trucking Associations (ATA)

Establishing a Trailer ABT Program Will Provide Fleets More Flexibility

ATA supports the use of Averaging, Banking, and Trading (“ABT”) by trailer OEM’s for a number of reasons. Fleets are wary of each trailer having to achieve a given compliance standard. As mentioned throughout these comments, maintaining fleet flexibility in spec’ing equipment is vital for our industry.
Fleets are best situated to determine what combinations of technologies perform effectively within their operational models and financial means. While it is certainly more convenient to conduct trailer compliance audits if each and every trailer were to hit a specific efficiency target, averaging will help maintain flexibility in purchasing decisions and promote greater acceptance. [EPA-HQ-OAR-2014-0827-1243-A1 p.24]

Response:

The agencies recognize that averaging, banking and trading have historically provided opportunities for vehicle manufacturers to maintain flexibility in complying with EPA’s standards, which, in turn, provided some level of flexibility for customers purchasing those vehicles. However, the trailer industry is unique compared to other vehicle sectors.

The final program includes averaging, but limits the option for trailer manufacturers to apply averaging exclusively to MYs 2027 and later for full-aero box vans only. We believe this delay provides the box van manufacturers sufficient time to develop, evaluate and market new technologies and to become familiar with the compliance process and possible benefits of averaging. This will also allow customers to become more familiar with the technologies and to recognize their benefits. This approach attempts to balance the advantage of an averaging program to allow for introduction of the most reasonably stringent standards for trailers, with the concerns articulated by manufacturers.

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Compliance requirements for trailers, trailer classification systems; Add aero requirements for non-box trailers; Change 50-foot demarcation to 47-feet; Remove belly boxes from the list of work-performing devices that inhibit the use of aerodynamic devices

The NPRM includes U.S. EPA and NHTSA’s proposal to regulate greenhouse gas emissions associated with trailers for the first time. The regulation will affect most trailers designed for use on highways. The proposed regulation requires that all affected trailers use LRR tires and ATIS, and that most box van trailers also use aerodynamic technologies. [EPA-HQ-OAR-2014-0827-1265-A1 p.69]

Although most aerodynamic technologies developed up until now have been designed for box van trailers, other trailer types, such as tanker trailers and flatbed trailers also stand to gain appreciable fuel economy benefits from these technologies. In wind tunnel testing conducted at the Auto Research Center in conjunction with Freight Wing, adding side skirts to a flatbed trailer reduced its wind-average drag coefficient by 8 to 9 percent at 50 mph, equivalent to a fuel savings of 3.5 to 4 percent at 50 mph, with larger savings possible at higher speeds. Manufacturers are working on developing technologies for these trailers. For example, Wabash has already released its DuraPlate Tanker AeroSkirt product. CARB staff believes that there are significant benefits from the use of aerodynamic equipment on non-box trailer types, especially for longer non-drop-deck flatbed trailers (greater than 50 feet in length). For this reason, CARB staff recommends that U.S. EPA and NHTSA consider adding aerodynamic equipment requirements on certain non-box trailers. For example, as part of Alternative 4, longer non-drop-deck flatbed trailers should start with a 5 percent adoption rate of Bin III technology by the 2021 MY, increasing to 15 percent by the 2024 MY. CARB staff believes that this standard for long non-drop-deck flatbed trailers is feasible given the relatively low adoption rate of 5 percent combined with the extra lead time by starting the requirements in 2021, three years after aerodynamic equipment requirements will have taken effect for box van trailers. [EPA-HQ-OAR-2014-0827-1265-A1 p.69-70]
Response:

The agencies are aware that some side skirts have been adapted for the non-box trailers considered in this rule (e.g., tank trailers, flatbed trailers, and container chassis), and appreciate the information that CARB submitted that notes that some of these technologies have shown potential for large reductions in drag. However, technology effectiveness is only one factor that we must consider when developing our non-box standards. Please see our response to UCS in Section 5.4 (page 1026). Consequently, we are adopting design-based tire technology standards for non-box trailers, as proposed. Non-box trailer manufacturers may choose to include aerodynamic improvements in their future trailer designs, but non-box trailer aerodynamic devices cannot be used for compliance at any point in the Phase 2 program as now constituted.

Organization: California Air Resources Board (CARB)

In addition to distinguishing between box van trailers and non-box trailers, the proposed regulation also subdivides box van trailers into nine subcategories, each with different standards. The division of box van trailers is based on whether the trailer is a dry or refrigerated van, whether it is long (over 50 feet) or short (50 feet and below), and whether positions where aerodynamic equipment are typically installed are occupied by a work-performing device. CARB staff is supportive of this classification system to determine the stringency of the requirements to which a trailer is subjected since it recognizes the fact that there is a greater availability of aerodynamic technologies designed for long box van trailers and also takes into account the presence of work-performing devices that may partially restrict the installation of aerodynamic devices. However, CARB staff recommends two changes to this classification system. First, CARB staff believes that the 50-foot demarcation should be changed to a 47-foot demarcation to account for the fact that 48-foot trailers are more similar to 53-foot trailers than they are to 28-foot trailers in terms of length and available aerodynamic technologies; and 28-foot trailers are typically used in tandem, limiting their ability to use rear aerodynamic technologies, unlike with 48-foot trailers. 48-foot dry van trailers constitute nearly 6 percent of the dry van trailer population. Hence, including 48-foot van trailers in the long box van trailer category, which essentially lowers the standard for these trailers by 42 to 45 percent, can lower overall emissions attributed to long and short dry box van trailers by about 2.5 percent, a significant amount. [EPA-HQ-OAR-2014-0827-1265-A1 p.70]

Response:

The agencies have included an analysis of trailer length in a memo to the docket of this rulemaking. While 48-foot vans are aerodynamically similar to longer vans and capable of adopting additional technologies, the agencies do not believe aerodynamic performance potential alone justifies a change in our proposed 50-foot demarcation for long and short box vans in the Phase 2 trailer program. In the analysis we show that 48-foot vans are more likely to travel fewer annual miles and their shorter trips indicate they are likely traveling at slower average speeds. These slower speeds would result in lower real-world performance, yet these trailers would need to adopt additional technologies compared to a 53-foot trailer in order to meet the same long box van standards. In addition, 48-foot trailers are estimated to make up less than 10 percent of the van trailer population and the additional CO₂ and fuel consumption benefits would be a relatively small improvement with more stringent standards. The agencies do not believe that standards predicated on the use of more effective aerodynamic technologies on 48-foot vans will provide a substantial enough additional reduction in CO₂ emissions and fuel

---

Page 1057 of 2127
consumption to justify more stringent standards for those trailers. For these reasons, the agencies are maintaining the proposed 50-foot demarcation between long and short box vans.

Organization: California Air Resources Board (CARB)

Second, U.S. EPA and NHTSA should remove belly boxes from the list of work-performing devices that inhibit the use of aerodynamic devices where the belly box is located. The NPRM defines “non-aero” and “partial-aero” trailers as trailers that have at least one of the work-performing features listed in paragraph (a)(1)(i) of the proposed 40 CFR 1037.107 in the redline version of U.S. EPA regulation. By including belly boxes on the list of work-performing devices, it is possible that certain fleets may exploit this as a loophole by specifying a small belly box in their trailer order instead of having side aerodynamic equipment installed. From CARB’s experience in implementing the Tractor-Trailer GHG Regulation, we know it is feasible to install a modified trailer skirt around the belly box. A wind tunnel testing project conducted jointly by Kentucky Trailer and Freight Wing at Auto Research Center showed that adding a modified trailer skirt around the belly box actually resulted in increases in fuel savings compared to the same trailer with unmodified trailer skirts and no belly box. As a result, CARB has modified its “Implementation Guidance for the Tractor-Trailer GHG Regulation” to allow the addition of a modified trailer skirt, as a CARB pre-approved modification, around a belly box. Pre-approval is based on testing demonstrating that a particular modification increases the wind averaged coefficient of drag (Cdw) by no more than 10 percent of the difference between the Cdw of the zero equipment baseline and the Cdw of the same trailer with the skirt. CARB staff has not experienced any difficulties implementing this provision, and recommends that U.S. EPA and NHTSA remove belly boxes from the list of work-performing devices that inhibit the installation of an aerodynamic device at the location where the belly box is located. Instead, U.S. EPA and NHTSA should identify belly boxes as a work performing feature that may require the installation of an aerodynamic device modified according to predetermined guidelines to be fitted around the belly box. This may require the preparation of an aerodynamic modification guidance document similar to that of CARB. [EPA-HQ-OAR-2014-0827-1265-A1 p.70-71]

Response:

The agencies agree that aerodynamic devices are feasible with smaller belly boxes. For the final regulations, we specify that to be eligible for “partial aero” or “non-aero” designation and the associated reduced standards, a trailer’s belly box needs to occupy at least half the length of both sides of the trailer between the centerline of the landing gear and the leading edge of the front wheels. Trailers with belly boxes that do not meet these criteria will not be eligible for the reduced standards for non-aero trailers.

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment –Exclusively using zero-yaw testing for trailer aerodynamic performance

U.S. EPA and NHTSA are proposing to determine the delta CdA for trailer aerodynamics using only the zero-yaw (or head-on wind) values for coefficient of drag. U.S. EPA and NHTSA are not proposing a reference method (i.e., the coastdown procedure in the tractor program). Instead, they are proposing to allow manufacturers to perform any of the proposed test procedures (e.g. coastdown, constant-speed, wind tunnel, computational fluid dynamics (CFD)) to establish a delta CdA. Since the proposed coastdown and constant speed procedures include wind restrictions, U.S. EPA and NHTSA are proposing to only accept the zero-yaw values from aerodynamic evaluation techniques that are capable
of measuring drag at multiple yaw angles (e.g., wind tunnels and CFD) to allow cross-method comparison and certification. [EPA-HQ-OAR-2014-0827-1265-A1 p.75]

CARB staff is concerned that using only the delta of the zero-yaw values to determine the delta CdA for trailer aerodynamics may not accurately reflect the aerodynamic benefit from improved trailer aerodynamics. U.S. EPA and NHTSA recognize that the benefits of aerodynamic devices for trailers can be better seen when measured considering multiple yaw angles. This is illustrated in Figure 22 from the RIA (shown below - Figure 4). The wind-average results were calculated at 55 mph vehicle speeds, consistent with the procedures in 40 CFR 1037.810. The wind-averaged analysis consistently results in a larger improvement (i.e., delta CdA) than the zero-yaw results. [EPA-HQ-OAR-2014-0827-1265-A1 p.75]

Therefore, CARB staff is recommending that U.S. EPA and NHTSA reestablish the performance bins and resulting proposed trailer standards based on wind-averaged drag results. Making this change is critical if the trailer standards are to reflect real-world gains in fuel efficiency and GHG reduction. In the real world, it is unreasonable to assume that tractor-trailers always travel when winds are coming straight at the vehicle. If the test method does not reflect wind-averaged drag, manufacturers run the danger of developing aerodynamic products that result in meeting standards that result in minimal or no benefit in real-world conditions. The opposite could also be true, where a technology that shows minimal benefit under zero yaw analysis can show measurable benefit when wind-averaging over multiple yaw angles are considered. This is illustrated in Figure 22 (shown below - Figure 4) for the gap fairing technology tested. [EPA-HQ-OAR-2014-0827-1265-A1 p.76]

CARB staff agrees with U.S. EPA and NHTSA decision to not require a reference test method, in order to reduce the test burden for manufacturers and allow them to choose an appropriate test method for their need and resources. However, the test method used must be capable of measuring wind-averaged drag. Wind tunnel testing and CFD are two viable methods. The use of reduced scale wind tunnel testing to evaluate the wind-averaged drag of aerodynamic technologies is common practice amongst trailer manufacturers. Several such manufacturers have submitted wind tunnel test results to CARB staff in accordance with requirements of California’s Tractor-Trailer GHG Regulation. [EPA-HQ-OAR-2014-0827-1265-A1 p.76]

Comment on Topic Where NPRM Requests Comment

**Comment – The use of Class 8 tractors for compliance simulation as well as performance testing**

The NPRM requests comment on the use of class 8 tractors when tractor-trailer combinations are used for compliance simulation as well as performance testing. We agree with the expediency of standardizing use of the class 8 tractors for determining trailer compliance even though the tractors pulling some trailer categories include a small portion of class 7 tractors. This approach will simplify compliance, and the differences between the results for a class 8 tractor pulling a trailer and a class 7 tractor pulling that same trailer are relatively minor. We recommend that this assumption be revisited if class 7 tractors grow in popularity or if the class 7 vs. class 8 tractor difference for tested trailers becomes significantly different due to evolving technology. [EPA-HQ-OAR-2014-0827-1265-A1 p.106]
Response:

The agencies evaluated the aerodynamic test data for our trailer program and concluded (consistent with this comment) that wind-averaging is able to better capture aerodynamic improvements from many devices, including several small-scale devices. We are adopting a wind-averaged approach for aerodynamic testing in the trailer program. See RIA Chapter 2.10.2.1.2.3.

Regarding the second comment, the final trailer program uses a Class 8 tractor for testing long box vans, as proposed. However, we allow short box vans to use either a Class 8 or Class 7 day cab tractor with a 4x2 axle configuration. The proposed 6x4 axle configuration was found to interfere with the landing gear of some trailers, which did not allow the tractor-trailer test vehicle achieve the regulation-specified gap spacing. We are confident that a 4x2 axle configuration will avoid similar interference and we based our short box van standards on aerodynamic testing with a Class 7 4x2 day cab tractor.

Organization: California Air Resources Board (CARB)

Comment – Requirements for emission control labels for trailers

CARB staff supports the proposal that emission control system identifiers be included on trailer labels. Having the emission control system identifiers on the emission control label is a simple and effective way of verifying that a vehicle is in a certified configuration, and is the most commonly used method of making a compliance determination during a vehicle inspection. CARB staff does recommend that an additional requirement be included to make labels readily visible to the average person (for example, amend 40 CFR 1037.135(b) to include: “Attached in a location where the label will be readily visible to the average person after the vehicle manufacture is complete.”) [EPA-HQ-OAR-2014-0827-1265-A1 p.110]

Response:

The labeling provision that CARB suggests is already part of EPA’s regulations and we are making a minor adjustment to clarify that it applies to trailers. (40 CFR 1068.45 and 1037.135).

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – A to B testing for trailer aerodynamic performance - the issue of varying performance for devices across the range of short van lengths, full credit for aerodynamic improvement

The NPRM requests comment on approaches to address the issue of varying performance for devices across the range of short van lengths. CARB staff supports U.S. EPA and NHTSA’s proposed grouping approach. [EPA-HQ-OAR-2014-0827-1265-A1 p.118]

Comment on Topic Where NPRM Requests Comment

Comment – Trailer aerodynamic compliance testing; pros and cons of exclusive use of zero-yaw data, allowing the use of wind-averaged results for compliance, strategy, supporting data
The NPRM requests comment regarding the pros and cons of exclusive use of zero-yaw data from trailer aerodynamic testing. CARB staff believes that there are advantages of using zero-yaw data. The primary advantage is that zero-yaw data is more reproducible than non-zero-yaw (multiple yaw angles) data. If U.S. EPA and NHTSA provide the option of using either zero-yaw or multiple yaw angle data, the same yaw angle must be chosen for both A and B cases to properly attribute aerodynamic benefits. [EPA-HQ-OAR-2014-0827-1265-A1 p.119]

35 Figure 22 from the RIA, page 2-162

Response:

The trailer program incorporates aerodynamic test procedures for trailers that require wind-averaged delta CdA values, as represented by an average of results from +4.5 and –4.5 degree yaw angles, for compliance. We are adopting wind tunnel as our primary test procedure with interim provisions allowing CFD to be used without adjustment (see 40 CFR 1037.150(x)). We are tightening the allowable yaw angle difference between A and B tests to within 1 degree for the limited number of trailers that may be tested using the coastdown procedures, and the interim provisions also allow these near-zero values to be used without adjustment, noting that the delta CdA results from coastdown were found to be similar to wind tunnel results for most devices in our testing. Manufacturers that do wish to correct their coastdown results to a wind-averaged value, have the option to work with EPA to identify a proper adjustment method.

Organization: Cummins, Inc.

With the addition of a trailer ABT program in Phase 2, Cummins supports creation of a trailer averaging set such that no exchange of credits between engines, vehicles and trailers can occur. [EPA-HQ-OAR-2014-0827-1298-A1 p.31]
The limited provisions for averaging in the later years of the phase-in of the trailer program do not allow exchange of trailer credits with credits generated by engine, tractor, or vocational vehicle manufacturers.

**Organization:** Exa Corporation

Because of the significant impact of real-world efficiencies due to the wind yaw effects, we feel it is imperative that wind effects be part of the standard for both tractors and trailers. [EPA-HQ-OAR-2014-0827-1420 p.265]

The negative consequences of not adopting wind effects into the standard for tractors and trailers include truck and trailer buyers, not realizing the fuel savings implied by the levels of which the truck and trailers are certified and the overall emission reductions promised for the program will not be achieved.

Some of the proposals attempt to address the inadequacies of the coast-down results by adjusting the coast-down results through the use of alternate tools for when they have the drag. We feel, as stated above, that the variations of wind average drag between the tools and facilities themselves is too significant and it would be an adverse consequence to allowing alternative tools for adjusting coast-down results. A standard that holds all the tools accountable to a real-world measure of the wind average drag performance of a vehicle, such as constant speed aerodynamic testing, is imperative in ensuring predictable behavior.

**Response:**

As noted in our response to CARB previously in this section on page 1061, the agencies are adopting aerodynamic test procedures based on wing-averaged values. Also see RIA Chapter 2.10.2.1.2.3.

We are adopting wind tunnel as our primary test procedure for trailer aerodynamic testing with interim provisions allowing CFD to be used without adjustment (see 40 CFR 1037.150(x)). We are tightening the allowable yaw angle difference between A and B tests to within 1 degree for the limited number of trailers that may be tested using the coastdown procedures, and the interim provisions also allow these near-zero values to be used without adjustment, noting that the delta CdA results from coastdown were found to be similar to wind tunnel results for most devices in our testing. Manufacturers that do wish to correct their coastdown results to a wind-averaged value, have the option to work with EPA to identify a proper adjustment method. See RIA Chapter 2.10.2.1.2.4. The agencies conducted a significant amount of constant speed testing, but were unable to develop a robust constant speed test procedure in time for the final Phase 2 rule. We do not anticipate device or trailer manufacturers will prefer constant speed testing to the other test options available in the trailer program, but a constant speed procedure is available for use, subject to the approval provisions outlined in 40 CFR 1037.526.

**Organization:** Great Dane

While we do furnish and install both LRR tires and ATIS on a customer-specified basis, we do not manufacture these items. As such we rely on the individual manufacturers of the devices and system by “passing thru” the warranties on these items. We are unaware of any trailer OEM that manufactures these items and we believe that other manufacturers also pass thru individual warranties as offered by the device producers. We further note that tire warranties vary greatly depending on the tires and application, and that to our knowledge the warranties provided by the popular ATIS do not exceed three years in length. This contrasts with the intent of the NPRM for trailer OEMs to offer warranties on these
technologies for up to one half of the useful life of the vehicle, which the agencies presume to be 10 years. [EPA-HQ-OAR-2014-0827-1219-A1 p.2]

The agencies have proposed to allow trailer manufacturers to “pass thru” certification data generated by the providers of fuel saving tire and aero technologies. We believe that the methodology of certification under the EPA SmartWay program is efficient and cost effective and should be continued and available to the trailer manufacturers as needed. [EPA-HQ-OAR-2014-0827-1219-A1 p.4]

We note that under the proposed regulation that trailer manufacturers will be held responsible for the correctness of the compliance information being passed thru by the trailer OEM and in the event information from the technology supplier is found to be incorrect the trailer manufacturer will be held responsible. Under the proposed rule a trailer manufacturer installing a technology found to be unintentionally misreported could be forced to recall trailers and may be subject to substantial fines on a per trailer basis. Under such a scenario we believe that any such recall obligations related to compliance correction should be borne by the supplier of the technology, with assistance by the trailer manufacturer as would be the case in a NHTSA safety recall, and any applicable fines should be paid by the device manufacturer as well. [EPA-HQ-OAR-2014-0827-1219-A1 p.4]

As stated above we note that the agencies propose that the trailer manufacturer should offer a warranty on fuel saving technologies for one half of the useful life of the trailer, which the agencies assume to be 10 years. Since in many cases the trailer manufacturers will not be designing, or actually manufacturing the technology we believe that such a warranty obligation should fall on the device manufacturer. We further note that the operational characteristics of the trailers principally benefiting from these technologies are in many cases long haul operations and thus, issues with devices or systems that are actually warrantable would be administered by a great variety of local service providers. Many of those service providers will not have any affiliation with the trailer manufacturer that produced the trailer. Thus, the warranty model potentially resulting from the proposed regulation for these technologies differs considerably from the typical automotive model where the automobile OEM specifies, manufactures, warranties and services emission controls. [EPA-HQ-OAR-2014-0827-1219-A1 p.4]

Finally, we understand that many of our competitors do not support the adoption of averaging provisions under the proposed rule, for various reasons. We at Great Dane believe that averaging may be an option that is necessary for trailer manufacturers to continue to supply cost effective and fuel efficient equipment to certain customers due to their equipment specification needs as a result of their operations. Thus Great Dane believes that averaging is an option that trailer manufacturers need depending on the definitions of exceptions and exclusions, and we recommend that averaging options be included in any final rule. [EPA-HQ-OAR-2014-0827-1219-A1 p.4]

Response:

Section 207 (a) of the CAA requires manufacturers to warrant their products to be free from defects that could otherwise cause non-compliance with emission standards. For purposes of the trailer program, EPA requires trailer manufacturers to warrant all components that form the basis of the certification to the CO₂ emission standards. The emission-related warranty thus covers all aerodynamic devices, lower rolling resistance tires, tire pressure systems, and other components that may be included in the certification application. Note that the emission-related warranty is completely separate from any other warranties a manufacturer might offer.

The trailer manufacturer needs to warrant that these emission-related components and systems are designed to remain functional for the warranty period. Based on the historical practice of requiring
emissions warranties to apply for half of the useful life, we are adopting a warranty period for trailers of five years for everything except tires. For trailer tires, we apply a warranty period of one year. We view the warranty of third-party components, such as ATIS, as a business decision by those manufacturers, rather than as a reflection of the actual durability of the systems. With proper maintenance, we are aware of no reason that these systems would be unable to meet the durability requirements of the trailer program. The agencies believe these systems (and similarly, the TPMS) should be designed to last the full useful life of the trailer if properly maintained. We believe a five year emission-related warranty is justified, but we note that trailer manufacturers can specify that this warranty depends on the proper maintenance of components. NHTSA is not adopting any warranty requirements relating to its trailer fuel consumption program.

The commenter notes that the current operational characteristics of the trailer industry differs from the automotive industry where customers can relatively easily bring their vehicles to an appropriate dealership for warranty-related issues. The statute and our regulations (see 40 CFR 1037.120) require manufacturers to provide warranty coverage without specifying the business arrangements for making that happen. Manufacturers will presumably continue similar business arrangements already in place for warranties unrelated to emission control. Manufacturers may develop their own procedure for providing emissions-related warranty coverage (e.g., set up contractual agreements with dealers or distributors, limit warranty coverage to a network of authorized service providers, and/or arrange payment to independent shops acting on behalf of the manufacturer), as long as the owner’s manual provides specific instructions describing how customers can get warranty coverage.

Similar to the proposal and EPA’s SmartWay technology verification program, the final trailer program provides for trailer aerodynamic device manufacturers to seek preliminary approval of the performance of their devices (or combinations of devices) based on the same performance tests described previously. Trailer manufacturers could then choose to use these devices and apply the approved performance levels in the certification application for their trailer families. A device manufacturer would need to perform the required A to B testing of their device(s) on a trailer that meets the requirements specified in 40 CFR 1037.211 and 1037.525 and submit the performance results, in terms of delta CdA, directly to EPA. Once a device manufacturer has obtained this preliminary approval, it could supply the same information to any trailer manufacturers that wish to install its devices. Note that both device manufacturers and trailer manufacturers are subject to 40 CFR part 1068, including the recall provisions described in 40 CFR part 1068, subpart F. In the event a device manufacturer submits false or inaccurate data to EPA, it could incur liability for causing a regulated entity to commit a prohibited act. See 40 CFR 1068.101(c). This same potential liability exists with respect to information provided by a device manufacturer directly to a trailer manufacturer.

As a result of the many comments opposing averaging from trailer manufacturers—the very stakeholders meant to benefit from an averaging program—the agencies have reconsidered how averaging is incorporated into the program. The final program does not allow averaging as a compliance option in the early years of the program, in MY 2018 through MY 2026. In those years, all box vans sold (beyond a manufacturer’s allowance of non-complying trailers) must meet the standards using any combination of available technologies.

However, the agencies have concluded that by late in the program, the value of an averaging option to many trailer manufacturers may well outweigh the concerns they have expressed. Therefore, the final program will provide a limited optional averaging program for MY2027 and later trailers. By that time, we believe that the trailer manufacturers will be experienced and comfortable with the program and the industry will be more familiar with the technologies. In addition, the final stage of the phase-in of the
standards for MY 2027 represents the most stringent standards in the program, and additional flexibility may be welcome by trailer manufacturers.

**Organization:** International Council on Clean Transportation (ICCT)

**Trailer procedures**

While this proposal for trailer standards lays a solid foundation, there are certain areas where modifications are warranted in order to close potential loopholes, increase compliance flexibility, and safeguard the expected fuel and emissions benefits from this portion of the Phase 2 program. The following topics are discussed in this section: (1) Averaging versus design-based compliance pathways; (2) Test procedure requirements; and (3) Aerodynamic performance assuming zero yaw versus wind-averaged yaw [EPA-HQ-OAR-2014-0827-1180-A4 p.15]

**Averaging.** In general, the ICCT is supportive of compliance based on sales-weighted averaging, as this gives manufacturers maximum flexibility to meet the standards using the technology deployment path that best matches their overall business strategy. If the agencies consider eliminating averaging-based compliance for a design-based approach, it is critical that the agencies maintain at least the same technology penetration for any alternative standards to avoid compromising the environmental benefits. This is clear, based on the facts that the technologies for the proposed standards are available and cost-effective, and have been already found to be highly attractive by leading fleets (e.g., see Sharpe and Roeth, 2014; Sharpe, Delgado, and Lutsey, 2015). In an attachment to our comments, we propose a concept for a design-based standard that would result in fuel and emissions reductions that are equal—or more—to the savings that could be achieved under the proposed averaging-based standards (Sharpe, 2015c). [EPA-HQ-OAR-2014-0827-1180-A4 p.15]

**Response:**

As proposed, the trailer program provides for manufacturers to comply with the box van standards through a combination of aerodynamic, tire, and tire pressure technologies of their choosing (or any other technologies), so long as the overall standard is met. We are limiting averaging to MY 2027 for full-aero box vans, where we have increased the stringency of the standards based on comments. Standards in the years prior to MY 2027, are similar to those proposed, indicating similar stringency and technology adoption. Design standards generally apply for trailer types where aerodynamic technologies provide little benefit.

The commenter also provides specific suggestions for flexibility if averaging is not available, as is the case in the final trailer program before MY 2027. The program addresses this concern through the allowances provided each manufacturer for a certain number of non-complying trailers. (See our response to Stoughton in Section 5.5 on page 1045).

**Organization:** International Council on Clean Transportation (ICCT)

**Test procedure requirements.** For assessing the aerodynamic performance of trailers, the agencies have proposed that manufacturers have the ability to use their choice of coastdown testing, wind tunnel testing, or computational fluid dynamics (CFD) software. Although there are merits to test procedure flexibility (e.g., among track testing, wind tunnel, or CFD) the lack of a ‘reference’ test method could open up opportunities for gaming. One of the important drawbacks of wind tunnel and CFD evaluation is that technologies are modeled as idealized versions, rather than the actual technologies themselves. For example, in wind tunnel or CFD testing, an aerodynamic device can be modeled as being
completely smooth and flush with the edges of the trailer, while in reality, there are small gaps and irregularities that affect the air flow and the overall performance of the trailer with the device. In addition, device vibrations that are part of normal operation and can take away from the efficiency benefits are all but eliminated in wind tunnel and CFD testing. Because of these inherent discrepancies between evaluating a modeled version of the device versus the actual device itself, there would ideally be a requirement to do at least one track test. This is aligned with the requirements for tractor manufacturers, who must perform at least one enhanced coastdown test and then can use wind tunnel or CFD testing for other models, provided that they adjust their results using a correlation factor that is linked to the coastdown results. We believe that requiring trailer manufacturers and device suppliers to also do track testing will decrease the opportunities for ‘cherry-picking’ the best results, which may not be reasonably representative of real-world conditions. We also recommend that the agencies consider allowing the SAE J1321 “Type II” fuel consumption test procedure, as it has been required for many years for SmartWay verification testing and is most familiar to the trailer industry. Trailer manufacturers would ideally be required to do at least one track test (coastdown or J1321) for each aerodynamic drag area (i.e., tractor-trailer gap, side or underbody, and rear) where they would like to certify products. We include further details in the associated memo attachment (Sharpe, 2015c). [EPA-HQ-OAR-2014-0827-1180-A4 p.15]

Response:

See our responses to CARB (page 1061) and Exa (page 1062) describing our use of wind-averaged drag results in the trailer program and the applicable test procedures. The protocols for coastdown, wind tunnel, and computational fluid dynamics analyses result in a CdA value. Note that SmartWay’s 2014 protocols allow SAE J1321 Type 2 track testing, which generates fuel consumption results, not CdA values. Commenters did not suggest a means of converting from the fuel consumption results to an appropriate delta CdA value for use in compliance. As a result and as proposed, the final program does not accept J1321 data for pre-approval.

Organization: International Council on Clean Transportation (ICCT)

Zero versus wind-averaged yaw. The Phase 2 regulation is meant to drive technologies into the market that provide real-world benefits to fleets and society as a whole. As such, trailer manufacturers would ideally have the option to certify their products under wind-averaged yaw conditions. The agencies acknowledge that evaluating under various yaw angles is a more realistic assessment of how the technology will perform on the road when faced with wind directions that can vary greatly. However, the agencies have proposed that aerodynamic performance be solely determined using zero yaw conditions. We propose that manufacturers be allowed to use wind-averaged results from wind tunnel or CFD testing, provided that these results are correlated back to the coastdown or J1321 results. We include further details in an associated memo attachment that we also submit to the docket (Sharpe, 2015c). [EPA-HQ-OAR-2014-0827-1180-A4 p.15]

Response:

As noted in our response to CARB on page 1061, we are adopting wind-averaged results using a surrogate yaw angle of the average of +4.5 and -4.5 degrees. Wind tunnel and CFD results must be submitted as wind-averaged values. Coastdown results can be submitted as near-zero values, or manufacturers can contact EPA to determine an appropriate adjustment factor to a wind-averaged result for technologies that are sensitive to yaw angle.

Organization: Michelin North America, Inc.
Trailer aerodynamic inputs to the GEM P2 v1.0 a.

Trailer yaw angle at 0° vs Tractor yaw angle at 0° — 6°

The NPRM appropriately proposes the inclusion of the 'total vehicle' for the tractor-trailer combination in the GHG and FE standards since that vehicle configuration makes up the majority of the commercial vehicles in use. In this NPRM, the trailer is now required to be part of the assessments and certifications. [EPA-HQ-OAR-2014-0827-1286-A1 p.6]

The NPRM states that tractor aerodynamic drag is determined by testing is conducted over a range of 0° — 6° yaw and averaged for the GEM P2 v1.0 input. [EPA-HQ-OAR-2014-0827-1286-A1 p.6]

The NPRM requires only a trailer aerodynamic drag delta $C_D$ for trailer aerodynamics using the zero-yaw, e.g. 0° (or head-on wind) values. [EPA-HQ-OAR-2014-0827-1286-A1 p.6]

For a realistic and complete assessment of the overall trailer aerodynamic performance, a range of yaw angles, e.g. 0° — 6°, needs to be included for an averaged aerodynamic drag delta $C_D$ GEM input, i.e. effects of real world cross winds on such tractor-trailer combinations. [EPA-HQ-OAR-2014-0827-1286-A1 p.6]

Michelin supports the use of wind averaging result for aerodynamic inputs into both the tractor and the trailer GEM models. From simulation results it has been found that different aero devices behave significantly different at changing yaw angles. While some devices do tend to improve their value as yaw angle increases, this is not always the case. Many devices improve, some remain constant, and others actually have a degradation of performance under cross wind conditions. [EPA-HQ-OAR-2014-0827-1286-A1 p.6-7]

The following chart is the normalized change of drag reduction for a number of aero devices going from a 0° yaw angle to a 6° yaw angle. The range of performance difference seen is 6% or approximately 3% fuel savings. This makes the yaw performance an important input to the GEM calculation. [EPA-HQ-OAR-2014-0827-1286-A1 p.7]

[Graph, 'Normalized change of drag reduction when going from 0 degree yaw to 6 degree yaw', can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1286-A1]

Actual inversions of total performance have been seen between two designs of comparable devices when 0° yaw is used instead of wind average results as shown in the following figure. Without the use of wind averaged results designs would sacrifice cross wind performance to improve the 0° yaw condition. [EPA-HQ-OAR-2014-0827-1286-A1 p.7]

[Graph, 'Drag reduction performance of two comparable devices', can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1286-A1]

In light of this understanding we also support $C_{D,aero}$ being centered about the wind averaged case rather than be centered about the 0° yaw condition. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

Therefore, the range of yaw performance of aerodynamic devices is a major design factor and the averaged aerodynamic drag delta, $C_D$, GEM input should be considered in trailer aerodynamic performance. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]
Response:

As mentioned in our response to CARB (page 1061), we are adopting provisions to incorporate wind-averaged aerodynamic results into the trailer program.

Organization: Michelin North America, Inc.

Aerodynamic Formula for Adding Trailer Components

As stated in a. above, the trailer is now required to be part of the assessments and certifications. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

The proposed drag formula provides a method for adding individual trailer components together that are not actually tested together. It provides 100% of the benefit of the most fuel saving device 90% of the savings of the 2nd and 80% of the savings for the devices added thereafter. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

Aerodynamics is a system, not just a collection of parts. As such, all too often devices do not work well together and the data supports this. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

Devices that have been tested together, and some designed to work together, have been shown to have less total benefit than the proposed formula. From our testing, the proposed formula favors a collection of devices that may only be effective when tested alone, and does not provide for integrated aerodynamic systems testing to assess the combined systems. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

One example would be using trailer skirts in addition to under-tray devices which would yield less savings than the EPA formula indicates. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

As an example, one of the best total performance combinations simulated was a particularly high performance trailer skirt and boat tail device. Each was also tested independently and their combined savings were significantly less than the EPA formula. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

For this example the second device only yielded 78% of the savings instead of 90% as currently proposed. In this example the end result may indeed be attractive as it does offer large fuel savings, but the proposed formula yields differing expectations and does not encourage the testing of these devices together. [EPA-HQ-OAR-2014-0827-1286-A1 p.8]

[Graphs, Simulations of skirts and other aerodynamic devices compared to EPA formulas, can be found on p.9-10 of docket number EPA-HQ-OAR-2014-0827-1286-A1]

In another example, trailer skirts and a device designed for use with trailer skirts were simulated separately and together. Despite the design intent, actual simulation results of the paired devices returned only 69% of the second device's individually tested fuel savings. [EPA-HQ-OAR-2014-0827-1286-A1 p.9]

A final example was a trailer skirt and a device frequently used in the market with trailer skirts. In this case the second device returned less than 53% of the individually tested fuel savings. [EPA-HQ-OAR-2014-0827-1286-A1 p.9]
Therefore, the testing of combined systems will provide fleets with expected savings. If a formula for adding devices is included such as in the NPRM aerodynamic formula, it should provide an incentive to also test combined solutions, and which may modify the proposed percentage factors when the devices are tested individually. [EPA-HQ-OAR-2014-0827-1286-A1 p.10]

Response:

Our wind-averaged test data, which is summarized in Chapter 2.10.2.1.2.5, shows that combinations of devices perform better than the sum of their individual effectiveness. Use of our proposed device discounting strategy with individual device effectiveness values ranged from 10-20% worse than the performance observed when the same devices were tested in combination, suggesting that our discounting strategy is a conservative estimate of the performance of device combinations, and we are finalizing this approach to provide incentive for packages of devices to be tested together for pre-approval.

Additionally, we specifically indicate that devices may be used in combination subject to good engineering judgment. Manufacturers using combinations of devices from the agencies’ pre-approved test data would be required to indicate which individual devices were combined in their certification application and the agencies’ compliance representatives would be able to see if inappropriate device combinations, such as skirts and an underbody device, were used.

Organization: SmartTruck

A component-specific validation structure would also allow the EPA opportunity to clarify how it intends to apply “family” designations to component manufacturers. In providing aero-device manufacturers the ability to identify components, and combinations of such, into aerodynamic bin categories, as outlined in the NPRM, the EPA gives the trailer OEM the ability to create families based on a mix of multiple aerodynamic devices, manufactured by a variety of companies. We believe this structure is more in line with the current framework which allows the customers of trailer OEMs to designate their mix of multiple aerodynamic devices, manufactured by a variety of companies. In providing aero-device manufacturers the ability to identify components, and combinations of such, into aerodynamic bin categories, as outlined in the NPRM, the EPA gives the trailer OEM the ability to create families based on a mix of multiple aerodynamic devices, manufactured by a variety of companies. We believe this structure is more in line with the current framework which allows the customers of trailer OEMs to designate the type of aerodynamic technology they would like to purchase and provides a more efficient reporting system. This also allows trailer OEMs to balance their families with different technologies in the event that a particular device fails the requirements of validation testing. The current designation of how families will be integrated into testing for component manufacturers needs to be clarified. A unique SEA and confirmatory testing structure should also disqualify trailer OEMs from using their own test results to validate or eliminate an aerodynamic device manufactured by potential competitors in the market. [EPA-HQ-OAR-2014-0827-1923-A1 p.5]

Response:

In the trailer program, the concept of “families” is associated with the trailer certification process and applies to trailer manufacturers. The program provides for aerodynamic data generated from testing of components to be pre-approved, but trailer manufacturers decide how to apply data for their individual compliance strategies. We are not adopting provisions outlining steps to retract pre-approval of test data submitted to EPA. However, we note that EPA may request more information or may perform our own confirmatory testing if needed prior to pre-approval. Similarly, we cannot prohibit OEMs from performing independent testing of devices and, while we would not directly use such test results to retract approval, we may use it to justify our own follow-up testing.

Organization: STEMCO

[Note: The docket for this rulemaking includes several footnoted references from STEMCO’s comments that are not included here.]

- STEMCO requests the addition of an early adoption incentive for trailers that meet the MY2027 compliance level in MY2018.

**Early Adoption Incentive**

STEMCO recommends that the EPA and NHTSA provide a financial reward for fleets who purchase MY2027 (or MY2024 in Alternative 4) compliance-level trailers in MY2018, the initial program year. From decades of experience selling into the trucking industry, we project that even a small financial incentive such as reimbursing the Federal Excise Tax (FET) on the cost of aerodynamic fairings not officially required until MY2027 will push a large segment of the industry to voluntarily achieve the program’s end goals nine years in advance of regulation (or six years ahead of the Alternative 4 schedule). If calculating MY2027 level device incremental cost on a per trailer basis is too cumbersome to implement for any reason, we suggest a simplified solution of a $140 reduction in FET for each trailer that achieves MY2027 greenhouse gas emission reductions in MY2018. We suggest that this reward apply only to trailers who achieve a MY2027 performance level at the “full aero” level, such that a “partial aero” trailer or trailer with work-performing devices would not qualify for the reward if it achieves its MY2027 compliance level in MY2018 through reduced standards. We also suggest that this reward only be available in MY2018 (i.e. not MY2019, MY2020, etc.). Finally, we ask the EPA and NHTSA to consider a weight exemption for these over-complying aerodynamic devices in MY2018.

We believe that this MY2018 incentive achieves two fundamental EPA and NHTSA program goals while significantly building on the desired two-way partnership with industry. First, the program’s environmental and economic achievements would significantly accelerate – each trailer that qualifies for this reward signifies 5-7% additional fuel savings and reduced greenhouse emissions. Second, voluntary over-compliance in MY2018 further ensures that a suite of properly-designed, high-performing, and industry-proven technologies are available to fleets at the onset of full compliance standards. Table IV-13 estimates that long box trailer adoption of Bin VII Aerodynamic Technologies will jump from 0% to 40% in between MY2026 and MY2027 and we believe that is highly advantageous to reduce this single year adoption spike by accruing industry experience and acceptance of these technologies years prior to this regulated milestone. Early adopter trucking fleets will expose any needed design or quality modifications before full industry adoption and a small financial reward, in addition to the initial competitive advantage early adopter fleets receive from lower fuel costs, will encourage them to continue leading industry adoption. The lost revenue opportunity to the U.S. Government from this one-time FET reduction should be minimal – Table IV-13 estimates that 0% of trailers will achieve MY2027 compliance in MY2018, so these unsold aerodynamic devices would not have generated tax revenue in 2018 anyway.

**Response:**

While the agencies agree in principle that incentives for early compliance can sometimes be useful, in the case of trailers, there no appropriate mechanism for such an incentive in this program. Within the trailer program, an incentive system would require a credit banking program in the early stages to manage the offsetting of early compliance credits for some trailer families with appropriate non-
compliance of other families. However, for reasons discussed elsewhere in this and the other rulemaking documents, the final trailer program does not include banking, and reserves the availability of averaging provisions for MYs 2027 and later. In the early years, without averaging, manufacturers have the option to install high-performing aerodynamic technologies on their box vans, allowing them to avoid installing tire or weight reduction technologies, or they could simply sell an over-compliant trailer if that is what their customer desired. An early-adoption incentive for the trailer program would require some kind of mechanism for trailer manufacturers to generate early credits and then use them later. Because the program does not incorporate a banking system (per the requests of many industry commenters), early credits are not possible.

Regarding other potential incentives like FET reduction or a weight exemption, these approaches are outside the scope of this rule, as discussed in section 15.10 of this Response to Comments document.

Organization: STEMCO

Trailer Aerodynamic Performance Testing

- STEMCO requests and recommends more stringency in the testing procedures used to certify trailer aerodynamic device performance (delta CDA value) in this regulation. We are particularly concerned that reduced-scale models and computer simulations can and do falsely represent the device rigidity required in the real world to achieve the stated reductions in fuel use. We believe at least a single full-scale test with a production model and two separate test methods should be required to achieve an EPA and NHTSA certified delta CDA value.
- STEMCO requests that on-road Type II testing, the most familiar method for trailer aerodynamic device manufacturers, be included as an acceptable testing procedure option. We also ask the EPA and NHTSA to clearly define a step-by-step process as a part of this regulation that will create a road map for approving additional aerodynamic testing procedures that are currently under development.

Number of test procedures needed to achieve approved CDA value

STEMCO requests that EPA and NHTSA require a trailer aerodynamic device be evaluated using two different test procedures before it achieves an approved CDA value. We further request requiring at least one of those two test procedures be conducted using a full-scale production unit of that aerodynamic device (as opposed to a computer simulation or scaled-down model). According to EPA and NHTSA’s current proposal, it is our understanding that this would require either a coastdown or constant speed test (STEMCO is requesting the allowance of additional full-scale test procedures in a later section), and then either a wind tunnel, computational fluid dynamic (CFD) modeling, or a different type of full-scale testing could be used as the other test procedure. [EPA-HQ-OAR-2014-0827-1259-A1 p.5]

Establishing accurate and credible CDA values is of the utmost importance to the overall goals of this regulation. No single testing procedure is perfect or evaluates all types of devices equally – the National Research Council (NRC) has identified the drawbacks of approximate physics in CFD, approximate boundary conditions in wind tunnels, and approximate measurements in road/track testing. In particular, coastdown testing measurement “uncertainties can exceed CD bin sizes.” STEMCO believes that only aerodynamic devices that can repeat their fuel saving results across multiple testing methods should be fully embraced by industry. We believe that the single greatest threat to the environmental goals of this regulation is if a lower-cost but under-achieving trailer aerodynamic device were to achieve
an inflated delta CDA value in a single test (either accidentally or mendaciously) and then be recognized by EPA and NHTSA as a valid compliance option. This aerodynamic device would instantly become an enticing option for trucking fleets interested only in regulatory compliance due to its low price, which would lead to a potentially significant percentage of trailers complying with this regulation but significantly underachieving CO2 and fuel savings in real-world use. In an extreme (but not impossible) example, a 1% fuel saving aerodynamic device incorrectly labeled as 4% would weaken this portion of the regulation’s environmental goals by 75% every time it is installed on a trailer. Requiring two separate test procedures does not completely eliminate this risk, but it would create a significant safety net in case an unforeseen testing loophole was discovered in a single test procedure. [EPA-HQ-OAR-2014-0827-1259-A1 p.5-6]

We are also specifically asking to require at least one full-scale testing procedure because, despite the existence of highly-calibrated wind tunnel and CFD facilities, both test procedures are limited by using device models instead of actual commercial devices. These device models are extremely rigid replicas and do not simulate the aerodynamic consequences of device movement or flutter during on-road travel. For example, a sideskirt or boat tail made out of a very thin, inexpensive material would not deform in CFD or wind tunnel testing, but it would most likely flutter during real-world travel, disrupting laminar air flow, and achieving much lower real-world drag reductions. It is important to note that if this device were accepted as a viable option for regulatory compliance, it would probably sell well in a very cost-constrained industry. [EPA-HQ-OAR-2014-0827-1259-A1 p.7]

As part of a two testing procedure compliance program, a trailer aerodynamic device would now have two delta CDA values – we recommend accepting the higher value as long as the lower value is at least 90% of that higher value. For example, if a sideskirt achieved a delta CDA value of 0.70 in coast down testing and a delta CDA value of 0.65 in wind tunnel testing, that sideskirt would receive an EPA/NHTSA approved delta CDA value of 0.7 because 0.65 is 93% of 0.7. However, we suggest that the lower delta CDA value be used when both values are not within 10% of each other. Therefore, if a sideskirt achieved a delta CDA of 0.80 in coast down testing and a delta CDA of 0.65 in wind tunnel testing, the EPA/NHTSA approved delta CDA value would only be 0.65. [EPA-HQ-OAR-2014-0827-1259-A1 p.6]

While this additional testing requirement would add to the financial burden placed on trailer aerodynamic device manufacturers, those companies, including STEMCO, will presumably benefit financially from increased sales of their aerodynamic devices as a result of this regulation, and therefore, this additional upfront testing investment should not be considered an undue burden. No additional burden would be placed on trailer manufacturers because the Aerodynamic Device Testing Alternative allows them to select devices that have been pre-approved by trailer aerodynamic device manufacturers. [EPA-HQ-OAR-2014-0827-1259-A1 p.6]

Accepted trailer aerodynamic test procedures

In addition to coastdown, constant speed, wind tunnel, and computational fluid dynamics (CFD) modeling, STEMCO requests that Type II Fuel Consumption testing (the SmartWay 2015 Verification Protocol version) be accepted as a procedure for generating the EPA and NHTSA’s approved delta CDA value for a trailer aerodynamic device. We also request that, in the final regulation, EPA and NHTSA clearly define a review process to allow for the inclusion of additional testing procedures, so that newer but promising test procedures, such as alternating, short duration on-road testing (discussed later in this section), can be included in the coming years. [EPA-HQ-OAR-2014-0827-1259-A1 p.6]
Type II (also known as SAE Type II or SAE1321, although there are protocol differences) is the test procedure used by 80% of Verified Trailer Aerodynamic Devices currently listed on the EPA SmartWay website. In the previous section of these comments, we presented the merits of requiring at least one full-scale device test and because both coastdown and constant speed tests are unproven and unfamiliar within the trailer aerodynamic device manufacturer community, we feel that it would be imprudent to eliminate Type II as an option. [EPA-HQ-OAR-2014-0827-1259-A1 p.7]

The rationale often presented for excluding Type II testing has been that it presents a “percent fuel saved” result instead of “delta CDA.” This can be easily overcome by applying the correlation between delta CDA and percent fuel saved already established in Table IV-9. As an example, if a sideskirt for a long dry van trailer achieved 5% fuel savings in a Type II test, it would receive a delta CDA value of 0.7 and qualify for Bin V. [EPA-HQ-OAR-2014-0827-1259-A1 p.7]

Alternating, short duration on-road testing is a methodology where a single vehicle drives a series of short laps (either on a closed track or public highway) while alternating between using an aerodynamic device and a baseline configuration. Engine data is used and analyzed instead of weighing auxiliary fuel tanks. Boat tails can quickly alternate between a deployed and baseline configuration by simply folding the tail closed, allowing 6-8 “A-to-B” lap sets to be generated in a single day (additional data and information are included as Confidential Business Information). Bolted-on sideskirts would not be as quick to “install” and “uninstall” as a boat tail, but because this testing is an inexpensive alternative to the other approved procedures, it would be financially feasible to hire a team of 10-15 technicians that could remove or reinstall a sideskirt in less than 5 minutes multiple times throughout a single day. STEMCO has been using this test procedure for the past 12 months with trucking fleets and we believe it to be even more reliable than Type II testing. The experimental design of short timed laps (<30 minutes) and alternating between two aerodynamic states minimizes the variability due to changing external variables and provides a smaller time effect than any currently accepted on-road test. Additionally, the method of data collection via the CAN Bus allows for a more granular data analysis of speed and operating condition effects than can be achieved through the single data point generated by weighing fuel tanks on a scale. We specifically request comment from the EPA and NHTSA on which steps STEMCO would need to take to get alternating, short duration on-road testing recognized as an accepted test procedure for this regulation. [EPA-HQ-OAR-2014-0827-1259-A1 p.7]

Response:

The agencies agree that no single test procedure is perfect for all devices. The final trailer program is designed to allow manufacturers to choose an appropriate test procedure for their device and resources. As described in Section IV.F.3.b of the Preamble to this rulemaking, we have structured our final regulations to make wind tunnel testing our primary method for measuring trailer aerodynamic performance as wind-averaged drag, but are adopting interim provisions that allow a manufacture to use wind-averaged CFD results or near-zero yaw coastdown testing without adjustment (see 40 CFR 1037.150(x)). Our test results in Chapter 2.10.2.1.2.4 and 2.10.2.1.3 of the RIA, show that most device performance from these three test methods are similar within the same aerodynamic bin. For devices that may be sensitive to yaw angle, manufacturers can work with EPA to establish an appropriate yaw adjustment for their coastdown results.

The protocols for coastdown, wind tunnel, and CFD analyses result in a CdA value. Note that SmartWay’s 2014 protocols allow SAE J1321 Type 2 track testing, which generates fuel consumption results, not CdA values. Commenters did not suggest a means of converting from the fuel consumption results to an appropriate delta CdA value for use in compliance. As a result, the final program does not accept J1321 data for pre-approval, as proposed.
Organization: STEMCO

- STEMCO requests that wind-averaged CDA values be used instead of zero-yaw CDA values.

Yaw and wind-averaged drag

STEMCO requests that trailer aerodynamic device manufacturers be allowed to use wind-averaged delta CDA drag values. As noted in EPA/NHTSA’s proposal, many trailer aerodynamic devices increase in efficiency at higher yaw angles and crosswinds, and we believe that an accurate delta CDA drag value for regulatory purposes should reflect the full spectrum of real-world conditions. Not only would zero-yaw assessments be an unfair penalty to existing devices that have already been optimized for crosswinds, we believe a dangerous priority shift would occur in future research and development, potentially creating a next generation of aerodynamic devices whose zero-yaw delta CDA values (EPA and NHTSA’s metric for environmental benefit) are substantially higher than their wind-averaged delta CDA values (real-world environmental benefit). [EPA-HQ-OAR-2014-0827-1259-A1 p.7]

EPA and NHTSA mention the benefit of cross-method comparison and certification as a rationale for only accepting zero-yaw values for wind tunnels and CFD. We believe that this cross-method comparison can still be accomplished by simply requiring trailer aerodynamic device manufacturers to submit both their zero-yaw and wind-averaged drag values. No additional testing is required and the zero-yaw value can be compared against coastdown, constant speed, or other wind-restricted procedures, while the wind-averaged drag value can be used as the official compliance value. If the EPA and NHTSA desire to apply a correction factor (such as “Falt,aero”) to a zero-yaw value, that same correction factor (x 1.10 was an example used in the proposal) could also be applied to the wind-averaged drag value. We are also encouraged by recent research and efforts by the National Research Council (NRC) to develop a wind-averaged drag method for coast down testing, so it is possible that in the coming years an accurate direct cross-method comparison can be made using wind-averaged drag values directly. [EPA-HQ-OAR-2014-0827-1259-A1 p.8]

Response:

As noted in our response to CARB on page 1061, we are adopting a wind-averaged approach for trailer aerodynamic testing.

Organization: STEMCO

- STEMCO requests that the EPA and NHTSA publish the testing methods and vehicle settings used to achieve certification by each approved trailer aerodynamic device.

Publishing test procedure settings for all certified trailer aerodynamic devices

STEMCO requests that the EPA and NHTSA publish online the aerodynamic test procedure settings for all trailer aerodynamic devices that have been awarded a certified delta CDA value. Examples of test procedure settings include, but are not limited to: test procedure method, testing facility name and location, tractor make/model/year used as the standard tractor, and trailer make/model/year used as the standard trailer. [EPA-HQ-OAR-2014-0827-1259-A1 p.8]

Prior to the SmartWay 2014 update, there was no visibility into the test settings used for a verified trailer aerodynamic device on their website. It has been suggested that certain testing advantages could be achieved by using specific tractors, trailers, or tractor-trailer gap settings, but without publishing...
these specifics for each verified device, those potential advantages became more trade secret than public knowledge. Although the test procedures presented here by the EPA and NHTSA appear more stringent, we believe test settings should be public information to better facilitate apples-to-apples device comparisons and to easily allow device manufacturers to match test settings with other high-achieving devices. This hopefully creates a level-playing field where the best aerodynamic devices rise to the top of EPA and NHTSA’s delta CDA value rankings and not the aerodynamic devices that were tested with the most favorable standard vehicle and/or using the most favorable test procedure. [EPA-HQ-OAR-2014-0827-1259-A1 p.8]

Response:

The agencies agree that there could be value in an online repository for aerodynamic test settings and data. However, requiring, collecting, presenting, and maintaining information at the level of detail suggested by the commenter would go well beyond what we have done historically in our motor vehicle programs, and we cannot commit to publication of such information at this time. We encourage industry stakeholders to investigate other options for such publication; perhaps through applicable associations or technical groups.

Organization: STEMCO

- STEMCO supports the Aerodynamic Device Testing Alternative because it minimizes the testing and certification burden placed on trailer manufacturers and ensures that aerodynamic device manufacturers have full control over the testing and certification of their own products.
- STEMCO recommends an EPA and NHTSA created website for computing the Trailer Compliance Equation and submitting compliance data, which will reduce the reporting and fleet education burden placed on trailer manufacturers. [EPA-HQ-OAR-2014-0827-1259-A1 p.2]

Use of the Compliance Equation for Trailer Compliance

STEMCO appreciates EPA and NHTSA’s desire to minimize compliance reporting paperwork for the industry (trailer manufacturers, trucking fleets, and aerodynamic device manufacturers). We request additional details on how reporting would be completed and submitted and present a specific suggestion below: [EPA-HQ-OAR-2014-0827-1259-A1 p.8]

First, EPA and NHTSA could create a website prior to 2018 that interactively computes overall trailer CO2 and fuel consumption using the Trailer GEM-Based Compliance Equation (IV-1). This website would display a pick-able list of approved trailer aerodynamic devices, tires, automatic tire inflation (ATI) systems, and light-weighting options, allowing a trailer manufacturer or trucking fleet to easily experiment with how different product choices can best satisfy regulatory compliance for their application. This website would also include, and make visible, the EPA and NHTSA’s discounting equation for combining multiple aerodynamic devices that is outlined on pages 312 and 313 of the proposal. This website should also include approved trailer types and work-performing devices that allow for a lower “partial-aero” compliance standard. For example, a visitor to this website should be able to select a drop-frame trailer, which would lower the compliance standard in the 2027 Alternative 3 timeframe (or the 2024 Alternative 4 timeframe). Lastly, once the resulting overall trailer CO2 and fuel consumption level has been computed, we request a color or message box that clearly indicates the model year of compliance achieved (ex. “Compliant with MY2021 but not MY2024”). [EPA-HQ-OAR-2014-0827-1259-A1 p.8-9]
By functioning as a central repository, this website would ensure alignment throughout the industry and assist trailer manufacturers when selling MY2018 and later new trailers to trucking fleets. A salesperson would be better equipped to show a trucking fleet the EPA and NHTSA website and let them choose a suite of options until the box at the bottom “goes green” than to perform the arithmetic outlined in the Trailer GEM-Based Compliance Equation. In the event that the EPA and NHTSA choose to allow the averaging option, this website could include an “over-compliance” indicator to inform trailer manufacturers about a surplus that may be applied to offset an under-complying trailer order. [EPA-HQ-OAR-2014-0827-1259-A1 p.9]

Second, this website could be used directly (or indirectly) as the end of year reporting submission tool for trailer manufacturers. Ideally, a trailer manufacturing representative would enter a password or manufacturer’s code to access additional cells to type in the number of trailers (and possibly VIN numbers) and then press a button to officially submit a batch of CO2 and fuel consumption values to the EPA and NHTSA. If this website was successful, it would allow trailer manufacturers to get in the regular habit of quickly submitting data every time they fulfill a trailer order, eliminating the need for end-of-year reporting. As an added advantage, the EPA, NHTSA, and the trailer manufacturer would be informed in real-time about their compliance progress for the year (we don’t recommend changing the three-year catch-up compliance provision, however). [EPA-HQ-OAR-2014-0827-1259-A1 p.9]

It is imperative that this website be well-built and easy-to-operate because taking more than a few minutes per order submission would quickly become an undue burden for trailer manufacturers. We also defer to trailer manufacturers if they would prefer to lump reporting into a year-end activity instead of this as-you-go basis. [EPA-HQ-OAR-2014-0827-1259-A1 p.9]

We are not aware of the complexity and burden that creating and maintaining this website would place on the EPA and NHTSA, but we believe that it is both a needed step and one whose cost may be offset by a reduction in the workload placed on each EPA and NHTSA compliance representative assigned to a trailer manufacturer. [EPA-HQ-OAR-2014-0827-1259-A1 p.9]

Response:

The agencies have outlined the general steps for reporting in the Preamble to this rulemaking. The complete list of compliance steps for trailer manufacturers can be found in the regulations (40 CFR Subparts G through I, starting with 1037.601). The process for obtaining preliminary approval of test data for aerodynamic device manufacturers is outlined in 40 CFR 1037.211. As noted in our previous response, we agree that there could value in an online repository for aerodynamic device performance, including the test setting requested previously. However, we cannot commit to publication of such information at this time. We encourage the industry to investigate other options for such publication; perhaps through applicable associations or technical groups. EPA’s Compliance Division has an established, secure database system for submitting compliance information. To maintain consistency, we cannot justify conversion to a new system when EPA’s staff and all of the currently regulated industries are familiar with the existing system.

Organization: Stoughton Trailers

The regulation document is written to allow for several types of tests to establish the coefficient of drag related to a product and its incorporation of drag reducing aerodynamic devices. The variables associated with each test raise question as to the validity of the reported outcome. Many devices have been tested numerous times in order to reach the opportune conditions required to allow performance at
the claimed level. An additional means of submitting data for consideration is the CFD program. This program is based on the ability of the model creation and applied conditions to replicate a real world condition. Simply stated the use of CFD is a valuable tool to consider iteration of design which may lead to an advantageous coefficient of drag result, but it is too easily gamed. [EPA-HQ-OAR-2014-0827-1212-A2 p.2]

Request 6: Since coefficient of drag is the measurement being used for aerodynamic consideration, please restrict the submission of data to a format requiring wind tunnel testing alone. [EPA-HQ-OAR-2014-0827-1212-A2 p.2]

Response:

As noted previously in our response to Exa (page 1062), and described in Section IV.F.3.b of the Preamble to this rulemaking, we have structured our final regulations to make wind tunnel testing our primary method for measuring trailer aerodynamic performance as wind-averaged drag, but are adopting interim provisions that allow a manufacture to use wind-averaged CFD results or near-zero yaw coastdown testing without adjustment (see 40 CFR 1037.150(x)).

Organization: Truck Trailer Manufacturers Association (TTMA)

In our “Averaging” section (8), we discuss the problems with the proposal’s averaging provisions and how what the agencies regard as beneficial to industry would actually be harmful to the trailer industry. We discourage the agencies from using this scheme in regard to trailers. [EPA-HQ-OAR-2014-0827-1172-A1 p.2]

8 - Averaging

While we understand that the agencies view Averaging, Banking and Trading programs as beneficial to the regulated industry, it’s important to realize that the trailer industry is not the automobile industry. The six year annual production average for trailers is 187,666 while for cars, it is 13,906,666. It would take the trailer industry 74 years to build what the automobile industry builds in a single year. [EPA-HQ-OAR-2014-0827-1172-A1 p.13]

Averaging will cause unnecessary disruption in the trailer industry. Currently, most trailers are built to customer specification and most customers have found a preferred manufacturer to build to that specification. With averaging, a given manufacturer may find that the mix of customers in a given year does not allow them to meet their target, which would require that manufacturer to turn away customers and force customers to seek new vendors for established trailers. Manufacturers who specialize in making trailers that are typically used transiently, such as trailers used for intra-city distribution, would be particularly hard hit, for example. They would specialize in efficiency while it would have many real-world penalties. Customers would be quick to recognize this and when the specialist manufacturers had to stop selling optimal trailers to meet the averages in the proposal, the customers would have to seek out a new trailer supplier. Large manufacturers aren’t looking forward to this either, as a flood of new customers looking for these trailers would skew their numbers and create problems for the larger customers they focus on. [EPA-HQ-OAR-2014-0827-1172-A1 p.13-14]

Rather than do this, we would prefer that averaging be done away with entirely: each trailer subject to regulation should be required to meet a given standard. This will require that certain users will have to change their specifications, but will cause minimal disruption to the industry. To do this with minimal
disruption to the greater freight industry, careful thought will be needed to be given to trailers that are excluded as mentioned above. The best option would be to allow market forces to work on the situation with the voluntary SmartWay program. [EPA-HQ-OAR-2014-0827-1172-A1 p.14]

More importantly, however, we request that the agencies demonstrate the commercial feasibility of the proposed rules before they can take effect –i.e., that EPA and NHTSA provide reliable evidence that the technologies imposed by the proposed regulations can be successfully marketed to motor carriers, given that these technologies already exist as options but are not being widely purchased by many motor carriers because their mix of drop-and-hook operations and multiple short, low-speed deliveries does not generate measurable fuel savings benefits. The proposed rules do not require motor carriers to purchase specific equipment or to attain specific fuel efficiency goals. Instead, the proposed rules will require trailer manufacturers to sell this equipment to an increasing majority of their customers whether these customers want it or not. More accurately, the proposed rules will require the larger manufacturers to sell this equipment, while exempting smaller manufacturers from that requirement at the outset, an exemption that will certainly divert sales to the smaller trailer manufacturers in early years and thereby fail to achieve the agencies’ desired goals while arbitrarily and unreasonably imposing the sales obligation on the larger manufacturers. As noted above, however, the reality is that all trailer manufacturers are small manufacturers when compared to the manufacturers of the millions of other motor vehicles sold in the United States annually, which, because of those huge volumes, have the ability to sell expensive and highly fuel efficient vehicles at little or no profit in order to offset sales of more popular less fuel efficient vehicles. Trailer manufacturers, by contrast, do not have the sales volumes needed to absorb trailer sales that produce little or no profit, which will certainly be the effect of requiring them to install equipment that their customers have so far refused to purchase and which those customers will simply refuse to pay for if the new rules take effect. The EPA and NHTSA have produced no reliable, measurable evidence that those motor carriers can be forced to pay for the required technologies, and instead the agencies are proposing to put (some) trailer manufacturers in the completely unreasonable position of insisting that their customers pay for equipment that is not wanted or accept delivery of unwanted equipment at the trailer manufacturer’s expense. In the latter instance, the cost of the proposed regulations, which are purportedly justified achieve a national benefit, will be arbitrarily and unreasonably (and in many cases impossibly) imposed solely on (some) trailer manufacturers and not passed on to the motor carriers and then on to their customers, the shippers and the public at large. Therefore, for the proposed rules to satisfy the legal requirements that they be reasonably drawn and achievable in fact, their commercial feasibility must be proven and not merely assumed, and the proposed rules must not establish unreasonable and arbitrary distinctions and sales requirements that disproportionately burden a minority of market participants. Alternatively, the legal requirements to purchase and install the desired equipment should be imposed on the motor carriers directly so that the free market for trailer sales will not be arbitrarily segmented and defeated. [EPA-HQ-OAR-2014-0827-1172-A1 p.14]

Response:

The agencies recognize that the trailer industry differs from other heavy-duty vehicles and we designed much of the Phase 2 trailer program to address these differences. As noted in our response to Great Dane (page 1063) the final program includes averaging, but the option is limited to MYs 2027 and later for full-aero box vans only. In the years prior to MY 2027, all trailers must meet their respective standards, consistent with this comment. In MY 2027 and later, when the standards for full-aero box vans are the most stringent, manufacturers have the option to average as an additional flexibility, but averaging is never a requirement. See our memo to the docket outlining possible technology packages.
that can be used to meet the MY 2027 standards with and without averaging.\textsuperscript{164} We are also adopting a minimum performance level (equivalent to MY 2018 standards) that box vans in an averaging program must meet to prevent manufactures with higher production volume or more diverse products from generating sufficient emissions credits to produce trailers with no emissions controls. This minimum performance level may also help manufacturers manage their relationships with customers seeking no-control trailers. Note that all non-box trailers and any box vans designated non-aero or partial-aero cannot be averaged at any point in the program, which partially aligns with this comment.

The partial- and non-aero designations, and their accompanying reduced standards, are intended to capture a majority of the box vans that are frequently used exclusively in urban environments where they would have less benefit from aerodynamic devices. Some box vans may also be used in urban environments, but may not have work-performing equipment that qualifies them for these designations. However, we expect they will spend at least some time at speeds of 55-mph or faster, where they will see a 1% or more benefit from aerodynamic devices (see our response to Stoughton on page 965, and RIA Chapter 2.10.2.1.1). We thus do not accept the premise of the comment that aerodynamic devices will be installed on trailers for no benefit and hence that trailer manufacturers will bear all of the cost because customers will not pay for devices which do not pay back.

The comment also makes note of the one-year delay for small business manufacturers, and claims that business will be diverted from large manufacturers to small manufacturers during that time. As seen in Figure 1-3 of Chapter 1 in our RIA, the cumulative annual production of all of the small business box trailer manufacturers is estimated to be less than 15 percent of the industry’s total production, which is significantly less than the annual production of the four largest manufacturers. Small businesses do not have the same resources available to become familiar with the regulations, make process and staffing changings, or evaluate and market new technologies as their larger counterparts. We believe a one-year delay provides additional time for small businesses to address these issues, without a large CO\textsubscript{2} and fuel consumption impact or substantial negative competitive effects.

The agencies regard the costs of the trailer program as reasonable. First, the trailer standards are cost effective, even without considering payback. See Section IV.C.3 of the Preamble to the final rule and Chapter 7.2.5 of the RIA. The $36 per CO\textsubscript{2}eq reduction presented for tractor-trailers compares favorably with the levels of cost effectiveness found reasonable for light-duty trucks (see 77 FR 62922). We present combined tractor-trailer values, because tractors and trailers are inherently used together in the real world. However, we understand that it may be of interest to ensure the tractor and trailer programs are individually cost effective as well. As described in a memo to the docket, we estimate the cost effectiveness of trailers in calendar year 2030 to be $21 per CO\textsubscript{2}eq and tractors to be $39 per CO\textsubscript{2}eq, suggesting that these programs are cost effective and provide significant net benefits both individually and combined.\textsuperscript{165}

\textbf{Organization:} Utility Trailer Manufacturing Company

\textbf{The EPA’s various test methods for establishing aerodynamic-drag coefficient are not repeatable.}

The scientific method requires that test results be repeatable, verified by third parties, and that equivalent tests yield equivalent results, all within reasonable margins of error. Coastdown, constant-

\textsuperscript{164} Memorandum to Docket EPA-HQ-OAR-2014-0827. “Example Compliance Scenarios for the Final HD GHG Phase 2 Trailer Program” August 2016.

\textsuperscript{165} Memorandum to Docket EPA-HQ-OAR-2014-0827. “Tractor-Trailer Cost per Ton Values” August 2016
speed, and various wind-tunnel test results – which the EPA used – are not necessarily repeatable over time and by third parties. This is especially likely for tests that use human drivers. Utility Trailer has conducted fuel-savings tests of the same model side skirt at different times at the same facility, and at different test facilities. Although Utility Trailer employed identical test protocols, the results varied significantly. [EPA-HQ-OAR-2014-0827-1183-A1 p.12]

A vetted computational fluid dynamic (CFD) test controls for these variations. Utility Trailer employed Exa Corporation (the same entity used by the EPA) to perform CFD tests on the proposed aerodynamic devices. Exa Corporation advised Utility Trailer to increase the aerodynamic drag area provided by the EPA’s Table 2-76 by 25% to match the CFD model to the EPA’s coastdown test results. Although this adjustment roughly approximated the results the EPA achieves from the coastdown test, it does not produce equivalently acceptable results for the constant-speed or wind tunnel method of computing the aerodynamic-drag coefficient. This calls into question the validity of the EPA’s tests used to establish the aerodynamic-drag coefficient. The Agency has failed to provide a proper analysis of equating the various test methods to one another; it also has not confirmed the results by independent, valid testing. [EPA-HQ-OAR-2014-0827-1183-A1 p.12]

The Agencies should permit manufacturers to submit efficiency numbers for their aerodynamic technologies that include realistic yaw angles.

The Proposed Rules permit manufacturers and suppliers to use alternative devices to achieve the required greenhouse-gas emission reductions, provided they establish the efficiency of those devices. The GEM model, however, requires that the efficiency be established at 0-degrees yaw – in other words, without cross winds. And for model years 2021 and beyond, the EPA requires that all aerodynamic devices be qualified again with 0-degree yaw angle. [EPA-HQ-OAR-2014-0827-1183-A1 p.21]

This requirement was done purely for the sake of the GEM model, regardless of the very significant and varying effect yaw angle has on the different aerodynamic device efficiencies. This is unrealistic and does not involve the real world, where crosswinds are more common than not. Constant-speed and coastdown tests all permit some amount of wind. This biases their results as compared with other test methods of determining aerodynamic-drag coefficients. [EPA-HQ-OAR-2014-0827-1183-A1 p.21-22]

Utility Trailer has performed computational fluid dynamic (CFD) analysis of many of the EPA SmartWay-approved trailer aerodynamic devices, using the same testing agency (Exa Corporation) that the EPA has employed for some of its tests. The EPA SmartWay-approved trailer side skirt reduce the tractor/trailer aerodynamic drag coefficient the most, especially with cross winds or with a significant yaw angle. As Utility Trailer and other manufacturers develop new devices and configurations to increase aerodynamic efficiencies, Utility Trailer urges the Agencies to permit the manufacturers to perform sufficiently sophisticated testing to account for the effect of yaw angle (crosswinds) on those devices. This will permit the proposed savings to better represent actual anticipated fuel efficiency savings. [EPA-HQ-OAR-2014-0827-1183-A1 p.22]

Response:

The agencies are aware that individual, absolute $C_dA$ values may differ between aerodynamic test methods, wind tunnel facilities, or CFD packages. The tractor aerodynamic test program is designed to apply a correction factor to a reference test method to address these differences. However, our results (as shown in RIA Chapter 2.10.2.1.2) indicate that the variability in $\Delta C_dA$ results are much smaller. The trailer program is designed such that we are measuring the improvement in aerodynamic performance, and that improvement is nearly the same for all three test methods.
The agencies proposed to determine the delta $C_dA$ for trailer aerodynamic performance using the zero-yaw (or head-on wind) values from any of the approved test procedures. However, based on comments received, including the comment above, we are revising the final program to be based on wind-averaged results, similar to the tractor program. We thus agree with the comment that effects of wind must be accounted for in aerodynamic testing. We also note that our GEM vehicle simulation does not require a zero-yaw value. In fact, the tractor program, which uses the same model for compliance, requires wind-averaged $C_dA$ values from its aerodynamic testing and GEM appropriately applies those results in its calculations. Our proposal to use zero-yaw values in the trailer program was for simplicity and to avoid the need to perform any corrections to wind-averaged values. We received no comments in support of use of zero-yaw results for the trailer program, and several supporting the use of wind-averaged values. Additionally, comments directed to the tractor program indicated that the average of results from $+4.5$ and $-4.5$ degrees is a representative surrogate for wind-averaged results, which would maintain simplicity for wind tunnel and CFD testing. While our final trailer program does consider wind tunnel testing to be our primary test method, we are adopting interim provisions that do not require a correction to wind tunnel results. Our aerodynamic testing (summarized in Chapter 2.10.2.1.2 of the RIA) shows that similar devices perform within the aerodynamic bins of the program, including many coastdown results from tests performed at near-zero yaw angles. Some devices did display a yaw dependence and their coastdown values were notably lower than wind-averaged results. Consequently, we are adopting interim provisions to allow manufacturers that choose to perform coastdown tests to work with EPA to identify an appropriate means of converting to wind-averaged values. Our interim provisions related to trailer aerodynamic testing can be found in 40 CFR 1037.150(x).

**Organization:** Utility Trailer Manufacturing Company

**The Agencies’ Compliance Program is Flawed; the Proposed Rule Should Delete Averaging and Bins from its Compliance Models as the Model as Drafted Imposes a Significant Administrative Burden and Allows Customers to Game the System**

As noted earlier, Utility Trailer does not believe the Agencies’ Proposed Rule is necessary. The free market is quite capable of continuing to obtain increasing fuel efficiencies while allocating as appropriate the resources needed to accomplish those goals. Operators and trailers that would benefit from installing the technologies – or that would achieve the EPA’s estimated two-year payback – should install those technologies. The Agencies have not offered any explanation as to why the free market is incapable of producing the desired results. [EPA-HQ-OAR-2014-0827-1183-A1 p.18-19]

But Utility Trailer also recognizes the political reality that the Agencies are unlikely at this point to rely on the free market to continue to solve this problem. Utility Trailer therefore offers the following suggestions to improve any Rule the Agencies adopt. [EPA-HQ-OAR-2014-0827-1183-A1 p.19]

The compliance program – with its system of averaging and bins – is unduly complex and unsuited to the trailer industry. Utility Trailer urges the Agencies to streamline the compliance aspects of the program in a way that will decrease the administrative burden on the trailer manufacturers while providing the Agencies with the level of compliance desired. Specifically, the compliance program should be modified as follows: [EPA-HQ-OAR-2014-0827-1183-A1 p.19] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.220.]]
• Develop clear categories of trailers that will be exempt from the Proposed Rules. These categories should include considerations of trailer configuration and the use that will be made of the trailer, including the environments and areas in which it will operate. Exemptions could relate only to some of the technologies required by the Proposed Rule. [EPA-HQ-OAR-2014-0827-1183-A1 p.19]

• Allow manufacturers to certify by label that the trailers manufactured comply with applicable Agency regulations. [EPA-HQ-OAR-2014-0827-1183-A1 p.19]

The Agencies should delete the bin-and-averaging approach currently described in the Proposed Rule and permit manufacturers to certify their compliance with the Rule rather than obtaining Agency approval for each plan year.

The Agencies’ proposed bin-and-averaging compliance model is unmanageable in the trailer-manufacturing industry. Utility Trailer and the other major manufacturers build semi-custom trailers. Although orders start with a base model and standard options, customers routinely add a large number of customer-specific options. Additionally, customers make numerous specification and quantity changes throughout the process, often up to the time actual manufacture of the unit begins. Some of these option changes, as noted previously, conflict with the aerodynamic devices. [EPA-HQ-OAR-2014-0827-1183-A1 p.20] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.220.]

Utility Trailer urges the Agencies to adopt a simpler, more straightforward approach: require the original equipment manufacturer to install specific approved devices on all non-exempt trailers. This provides the following advantages. [EPA-HQ-OAR-2014-0827-1183-A1 p.20]

First, it is manageable. The administrative burden required by the Proposed Rule is oppressive. The Proposed Rule would require each manufacturer to obtain Agency approval before the start of each year of a plan for weighted average compliance to the GEM formula for all production. Then, at the end of the year, the manufacturer would need to obtain Agency approval of the actual production results and for rollover into the next year. Also significant is the administrative burden associated with scheduling production slots and allocating those requiring different complying devices throughout the year. Because of the assembly-line manufacturing process, it is far more efficient to avoid changing technologies from order to order, to the extent practical. [EPA-HQ-OAR-2014-0827-1183-A1 p.21] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.220.]

Far simpler and equally effective would be to require each manufacturer to install a label on each trailer certifying to that compliance and to keep records of the weighted averages to achieve compliance if the averaging approach is part of the Rule. The Agency, if it desired, could inspect those records as needed. This would be approximately the same system as trailer manufacturers use to comply with the NHTSA’s Federal Motor Vehicle Safety Standards. This is a time-proven, successful system. [EPA-HQ-OAR-2014-0827-1183-A1 p.21]

Second, eliminating averaging avoids gaming the system. The Agencies’ one-size-fits-all approach is unworkable in the trailer industry. For many operators, the aerodynamic devices are unworkable or undesirable. But because the Proposed Rule requires the manufacturer to achieve an average specified reduction in aerodynamic and rolling-resistance drag (i.e., some of its trailers will have a grouping of the devices (bins); others wouldn’t), the manufacturer will be placed in the position of deciding which customers must buy the devices and which ones will be exempt. This provides huge incentives for larger fleets to use their market pressure to force the manufacturer to exempt them from purchasing the devices the larger fleets do not want, leaving the smaller customers without market power to purchase a
disproportionate amount of the technology. This, of course, would also increase costs for the smaller competitors. [EPA-HQ-OAR-2014-0827-1183-A1 p.21]

Thus, we urge the Agencies to modify the requirements from a maximum CO2 output in grams per ton-mile as currently proposed. Rather, the requirements should be written to specify types of drag-reducing devices that meet specific qualification requirements for all non-exempt trailers. [EPA-HQ-OAR-2014-0827-1183-A1 p.21]

Response:

The commenter supports a simplified compliance approach that would be based on the agencies requiring trailer manufacturers to install specific devices, an approach that we generally call a “design-based standard.” However, an important principle of all of our motor vehicle programs is to focus on emissions or fuel consumption performance, and thus “performance-based standards” whenever possible. By focusing on performance, the agencies try to avoid pre-judging or restricting manufacturer choice in determining the best mix of technologies for a company and its specific applications in achieving the emission and fuel consumption reduction goals of the program. In some ways, it is the commenter’s preferred design-based approach which is one size fits all. Although the program applies design-based standards (specific tire and tire pressure technologies) to some trailer types for which aerodynamic technologies are generally not appropriate, manufacturers of most trailers covered by the program (i.e., box vans) comply by choosing whichever mix of aerodynamic, tire, and weight reduction technologies they believe best. The commenter expresses concerns about the additional administrative burdens potentially associated with performance-based standards, we have designed a unique compliance program for trailers (chief facets of which are the GEM equation, eliminating banking and trading, and limiting the option to average until MY 2027) that we believe provides an appropriate balance between manufacturer flexibility and reasonable compliance burden.

The commenter also proposes that the trailer compliance program not involve averaging. In response to suggestions elsewhere in this Response to Comments document from this commenter and others, final program includes averaging, but only late in the program, limiting the option for trailer manufacturers to apply averaging to MYs 2027 and later exclusively, and for full-aero box vans only. The commenter suggests a large customer may use its market pressure in an averaging program to purchase all of a manufacturer’s allotted trailers with limited technologies. This situation is avoided during the early years of the program when we do not allow averaging (i.e., all trailers sold will have to meet their respective standards using some combination of technologies). As noted in our response to TTMA (page 1078), if a manufacturer opts into the averaging program in MYs 2027 or later, we are adopting an minimum level of performance (based on MY 2018 standards) that each trailer must meet, which prevents a customer from requesting a no-control trailer.

The commenter requests that the agencies provide “clear categories” of trailers that will be exempt. In response to these and other comments, the final program applies to many fewer trailer types than did the proposed program. Only three types of non-box trailers are covered, with all other trailer types completely excluded from any requirements of the trailer program.

To clarify, the aerodynamic bins of the trailer program are similar to the performance metric used by EPA’s SmartWay technology verification program. Instead of levels of 1%, 4%, 5% and 9% fuel savings as used by SmartWay, the Phase 2 trailer program has seven aerodynamic performance thresholds measured as delta CdA. The bins are designed to account for variability between test procedures, device manufacturers, and tractor-trailer combinations in testing, and the performance values obtained from testing are used as an input to the GEM-based trailer compliance equation. We do
not have aerodynamic requirements, but the performance standards for box vans were designed using a reasonable combination of technologies, including some level of aerodynamic improvements each phase. These performance standards could be met with very little aerodynamic improvements if manufacturers can remove sufficient weight, install tire inflation systems, and adopt tires with very low rolling resistances. Manufacturers can use the equation to evaluate what technology performances will result in the desired CO$_2$ reductions.

We note that aerodynamic bins are unrelated to averaging. All manufacturers evaluate their overall trailer performance by applying the technology performance values (including aerodynamic bin values if aerodynamic improvements were made) in the compliance equation to get a CO$_2$ emissions rate in grams CO$_2$/ton-mile. This emissions value is submitted for compliance. Manufacturers that opt to use averaging in MY 2027 or later would calculate a production-weighted average of all of their overall trailer performances (i.e., the CO$_2$ results) according to 40 CFR 1037.107(5). This average may include some trailers that do not meet their standard and others that over-comply with the standard, as long as the standard is met on average based on production volumes.

**Organization:** Wabash National Corporation

[Note: Wabash’s full comments placed in the docket include several footnoted references that do not appear in this summary.]

**The Proposed Averaging Program Is Unnecessary, Unduly Complex, and Hinders Innovation**

EPA has proposed an “averaging” compliance program for trailers. Manufacturers could average the emissions of all their trailers in a given subcategory model year of trailers to comply with the proposed CO$_2$ emissions standards. Thus, a manufacturer could produce some individual trailers that fail to comply with the proposed standards when other trailers in the subcategory “over-comply,” such that, on average, the over-compliant trailers “make up” for any shortfall in the remaining trailers. The subcategory of trailers that EPA has proposed for averaging are “full-aero” trailers, i.e., short and long dry and refrigerated box trailers capable of accommodating aerodynamic technologies. [EPA-HQ-OAR-2014-0827-1242-A2 p.9-10]

The proposed averaging scheme for trailers is a truncated version of an averaging, banking, and trading (“ABT”) program. For several years, EPA has used ABT programs to assist engine and vehicle manufacturers in complying with emissions programs under Title II of the Clean Air Act. In an ABT program, manufacturers may create “credits” from over-compliance that can be (1) used to achieve “average” compliance in a given model year, (2) banked for use in future years, or (3) traded to third-party manufacturers for their own compliance purposes. The Proposal limits averaging to a single model year, except compliance deficits could be made up within three years. Neither credit banking, nor trading, would be permissible. [EPA-HQ-OAR-2014-0827-1242-A2 p.10]

**A. The Proposed Averaging Program Is Impracticable and Creates Barriers to Innovation**

Wabash appreciates the opportunity to comment on EPA’s good faith efforts to develop alternative compliance methods for trailer manufacturers. Respectfully, however, Wabash opposes averaging because it is unworkable in the trailer industry. As EPA acknowledges in the Proposal, the “reality” of the trailer market “can limit the value of the flexibility that averaging could provide to trailer manufactur[ing] . . .” “Compared to other industry sectors,” trailer manufacturers “have little control
over their customers’ demands and thus limited ability to manage the mix and volume of different products.”[EPA-HQ-OAR-2014-0827-1242-A2 p.10]

Wabash strongly agrees with EPA’s observations about the trailer market. The reality is that an averaging program would fail to provide any flexibility, hinder compliance, and act as a drag on innovation. As the leading trailer manufacturer in the United States, Wabash provides these additional insights into the market to aid EPA’s decision on whether to include averaging. [EPA-HQ-OAR-2014-0827-1242-A2 p.10]

- The theoretical flexibility offered by averaging is illusory because of the unique customization of trailers. While ABT programs have provided needed flexibility for engine and vehicle manufacturers, the trailer market differs markedly from those sectors. Engine makers and vehicle manufacturers typically produce a standard or base configuration of their products, which is then offered to customers with only limited customization. As a consequence, engine makers and vehicle manufacturers possess a high degree of control over the products they offer into the market. The reverse is true in the trailer market: trailers are highly customized and built to customers’ specifications. Customers dictate the features for trailer applications, and in many cases, customers supply parts for the trailers they order—e.g., tires and aerodynamic devices.[EPA-HQ-OAR-2014-0827-1242-A2 p.10-11]

- Market dynamics preclude reliable annual predictions of trailer sales needed for averaging. Averaging presupposes that a trailer manufacturer may predict with a reasonable degree of certainty the mix of trailers sold over a year, the relevant compliance period for purposes of EPA’s emission standard. In other words, averaging assumes that a trailer manufacturer could plan in advance a year’s worth of “over-compliant” and “under-compliant” trailers, so that, on average, the emission standard is met. However, such predictions would be impracticable because of the dynamic nature of the trailer market. The lead time for trailer design and manufacturing is far less than for engines and vehicles, providing customers flexibility in timing their trailer orders.13 Trailer orders are taken year-round, but early spring and fall tend to be the busiest ordering seasons for the next year’s production. Even after orders are made for trailers, order cancellations are common in the industry. Accordingly, trailer manufacturers are unable to reliably predict the product mix they will sell in a given year. Cancellation of large orders, for example, could easily derail a compliance strategy built on averaging. Additionally, the trailer industry is highly cyclical, with history demonstrating that it is common for manufacturers to experience 100-200% swings in sales volumes from one year to the next. Such large swings in yearly order volume would also upset any compliance strategy built on averaging. [EPA-HQ-OAR-2014-0827-1242-A2 p.11]

- Averaging could act as a barrier to innovation to aerodynamic trailers. Averaging creates a barrier to trailer innovation. While aerodynamic trailers provide fuel savings, the trailer customer may not reap those savings when the trailer is pulled by a tractor owned by another company.14 Averaging entrenches this barrier to aerodynamic trailers because demand may cause all manufacturers to produce at least some conventional trailers regardless of whether averaging is optional. The continuing production of conventional trailers risks three scenarios that could impede progress toward advances in aerodynamic technologies: (1) customers may demand the conventional, non-compliant trailers that averaging allows; (2) customers could refuse to pay for the aerodynamic devices and the trailer manufacturer would have to absorb the costs, further reducing the profit margin in an already small operating margin business (typically less than 5%, and even less than 1% in some years); or (3) customers could take their business to another trailer manufacturer.15 A single federal standard would best promote the market for innovative aerodynamic technologies. [EPA-HQ-OAR-2014-0827-1242-A2 p.12-13]
B. EPA Precedent Supports Forgoing an Averaging Program for Trailers

Declining to create an averaging program for trailers would be consistent with agency precedent on ABT programs. Nothing in the Clean Air Act, or EPA’s regulations, requires an ABT program for every mobile source regulation. EPA has declined to create ABT options where it would be unnecessary or inappropriate for a particular segment of the engine or vehicle industry.  

In deciding whether to promulgate an ABT program, EPA has cited factors such as manufacturer interest in ABT and the impact of ABT on innovations and compliance, all of which cut against an averaging program for trailers.  

C. CARB'S Tractor-Trailer Regulation Shows Averaging Is Unnecessary

The experience with California’s trailer greenhouse gas regulation shows that averaging is unnecessary. In 2008, the California Air Resources Board (“CARB”) enacted the Tractor-Trailer GHG regulation, which became effective in 2010. The CARB regulation applies to long-haul tractor-trailers in California, specifically all model year 53-foot or longer dry van and refrigerated van trailers and the tractors that pull them. Covered trailers must be SmartWay certified or retrofitted with SmartWay aerodynamic devices (including skirts and end fairings) and use specified low rolling resistance tires. Averaging is not an option under CARB’s regulation. Despite the lack of averaging, EPA approved CARB’s tractor-trailer regulation last year. The Clean Air Act preempts California’s motor vehicle regulations unless EPA approves a waiver of preemption pursuant to Section 209(b), as it did for the tractor-trailer regulation. In granting the waiver, the agency found that CARB’s tractor-trailer regulation is consistent with Section 202(a) of the Clean Air Act, the same authority that EPA relies upon in proposing the Phase 2 rule at issue. EPA also determined that CARB’s regulation was reasonable and protective of human health and the environment.

D. Averaging Imposes Undue Burdens on Trailer Manufacturers

Averaging would be burdensome. As EPA recognizes, “an averaging program would inherently require a higher degree of data management, record keeping, and reporting than one without averaging,” and specifically requested comment on whether “the burden of managing an averaging program could be more trouble than the flexibility is worth.” As explained in detail below, the costs of setting up and maintaining compliance systems would be far higher than EPA suggests. The Phase 2 Proposed Rule represents EPA’s first attempt to regulate trailer-related emissions. As trailer manufacturers enter the regulatory program, compliance would be facilitated by simplicity and clarity. To that end, EPA should require that trailers meeting specific characteristics meet a minimum stringency level without averaging.

Response:

As noted in our response to Great Dane on page 1063 and elsewhere, we are limiting the option for trailer manufacturers to apply averaging to MYs 2027 and later for full-aero box vans only. This approach attempts to balance the advantage of an averaging program to allow for introduction of the most reasonably stringent standards for trailers, with the concerns articulated by manufacturers.

The commenter proposes that the trailer compliance program not involve averaging. In particular, the comments notes that it would be difficult for trailer manufacturers to reliably predict their next years’ sales. In the event that a manufacturer opts into the averaging program, the agencies understand that it
is possible for them to misjudge production and come up short at the end of the model year. While we are not adopting banking provisions as part of the final trailer program, the program provides for a manufacturer to generate a credit deficit that would need to be resolved through over-compliance within the following three years.

The comment refers to averaging as a “barrier to innovation” noting that some trailer manufacturers may continue to produce no-control trailers if they have sufficient demand for higher-performing trailers. As we described in our response to TTMA on page 1078, we are setting a minimum level of performance for trailers (based on MY 2018 standards) if manufacturers opt into an averaging program in the later years. While MY 2018 standards are relatively low performing trailers, they provide a level of confidence that some improvements will be made for all future trailers.

**Organization:** Wabash National Corporation

**E. The Final Rule Should Provide a Flexible and Simplified Exemption Process**

Additionally, EPA should provide a simplified process for obtaining exemptions, rather than simply having an exclusive list of exemptions in the proposed regulations. This could be accomplished by specifying certain criteria, which, if met, would result in an automatic exemption for the proposed trailer configuration, or by establishing a process by which trailer manufacturers may petition EPA for additional exemptions. [EPA-HQ-OAR-2014-0827-1242-A2 p.13]

A similar process exists under the CARB tractor-trailer regulation. CARB allows “modified” SmartWay aerodynamic devices on trailers without prior approval where the modifications only have a “minimal” impact on aerodynamic surfaces. Additionally, CARB has pre-approved several modifications based on “necessity” and whether the modification had a “significant” impact on aerodynamic drag. As a third option, CARB allows companies to seek approval of new modifications to aerodynamic devices based on a description of the modification and wind tunnel testing. [EPA-HQ-OAR-2014-0827-1242-A2 p.13-14]

Having a similar program for federal exemptions would assist the trailer industry in complying while meeting customer needs. It is impossible to predict in a rule all of the possible modifications and other issues that may arise in the trailer industry because it is a highly customized manufacturing process. Flexibility is necessary to allow for the future advancement of aerodynamic technologies and to address the development of currently unforeseen scenarios. Allowing for such exemptions would also be consistent with past regulatory approaches, including the Phase 1 provisions allowing off-road vehicle manufacturers to petition for an exemption for off-road vehicles that do not meet the listed exemption criteria in the regulations. [EPA-HQ-OAR-2014-0827-1242-A2 p.14]

**Response:**

As noted previously in our responses to ATA (page 1040) and XL Specialized (page 1054), the final program completely excludes all non-box trailers except flatbeds, tanks, and container chassis, as well as a small number of other specific exclusions. Specific definitions of the trailers excluded from the program are available in 40 CFR 1037.5. Although we believe that a formal process for excluding individual trailer models would be resource-intensive and would not be appropriate, the program does encourage trailer manufacturers to discuss any situations where the criteria for exclusion identified in the program may be unclear for specific trailer models before production begins.

**Organization:** Wabash National Corporation
Light-Weighting Deserves Greater Credit and Compliance Flexibility

EPA and NHTSA recognize that reduction in trailer tare weight can reduce fuel consumption in two ways: (1) for applications where payload is not limited by weight restrictions, the overall weight of the trailer would be reduced, improving fuel efficiency, and (2) for applications where payload is limited by weight restrictions, the lower trailer weight would allow a corresponding increase in payload, thereby reducing emissions and fuel consumption on a ton-mile basis. The agencies note the weight reduction opportunities available in both the structural components of trailers and in the wheels/tires. Replacing heavier weight materials such as steel with aluminum or lighter-weight composites is currently feasible for trailer components such as roof bows, side and corner posts, cross members, floor joists, floors, and van sidewalls. Similar material substitution is feasible for wheels, and replacing two dual tires with single wide-based tires can also reduce weight. [EPA-HQ-OAR-2014-0827-1242-A2 p.15]

Because there is no clear baseline for current trailer weight against which lower-weight designs could be compared for regulatory purposes, EPA and NHTSA do not believe it would be appropriate or fair across the industry to apply overall weight reductions toward compliance. Instead, the agencies are proposing to allow manufacturers to account for weight reductions involving substitution of very specific, traditionally heavier components with lower-weight options that are not currently widely adopted in the trailer industry. EPA and NHTSA are proposing compliance provisions that would limit the weight-reduction options to the substitution of specified components and have identified several conventional components with available lighter-weight substitutes (e.g., substituting conventional dual tires mounted on steel wheels with wide-based single tires mounted on aluminum wheels). The agencies are proposing values for the associated weight-related savings from these substitutions that would be used in GEM for compliance purposes. [EPA-HQ-OAR-2014-0827-1242-A2 p.15]

The agencies should give greater credit for light-weighting and include a process for manufacturers to add to the list of qualifying components and materials. As currently proposed, the equation for trailer compliance gives a 1% credit per 1,000 pounds of weight. The agencies appear to be unnecessarily discounting light-weighting by assuming that one-third of it goes to increase payload capacity. [EPA-HQ-OAR-2014-0827-1242-A2 p.15]

Instead, the agencies should award greater credit to light-weighting—2% per 1,000 pounds, consistent with the 2011 research by the Oak Ridge National Laboratory (“ORNL”) examining the effect of weight on the fuel economy of Class 8 freight trucks. ORNL used the extensive database of information collected in the Department of Energy Heavy-Truck Duty Cycle (“HTDC”) project, which, in 2006-2008, had collected real-world performance and situational data for long-haul operations of Class 8 trucks from a fleet engaged in normal freight operations. The HTDC data was parsed by roadway grade categories (e.g., severe and mild upslope, severe and mild downslope, and flat terrain), vehicle speed intervals (of 1 and 2 mph), and vehicle weight levels going from tractor-only to fully loaded vehicles by 5,000 lb. For two of the terrain categories (i.e., flat terrain and mild upslope terrain), which cover over 70% of the total miles logged in the HTDC project, ORNL investigated the effect of vehicle weight and vehicle speed on fuel economy using the parsed data. [EPA-HQ-OAR-2014-0827-1242-A2 p.15]

In addition, EPA should incentivize the development of new weight-reduction technologies by providing credit for them, rather than relying on an exclusive list of eligible technologies in the regulations. In the Proposal, EPA lists only 11 trailer components with lighter weight options—only one of which includes a material other than aluminum: structure for suspension assembly, hub and drum (per axle), floor (aluminum and wood/plastic composite), floor crossmembers, landing gear, rear door, rear door surround, roof bows, side posts, slider box, and upper coupler assembly. EPA should incorporate a process for adding to the list either by specifying certain criteria, which, if met, would result in the
additional materials automatically receiving credit, or by establishing a process by which trailer manufacturers could petition and EPA would approve additional components and materials for inclusion in the list. [EPA-HQ-OAR-2014-0827-1242-A2 p.16]

A flexible approval process for new light-weight materials would be consistent with EPA and CARB precedent. In Phase 1 of this rule, the agencies allowed manufacturers to petition for innovative technology, or “off-cycle,” credits for components not measured in GEM. The agencies recognized that emerging and innovative technologies in various stages of development with CO2 emissions and fuel consumption reduction potential existed that might not be adequately captured on the final certification test cycles or are not inputs to the GEM, and that some of these technologies would merit additional credit-generating potential for the manufacturer. Because light-weight materials are an innovative and emerging technology for trailers, the CARB GHG tractor-trailer rule also provides a petition process for obtaining approval for trailer technologies not previously verified through the SmartWay process. No reasonable basis exists for providing trailer manufacturers less flexibility than companies regulated under Phase 1 of this rule and CARB’s tractor-trailer rule. [EPA-HQ-OAR-2014-0827-1242-A2 p.16]

Response:

The comment requests that the agencies remove the distribution of weight reduction applied in GEM. For tractors and trailers, GEM assigns 1/3 of any weight reduction applied to increase the payload and the remaining 2/3 reduce the overall vehicle weight. The agencies apply this strategy to account for the nearly 1/3 of tractor-trailers that reach their weight limit before they reach the volume capacity of their trailer (weigh-out). The commenter interpreted this strategy as a penalty, noting that the full weight reduction is not being applied to the vehicle and the model would not predict sufficient benefit. However, the standards adopted in this rulemaking account for payload (i.e., g CO\textsubscript{2}/ton-mi and gallons/1000 ton-mi). We created a memo to the docket to demonstrate that this weight reduction distribution will not negatively impact the results from the model, and in some cases will even provide an additional benefit versus simply reducing the overall vehicle weight.\textsuperscript{166}

In light of this comment and further consideration of the issue, the agencies believe that the off-cycle technology process is an appropriate way for box van manufacturers to receive credit for future lightweighting or other technologies that are not recognized in the compliance equation. For this reason, we have incorporated trailers into the existing off-cycle provisions. (See Preamble Section IV.F.5.d). In the case of lightweighting, a measured difference in trailer weight could substitute for the weight component of the compliance equation, for other such technologies (should any exist), the general off-cycle provision apply. See 40 CFR 1037.515(e).

Organization: Wabash National Corporation

VIII. The Proposed Warranty, Labeling, and Owner’s Manual Requirements Are Unduly Complex and Burdensome

Wabash has concerns with EPA’s proposed requirements for trailer warranties, emission control labels, and owner’s manuals. EPA must recognize that the composition and operation of the trailer industry is quite different from the engine and vehicle manufacturing industries, and adjust its regulatory requirements accordingly, as explained below. [EPA-HQ-OAR-2014-0827-1242-A2 p.16]

A. Warranty

EPA’s proposed regulations would require trailer manufacturers to provide a five-year warranty on aerodynamic devices and a one-year warranty on tires. The warranty “covers these components even if another company produces the component.” [EPA-HQ-OAR-2014-0827-1242-A2 p.36]

Imposing the warranty burden on trailer manufacturers ignores the fundamental realities of the trailer manufacturing process, which differs substantially from auto, truck, or engine manufacturing sectors. In those industries, OEMs choose their suppliers and have a modicum of choice and commercial control over the devices installed in their vehicles (or engines). In the trailer industry, by contrast, aerodynamic devices and tires are frequently purchased directly by customers and shipped to the trailer manufacturer for installation, or in the case of aerodynamic devices, often installed by the customer at a later time. As a result, the warranties on these parts are extended to customers directly by the part manufacturers, with no involvement by the trailer manufacturer. Thus, the trailer manufacturer does not design, test, certify, or purchase the equipment. As a practical matter, trailer manufacturers cannot reasonably provide warranties on any potential third-party part which a customer happens to ask to be installed on a trailer. This is similar to a situation where a vocational vehicle is assembled in multiple stages under a customer’s direction and according to their specifications. A cab-chassis manufacturer would provide a warranty on the components it assembled, as would the body-builder. Suppliers providing other components, e.g., safety technology and air suspension and control systems, would extend their warranties for those components directly to the customer. The cab-chassis manufacturer would not be expected to provide warranties for those components for which it had no responsibility. [EPA-HQ-OAR-2014-0827-1242-A2 p.17]

EPA should re-orient the warranty program for trailers to place the obligation on suppliers who provide customers with aerodynamic devices or tires for installation on trailers. Trailer manufacturers would collect information on the parts and warranties provided by the suppliers and share that information with EPA. Those part manufacturers would then be responsible for the warranties they provide. Shifting the point of warranty obligation to the parts suppliers would simplify the warranty system, facilitate prompt remediation of warranty claims, and make compliance and enforcement more direct and expedient. [EPA-HQ-OAR-2014-0827-1242-A2 p.17]

Response:

Section 207 (a) of the CAA requires manufacturers to warrant their products to be free from defects that could otherwise cause non-compliance with emission standards. For purposes of the trailer program, EPA requires trailer manufacturers to warrant all components that form the basis of the certification to the CO2 emission standards. The emission-related warranty covers all aerodynamic devices, lower rolling resistance tires, tire pressure systems, and other components that may be included in the certification application. In response to this comment, we would note that the emission-related warranty is completely separate from any other warranties a manufacturer might offer. The trailer manufacturer needs to warrant that these emission-related components and systems are designed to remain functional for the warranty period.

To further clarify, we view commercial warranties offered by component manufacturers as business decisions rather than as a reflection of the actual durability of the systems. With proper maintenance, we are aware of no reason that the technologies that we anticipate that trailer manufacturers will use for compliance would be unable to meet the durability requirements of the trailer program. The agencies believe these components, including tire pressure systems, should be designed to last the full useful life of the trailer if properly maintained. We believe a five year emission-related warranty is justified, but
we note that trailer manufacturers can specify that their warranty depends on the proper maintenance of components. NHTSA is not adopting any warranty requirements relating to its trailer fuel consumption program.

**Organization:** Wabash National Corporation

**C. Owner’s Manual**

EPA is proposing to require that an owner’s manual be provided for, and remain with, each trailer that is manufactured. This requirement simply does not fit the trailer industry. Again, each trailer is custom, so a unique owner’s manual would be required for each potential configuration. Further, ensuring that a manual remains with the trailer would be difficult. Customers frequently create their own owner’s manual, expressly outlining the information they wish their operators to have access to and limiting their access to other information that is not in keeping with the customer’s business and operational practices. Wabash recommends omitting this requirement from the Phase 2 Proposed Rule. [EPA-HQ-OAR-2014-0827-1242-A2 p.18]

**Response:**

Our regulatory provisions were designed assuming vehicle manufacturers have an existing owner’s manual. The agencies acknowledge that currently it is not common for trailer manufacturers to provide printed owner’s manuals to their customers. We are not requiring manufacturers to create a comprehensive manual describing all aspects of each individual trailer produced. However, it is important for customers to have access to information about emissions-related components added to their trailers for compliance with our Phase 2 program, such that they can adequately maintain, repair, and possibly replace these components. We believe that with the new requirements of the trailer program, trailer manufacturers should be capable of providing basic information related to compliance to their customers. Additionally, we note that the “owner’s manual” need not be a physical document, but can be made available on line.

**Organization:** Wabash National Corporation

**IX. The Compliance Costs of the Proposal Far Exceed EPA’s Estimates**

EPA appropriately recognized that “[t]railer manufacturers, who would be subject to CO2 and fuel consumption standards for the first time, would have to put in place entirely new testing programs, reporting, labeling, and recordkeeping systems.” Unfortunately, EPA severely underestimated the costs of these compliance systems. EPA estimated a 2017 compliance cost of $127,000 for each large trailer manufacturer, which would then increase slightly to $128,000 per year beginning in 2018, the first year trailers must comply with the rule. These total cost estimates include three components: (1) labor costs; (2) start-up and capital costs of acquiring test equipment, information management systems for recordkeeping, labeling, and reporting; and (3) operations and maintenance for laboratory time, use of test equipment, and other supplies. [EPA-HQ-OAR-2014-0827-1242-A2 p.18]

EPA’s analysis of labor costs is flawed. EPA used outdated 2009 Bureau of Labor Statistics’ estimates of labor costs, rather than the current version of those estimates. Unsurprisingly, the current labor costs are materially higher than the 2009 estimates. As an illustration, the mean hourly rate of an engineering manager increased from $50.71 an hour in 2009 to $66.69 in the latest estimate. EPA also assumed that lawyers would need to assist trailer manufacturers in complying with the rule, but used hourly rates
of $66 to $138. In Clean Air Act litigation, EPA has stipulated to hourly rates in fee awards that far exceed those used in the Proposal. [EPA-HQ-OAR-2014-0827-1242-A2 p.19]

EPA’s analysis of the other cost categories is equally problematic. Without any real-world data, the agency assumed that a large trailer manufacturer would only spend about $50,000 on the software, testing equipment, and other infrastructure needed to comply with the rule. This cost estimate appears to assume that manufacturers need to incur only start-up costs for trailer certification and labeling, but that ignores several categories of additional costs, including (1) the costs of owner’s manuals, (2) the significant cost of developing training programs, and (3) the quality control procedures that must be developed and integrated into a manufacturer’s compliance systems. [EPA-HQ-OAR-2014-0827-1242-A2 p.19]

In addition to these start-up costs, EPA grossly underestimated ongoing operations and maintenance costs. Perhaps the best illustration is that EPA calculated a $3,000 total annual cost to prepare a certification application for each model year of trailer, including engineering fees, testing fees, and legal fees. In the engine and auto context, the cost of certification applications can range from $25,000 for simple applications that build on existing testing to several hundred thousand dollars.

To provide EPA a sense of how much it underestimated costs, Wabash submits a confidential estimate of its compliance costs for the Phase 2 Proposal. This estimate should be treated as confidential business information under 40 CFR Part 2 and 49 CFR Part 512 and not placed in the docket for the Proposal. Nonetheless, it will give EPA and OMB insight into the real-world costs of complying with the Phase 2 Proposed Rule and provide a basis for further due diligence on the agencies’ part for investigating the true costs of compliance. [EPA-HQ-OAR-2014-0827-1242-A2 p.19]

Response:

For the final rule, the agencies updated the cost assumptions from the proposal, as discussed in Chapter 7.2.1.2 of the RIA and our Supporting Statement for the Information Collection Request (ICR) with this rulemaking. In the NPRM, the agencies assumed $1.2 million for testing, reporting, and capital costs for the trailer manufacturing industry. In the NPRM, these estimated costs were increased to $7 million. The new compliance costs now include updated labor costs, increased initial capital costs that include computer software, labeling equipment, and infrastructure upgrades, and updated operational costs considering the information provided in this comment. These updates are summarized in the ICR, but we also refer the commenter to the calculations for our small business economic burden estimates. The attached spreadsheet includes the cost estimates for both small and large manufacturers on which we based our ICR costs and general compliance costs.

Organization: Wabash National Corporation

XIII. EPA Must Ensure a Level Playing Field Between Domestic and Imported Trailers

Wabash’s strong domestic manufacturing presence depends on a level playing field with importers. Yet the rule only makes a single, passing reference to importers’ obligation to follow the rule. The scant

---

attention paid to this issue is deeply disturbing because, as EPA knows, a flood of illegally imported engines and vehicles have been streaming into the U.S. since at least 2008. EPA must proactively engage on this import issue to prevent a pattern of similar violations from developing in the trailer industry. Otherwise, the ability of domestic manufacturers to fairly compete would be undermined. [EPA-HQ-OAR-2014-0827-1242-A2 p.23]

A. The Final Rule Must Clearly and Unequivocally Cover Importers

The final rule must make clear that imported trailers must comply with the Phase 2 emissions and fuel economy requirements. Despite stretching 629 pages, the Proposal makes only one indirect reference to the fact that imported trailers must comply with the rule.64 The scant attention paid to the issue of imported trailers may lead some companies to misunderstand the rule’s coverage of imports or seek to circumvent it. As a leading domestic manufacturer of trailers, Wabash depends on a level playing field with importers to ensure fair competition. To put to rest any argument about the scope of the rule, Wabash respectfully requests a few modest changes to the rule. [EPA-HQ-OAR-2014-0827-1242-A2 p.23-24]

First, it would be helpful to have the agencies discuss their authority to regulate emissions and fuel economy of imported trailers under the CAA and Energy Independence Security Act (“EISA”). Section 203(a) of the CAA prohibits the importation of new motor vehicles or engines unless covered by a valid emissions certificate of conformity. Likewise, the fuel economy requirements under EISA extend to importers of new motor vehicles. Explaining how these import provisions extend to trailers as motor vehicles would assist the regulated community in understanding its legal obligation to comply with the rule. [EPA-HQ-OAR-2014-0827-1242-A2 p.24]

Second, the definitions used in the text of the final rule should reflect the coverage of imported trailers. EPA’s definition of “motor vehicle” should specifically reference that it includes trailers, particularly the proposed definitions found at 40 C.F.R. §§ 1037.801 and 85.1703. EPA’s definition of “manufacturer” should be revised as follows: “Manufacturer... covers includes importers who import vehicles or vehicles for resale (including trailers) and entities that assemble glider kits.” NHTSA’s Proposal cross-references the statutory definitions of “manufacture” and “manufacturer” in EISA, which includes imports, but does not make specific reference to trailers. A regulatory definition of “manufacture” and “manufacturer” that includes “importers of heavy-duty trailers” would provide greater clarity to the regulated community. [EPA-HQ-OAR-2014-0827-1242-A2 p.24]

Third, EPA’s Part 1068 rules on mobile source enforcement and compliance should mention trailers, including imported trailers. NHTSA’s proposed fuel economy regulation expressly states that it “includ[es] trailers” as do EPA’s Part 1037 regulations that set emissions standards for trailers. In contrast, EPA’s Part 1068 enforcement rules make no specific mention of trailers, but instead contain broad cross-references to numerous other EPA rules, one of which—Part 1037—includes trailers. [EPA-HQ-OAR-2014-0827-1242-A2 p.24-25]

Wabash recommends that EPA amend Part 1068 in the following respects to make clear that it covers imported trailers:

Emphasize that each illegally imported trailer may result in a potential statutory maximum civil penalty of $37,500 per trailer. [EPA-HQ-OAR-2014-0827-1242-A2 p.25]

Reference trailers in other import provisions of Part 1068. See 40 C.F.R. § 1068.101(a)(1), 80 Fed. Reg. at 40,719-20 (“You may not sell, offer for sale, or introduce into commerce in the United States or import into the United States any new engine/equipment (including trailers) after emission standards take effect for the engine/equipment, unless it is covered by a valid certificate of conformity for its model year and has the required label or tag.”); 40 C.F.R. § 1068.101(a)(5), 80 Fed. Reg. at 40,7120 (“You may not import an uncertified engine or piece of equipment (including trailers) if it is defined to be new in the standard setting part with a model year for which emission standards applied.”); 40 C.F.R. § 1068.301, 80 Fed. Reg. at 40,7128 (“In general, engines/equipment (including trailers) that you import must be covered by a certificate of conformity unless they were built before emission standards started to apply.”). [EPA-HQ-OAR-2014-0827-1242-A2 p.25]

B. Enforcement Is Critical for Imported Trailers

In addition to these textual changes to the rule, Wabash supports a vigorous enforcement program for imported trailers to ensure that domestic trailer manufacturing remains an important source of good-paying jobs in our nation. Import violations are a chronic issue for EPA’s mobile source programs. As EPA has noted, “there has been a steady flow” of illegally imported engines and vehicles into the United States. Nearly all of the mobile source civil settlements in 2015 involved import violations: importers failed to obtain valid certificates of conformity, install emission controls, or take other actions to comply with the CAA. [EPA-HQ-OAR-2014-0827-1242-A2 p.25-26]

EPA’s mobile source enforcement against importers has been hampered by several factors. Importers have relied on falsified certificates of conformity for engines and vehicles, making detection of violations more difficult. When violations have been discovered, EPA has frequently been unable to locate U.S. registered agents and assets. Importers that have vehicles and engines seized at port “often change the port of entry for subsequent shipments.” [EPA-HQ-OAR-2014-0827-1242-A2 p.26]

In light of ongoing compliance problems with imports, EPA should incorporate “Next Generation Compliance” into the final rule in order to enhance enforcement against import violations, particularly those involving trailers. EPA’s Strategic Plan on Next Generation Compliance takes advantage of new tools and strategies to leverage greater compliance, including electronic reporting, data transparency, and data analytics. [EPA-HQ-OAR-2014-0827-1242-A2 p.26]

Consistent with these principles of Next Generation Compliance, the final rule should require declaration forms and other import documents to be electronically submitted and publicly available in an EPA-maintained database. Access to electronic data on imports would allow agency staff and the public to better detect non-compliance patterns, identify repeat violators who shift from port-to-port, and deter fraud. Importers should also be required to electronically file annual reports certifying under oath compliance with the CAA for the past year, and disclosing the names of the test labs or consultants used to support the certificates of conformity for imported trailers. Certifying compliance would potentially provide an additional measure of deterrence for future violations, while disclosure of test labs would help validate that certificates of conformity resulted from legitimate testing. [EPA-HQ-OAR-2014-0827-1242-A2 p.26-27]
Response:

The agencies acknowledge that enforcement of emission standards for new trailers that are imported into the United States poses unique challenges at the point of entry, because new trailers may be carrying cargo and are therefore nearly indistinguishable from trailers that have already been imported or otherwise placed into service. We are not adopting any new or different compliance provisions in this rulemaking to address this; however, we intend to work cooperatively with Customs and Border Protection and other agencies to ensure that first-time state registration of new trailers includes verification that the trailer manufacturers have certified them to meet U.S. emission and fuel consumption standards. We expect this to be similar to the current system for ensuring that new, imported trailers meet NHTSA safety standards.

A related concern applies for foreign-based trailers traveling in the United States for importing or exporting cargo. Such trailers are not subject to emission and fuel consumption standards unless they are considered imported into the United States. U.S. cabotage law prohibits foreign truck drivers from carrying product from one point to another within the United States. Effective enforcement of this cabotage law will help prevent manufacturers of noncompliant foreign-produced trailers from gaining a competitive advantage over manufacturers of compliant domestic trailers.

EPA is revising the definition of “manufacturer” in 86 CFR 1037 and the applicability language in 86 CFR 1068.1 to reinforce that manufacturers that import trailers into the U.S. are covered by the trailer program.

5.7 Proposed Non-CO2 GHG Standards for Trailers

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Non-CO2 GHG emissions from trailers

The NPRM requests comment on the issue of HFCs refrigerant leakage from transport refrigeration units (TRU). U.S. EPA and NHTSA believe TRU refrigerant leakage is insignificant because they contend that trailer TRU owners have a strong incentive to limit this leakage in order to maintain the operability of the trailer’s refrigeration unit and avoid financial liability for damage to perishable freight due to failure to maintain the agreed-upon temperature and humidity conditions. Also, U.S. EPA and NHTSA believe that refrigerated van units represent a relatively small fraction of new trailers. U.S. EPA and NHTSA also asked for data on typical TRU charge capacity and the frequency of HFC leakage. [EPA-HQ-OAR-2014-0827-1265-A1 p.146-147]

Overall, CARB staff believes U.S. EPA and NHTSA are underestimating potential refrigerant leakage from TRUs. CARB staff recommends, as discussed further below, that 1) U.S. EPA and NHTSA establish an HFC refrigerant usage monitoring program for TRUs to inform future “cause and contribute findings” and decisions to regulate refrigerants used in TRUs, and 2) U.S. EPA and NHTSA provide incentive funding for zero- and near-zero-emission transport refrigerators, such as cryogenic transport refrigerators. [EPA-HQ-OAR-2014-0827-1265-A1 p.147]

CARB staff believes U.S. EPA and NHTSA may be overly optimistic when it comes to TRU owners proactively preventing and repairing refrigerant leaks. That may be partially true for the first generation owners, but many TRUs receive less maintenance as they age and their second, third, or fourth
generation owners are not financially able to pay for repairs. CARB staff believes that for a considerable number of TRU owners, repairs and maintenance issues are typically addressed only when there is a performance issue with the TRU. Excluding TRUs from leakage requirements shifts the responsibility for these systems to the users, leaving manufacturers free to develop systems that may be more prone to leakage. TRU manufacturers should be held accountable for manufacturing quality products that are not prone to leakage. CARB staff is not aware of any tracking programs for HFC usage to recharge leaky TRU systems or determine leakage frequency; but, those types of programs should be considered to provide the data that is needed to assess the impact on climate change due to TRU refrigerant leakage. [EPA-HQ-OAR-2014-0827-1265-A1 p.147]

TRU models that use open-drive refrigeration compressors are more susceptible to shaft seal leakage as they age. Many TRU models still use open-drive refrigeration compressors. Hermetically sealed refrigeration compressors do not have shaft seal refrigerant leakage issues because the electric drive motor is enclosed inside a housing with the refrigeration compressor. Unfortunately, hermetically sealed refrigeration compressors have not been incorporated into all TRU platforms. When used in conjunction with more energy efficient scroll compressors, GHG emissions are greatly reduced through a combination of lower fossil fuel use and the elimination of high-GWP refrigerant leakage from shaft seals. [EPA-HQ-OAR-2014-0827-1265-A1 p.147]

A quick review of current, on-line TRU specification sheets revealed refrigerant charge capacities are 13 to 16 lbs per trailer TRU. Previous to 2013, when both of the major TRU manufacturers re-designed and optimized their trailer TRU platforms, refrigerant charges averaged about 20 lbs per unit. This value is consistent with the value reported in Table S4 (page S8) of the Supporting Information Document for the article titled “High Global Warming Potential F-Gas Emissions in California: Comparison of Ambient-based verses Inventory-Based Emission Estimates, and Implications of Refined Estimates” by Glenn Gallagher, et al. This document also includes average annual leakage rates for TRUs (18.3 percent). The data sources and methodology for TRU refrigerant emissions are explained on pages S19-S21. [EPA-HQ-OAR-2014-0827-1265-A1 p.148]

ACT Research estimates there are over 370,000 refrigerated trailers in the U.S. in 2015 and the average fleet age is 5.63 years. This means that the total TRU refrigerant charge in the U.S. subject to potential leakage could range from 2,405 short tons to 3,700 short tons. [EPA-HQ-OAR-2014-0827-1265-A1 p.148]

Refrigerant emissions may be small compared to some other commercial and industrial sectors, but significant emission reductions in this sector can be achieved by adopting lower GWP refrigerants. CARB staff believes it is hard to rationalize refrigerant leaks on the basis of small sector numbers when the GWP is so high for currently used TRU refrigerants (R-404A, used in trailer TRUs, has a GWP of 3,922) and near “drop-in” refrigerants, such as R-452A, has a GWP of 2,141. [EPA-HQ-OAR-2014-0827-1265-A1 p.148]

Refrigerant R-452A is a blend of the hydrofluoro-olefin (HFO) R-1234yf that has a very low-GWP of 4 and higher GWP HFCs. Blends with greater R-1234yf cause reduced refrigeration capacity. Lost capacity could be offset by improvements in refrigeration system efficiency (requiring less energy) and more thermally efficient insulated cargo vans (requiring less refrigeration capacity). Integrated designs that balance these effects and produce net improvements in total equivalent warming impact are needed. [EPA-HQ-OAR-2014-0827-1265-A1 p.148]

In the long-term, natural refrigerants, such as CO2, may become viable if associated energy use rates can be reduced through continued design optimization. CO2 systems have been demonstrated in Europe
for refrigerated shipping containers but industry has been slow to adopt them because costs are still high as a result of low production numbers and economies of scale. Incentive programs are needed to encourage adoption of existing CO2 refrigerant systems for shipping containers and to develop CO2 refrigerant systems for higher ambient temperature conditions and larger capacity systems needed for 53 foot trailer TRU applications. [EPA-HQ-OAR-2014-0827-1265-A1 p.149]

Cryogenic transport refrigerators also offer an alternative to vapor compression refrigeration systems that use high-GWP refrigerants. A cryogenic fluid, such as liquid nitrogen, liquid CO2 or liquid air, is used to provide cooling to the cargo space. There are some GHG emissions associated with the production of these cryogenic fluids. For liquid nitrogen, the most common type of cryogenic transport refrigerator, well-to-wheel (WTW) GHG emission reductions are 50 to 60 percent less than a conventional TRU. This technology, as well as other zero- and near-zero-emission technologies, is discussed in CARB’s Technology Assessment: Transport Refrigerators. [EPA-HQ-OAR-2014-0827-1265-A1 p.149]

In addition to establishing an HFC refrigerant usage monitoring program and providing incentive funding for zero- and near-zero-emission transport refrigerators, CARB staff also recommends that U.S. EPA use its SNAP program to phase out high-GWP refrigerants, such as R404A, as soon as it determines that viable alternative are available. [EPA-HQ-OAR-2014-0827-1265-A1 p.149]

**Support Comment**

**Comment – Refrigerated Trailer Problems**

CARB staff agrees with U.S. EPA and NHTSA’s statements: “Over time, refrigerated trailers can also develop problems that interfere with their ability to keep freight temperature-controlled. For example the insulting material inside a refrigerated trailer’s walls can gradually lose its thermal capabilities due to aging or damage from forklift punctures. The door seals on a refrigerated trailer can also become damaged or loose with age, which greatly affects the insulating characteristics of the trailer.” [EPA-HQ-OAR-2014-0827-1265-A1 p.150]

The refrigerated transport industry is well aware of the thermal performance degradation that insulated trailers go through as a result of blowing agent outgassing, moisture intrusion, insulation breakdown caused by road-induced vibration and panel flexing, forklift damage, tree side-swiping damage, and other normal wear-and-tear. Low permeability barriers can be used to slow down outgassing. Aluminum and stainless steel sheets, various types of polymeric films, laminated foil/plastic films, metalized films, fiberglass, glass mat, and composite liners are offered as options to prevent damage and subsequent moisture intrusion. Great Dane has published charts that show up to 40 percent degradation of insulation performance over several years and much slower degradation when various options are used to conserve insulation performance. [EPA-HQ-OAR-2014-0827-1265-A1 p.150]

There are no standards in the U.S. to ensure all refrigerated trailers meet minimum thermal performance standards when they are new. There are also no standards in the U.S. that measure thermal performance as an insulated trailer ages to ensure they are retired or delegated to less demanding service when thermal performance degrades. As this performance degrades, energy efficiency is compromised and TRU engines must run harder and longer to maintain temperature set points, resulting in greater GHG emissions. Market forces drive the thermal efficiency of refrigerated trailer designs in the U.S. [EPA-HQ-OAR-2014-0827-1265-A1 p.150]
CARB staff encourages U.S. EPA and NHTSA to look at the regulatory requirements that must be met in Europe regarding refrigerated van insulation. The 26 members of the European Union and 23 other European, former Soviet Union, North African and Middle Eastern counties have signed on as contracting parties to the United Nations Economic Commission for Europe’s (UNECE) standards under the Agreement on the International Carriage of Perishable Foodstuffs and on Special Equipment to be Used on Such Carriage (ATP). ATP requires testing and certification of the insulation and cooling capacity of refrigerated transport equipment, and provides for separate testing of TRUs. France, Italy, Russia, and Spain apply ATP standards to domestic transportation within their borders. Although the U.S. is a contracting party to ATP, the U.S. made a declaration under article 10 of the International Carriage of Perishable Foodstuffs Act of 1982 and the implementing regulations at title 7 Code of Federal Registration (CFR) 3300, resulting in ATP standards being voluntary in the U.S. [EPA-HQ-OAR-2014-0827-1265-A1 p.150-151]

Under the ATP, samples of new-model insulated vans are tested to ensure they meet the appropriate overall heat transfer coefficient standard (K-value). Passing models are certified for six years. Certification of insulated vans may be renewed at six year intervals by inspecting and/or testing a sample of aged insulated vans to determine if they still meet the ATP K-value standard. [EPA-HQ-OAR-2014-0827-1265-A1 p.151]

In addition, market forces are at work in Europe, because diesel fuel typically costs two to three times more than U.S. fuel due to differences in government subsidies, taxes, and other influences. Greater thermal efficiency in truck and trailer vans makes legal and economic sense in the Europe, so insulation is generally thicker there (side walls are typically about four inches thick compared to two inches thick in the U.S.). [EPA-HQ-OAR-2014-0827-1265-A1 p.151]

The high cost of diesel fuel, the above-mentioned thermal efficiency standards, and greater prevalence of noise ordinances have also made European refrigerated fleets more open to trying new or alternative transport refrigeration technologies. For example, there is greater use of cryogenic transport refrigerators, all-electric, and hybrid electric TRUs with various range extender strategies in Europe. [EPA-HQ-OAR-2014-0827-1265-A1 p.151]

CARB staff recommends U.S. EPA and NHTSA continue to evaluate appropriate technologies and approaches that can achieve substantial emission reductions for TRUs and insulated trailers. CARB’s Technology Assessment: Transport Refrigerators provides information on zero- and near-zero-emission technologies and includes a discussion on energy efficiency for refrigeration systems and thermal efficiency for insulated cargo vans. Incentive programs are needed to transition these technologies to commercial readiness so they can be included in later phases of GHG rules. [EPA-HQ-OAR-2014-0827-1265-A1 p.151]

ELECTRIFIED PARKING SPACES PROVIDE A CRITICAL NETWORK FOR ELECTRIFIED TRANSPORT REFRIGERATED UNITS AND ELECTRIC VEHICLE CHARGING INFRASTRUCTURE

**Long range** Transport Refrigerated Units (TRUs) are cooled by unfiltered diesel compressors that idle 24-hours per day. IdleAir and other EPS providers are establishing a network for refrigerated fleets to be able to plug in and power down while the trailer is at rest. To the extent the TRU contains battery or solar, it can offset idling during drive time as well. Long Range TRU fleets are unlikely to abandon diesel backup, but more than 70% of TRU idling can be addressed with hybrid electric TRUs that can connect to our charging stations at the terminals of the largest refrigerated fleets in the country, their customer facilities, and public truck stops. The existing EPS network will prop up this nascent industry of TRU conversions to hybrid units, but only if EPS providers are in business long enough to reach the tipping point. [EPA-HQ-OAR-2014-0827-1250-A2 p.3]

**Response:**

In addition to the impact of trailer design on the CO₂ emissions of tractor-trailer vehicles, EPA recognizes that refrigerated trailers can also be a source of emissions of HFCs. Specifically, HFC refrigerants that are used in transport refrigeration units (TRUs) have the potential to leak into the atmosphere. When powered by internal combustion engines, TRUs also emit criteria pollutants and CO₂ and consume fuel.

In their comments, CARB said they believe that EPA has underestimated the potential for TRU refrigerant leakage. However, CARB and other commenters did not provide sufficient information for EPA to introduce new regulatory requirements for TRUs at this time. EPA did not propose any action related to TRUs in this rule and does not take such action in the final program. In general, however, EPA will continue to monitor the state of TRU technology and operation, and may pursue appropriate action if warranted in the future. Similarly, regarding incentives for lower-emission TRUs, EPA is unaware of financial or regulatory mechanisms at this point that could be implanted to encourage such a market shift. We will continue to monitor both the potential need for and mechanisms for such incentives.

We also note that EPA has separately proposed a regulation under Title VI of the CAA, specifically section 608. See 80 FR 69457 (November 9, 2015). This proposal would extend existing regulations on ozone depleting refrigerants to many alternative refrigerants, such as HFCs, which are the most common refrigerants used in TRUs. If finalized as proposed, EPA would require that appliances like TRUs be subject to the applicable requirements of 40 CFR subpart F, including requirements for servicing by a certified technician using certified recovery equipment and for recordkeeping by technicians disposing of such appliances with a charge size between five and fifty pounds, which would include TRUs, to help ensure that the refrigerant is not vented.
In response to the comment about the phase-out of high-GWP refrigerants, under Section 612 of the Clean Air Act (CAA), EPA’s Significant New Alternatives Policy (SNAP) program reviews substitutes within a comparative risk framework in the following industrial sectors: Adhesives, Coatings & Inks; Aerosols; Cleaning Solvents; Fire Suppression and Explosion Protection; Foam Blowing Agents; Refrigeration & Air Conditioning; Sterilants; and Tobacco Expansion. Section 612 also provides that EPA must prohibit the use of a substitute where EPA has determined that there are other available substitutes that pose less overall risk to human health and the environment. The SNAP program does not provide a static list of alternatives but instead, evolves the list as EPA makes decisions that are informed by its overall understanding of the environmental and human health impacts as well as its current knowledge about available substitutes. EPA will continue to review the availability of alternatives for the refrigerated transport end-use, including TRUs.

Finally regarding the CARB comment about the deterioration of insulating efficiency, the passage that they quote from the proposed rule was a general observation about factors contributing to trailer aging and replacement. We are not aware specific data relating to such impacts on TRU fuel use, and, regardless, are not addressing TRU emission or fuel consumption issues in this Phase 2 program.

### 5.8 Trailer-Specific Small Business Concerns

**Organization:** Wabash National Corporation

Creating Exceptions for “Small” Trailer Manufacturers Discourages Innovation and Breaks from the Clean Air Act

Pursuant to the Regulatory Flexibility Act, EPA convened a Small Business Advocacy Review Panel to evaluate the impact of the proposed Phase 2 emissions requirements on small businesses, including small trailer manufacturers. Based on the Panel Report, EPA proposes a one-year delay in the compliance deadlines for small manufacturers and invited comment on additional compliance delays. In defining a “small” trailer manufacturer, EPA relied on a Small Business Administration (“SBA”) regulatory definition of a manufacturer with 500 or fewer employees. [EPA-HQ-OAR-2014-0827-1242-A2 p.20-21]

**A. EPA’s Proposed “Small” Trailer Manufacturer Exemptions Are Overly Broad and Punish Innovation**

EPA’s proposed approach for small trailer manufacturers appears overly broad and creates disincentives for technological innovation to address climate change. Trailer manufacturing is far less labor-intensive than other segments of the heavy-duty sector such as engine manufacturing, cab chassis manufacturing, and other vehicle production. As a result, over 80% of trailer manufacturers would qualify as small businesses under EPA’s proposed definition. Delaying compliance for most of the manufacturers in the trailer industry would unfairly punish Wabash and other forward-leaning companies that worked with EPA, NHTSA, and the technical community to improve fuel economy and reduce CO2 emissions. As the agencies are well aware, Wabash has spent years of effort and devoted substantial resources to developing innovations in trailers, particularly industry-leading aerodynamic devices. EPA’s Proposal ignores those efforts and would potentially distort the market in favor of companies that had neither the inclination, nor the resources, to move the industry forward. The Proposal therefore runs counter to EPA’s longtime position that emissions standards under CAA Section 202 should encourage the development of new technologies in the motor vehicle industry. [EPA-HQ-OAR-2014-0827-1242-A2 p.21]
Response:

The agencies have provided a one-year delay for small businesses but have not established a small business trailer manufacturer exemption from the regulatory requirements for the remainder of the Phase 2 program. The agencies agree with Wabash that including small businesses in the regulation is important to the introduction of fuel efficiency improving trailer technologies. At the same time, we have heard from small businesses that they do not have the same resources available to become familiar with the regulations, make process and staffing changings, or evaluate and market new technologies as their larger counterparts. We believe a one-year delay provides sufficient time for small businesses to address these issues, without a large CO₂ and fuel consumption impact. The cumulative annual production of all of the small business box trailer manufacturers is estimated to be less than 15 percent of the industry’s total production (Figure 1-3 of Chapter 1 in our RIA), which is significantly less than the annual production of the four largest manufacturers. We expect any diverted sales for this one year will be a small fraction of the large manufacturers’ production and we are finalizing the one-year delay for all small business trailer manufacturers.
6 Class 2b-8 Vocational Vehicles

6.1 General Comments

6.1.1 NOx from Idling Emissions

Allison Transmission

NOx Benefit from Stop-Start and Idle Reduction Technologies

The agencies have requested comment regarding whether there may be a NOx co-benefit to Stop-Start idle reduction technologies, e-PTO, and neutral idle. [EPA-HQ-OAR-2014-0827-1284-A1 p.47]

With respect to such co-benefits, Allison has confirmed an engine Stop-Start system NOx and after treatment temperature co-benefit. During powertrain testing of a hybrid bus powertrain on the OCTA cycle, Allison documented an average 7% NOx decrease with engine Stop-Start vs. NOx baseline with no engine Stop-Start. The testing also showed an increase in average after treatment temperatures over the drive cycle and a slight increase in Fuel Economy. The following chart shows data taken from that testing. [EPA-HQ-OAR-2014-0827-1284-A1 p.47]

[Chart, 'Data summary average of samples', can be found on p.47 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

Organization: Odyne Systems LLC

Odyne believes co-benefits beyond fuel efficiency improvements and greenhouse gas reductions, like Odyne technologies’ verified ability to reduce NOx emissions, should be valued in the Phase Two rulemaking, especially given potential future regulatory actions from EPA and current developments from CARB on NOx. Most of the benefits that Odyne achieved in the reduction of NOx came from the hybrid power take off (PTO) activities (stationary / work site). [EPA-HQ-OAR-2014-0827-1920-A2 p.12]

Organization: Daimler Trucks North America LLC

NOx Emissions From Idling – Note that all of our engines meet the ARB’s 30 g NOx/hr idle level. [EPA-HQ-OAR-2014-0827-1164-A1 p.28]

NOx Benefit from Stop-Start Technologies - The agencies state a belief there may be a NOX co-benefit to stop-start idle reduction technologies, e-PTO, and possibly also to neutral idle. For this to be true, the benefits of reduced fuel consumption and retained aftertreatment temperature would have to outweigh any extra emissions due to re-starts. The agencies requested comments regarding this issue. DTNA is also investigating the potential for this technology in lighter classes of HDV applications as a measure to improve fuel efficiency. DTNA also recognizes and is investigating the potential for improving heat retention in the SCR system via stop-start but because of early stages of development cannot verify or quantify actual benefits. That said, EPA should allow manufacturers to demonstrate reduced NOx levels on transient FTP test procedures, from implementation of this technology. [EPA-HQ-OAR-2014-0827-1164-A1 p.29]
Response:

The agencies will retain this preliminary information provided by commenters on the relationship between NOx emissions from vocational vehicles and workday idle reduction technologies. The agencies also conducted independent NOx testing of engines at idle; however, the data are not conclusive enough for the agencies to quantify the NOx co-benefits of vocational workday idle reduction as part of this rulemaking. As part of the final Phase 2 program, NOx emissions will be measured and reported as a part of powertrain testing. This will allow EPA to monitor NOx performance. The information collected will also be used to inform EPA as to the merits of future rulemaking.

6.1.2 Comments Generally Supporting Stronger Standards

Organization: Natural Resources Defense Council (NRDC)

Increase the stringency of the standards. NRDC believes standards that achieve fuel consumption and emissions reductions of at least 24 percent by 2024 and at least 31 percent by 2027 relative to Phase 1 would meet the agency obligations for setting standards that are maximum feasible (for NHTSA) and appropriate (for EPA). Important areas where the Phase 2 program stringency can be improved significantly include the standards for tractor diesel engines and for vocational vehicles. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

Organization: Proterra

Proterra supports the proposed Phase 2 standards that, for vocational vehicles, would achieve up to 16% lower CO2 emissions and fuel consumption compared to Phase 1 by the year 2027. [EPA-HQ-OAR-2014-0827-1160-A1 p.2]

Organization: Odyne Systems LLC

At a minimum, we would recommend the EPA increase full compliance fuel consumption and emission reductions for the vocational sector beyond the 16%, to at least 20% or higher – as recommended by groups like the Union of Concerned Scientists in their comments. [EPA-HQ-OAR-2014-0827-1239-A1 p.4-5] [[This comment can also be found in EPA-HQ-OAR-2014-08267-1372, pp.230-231.]]

Organization: Union of Concerned Scientists (UCS)

Vocational vehicles range from delivery vans to city buses and from bucket trucks to garbage trucks. This complexity makes it one of the most difficult segments to regulate. In Phase 1, the agencies chose to regulate these vehicles primarily through separate vocational engine standards. In Phase 2, the agencies have added significant complexity and identified a much broader array of viable fuel consumption reduction technologies in this sector. In the following sections, we focus on ways in which the agencies can strengthen the regulation, both with increased stringency and increased flexibility for manufacturers. The agencies' proposal must be 'technology-forcing' and achieve the 'maximum feasible' reductions in the timeframe of the rule. To do this, the agencies must strengthen Alternative 4 by: Increasing the stringency for gasoline-powered vocational vehicles by 7.8 percent and those for diesel-powered vocational vehicles by 3.6 percent in 2024 to fully reflect the ability for conventional technologies to reduce fuel use from this sector, while incentivizing the adoption of more advanced technologies where appropriate; [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

Organization: Environmental Defense Fund (EDF)
Class 2b-8 vocational trucks, which include a broad variety of trucks that have many different functions, consume about 20% of the fuel used by the heavy-duty vehicle sector. EPA and NTSA proposed vehicle standards that would result in about a 16% fuel consumption reduction from diesel-powered trucks and about a 13% reduction for gasoline-powered trucks, by 2027. The difference in stringency is explained by the fact that the agencies did not update standards for gasoline engines. In addition to finalizing a fuel neutral engine standard, the vehicle standards can also be strengthened. [EPA-HQ-OAR-2014-0827-1312-A1 p.37]

Weak standards for this segment send a negative signal to the emerging market for advanced technologies and discourage on-going investment and development. We strongly encourage the agencies to finalize more protective standards for vocational vehicles that include a meaningful role for advanced technologies such as hybrid and electric vehicles, and promote innovative companies that can provide high quality jobs. [EPA-HQ-OAR-2014-0827-1312-A1 p.38]

Organization: McNicols

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 271-272.]

Specifically, the sub-category for vocational vehicles and multiple route applications makes the regulations more clear and progress more easily identified.

However, regarding the vocational vehicles target improvements, the proposed requirement of 16 percent improvement may fall short of bringing about the necessary technologies to significantly impact this sector. With roughly 30 percent of the greenhouse gas pollutants coming from the vocational vehicle and medium and heavy duty pickup truck sector, a greater percentage should be considered to drive the innovation even higher.

Organization: Motiv Power Systems

We applaud the agencies for their commitment to work with manufacturers and craft the strongest standards to reduce fuel usage, save fleets money, and minimize the environmental impacts of the trucking sector. The agencies have taken some key first steps to build upon the success of Phase 1, and we look forward to working with EPA and NHTSA to ensure that the regulation adequately captures and incentivizes the levels of fuel consumption and emissions reductions we know can be achieved in this timeframe. [EPA-HQ-OAR-2014-0827-1184-A1 p.2-3]

Organization: California Air Resources Board (CARB)

CARB staff recommends that Alternative 4 be chosen, with the regulation proposing standards out to MY 2024 vehicles. CARB staff believes the proposed rule in its current framework is conservative and leaves obtainable emission benefits on the table. CARB staff does not believe that the current stringencies require the additional three years of lead time that is proposed in Alternate 3. Multiple manufacturers have made it clear to CARB staff that the proposed stringencies can easily be met in the MY 2024 compliance time frame. In the current Alternative 3 framework, most technologies do not see significant changes in penetration from MY 2024 to MY 2027.

The NPRM proposes an overall 16 percent CO2 emission benefit for the final MY vocational vehicles. The additional stringencies recommended by CARB staff result in additional incremental CO2 benefits of about 2.5 percent for vocational vehicles. CARB staff therefore recommends U.S. EPA and NHTSA
pursue Alternative 4 with a final stringency level of approximately 18.5 percent for vocational vehicles.\[EPA-HQ-OAR-2014-0827-1265-A1 p.56\]

- Alternative 4 achieves greater emission benefits and greater net societal benefits than Alternative 3. As summarized in Table 10 below, Alternative 4 for vocational vehicles would achieve 33.5 more total MMT CO2 reductions and a $5.2 billion greater total societal benefit nationally through MY 2029.

- The projected payback period for Alternative 4 is still acceptable and within the same year as the projected payback period for Alternative 3. [Table 10 can be found on p.54 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

**Organization:** CALSTART

As we shared at the Long Beach workshop, CALSTART recently published a report, titled “Higher Fuel Efficiency: Working for Fleets,” which assessed the business case for fleets from higher fuel efficiency trucks that might be driven by a new fuel economy rule. This report has highlighted two core issues: that there are achievable technologies that can provide higher efficiency on the rule timeline, and that these technologies on whole can be cost-effective and provide reasonable payback to fleets using them. [EPA-HQ-OAR-2014-0827-1190-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.152.]]

To understand the payback issue we took a different approach from the agencies. We worked with a cross section of fleets representing various applications and truck types nationwide to validate the key components of a fleet business case assessment model, collaborating with the NAFA Fleet Management Association and its fleets.

In developing the model, we also surveyed fleets on their support for and concerns about increased fuel efficiency.

- Interestingly, we found 87-percent of fleet managers responding supported rules driving higher fuel efficiency.

- Their primary concern was cost; though 89-percent said they would be willing to pay more up front for fuel efficient trucks if they knew they would pay back over their life.

- They also expressed concern about reliability and maintenance costs. This does have relevance for the rule duration.

We looked at different technology packages that were most applicable to each use profile, assembling packages that could achieve up to a 40 percent reduction of fuel use over 2010 baseline trucks. These packages, and their projected costs, were adapted from National Research Council and Transportation Research Board studies.

Our top level findings were these:

- We found there is a reasonable business case payback, based on fleet-validated cost assessment tools, for higher fuel economy trucks at levels proposed in the rules.
- The stringency levels we modeled in the report were, in most cases, actually higher than those proposed in the Alternative 3 language.

- We saw the potential for higher fuel economy targets than those proposed in several use profiles – particularly urban trucks, regional trucks and those vehicles with high work site idle time.

- The biggest variables for payback were utilization – the mileage and fuel used – and the upfront cost of the technology.

- Fleets have suggested that modeling payback sensitivity to maintenance cost would be helpful and we encourage the agencies to develop this information to address fleet concerns.

As mentioned, the report used different – and generally higher – assumptions for stringency than those recommended in the agencies’ preferred Alternative 3. Below we highlight the comparisons between the segments we studied, the corresponding segment in the rule (where there is one), and the stringency proposed in the draft rules compared with those studied in the report. [EPA-HQ-OAR-2014-0827-1190-A1 p.3]

[Table of segments studied and results can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1190-A1]

We are concerned that the vocational segments as proposed do not meet the same level of reduction path and we believe they could, while still providing fleet users with the functionality they need and a payback they can afford.

In shaping the final rule, we believe the agencies’ payback projections from efficiency are reasonable and real. Indeed, we see a strong case for higher efficiency targets than those currently called for particularly in several vocational segments. We also see the ability to further push improvements in engine technology than proposed while still making sure those engines are a component of a full vehicle strategy. [EPA-HQ-OAR-2014-0827-1190-A1 p.9] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.155-156.]]

We strongly support increasing the stringency requirements of these vocational segments, with a minimum target of 20% (though varied by different segment). In terms of the rule timeline, we remain sensitive to both OEM and fleet desires for a longer investment horizon and a more measured, stair-step regulatory approach to ensure quality product delivery. However, we believe any longer regulatory timeline (2027) would only make sense in the context of increased stringency, with some commensurate added flexibility.

Response:

We have carefully considered all the comments asking the agencies to adopt more stringent standards for vocational vehicles than proposed. Please see Section 8.2.1 for responses to comments related to the pace of phasing in the Phase 2 standards. See also Section 1.5 for responses to comments on the need for lead time for some technologies. In the sections below where we address specific comments on individual technologies, we describe the ways in which we have adjusted technology adoption rates and
effectiveness projections to form the basis for the final vocational vehicle standards that are more stringent than we proposed, but still afford sufficient lead time to achieve those standards.\footnote{However, we note an error in UCS’ assertion that standards under CAA section 202 (a)(1) and (2) must be technology forcing. This is not correct, although standards adopted pursuant to this authority may permissibly be technology forcing (i.e. based on performance of technologies not yet on the market but available with sufficient lead time). See 76 FR 57129-130 (Sept. 15, 2011).}

6.1.3 Other General Comments

Organization: Truck & Engine Manufacturers Association (EMA)

The agencies should not proceed with the Proposed Phase 2 Standards for vocational vehicles for the many reasons previously noted. The agencies are proposing an inordinately complex, flawed and ultimately infeasible Phase 2 Program for vocational vehicles. As explained below, the agencies need to make fundamental changes to that proposal. Other reasons relating to the agencies’ underlying assumptions regarding available technologies for vocational vehicles support this conclusion as well. [EPA-HQ-OAR-2014-0827-1269-A1 p.59]

The agencies’ proposed segmentation of the vocational market, the assumed deployment and penetration rates of the envisioned GHG-related technologies, and the “normalization” process that the agencies are using to align the relative stringency of the various proposed vocational vehicle standards are all extremely problematic. The net result is an uncertain and unworkable proposal that fails to meet the basic requirements of an administrative rulemaking. Given this untenable situation, EMA recommends that the agencies consider the option of maintaining the Phase 1 program for vocational vehicle standards until such time as a better-reasoned and better-designed Phase 2 program can be developed. Deferring the Phase 2 standards for vocational vehicles will also allow manufacturers to focus their efforts on the successful implementation of the Phase 2 program for Class 7 and 8 tractors, the heavy-duty vehicles that represent more than 80% of the modeled benefits from the pending rulemaking. [EPA-HQ-OAR-2014-0827-1269-A1 p.4-5]

The net result is that the agencies’ Proposed Phase 2 Standards for vocational vehicles are unworkable and infeasible in their current form. The applicable duty cycles, vehicle subcategory definitions and GEM “normalization” for vocational vehicles are all still moving parts in the agencies’ still-evolving proposal. Moreover, given the agencies’ announced schedule for finalizing the Phase 2 Standards, there is not enough time for manufacturers to develop detailed comments on how an appropriate, fully integrated Phase 2 program for vocational vehicles – a program based on more accurate methods, baseline assumptions and efficiency targets – should be structured and implemented. Rather, the agencies should consider the option of undertaking a new rulemaking process to craft that type of a fully integrated Phase 2 program for vocational vehicles. EMA is committed to cooperating with the agencies in such a supplemental rulemaking. [EPA-HQ-OAR-2014-0827-1269-A1 p.32]

In the interim, the agencies could maintain the Phase 1 program for vocational vehicles, with potential additions to the GHG technology drop-down menu to include a broader range of available GEM credits (broadier than just tires) for features such as anti-idle technologies and improved transmissions. Simplifying the vocational vehicle program in this manner could allow manufacturers to focus their nearer-term efforts on the successful implementation of the Phase 2 standards for line-haul vehicles, the vehicles that use more than 80% of the fuel consumed by the heavy-duty and medium-duty vehicle segments. [EPA-HQ-OAR-2014-0827-1269-A1 p.32]
Organization: Truck & Engine Manufacturers Association (EMA)

**Remaining Fundamental Uncertainty Regarding the Vocational Vehicle Program**

The inclusion in the NODA of new data developed by the National Renewable Energy Laboratory (‘‘NREL’’) regarding vocational vehicle duty cycles still fails to sufficiently fill the significant gaps that continue to exist with respect to the Proposed Phase 2 Standards for vocational vehicles. The manner in which the agencies intend to divide and categorize vocational vehicles, the fuel efficiency technologies and percentage improvements that the agencies are ascribing to those different segments of vocational vehicles, the assumed respective penetration rates of those various technologies, and the derivation of potential unique “carveouts” from the vocational vehicle program (e.g., for certain custom chassis, such as cement mixers) are all still unknown, undefined, and unvalidated. The agencies have not articulated how vocational vehicles will be segmented under the Phase 2 Standards, what the Phase 2 Standards will be for those various vehicle segments, or how those standards were derived. GEM does not yet contain sufficiently certain inputs to conduct any assessment of the Phase 2 program for vocational vehicles, the stringency targets for which remain unknown. That makes it difficult for interested parties to provide meaningful comment on the agencies’ proposal for vocational vehicles, and calls into question whether the agencies have fulfilled the necessary requirements of the Administrative Procedures Act (“APA”) and Section 307 of the Clean Air Act (“CAA”). [EPA-HQ-OAR-2014-0827-1891-A1 p.2-3]

Organization: Association for the Work Truck Industry (NTEA)

**Regulatory Structure**

The NTEA supports the agencies’ structural approach to the rules. It is logical to separate out the four vehicle categories as they tend to be both built and utilized in different manners. Of the categories, vocational trucks will be the most diverse vehicle population, as noted by the possible chassis, body and equipment configurations available in the marketplace. This diversity also continues in the manufacture process. [EPA-HQ-OAR-2014-0827-1187-A1 p.2]

In order to complete a vocational truck, multiple manufacturing companies may be involved from the engine manufacturer, chassis manufacturer, intermediate stage manufacturers (perhaps adding axles) to the final stage manufacturer who completes the vehicle for final delivery. Also included in the manufacture chain are the body and equipment manufacturers who separately build products to be mounted on the vehicles for completion. Lastly, there can be what are known as “alterers” who work on completed (but neither titled nor sold yet at retail). Alterers, for instance, might take a completed pickup truck, remove the bed and replace it with another body type prior to the first retail sale. Another common alteration would be installation of a snow plow on an appropriate truck. [EPA-HQ-OAR-2014-0827-1187-A1 p.2]

The proposed regulatory structure recognizes the manufacturing complexity of vocational trucks and attempts to regulate in a less complex manner. [EPA-HQ-OAR-2014-0827-1187-A1 p.3]

Due to the complexity of the vocational truck industry, longer lead times and regulatory consistency is valued. Having regulatory certainty to 2027 is helpful as would be a consistent, national program. [EPA-HQ-OAR-2014-0827-1187-A1 p.3]

We do believe that some alterations to the proposed standards with regard to vocational trucks may be appropriate given the cost to industry and the stated benefits from increased fuel efficiency. [EPA-HQ-OAR-2014-0827-1187-A1 p.3]
Organization: Navistar, Inc.

Some of Navistar’s most significant concerns regarding the feasibility of the Proposed Rule itself are directly related to the provisions applicable to vocational vehicles. While Navistar supports the agencies’ general intent to expand the reach of the GEM model to vocational vehicles, we have serious concerns that the Proposed Rule, as written, is simply not ready or feasible as it pertains to vocational vehicles. [EPA-HQ-OAR-2014-0827-1199-A1 p.31]

As we pointed out in our NPRM Comments, Navistar believes that the vocational regulations as proposed are not feasible or even fully conceptualized. Vocational vehicles are an extremely complex and diverse portion of the heavy duty sector, while also small volume relative to tractors. This complexity and relatively small volume potentially magnifies the impact of any distortion created by the rules. The potential for tilting the playing field through an ill-conceived rule is very real and very concerning. With the NODA (as well as EPA documents contemporaneous in the docket but not in the NODA), the agencies have increased the risk of adverse impacts. In short, the new materials in the docket actually increase rather than reduce the uncertainty. [EPA-HQ-OAR-2014-0827-1919-A2 p.2]

Navistar’s NPRM Comments stated that the “[t]he vocational vehicle standards must start from the actual baseline MY17 standards and must be simplified and revised throughout.” Specifically Navistar felt like the vocational rule was not ready and needed significant work. The NODA included a revised Greenhouse Gas Emission Model (“GEM”) and NREL report which will significantly impact the Vocational standards and technologies. [EPA-HQ-OAR-2014-0827-1919-A2 p.2]

Organization: Navistar, Inc.

Class 5-7 vehicles are in an averaging set with either no tractors or few tractors; therefore, it is critical that the Vocational regulations be achievable. Navistar had significant concerns with the NRPM technology penetrations and continues to be concerned as the agency have not shared any additional details of the structure, baseline, or standards for Vocational. We believe that the agencies must work with the industry to avoid all unintended consequences and for the agency to design a high quality rule that does not disrupt the market or force specifications inappropriate to the task a specific vehicle is to perform. Navistar is committed to helping develop a high quality rule, but we believe that agencies should take more time to do so and delay the inclusion of the vocational rule in the final rulemaking until these issues can be resolved adequately. [EPA-HQ-OAR-2014-0827-1919-A2 p.3]

Organization: Waste Management (WM)

WM has significant experience testing new technologies on our vocational refuse vehicles in the field. We have learned a great deal from those road tests, where we can evaluate equipment while operating in the various duty cycles that we use in serving our customers. Refuse vehicles are not typical of most vocational fleet vehicles. They are extremely heavy and have difficult duty cycles that place substantial demands on the vehicle. We have found that it is often necessary to test new technologies using a typical refuse duty cycle to assess whether they can achieve the advertised fuel or GHG reductions, or even operate properly in our work environment. We are very concerned that expediting the compliance schedule by three years would preclude much of the valuable field-testing time that we need to assure ourselves that we are purchasing vehicles and equipment that can serve our and our customer’s needs. [EPA-HQ-OAR-2014-0827-1214-A2 p.6]

Organization: Daimler Trucks North America LLC
Of all of these problems we noted above, the biggest problem is that we are unable to repeat and verify the agencies’ stringency analysis. Ideally, for us to do so, the agencies would provide an updated spreadsheet that outlines their assumptions for baseline setting and stringency setting vehicles (because the assumptions have changed since the NPRM). Unfortunately, we were only provided information about baseline vehicles on March 24, giving us too little time to do the analysis necessary to respond to the agencies. In particular, we have received only limited feedback from the agencies regarding our concerns about expected technology benefits and penetrations used for stringency setting in the NPRM. We therefore cannot yet conclude that the agencies’ stringency analysis is correct or even reasonable. There may be significant errors, but we do not know. We will try to respond to the agencies promptly on GEM and the stringency analysis. [EPA-HQ-OAR-2014-0827-1918-A2 p.3]

Organization: Daimler Trucks North America LLC

Alternative Vocational Vehicle Standards Considered - The agencies request comment on risks or challenges associated with Alternative 4 for vocational vehicles. 80 FR 40289. Because some of the technologies on which the agencies premised the vocational standards are not yet developed to the level that is necessary for the heavy-duty vehicle industry, and because there is such a diverse array of vehicles for which technologies need to be developed and tested, we agree that Alternative 4 presents too grave a risk of unintended consequences such as unreliable performance of the new technologies. The agencies should follow a measured approach in forcing improvements only when it is clear that such improvements are ‘achievable’ (quoting the Clean Air Act's mandate to the EPA, CAA § 202(a)(3)(A)). [EPA-HQ-OAR-2014-0827-1164-A1 p.74]

Organization: Allison Transmission, Inc.

Unique Characteristics of MD/HD Market Preclude Alternative 4

The MD/HD vocational vehicle market is comprised of primarily vehicles that do work. Fleets in this market tend to be conservative with respect to the adoption of new technologies and they have a long memory for market failures. Prior to the widespread adoption of new technology, fleets will either test vehicles themselves in fleet operations, or require information from a third party or another fleet with whom they previously relied on for technology assessments. EPA’s and NHTSA’s Phase 2 rulemaking will not change these market dynamics. Instead the prime purchasers of new vehicles may be even more careful in verifying the performance and integration of multiple, new technologies and their suitability for the actual work demands that will be placed upon them. [EPA-HQ-OAR-2014-0827-1284-A1 p.10]

The Phase 2 proposal will require adoption of several new technologies across a wide variety of vehicle and engine components in order to achieve 16% lower CO2 levels in 2027 compared with CO2 emissions in the 2017 baseline. Given the aggressive nature of these requirements which are layered on top of GHG improvements made in the Phase 1 rule, Allison expects that the adoption of many new components to be viewed as a “high risk” by fleet operators. This becomes problematic for the assumed adoption rates since fleet operators have been historically concerned to keep the up-time (i.e., availability) of their vehicles at high levels. [EPA-HQ-OAR-2014-0827-1284-A1 p.10]

Second, the projected payback for incorporation of fuel efficient technologies is not until the 6th year. Many fleets turn trucks over in normal buying cycles of less than 6 years -- so they will either not realize a payback or not factor this payback into their initial purchase decisions. As a result, the long payback period (coupled with perceived technology risks) is likely to result in an increase of pre-buys and in delayed purchases to allow fleets to run existing trucks longer than originally projected. The 2010 NAS
Report (see Regulatory Impact Analysis (“RIA”) Section 8.4.2) also recognizes this dynamic in the MD/HD market. [EPA-HQ-OAR-2014-0827-1284-A1 p.10]

Overall, as compared with Alternative 3, Alternative 4 carries with it a much higher risk of market disruption. As noted above, under Alternative 4 there could be a surge in vocational truck sales, followed by a depressed market. Employment levels would follow suit. That is, employment levels would be increased to meet the pre-buy demand, only to rapidly fall due to an ensuing period of weak demand. In this situation, manufacturing companies who strive to manage cost and quality through stable production volumes and employment levels, would be negatively impacted. If the depressed demand were to be extended for a long time, then some businesses might not be able to continue operations. [EPA-HQ-OAR-2014-0827-1284-A1 p.11]

The RIA recognizes the possibility of a pre-buy, but the analysis concentrates only on what is viewed as favorable fuel costs and savings that will be recognized by vehicle owners. Specifically, the agencies “are not projecting a change in fleet turnover characteristics due to this regulation.” Allison recommends a more thorough analysis of the market history to predict behaviors and economic impact due to the technology risks that are inherent in the proposed rule. Based on that analysis, changes in timing or stringency levels may have merit. For example, fuel costs per mile were calculated using EIA’s 2014 Annual Energy Outlook for diesel prices. Yet more recent EIA projections indicate a substantial decline. This is significant since the agencies’ assumptions concerning “pre-buy” are that the value of saving money in future fuel purchases will outweigh the upfront additional costs of new vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.11]

Organization: Association for the Work Truck Industry (NTEA)

Fuel Efficiency Payback

The NTEA requests that standards similar to those described as “Alternative 2” be considered for the vocational truck segment. [EPA-HQ-OAR-2014-0827-1187-A1 p.3]

While we conceptually agree with the proposed application of the same general certification procedures for Phase 2 as are currently being used for certifying to the Phase 1 standards, we are concerned, about the expected payback period for vocational trucks using the “preferred” Alternative 3.

With regard to Alternative 3, in 2027 when the standard is fully phased in, heavy-duty vehicles across all classes would achieve up to 16 percent emissions and fuel use reductions for vocational vehicles when compared to Phase 1 standards. Further, the proposal calculates figures for expected payback periods based on the additional costs associated with the proposed standards and the economic savings based on the increased fuel efficiency expected with Alternative 3. The proposal estimates “Reasonable Payback Periods for the Trucking Industry In model year 2027,” for the buyer of a new vehicle. The notice states that the buyer would recoup the extra cost of technology used to achieve the standard (Alternative 3) within 6 years for vocational vehicles such as garbage trucks, buses and on-road construction trucks (e.g. cement mixers, dump trucks, etc.), which are typically used longer than vehicles in other heavy duty sectors.

The expected payback period of 6 years for vocational vehicles is not acceptable.

The NTEA surveyed over 40 vocational fleet companies with regard to fuel efficiency investment. More than 80% of the surveyed fleets said that a payback period beyond 6 years for 16% fuel efficiency gain that cost $3,500 would not be acceptable.
More than 50% of the surveyed fleets found a 3 year payback period acceptable. Additionally, almost one-fourth of the respondents noted that the useful life of their Class 3-7 vocational trucks was less than 6 years. On the average, each of these fleets operated over 3,400 Class 3-7 vocational trucks.

The NTEA supports the overall regulatory structure of the proposed standards. We believe that the burden faced by vocational truck owners is out of proportion to their fuel use and the agencies should consider ways to reduce that burden such as provided by Alternative 2. [EPA-HQ-OAR-2014-0827-1187-A1 p.5]

Organization: National School Transportation Association (NSTA)

We understand that the proposal aims to establish a comprehensive Phase 2 Heavy-Duty National Program to reduce greenhouse gas emissions and fuel consumption for new on-road heavy-duty vehicles. In addition, we note that this program would phase in over the long-term, beginning in 2018 model year and culminating in standards for model year 2027. Our comments are specific to school buses, which fall under vocational vehicles, and do not speak to any of the other vehicles addressed in this proposal. [EPA-HQ-OAR-2014-0827-1301-A1 p.2]

NSTA is proud to be part of the largest and safest transportation system in the country. The nation’s fleet of 480,000 yellow school buses provides safe, fuel-efficient and environmentally-friendly transportation to school children across the United States. [EPA-HQ-OAR-2014-0827-1301-A1 p.2]

NSTA members welcome efforts to improve fuel economy for school buses, but efforts to improve fuel economy should not come at the expense of reducing safety for school children riding the school bus. There can be no higher priority than protecting our precious cargo. While catastrophic school bus crashes have occurred, they are rare events. Most school bus crashes are minor, and in most crashes involving passenger cars and light trucks, the school bus has the advantage of its larger size and weight. That larger size and weight helps protect occupants, but may also exist at the expense of fuel economy. [EPA-HQ-OAR-2014-0827-1301-A1 p.2]

Yellow school buses are designed to protect students with special safety features not available on any other vehicle. These features include their recognizable color and size, height, reinforced sides, protective passenger seating, crash protected fuel systems, flashing red lights, cross view mirrors and crossing and stop sign arms to ensure children are protected and secure on and off the bus. School bus drivers also receive specialized training in student behavior management, loading and unloading security, emergency medical procedures. Drivers receive driving record checks, criminal background checks and pre-employment and random drug and alcohol testing. [EPA-HQ-OAR-2014-0827-1301-A1 p.2]

The typical school bus is not only the safest vehicle on the road, but it also achieves significant fuel economy and emission reduction benefits. New diesel engine standards make today’s buses 98% cleaner than buses manufactured two decades ago. Additionally, thousands of older buses have been modified with high-tech filters and catalysts to reduce emissions. In addition, school bus transportation eases the traffic congestion surrounding schools each morning and afternoon by keeping millions of cars off roads. Encouraging school bus use can achieve significant fuel economy and greenhouse gas reduction benefits. [EPA-HQ-OAR-2014-0827-1301-A1 p.2]

We are concerned, however, with the extremely aggressive timeline suggested by NHTSA and EPA in this proposal. We are aware that our manufacturer partners have significant concerns with meeting the requirements outlined in the proposal. We urge NHTSA and EPA to continue the dialogue on these requirements to ensure that the manufacturing industry can meet the requirements and not disrupt production in the process. To be effective, efficient and safe, school transportation is reliant upon the
availability of school buses. Any requirement which could potentially affect the availability of school buses could affect a provider's ability to secure enough vehicles to effectively manage their fleet. As currently proposed, we fear a significant effect on our ability to manage fleets and secure additional vehicles when needed. [EPA-HQ-OAR-2014-0827-1301-A1 p.2-3]

OshKosh

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, pp.166-171.]

The Phase 2 plan mandates a 16 percent improvement for heavy vocational trucks, four percent of this coming from the engine. The remaining 12 percent is expected to come from applying seven technologies. Of these seven check the box technologies, none of them can be practically applied to most vocational applications.

The Phase 2 proposal requires that vocational vehicle manufacturers check these boxes on the seven technologies in order to show compliance. As we can see, these boxes either can't be checked, or if they are checked, doing so will not result in actual real world improvements. Besides being ineffectual, the checkbox approach creates an unfair hardship for those manufacturers whose only products are vocational in nature. Large truck manufacturers have the option to offset noncompliant vocational trucks with credits from line haul products. This is not possible if you only produce vocational products.

This dilemma deals a double whammy to business, vocational only manufacturers will be out of the business and new entrepreneurial ventures will be blocked. We propose the following solution. We suggest that the U.S. Congress and the EPA acknowledge the fact that the laws of physics simply do not allow heavy vocational work trucks the same potential for CO2 and fuel economy improvements as is possible for the higher speed line haul application. Slower speeds, low volumes, off road operation, complex duty cycles, lack of engine and transmission supplier market drivers, and the nature of the work being performed all work against the vocational product.

The Phase 2 regulations should, therefore, continue the current Phase 1 tire regulations as is and limit further mandates to whatever can be gleaned from the engine improvements alone.

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

The UAW recognizes and supports the high level of communication and collaboration between regulators, the industry, and other stakeholders in crafting a very complex standard. We urge all parties to continue working together to solve outstanding issues before regulations are finalized. It is also critically important to have flexible and adaptable regulations for vocational vehicles. This is a complex and difficult task as this class of vehicles have a wide array of applications and have not previously been subject to stringent emission standards. This is why the viability of certain technologies on vocational vehicles needs to be carefully considered.

Organization: Autocar, LLC

Autocar Requests an Extension of the NODA Comment Period and an Official Notice and Comment Period on the Memorandum.
Autocar requests additional time to review and comment on the documents under the NODA and requests formal notice and opportunity to comment further on the Memorandum, as set forth in Appendix 2. [Appendix 2 can be found in docket number EPA-HQ-OAR-2014-0827-1885-A2][EPA-HQ-OAR-2014-0827-1885-A1 p.13]

Autocar requests that the agencies open a comment period with respect to EPA’s February 12, 2016 memorandum entitled “Vocational Vehicle Technology Packages for Custom Chassis.” EPA-HQ-OAR-2014-0827-1719. The memorandum purports to establish technology based packages and adoption rates for custom chassis vehicles. In response to comments from stakeholders indicating such standards were not currently feasible, the memorandum includes a “specific technical feasibility analysis ... for vehicles in seven vocations,” including refuse trucks, which Autocar manufactures. However, the agencies have not provided a formal opportunity to comment on the memorandum or the information contained therein. [EPA-HQ-OAR-2014-0827-1869-A1 p.3]

Because this information (i) will likely affect the present rulemaking and (ii) is new, the public must be allowed an opportunity to provide substantive input. It is well settled that agencies must afford interested stakeholders the opportunity to comment on new data integral to a rulemaking. See generally Kern County Farm Bureau v. Allen, 450 F.3d 1072, 107677 (9th Cir. 2006); see also Weyerhaeuser Co. v. Costle, 590 F.2d 1011, 1031 (D.C. Cir. 1978) (“[I]n this case, the Agency’s final conclusions are far from the ‘logical outgrowth’ of the preceding notice and comment process and instead are the result of a complex mix of controversial and uncommented upon data and calculations. Given the lengths that the Agency must travel to justify its revisions between the interim and final stages, we cannot be sure that further and ultimately convincing public criticism of those changes would not have been forthcoming had it been invited by the Agency.” (emphasis supplied) (citation omitted)); cf. Crawford v. F.C.C., 417 F.3d 1289, 1295 (D.C. Cir. 2005) (“Whether the ‘logical outgrowth’ test is satisfied depends, in turn, on whether the affected party ‘should have anticipated’ the agency’s final course in light of the initial notice.”). [EPA-HQ-OAR-2014-0827-1869-A1 p.3]

Here the information included in EPA’s February memorandum is highly technical, applies to a variety of vehicle types (while excluding others), and will likely have significant repercussions for various manufacturers including Autocar. Again, the agencies only provided this memorandum in February and have not invited comment upon it. To ensure that any final rule mandating technology packages for custom chassis complies with established administrative procedural requirements, Autocar and other stakeholders must be afforded the opportunity to respond to the technical and data-based analysis underlying and set forth in EPA’s memorandum. [EPA-HQ-OAR-2014-0827-1869-A1 p.4]

As detailed in our October 1, 2015 comments, Autocar, LLC and Autocar Industries, LLC (‘Autocar’) are small, privately-owned Indiana vocational chassis assemblers producing specialized heavy-duty vocational trucks and tractors used in America to collect solid waste, sweep streets and shunt freight at warehouses, railroads and harbors. [EPA-HQ-OAR-2014-0827-1885-A1 p.1]

Autocar submits these supplemental comments to object to recent compliance proposals that appear to indicate that Autocar’s small business impact comments have not been fully considered and that our request for extension will not be granted. We also request additional time to review and comment on the Memorandum and the underlying research set forth in documents included in the NODA. [EPA-HQ-OAR-2014-0827-1885-A1 p.2]

Organization: Volvo Group
Heavy-duty trucks are commercial vehicles purchased to enhance the profitability of a business. Purchasers must consider the initial cost (including Federal Excise Tax and state tax), operating and maintenance costs, plus any cost of vehicle downtime. Class 8 tractors, in particular, are generally purchased for regional or long-haul operation accumulating 100,000 or more miles annually. Most fleets require payback for efficiency technology in 18-24 months to cover the risk factors (actual efficiency delivered, maintenance and downtime costs, etc.), recoup their investment, and to provide a profit margin within their 4-5 year trade cycle. Fleets are particularly leery of complex new systems with unproven reliability and unknown maintenance cost. Rather than purchase such technology, fleets have delayed new purchases by extending the life of older equipment and/or pre-buying vehicles before such systems were forced into the market. This was amply demonstrated in 2007 when diesel particulate traps were forced into the market by PM emissions targets. Factories ran at full capacity at the end of 2006 only to nearly shut down for long periods in 2007. Production was then further curtailed by the severe recession in 2008. Vehicle manufacturers’ and suppliers’ employees suffered from lay-offs, pay reductions, and lack of work. One major supplier, Caterpillar, dropped out of the on-road engine business. Since 2010, the increased cost and complexity of emissions technology has spawned a booming business in trucks built from glider kits, a completely new truck chassis and body that is up-fitted with a rebuilt engine, driveline and axle, skirting emissions and efficiency regulations. [EPA-HQ-OAR-2014-0827-1290-A1 p.18]

We find a number of the technology assumptions in the NPRM are not justified because the technology is not demonstrated, does not deliver the assumed efficiency, or cannot be forced into the market at the agencies’ assumed penetration rates. These include aerodynamic drag reduction, start/stop technology, neutral idle, low rolling resistance tires, 6x2 axles, new transmissions, idle shutdown, vehicle speed limiters, hybridization, “deep integration” of driveline, and vehicle weight reductions. [EPA-HQ-OAR-2014-0827-1290-A1 p.19]

Response:

In response to the above comments that express concern about expediting market adoption of technology as described in the proposed Alternative 4, the agencies have adjusted lead times and technology adoption rates to reflect the feasibility of developing technologies as described below in the sections for individual technologies. See Section 8 for further discussion of comments related to more stringent alternatives.

In response to the comments above that express concerns about the complexity of the vocational vehicle program and the standard-setting process, the agencies are adopting a final vocational vehicle program structure that is more straightforward than was proposed, as discussed in Section 6.2.2 below. Navistar noted particular concerns regarding the structure and feasibility of the vocational vehicle standards. Specific issues relating to duty cycle-based subcategorization are addressed in Section 6.1.4 below and in the Preamble at V.B.1.a. We appreciate that the medium heavy-duty averaging set has challenges distinct from HHD vehicles, and in addition to revisiting the technology adoption rates in response to comments (discussed in Section 6.3 below), we are adopting program flexibilities that should address Navistar’s concerns with respect to transitioning from Phase 1 to Phase 2. Specifically, we are adopting extended credit life for LHD and MHD averaging sets so that all credits generated in these averaging sets in MY 2018 and later will last at least until MY 2027 (see Section 1.4.6 of this RTC and Section I.C.(1)(b)(i) of the Preamble). We note further that these are issues the agencies have analyzed carefully, and analyzed carefully with EMA members, including Navistar, as discussed in the next paragraph.

In response to the comments that express concerns about opportunity for notice and comment, the agencies conducted timely outreach to affected stakeholders. The agencies did so both during the public
comment period, and thereafter. These meetings including sharing interim information about program revisions being considered in response to the initial round of public comments. As explained in detail in the meeting log in the docket, EPA and NHTSA staff met repeatedly with EMA representatives, and with representatives of EMA member companies (including Daimler and Navistar whose comments appear above), both before and after the proposal to discuss details of many aspects of the rulemaking, including potential standards for vocational vehicles. We also spoke and met with Autocar on multiple occasions between August 2015 and June 2016. Among the issues discussed with Autocar were the structure of the vocational vehicle program and feasible technologies for special-purpose vehicles. The agencies also provided public notice of potential changes from proposal in a Notice of Data Availability (81 FR 10824, March 2, 2016) which presented information, among other issues, of further modification to the GEM compliance tool (used for vocational vehicle standard compliance), and a draft report from NREL with analysis of drive cycles and segmentation recommendations. In addition, EPA held a web conference for chassis manufacturers on March 22, 2016 to discuss our evolved thinking with respect to several types of special-purpose vehicles.

In sum, many face-to-face meetings and telephone conferences were held during the deliberative phase, providing actual notice and opportunity for stakeholder feedback throughout this process. The commenters are therefore mistaken in asserting that the agencies provided inadequate notice and public comment opportunities. Meetings between EPA staff, EMA, Autocar and other significant stakeholders regarding the structure of the vocational vehicle standards continued up until a few weeks before promulgation. See Section 15.5 for further discussion of responses to comments related to public participation in the rulemaking process.

In response to comments requesting less stringent vocational vehicle standards with less upfront costs and a faster payback period, the agencies have made revisions to projections of technology adoption rates as well as incremental technology costs. These changes are described in more detail below in Section 6.3 for each technology, but in general the average vocational vehicle package costs have decreased slightly since proposal for vehicles certified as Urban and Multi-purpose, and average package costs have increased slightly for vehicles certified as Regional. We anticipate that Regional vehicles would be those most likely to accumulate the most miles among the vocational fleet, while Urban and Multi-purpose vehicles are likely to accumulate fewer miles. Therefore we believe the revised average technology package costs should shift the payback period in a more favorable position for many vehicle owners. While the average payback is now projected to be closer to four years than six years as it was at proposal, vehicle owners may see different actual cost recovery periods, as payback periods are calculated on a hypothetical fleet-average vehicle. Moreover, payback is calculated assuming all vocational vehicles are certified under the primary program, a very conservative assumption. See Preamble Section V.C: “[u]sing this assumption, the vocational vehicle type with the shortest payback is intercity buses (less than one year), while most other vehicles (with the exception of school buses and motor homes) are projected to see paybacks in the fourth year or sooner. See Section 6.2.3 below for some ranges of estimated technology package costs for custom chassis. We expect that manufacturers will certify to the optional custom chassis standards where it is more cost-effective to do so; therefore, our analysis may be overly conservative where it indicates very long paybacks for some vocational vehicles.” See also the Preamble to this rule at Section IX.M, the RIA Chapter 7.2.4, and Section 11.13 of this response to comments document for further discussion of incremental costs and payback periods.

6.1.4 Framework: Duty Cycles

Organization: Volvo Group

Volvo’s extensive database shows that NREL’s study does not provide representative duty cycle weighting factors for Class 8 vehicles. We believe this is because of NREL’s limited inclusion of representative Class 8 vocational vehicles. This has biased the data towards more low-speed operation not representative of typical Class 8 vocational duty cycles. [EPA-HQ-OAR-2014-0827-1928-A1 p.7]

As noted in the NREL report, the population used for the NREL analysis was a total of 754 vocational vehicles comprising 10,765 daily drive cycles (see figure 1). Assuming an average of 200 miles per day the total mileage accumulation would be approximately 2.2 million miles for the Class 2b-8 vocational vehicle population. This results in an average of 2,855 miles of data per vehicle. In addition to the limited sample size for Class 8 vocational vehicles, NREL aggregated all weight classes in their determination of drive cycle weightings for each cluster (see figures 2 and 3). [EPA-HQ-OAR-2014-0827-1928-A1 p.7] [Figures 1-3 can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1928-A1] Duran, Phillips, Wood, Konan, Kelly, and Gonder, “The Development of Vocational Vehicle Drive Cycles and Segmentation” Draft, National Renewable Energy Laboratory, EPA Docket I.D. EPA-HQ-OAR-2014-0827-1621 /1/ It is not made clear in the NREL report what types of vehicles are represented by “N/A,” though this author assumes they represent the 108 long-haul tractors in Figure 1. /3/ It is not made clear in the NREL report what weight classes distribution is represented by the “N/A” vehicles.

Volvo performed analysis utilizing data from over 12,000 in-fleet Class 8 vocational vehicles representing over 1.3 billion miles of operation, with an average data accumulation of approximately 110,000 miles per vehicle. The Volvo in-fleet vehicle data is represented by refuse trucks, vocational construction straight trucks (dumps, mixers, etc.), and vocational tractors. The data do not include transit buses or motor coaches; however, the volumes are so low as to have minimal impact on the resulting distribution. [EPA-HQ-OAR-2014-0827-1928-A1 p.9]

It is not entirely clear from the NREL report whether the results were based on the full Fleet DNA population, or the resampled population, but it is clear that, when compared to the large data set utilized by Volvo, Volvo’s data is far more representative of Class 8 vocational vehicle operation. [EPA-HQ-OAR-2014-0827-1928-A1 p.9]

Volvo performed analysis based on two segmentation methods. First, as seen in Table 1, we performed segmentation as proposed in the NPRM (1037.510 (c)(2)). Second, as seen in table 2, we performed segmentation based on our understanding of our vehicle models and their applications and where we believed they would fall in the EPA’s intended segmentation sub-categories. [EPA-HQ-OAR-2014-0827-1928-A1 p.9][Tables 1-2 can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1928-A1]

The comparative results are shown in Table 3. Based on Volvo’s two segmentation methods we believe that the NREL derived vocational duty cycle weightings in EPA’s GEM P2v2.1 are more representative of vocational vehicle operation than the NPRM values, though we find that the proposal does not provide for sufficient 65 mph operation in multi-purpose and urban duty cycles. From this we conclude that the NREL result does not fully match real-world operational characteristics for Class 8 vocational vehicles, suggesting the need for HHD unique vocational duty-cycle weightings. In addition, we find limited differences in duty cycle weighting between the two segmentation methods used in Volvo’s analysis. As such, we recommend finalization of vocational duty cycle weightings with either unique HHD
weightings, or additional distance at 65 mph as noted above. [EPA-HQ-OAR-2014-0827-1928-A1 p.9] [Table 3 can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1928-A1]

- As with the newly proposed GEM P2V2.1 urban cycle weighting, Volvo does not believe the Refuse cycle is representative and needs additional high speed operation.

Volvo Group has been actively sharing Class 8 vehicle duty cycle information with EPA. We provided data on the operation of over 11,000 vocational trucks and motor coaches downloaded from the electronic control systems on our vehicles, spanning the full range of Class 8 vocational vehicles. This data showed that the actual vocational duty cycles for all segments included far less low speed transient and much more high speed operation (with a significant amount over 65 MPH) than the duty cycles proposed in the NPRM. In addition the in-use data showed higher idle time than the proposed duty cycles. Since the effectiveness of various efficiency technologies is highly dependent on duty cycles, it is essential that the regulatory duty cycles mirror actual vehicle usage as closely as possible. It is our understanding that the proposed vocational duty cycles are based on very limited data. Therefore, the agencies must take into account the submitted data to adjust the regulatory duty cycles, the technologies effectiveness, application rates, and standards for vocational vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.43]

The tractor duty cycles are the same as for the Phase 1 rule, except for the addition of grade to the highway portions that make up the bulk of the cycles. In addition, the speed targets and grades are expressed as a function of distance travelled. We support both of these changes since the addition of grade is essential to exercise the engine over its torque/speed range and the transmission shifting in response to steep grades. By using distance as the independent variable (rather than time), the simulation ensures that all vehicle cover the full distance even if the target speed is not always achieved. We do note that many tractors spend significant time above 65 MPH, which is the maximum speed in the regulatory cycles. However, we also note that NHTSA has stated their intention to promulgate a mandatory maximum road speed limit that would presumably limit speeds somewhere in the range just above 65 MPH. The final GHG/Efficiency rule should incorporate duty cycles with maximum speeds that correlate with the speed that NHTSA chooses for the mandatory limit. [EPA-HQ-OAR-2014-0827-1290-A1 p.43-44]

Motor Coach Duty Cycle

Volvo Group has provided motor coach duty cycle data to EPA that shows these vehicles run predominantly highway duty cycles. 65% of the distance was run above 65 mph and 10% between 55 and 65 mph, with the balance (25%) below 55 mph. Idle time was 38%. These vehicles do most of their travel on interstate highways with some time in cities for tour groups or to access bus stations. Many of them are used for high-end motor homes with very limited time in cities. Extensive idling is done to maintain cabin comfort. Accessory loads are much higher due to air conditioning, electrical, and cooling fan loads (limited ram air available in rear engine configuration). Technologies such as stop-start and hybrid are not feasible. With motor coach volume quite limited, there is not a large staff available for product development, even though the vehicle requirements are quite unique from other commercial vehicles. The agencies should consider the unique requirements of this segment rather than lumping motor coaches in with other vocational vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.44]

We also note that motor coaches are an extremely efficient means of transporting people. The agencies should be encouraging this mode of travel and must be careful to avoid creating disincentives to coach travel. In particular, reliability problems and down-time are not tolerated by travelers, so complex systems that increase failure rates have a large negative impact. This is already a problem with the US10 criteria emissions technology. In fact, we request that EPA consider less rigorous requirements for motor coach...
emissions systems that cause increased downtime, such as SCR inducements. [EPA-HQ-OAR-2014-0827-1290-A1 p.44]

**Buses**

Urban buses have a unique duty cycles, but we have little detail data since Volvo buses in the US do not currently use Volvo powertrains and therefore are not part of our vehicle data collection system. We do note that this is the one heavy duty vehicle segment that has been utilizing some level of hybrid powertrains. But it is significant that we have not even certified our bus hybrid system under the Phase 1 rule due to the complexity and cost of coordinating testing of an engine and hybrid system from different suppliers, combined with the low sales volume. Unfortunately, one of the realities of the heavy duty market is that unique solutions are demanded for different market segments so this situation (low volume, multiple suppliers) means that few if any hybrid systems will ever be GHG certified. [EPA-HQ-OAR-2014-0827-1290-A1 p.44]

Buses offer the same opportunity for very efficiently transporting people as motor coaches and should also be incentivized in the larger scheme of reducing GHG emissions and fuel consumption. The same concerns are raised relative to complex systems reducing reliability, driving up cost, and resulting in rider dissatisfaction due to failures. As we did for motor coaches, we request that EPA consider less rigorous requirements for bus emissions systems that increase downtime, such as SCR inducements. [EPA-HQ-OAR-2014-0827-1290-A1 p.44-45]

**Organization:** Recreational Vehicle Industry Association (RVIA)

While actually driving, motorhome owners report that they spend about 53% of the time cruising at 55 mph and 32% of the time cruising at 65 mph. Time spent idling is 16%. Given these numbers, we support putting motorhomes in the regional cycle. [EPA-HQ-OAR-2014-0827-1261-A1 p.9]

**Organization:** Effenco Hybrid Solutions

Our main concern regards the proposed composite cycle weightings for the three vocational vehicle duty-cycle-based subcategories: Urban, Multi-Purpose, and Regional. Indeed, the weighting of idle between 10 and 20% depending of the composite test cycles is very much lower than what can be observed with the publicly available data published by NREL (http://www.nrel.gov/transportation/fleettest_fleet_dna.html) as well as with the data collected by Effenco over years of activities. In section 2.9.3.4 of the draft Regulatory Impact Analysis, it is however recognized that the data used to establish the proposed weightings are not representative of the national vocational vehicle fleet and that EPA has entered into an interagency agreement with NREL to further characterize workday idle among vocational vehicles. Still, it is mentioned that the preliminary range of daily idle operation per vehicle indicated by this work is about 18 to 33 percent when combining the data from all available vehicles. We reviewed the data published by NREL on the Fleet DNA webpage and summarized below the proportion of idle for different vocations. [EPA-HQ-OAR-2014-0827-1148-A1 p.2]

[Tables of NREL and EFFENCO data, 'Immobile Time as a Proportion of Operating Time', can be found on p.2-3 of docket number EPA-HQ-OAR-2014-0827-1148-A1]

Furthermore, the statistics above, coming from Effenco’s own data base, suggest higher proportion at idle as well. As these numbers show, the daily idle operation per vehicle included in the Proposed Rules is far below was can be observed in real operating conditions for vocational vehicles. We suggest that the idle
weightings should rather be 35, 45 and 55% for the Regional, Multi-Purposes and Urban composite cycles, respectively. [EPA-HQ-OAR-2014-0827-1148-A1 p.3]

**Organization:** Motiv Power Systems

*Further Refine Duty Cycles to More Fully Capture Technology Benefits*

Despite significant improvement to the duty cycle, particularly for urban and multipurpose vehicles that spend much of the day parked or in transient operation, further improvements can be made to ensure that the broad spectrum of vocational vehicles is adequately represented and that the regulation drives the full spectrum of fuel consumption reduction technologies applicable to such a diverse fleet. Work trucks frequently experience idle time exceeding those of even the urban vehicle category, and emissions from such idle operations are not fully recognized. [EPA-HQ-OAR-2014-0827-1184-A1 p.2]

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)

The Phase 1 rule’s segmentation of vocational trucks is based on weight class only and does not reflect vehicle use. Inadequate segmentation of vocational vehicle prevented the Phase 1 standards from promoting technologies that provide major benefits for only a subset of vocational duty cycles. ACEEE applauds the agencies’ segmentation of vocational vehicles into nine subcategories in Phase 2, reflecting both weight and usage profile, together with the appropriate reweighting of cycles to capture these usage profiles. [EPA-HQ-OAR-2014-0827-1280-A1 p.19] We also support the agencies’ proposal to include an idle cycle in vocational vehicle certification. The three cycles used in the Phase 1 program could not properly represent the operation of certain vocational vehicles in the real-world. Many vocational vehicles, including urban buses have average speed less than 10 miles per hour. Consequently, the transient cycle, with 15 mph average speed, and 55-mph and 65-mph constant speed cycles could not reproduce the appropriate average speed. Inclusion of an idle cycle will resolve this problem in Phase 2. [EPA-HQ-OAR-2014-0827-1280-A1 p.19]

**Organization:** American Council for an Energy-Efficient Economy (ACEEE) et al.

Recent information included in the docket provides additional research on the diversity of the vocational vehicle fleet and the real world behavior of these vehicles, many of which may be certified as incomplete. It is our assessment that this new information not only strengthens the case for increasing the stringency of the regulation of this class of vehicles but necessitates it in order to ensure the environmental benefits of a “maximum feasible” and “technology forcing” standard.

The National Renewable Energy Lab study utilizes its Fleet DNA database to show that vehicles largely fall into two classes of operation, high- and low-speed, with a much smaller fraction of vehicles bridging the two duty cycles. The study finds that the high-speed vehicles spend a much higher fraction of time at cruise speeds above 55 mph than the weightings of the vocational regional category from the proposal, while all vehicles spend a much higher fraction of time at idle than the idle cycle weighting in the proposal. [EPA-HQ-OAR-2014-0827-1896-A1 p.5]

**Organization:** Isuzu Motors Limited

The duty cycles for Regional, Multi-Purpose, and Urban use are not accurate compared to real world data. Isuzu would like to work with the agencies and submit data to help generate more accurate duty cycles for the final rule. [EPA-HQ-OAR-2014-0827-1263-A1 p.3]
Organization: National Waste & Recycle Association

*Route distance and number of stops:* The distance a refuse truck travels in a day varies primarily by population density. In a densely populated urban area the truck can travel as little as 50 miles from the time it leaves the fleet yard to its return at the end of the day. In less densely populated suburban and rural areas, the daily route can be longer due to the longer distances between individual “stops.” [NHTSA-2014-0132-0071-A1 p.3]

More importantly, refuse trucks constantly stop and go while on-route in order to collect a load of waste or recyclables. This constant stopping and going has a major impact on fuel consumption. As an example of the number of daily stops, residential routes normally have somewhere between 800 and 1200 stops per day. Some automated collection routes, however, are capable of as many as 1500 stops in a day. Commercial routes tend to have fewer stops than residential routes, but can easily have well over 100 stops. Moreover, those stops often involve more backing up and maneuvering to obtain access to the container. [NHTSA-2014-0132-0071-A1 p.3]

Organization: United Parcel Service (UPS)

*Given the relationship between vehicle speed and technology benefits, it is imperative that EPA and NHTSA develop drive cycle weightings that are representative of real-world operating conditions. The agencies should contact the Federal Highway Administration and American Transportation Research Institute to determine how available data can be used to characterize the speeds at which trucks actually operate and incorporate this information into the speed weightings and technology assessments.* [EPA-HQ-OAR-2014-0827-1262-A1 p.11-12]

Organization: CALSTART

Using the life cycle cost model we validated with fleets we assessed business cases in seven specific truck use profiles including Class 8 Regional Haul and three medium duty use profiles: Urban, rural/intra-city and work site support.

While structured before your draft rules were released, the categories are very similar to the three vocational segments you are proposing and which we do support. [EPA-HQ-OAR-2014-0827-1190-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]]

Organization: CALSTART

Coupled with the segmentation changes, we support as well changes to the test process that incorporate a larger component of transient operation, idle operation as well as the addition of an idle-only cycle. These changes to the regulatory test cycles better reflect the diversity of the vocational fleet and the duty cycles and general use profiles of end users, which will help identify the appropriate technology solutions for reducing fuel use from this sector. However, we believe that even the current draft cycles do not adequately reflect the percentage of driving idle time and are working with industry partners to share data they have that quantifies this. [EPA-HQ-OAR-2014-0827-1190-A1 p.5]

An important consideration around the idling and speed component, however, involves accounting for the transition to and from idling states. While we applaud the agencies’ inclusion of more idling time and openness to expanding it as data justifies, simply adding in an idle element to the cycle is still misleading. By its very nature, idling occurs during a driving cycle, not in a vacuum – it is connected to the driving. This means there are deceleration and acceleration events surrounding them that have an impact on
average speed, engine transients, and fuel used that are important to the strategies to address them. Just “dropping” idle in and providing it with more time in the cycle is insufficient to understand its impacts. This is clearly most important to vocational cycles, though not unimportant to Class 8 tractors. [EPA-HQ-OAR-2014-0827-1190-A1 p.5]

Additionally, there is a separate category of idling we will call “work site idle” that carries a very different characteristic and duration that we do not believe is at all captured in the driving cycle but also may not be effectively captured by the “off-cycle” credit process. Work site idle is generally characterized by higher idle RPM and therefore higher fuel use as the engine is driving pumps or other devices to operate equipment or tool circuits. Examples include underground compressor trucks, overhead crane or boom trucks, and cement mixer vehicles. The duration of such high-idling is measured in minutes and hours, not seconds, in contrast with driving idle events. [EPA-HQ-OAR-2014-0827-1190-A1 p.5]

**Organization:** CALSTART

Segmentation and Duty Cycles. We support changes made relative to Phase 1 in the proposed Phase 2 regulation in providing additional market segmentation options for the vocational segment. Overall, we believe the agencies’ have reasonably captured a more useful description of the high level differences in how trucks are used in the vocational truck space while still keeping complexity to a minimum. While not perfect, it is sensitive to the multi-stage manufacturing nature of the vocational segment – OEMs do not always know exactly in what vocation a truck will end up. [EPA-HQ-OAR-2014-0827-1190-A1 p.4]

**Organization:** Union of Concerned Scientists (UCS)

Dividing vocational vehicles into three distinct duty cycles is a reasonable compromise with the complexity and diversity of real world duty cycles experienced by these vehicles, and it represents a substantial improvement over Phase 1. Acknowledging the diversity of vehicle operation and including cycles with a significantly higher fraction of low-speed, transient operation will help incentivize a broader selection of technologies. Furthermore, acknowledging the high fraction of idle with a separate idle cycle will similarly incentivize idle reduction technologies that reduce fuel usage and emissions from these vehicles. [EPA-HQ-OAR-2014-0827-1329-A2 p.23]

However, there are still classes of vehicle that are not necessarily well-represented by this characterization of the vocational vehicle sector, which may mean that the rules are not necessarily fully incentivizing all technologies applicable to the sector. Refuse trucks, for example, undergo extremely heavy stop-start operation beyond what is captured in the transient cycle and use a lot of fuel running the compactor from the PTO. Many other vehicles use a tremendous amount of fuel during worksite idling, which can be a high-speed idle that is not currently modeled by GEM. [EPA-HQ-OAR-2014-0827-1329-A2 p.23]

Work site usage is currently only captured under the hybrid PTO test procedure. While this will help incentivize technologies designed to reduce such usage, the agencies have not considered this in setting their stringency, and therefore they may also not be accurately assessing the fuel use from this sector, which would affect the total benefits of these regulations. [EPA-HQ-OAR-2014-0827-1329-A2 p.23-24]

**Organization:** Autocar, LLC

The NREL draft report is intended to support the final rulemaking with respect to vocational vehicle drive cycle weightings. However, Autocar has identified deficiencies in the study that warrant further analysis. For instance, the NREL report summarizes data collected from 57 refuse trucks. Autocar believes that it...
