Most of these commenters (Amy’s Kitchen et al., Business for Innovative Climate & Energy Policy (BICEP), CFO, CFA, Edison Solar, EDF, Hoosier Environmental Council, Illinois PIRG, Investor Network on Climate Risk (INCR), Mass Comment Campaign sponsored by the Pew Charitable Trusts (Pew), Midwest Truckers Association, Quasar Energy Group) state that the standards will save consumers money, with estimates ranging from $150 per year by 2030 (DFO, Edison Solar, Pew, Quasar Energy Group), to $250 per year in an unspecified year (BICEP, INCR) to $400 in 2035 (EDF). CFA estimates that households spend about $1,200 per year on freight vehicle fuel, but do not in their comments provide an estimate for the savings per household from implementation of the standards. The agencies have not estimated the per-household savings. Preamble Section IX.M. includes estimates of the payback period for MY 2027 vehicles. For HD pickups and vans, the payback period is in the third year of ownership; it is in the fourth year of ownership for vocational vehicles; and early in the second year for tractors/trailers.

CFA argues that the full net benefits of the standards will be passed along to households. As discussed in Preamble IX.L.3.c, the agencies do not take a position on whether the savings will be passed along fully to households, or whether some of those savings will instead either be retained by firms for investment, or distributed instead to firm owners. Regardless, the net savings will accrue to some segment of consumers, and we expect that there will be increased spending in other sectors of the economy. We agree with CFA that stronger GHG/fuel economy standards will reduce fuel consumption relative to the reference case.

CFA also notes the relatively high multiplier for transportation in California as a measure of the importance of transportation in economic activity. Multipliers, such as those used in input-output models, assume fixed relationships between inputs and outputs; they do not allow for substitution effects due to changes in prices, either for inputs or for outputs. They may provide a reasonable approximation of short-run effects for a small region or sector, where substitution effects may not be very large, but they may be less suited for national-scale policies over time, where market adjustments are more likely.  

As discussed in Preamble Section IX.L.2. and RIA Chapter 8.11.2.2, the agencies have used various factors to estimate the effects on employment specifically of the increased costs due to the new standards (employment due to substitution effects). As described there, these are the expected employment requirements in the directly regulated sector per $1 million in expenditures in that sector; they do not include multiplier effects in other sectors. We focus on the directly regulated sector because it is likely to be the most strongly affected, and because other sectors typically are not solely reliant on the regulated sector, and thus are likely to be more difficult to model well.

The International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW) notes the importance of the motor vehicle industry to the U.S. economy and asks for recognition of the effects on the supply chain, and investment cycles. The lead-time considerations in the standards are intended to facilitate feasibility throughout the supply chain and over investment...  

---

cycles. As UAW recognizes, setting the standards through 2027 provides the industry with the regulatory certainty needed to plan for and achieve these requirements.

The National Ready Mixed Concrete Association (NRMCA) asks that more attention be placed on costs that will affect consumers of new heavy-duty vehicles. As other commenters observe, the fuel savings as well as the up-front vehicle costs will affect the expenses to users of heavy-duty vehicles. The specific impacts on costs to consumers of heavy-duty vehicles will depend on the time period over which the vehicle owners amortize costs and the pass-through of both benefits and costs. Both of these factors will depend on such factors as the market structure in the particular sector and the typical length of ownership of vehicles in that sector.
12 Natural Gas Vehicles and Engines

This section addresses comments related to emission standards, test procedures, and other regulatory provisions as they relate to natural gas vehicles and engines. This section also addresses comments related to economic and environmental issues related to natural gas as a market fuel. Some of these issues may also relate to LPG or other alternative fuels. See the rest of this document for issues of general interest that also apply to natural gas and other alternative-fuel vehicles and engines.

12.1 General Comments on Natural Gas

Organization: American Trucking Associations (ATA)

Natural Gas Vehicle Development and Deployment Must not be Stymied

Natural gas still remains the most promising alternative fuel available to the trucking sector. The continued interest and investment in both vehicles and infrastructure, both in the public and private sectors, has clearly indicated the potential of natural gas as a transportation fuel. Continued research and improvements in both the efficiency and performance of such vehicles continues to grow. [EPA-HQ-OAR-2014-0827-1243-A1 p.22]

In-Use Natural Gas Fuel Standards Should be Addressed Outside of the Rule

Several standards organizations currently are in the process of reviewing fuel specifications for natural gas used as a motor fuel and may finalize such a standard in the future. SAE J1616 currently addresses fuel specifications for natural gas motor fuel but is a recommended practice, not a required standard. Based on the current level of discussion and level of usage of natural gas as a transportation fuel it is not clear whether the current discussions will result in any changes to J1616 or a new fuel standard for natural gas. Given that these discussions are currently ongoing, it would be premature for EPA to propose a standard. [EPA-HQ-OAR-2014-0827-1243-A1 p.22]

Organization: NGVAmerica

NGVAmerica supports the decision by the agencies not to propose an in-use standard for natural gas that is used as a motor fuel. Several standards organizations currently are in the process of reviewing fuel specifications for natural gas used as a motor fuel and may finalize such a standard in the future. SAE J1616 currently addresses fuel specifications for natural gas motor fuel but is a recommended practice, not a required standard. Based on the current level of discussion and level of usage of natural gas as a transportation fuel it is not clear whether the current discussions will result in any changes to J1616 or a new fuel standard for natural gas. Furthermore, most, if not all, natural gas motor vehicle fuel is primarily transported by natural gas pipeline utilities which are subject to regulation by their respective state public utility agencies. Consequently, natural gas quality specifications almost always differ from state to state, and sometimes between gas utilities within the same state, depending upon the sources of the natural gas supplied to these utilities. Given the above circumstances and the lack of consensus on a proper in-use standard, it would be premature for EPA or NHTSA to propose a standard. [EPA-HQ-OAR-2014-0827-1270-A1 p.2]
Response

and NGVAmerica, this final rulemaking does not contain any natural gas fuel quality regulations for the natural gas consumed by the transportation sector. Such regulations were not proposed.

**Organization:** Autocar, LLC

Autocar has worked hard to support emissions reduction consistent with EPA’s and NHTSA’s objectives. Across all three of its product lines, Autocar has aggressively embraced next-generation clean engine technology. Over the past five years, 50-70% of Autocar’s refuse trucks were assembled with compressed natural gas (“CNG”) engines or hydrostatic hybrid drive units. No other refuse truck maker’s product mix reflects a higher concentration of clean-burning vehicles. Autocar has built and sold more than 6,000 CNG vehicles. The Company has dedicated itself to assembling environmentally-sound products, which are then used in environmentally-sound processes such as recyclables collection and transport of waste to landfills harvesting methane gas, which reduces greenhouse gases and offers a source of renewable energy. [EPA-HQ-OAR-2014-0827-1233-A1 p.6]

4.4.1 CNG and Hybrid Power. As set forth in the introduction to this letter, Autocar is an industry leader in the integration of fuel-efficient CNG engines and hybrid power units\(^\text{11}\) in refuse trucks and street sweepers. The positive effects of CNG and hybrid technology on fuel efficiency and pollutant emissions are widely recognized and are acknowledged in the Proposed Regulations. Autocar’s applications may be more suited to CNG and hybrid power than other vocational applications. But these sophisticated technologies come with a significantly higher purchase price. Autocar and its customers actively participate in CNG and hybrid incentive programs from coast to coast. These programs have been successful in bridging the cost gap between diesel trucks and CNG or hybrid trucks and infrastructure. We encourage the agencies to build on that proven success and provide additional incentives for the purchase of CNG and hybrid trucks, for Low-speed/Frequent-stop Vehicles as well as other vocational and non-vocational vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.15][This comment can also be found in section 6.4 of this comment summary]

\(^{11}\) As currently designed for use in refuse vehicles, hybrid technology captures normally-wasted energy from braking, converting that energy into available power to accelerate or drive the vehicle, thus reducing fuel consumption and emissions. Testing methodologies for this technology must accommodate the braking, load and terrain factors that are integral to measuring the gains derived from hybrid refuse vehicles. Dynamometer testing will not demonstrate actual improvements in GHG emissions and fuel consumption.

Response

The agencies have adopted interim provisions that allow the potential for small manufacturers like Autocar to generate Phase 1 credits for producing natural gas vehicles. See Chapter 6.3 for responses to comments on applying hybrid technologies to vocational vehicles including refuse trucks.

**Organization:** American Gas Association (AGA) et al.

More specifically, our comments pertain to the components of the Proposal that relate to the use of natural gas in our nation’s trucks and buses. While natural gas fuels only a small percentage of our
nation’s new trucks, this clean, domestic, non-petroleum fuel powers a growing number of trucks and buses in key niches, such as sanitation and solid waste, school and transit buses, urban delivery, port drayage, and, where the fueling infrastructure supports it, long-haul trucking in certain locations. [EPA-HQ-OAR-2014-0827-1223-A1 p.1-2]

We believe our recommendations will have meaningful impacts on the future use of natural gas in the American trucking sector – a sector that delivers reduced greenhouse gas emissions, criteria air pollutants, and operating costs for the companies that deliver our goods and for the public fleets that serve our cities. [EPA-HQ-OAR-2014-0827-1223-A1 p.2]

**Organization:** Clean Energy

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 248-249, 250-251.]

New territory is being blazed as the rule proposes to regulate additional aspects of natural gas vehicles, which will ensure NGBs are providing their lowest emissions possible. These include standards for LNG tank hold times and addressing possible methane emissions from open crank cases.

While we will ultimately defer to tank and engine manufacturers on how best to accomplish the aim of these new regulations, we applaud EPA and NHTSA for addressing these issues that will ensure the elimination of unnecessary methane leaks in engine systems.

Of course, the natural gas industry is not only a pioneer in eliminating the real impacts of mobile source criteria emissions. It is also a leader in finding solutions to reduce greenhouse gas emissions by investing heavily in renewable natural gas space. We would like to thank the EPA for updating the renewable fuel standards to provide an even greater incentive to produce renewable natural gas on par with other cellulosic fuels.

In conclusion, further greenhouse gas reductions from renewable natural gas, which is an ultra-low-carbon fuel, have proven to be the lowest carbon fuel source for heavy-duty class 7 and 8 trucks, outperforming both electric and fuel cell strategies. Combining both the advanced engine technology of natural gas with renewable natural gas blends, and you suddenly have a cost-effective alternative that can deliver power plant-equivalent criteria emissions and superior greenhouse gas performance for the medium- and heavy-duty truck space.

**Organization:** National Waste & Recycle Association

Alternate technology and alternate fuel refuse trucks: Vehicles powered by alternative fuels such as compressed natural gas (CNG) or liquefied natural gas (LNG) are becoming commonplace in our industry. The move toward further adoption of alternative fuel trucks is inexorable. These fuels can lower the fleet’s carbon output because they are less carbon-dense. In addition, a very small number of vehicles are powered by methane biofuels produced from landfill gas. Expanded use of these alternative fuels is limited in part by the need to develop a new infrastructure for fuel delivery. All new technologies also face cost considerations. [NHTSA-2014-0132-0071-A1 p.4]

**Organization:** National Automobile Dealers Association (NADA)
The final Phase 2 rule must do more to incentivize the purchase of alternate fuel and new technology vocational trucks and tractors. Natural gas, propane, biofuel, hybrid, and/or plug-in electric vehicles each offer a significant potential for reducing fuel use and GHG’s. However, each of these alternatives involves significant cost ($20,000-150,000 per vehicle), performance, infrastructure, and other concerns. ATD supports the approach initiated in Phase 1 where an advanced technology credit scheme is utilized to promote and reward the in-use adoption of these alternative fuels and new technologies. In addition, the Phase 2 rule should strive to be fuel and technology “neutral,” leaving it up to new vehicle customers to determine the technologies and fuels that work best for them. [EPA-HQ-OAR-2014-0827-1309-A1 p.9-10]

Organization:  City of Lawrence, Indiana

A major beverage company in Lawrence has converted all of their semi-trailers to natural gas from diesel. The transition began in October of 2013 with one tractor. The first eight compressed natural gas tractors travel around 465,000 miles per year delivering beverages to 500 retail locations. The tractors reduce emissions of greenhouse gases by approximately 5 percent, or 266,561 pounds, annually and displace 75,000 gallons of diesel fuel. CNG is also nontoxic, which means the new tractors won't harm Indiana's vast farming lands. They now operate 79 CNG tractors throughout the State of Indiana. [EPA-HQ-OAR-2014-0827-1226-A1 p.1]

Response

As acknowledged by the AGA, SAFE, Clean Energy, the National Waste and Recycle Association, NADA and the City of Lawrence, Indiana comments, natural gas is being used by a small portion of the heavy-duty fleet here in the U.S., and its use could increase in the future. Natural gas likely provides criteria pollutant emission reductions compared to conventional petroleum fuels. However, since the purpose of this rulemaking is to reduce greenhouse gas emissions and fuel consumption, the goal of the agencies is to set fuel-neutral, heavy-duty truck tailpipe greenhouse gas emissions standards which will neither encourage nor impede the possible use of natural gas. This way the market will decide the extent that natural gas will play a role in fueling heavy-duty trucks. In keeping with the tailpipe emissions approach, EPA is further regulating aspects of both the upstream and downstream methane emissions points of the natural gas system in other regulatory actions. Because methane gas from landfills is renewable, it receives a renewable fuel credit under the Renewable Fuels standard. See Chapter 6.3 for responses to comments on applying hybrid and electrification technologies to vocational vehicles. See Chapter 1.4 for responses to comments on advanced technology credits.

Organization:  National Propane Gas Association (NPGA)

The NPRM proposes many standards regarding greenhouse gas emissions (GHG) and fuel efficiency for medium- and heavy-duty vehicles over 14,000 GVWR. Comments submitted herein are limited to GHG and fuel efficiency standards in relation to liquefied petroleum gas or propane as a vehicular fuel (“autogas”). [EPA-HQ-OAR-2014-0827-1272-A1 p.1]

Propane gas is used in millions of installations nationwide for home and commercial heating and cooking, in agriculture, in industrial processing and as a clean air alternative engine fuel for both over-the-road vehicles and industrial lift trucks. [EPA-HQ-OAR-2014-0827-1272-A1 p.1]

In the NPRM, the agencies detail extensive assessment of gasoline, diesel and natural gas fuels without inclusion of the progress and viability of autogas as an alternative fuel. Autogas offers unique fueling possibilities with potentially substantial economic and environmental advantages. The low carbon
content and high octane rating present a low GHG emission fuel optimum for spark-ignited combustion engines.\textsuperscript{2} Comparatively, autogas produces 80 percent less GHG emissions than diesel, which is the common fuel for medium- and heavy-duty vehicles.\textsuperscript{3} In addition, the estimated infrastructure development is less expensive than diesel or gasoline.\textsuperscript{4} As a by-product of natural gas production, the volume of autogas continues to increase with greater domestic availability of natural gas.\textsuperscript{5} To this end, NPGA urges EPA to recognize autogas as an exceptional alternative fuel capable of dramatically improving the environmental impact of vehicle emissions. [EPA-HQ-OAR-2014-0827-1272-A1 p.1-2]

\textbf{Autogas}

The NPRM presents considerable analysis of the features and future potential of natural gas; however, we believe the agencies are remiss in not acknowledging the progress and possibilities of autogas. The agencies recognize the small but developing proliferation of natural gas powered medium- and heavy-duty trucks.\textsuperscript{6} The agencies also recognize the potential of natural gas to displace diesel, particularly in regards to heavy-duty trucks.\textsuperscript{7} Moreover, the agencies detail and assess the varying infrastructure requirements, engine design and potential emissions concerns of compressed natural gas (CNG) and liquefied natural gas (LNG).\textsuperscript{8} [EPA-HQ-OAR-2014-0827-1272-A1 p.2]

We believe that autogas is on a parallel path of expansion and, supported by the environmental and economic advantages,\textsuperscript{9} earns equal consideration from the agencies. The absence of its acknowledgement among agencies’ regulations and programs, in general, creates an unnecessary hindrance. Relatively, the agencies recognize that without particular allowances the utilization of natural gas would be jeopardized.\textsuperscript{10} We argue that autogas is similarly situated in need, possesses an emissions profile very similar to natural gas and should be treated with equal consideration as natural gas. Autogas serves as a complementary fuel to natural gas that present unique capabilities to displace diesel. [EPA-HQ-OAR-2014-0827-1272-A1 p.2]

The agencies rely on forecasts by the Energy Information Administration (EIA) to evaluate likely fuel trends\textsuperscript{11} and, from there, prescribe GHG emissions and fuel efficiency standards that may be achievable beyond the next decade.\textsuperscript{12} Review of the latest projections from EIA demonstrate that popularity of autogas is growing, “Consumption of ethane and propane . . . shows the largest increase of all petroleum products in the AEO2015 Reference Case from 2013 to 2040.”\textsuperscript{13} The Annual Energy Outlook (AEO2015) further predicts a 1.3 percent annual growth rate of autogas over the next twenty years.\textsuperscript{14} The report also indicates that autogas use will largely parallel use of natural gas in the transportation field over the next fifteen years.\textsuperscript{15} We request that the agencies review the latest data and estimations from EIA in AEO2015, which substantially adjusts trend predictions originally featured in the previous report, specifically in relation to the use of propane in the transportation industry.\textsuperscript{16} [EPA-HQ-OAR-2014-0827-1272-A1 p.2]

We also believe that propane has particular characteristics that accentuate and may propel future utilization of dimethyl ether (DME). The agencies generally summarize the advantageous nature of DME as a potential alternative fuel,\textsuperscript{17} but the possibilities are somewhat limited due to the lack of necessary infrastructure, engine design and the high costs to supply refueling stations.\textsuperscript{18} However, research studies have discovered that blends of propane and DME at varying ratios could provide an optimum alternative fuel.\textsuperscript{19} Blends of propane and DME are a marriage of high fuel economy, low emissions and high efficiency.\textsuperscript{20} Moreover, only modest modifications of diesel engines are necessary for a DME/propane blend.\textsuperscript{21} The agencies briefly summarize the potential benefits of DME in the NPRM,\textsuperscript{22} but, in light of the evident advantages propane offers in combination with DME, we believe it is erroneous to omit discussion of incentives to encourage advancements in propane as an alternative fuel. Further to this, NPGA continues to actively pursue research and development for the expanded use
of autogas, particularly in regards to conventionally-fueled (gasoline or diesel) medium- and heavy-duty vehicles that are significant contributors to GHG emissions. [EPA-HQ-OAR-2014-0827-1272-A1 p.2-3]

Response

In response to the NPGA and Autogas comments, the focus on diesel fuel and gasoline in the rulemaking is, of course, due to the extent that these fuels are commonly used by heavy-duty trucks today. While there is little natural gas use by heavy-duty trucks today (less than 1 percent), several projections show a large increase in natural gas use because natural gas has been priced much lower than diesel fuel in recent years and is projected to be priced favorably low again in future years. This potentially is a concern because methane, the primary component of natural gas, is a very efficient heat trapping gas which has the potential to exacerbate climate change. For these reasons, we conducted a lifecycle analysis of natural gas trucks and reviewed projections of future use of natural gas use by trucks. See Preamble section XI.B. We concluded there that CNG trucks are estimated to emit less GHG emissions than diesel trucks and that LNG trucks with an average extent of boil-off emissions can have about the same greenhouse gas footprint as diesel trucks (both estimates being dependent on the assumed rate of thermal efficiency of the engines). Even though the Energy Information Administration (EIA) projects increased use of LPG by heavy-duty trucks in the future, because LPG poses a much smaller climate change risk compared to natural gas, we did not conduct a lifecycle analysis of LPG trucks.

Organization: Siemens

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 252.]

And Siemens wishes to encourage the EPA to give high priority to implementing solutions that enable renewable energy, such as decarbonized electricity, to achieve a similar shift in freight emissions, as has been achieved for passenger transport.

Organization: United Parcel Service (UPS)

The proposed rule should recognize the potential carbon advantage of natural gas, especially as renewable natural gas (bio-methane) from landfills and dairy facilities is becoming a viable means of reducing carbon emission of trucks to near zero. To be attractive as a truck fuel, this bio-methane must be ‘drop-in’ and pipeline quality, so there is no way for the OEM to distinguish which, and how much of each, fuel will be used in the future. Because the low carbon fuel standard is making renewable natural gas competitive in price with natural gas in some areas for transportation, UPS suggests that the natural gas vehicle be given a credit based on the average amount of renewable natural gas that is anticipated for future use. UPS is already using renewable natural gas in California and looking for opportunities in other areas of the nation. [EPA-HQ-OAR-2014-0827-1262-A1 p.12]
While RNG can be substituted for fossil natural gas in any end use, including heating and power generation, its strongest driver going forward will be the transportation sector. The reasons are two-fold. First, because RNG as a motor vehicle fuel competes primarily with gasoline and diesel prices, it has a greater economic advantage compared to competing against lower-cost coal and/or natural gas in the heating and power sectors. [EPA-HQ-OAR-2014-0827-1208-A1 p.1-2]

Perhaps more importantly, the economics of RNG in transportation are helped enormously by the generation and sale of credits under EPA’s Renewable Fuel Standard (RFS) program – under which it is counted as a highly valued cellulosic biofuel – and the California Low Carbon Fuel Standard (LCFS) program, under which it has the lowest carbon intensity of any fuel. These RFS and LCFS credit revenue streams make RNG competitive on a cost basis with fossil natural gas, and are unavailable to RNG used for non-transportation purposes. [EPA-HQ-OAR-2014-0827-1208-A1 p.2]

According to the RNG Coalition, the competitiveness of RNG with fossil CNG has enabled RNG to account for 25% of NGV fueling nationally and 35% of NGV fueling in California – and these shares could double by next year. The problem is that overall NGV fueling volumes are small because of the relatively few NGVs currently on the road. In order to maximize the potential of RNG to deliver methane emission reductions, NGVs fueled on RNG need to be counted in the millions rather than the approximately 110,000 now on the road. [EPA-HQ-OAR-2014-0827-1208-A1 p.2]

Because the medium- and heavy-duty market is likely to provide the strongest demand driver for natural gas and RNG vehicle fuel in the near term, advanced technology multipliers for NGVs in the current rulemaking would help provide the demand growth needed to significantly accelerate the development of this ultra-low carbon renewable fuel. Moreover, because of the enormous GHG benefits of RNG on a lifecycle basis, these incentives would likely increase, not reduce, the overall benefits of this rule. [EPA-HQ-OAR-2014-0827-1208-A1 p.2]

Increasing demand for RNG will yield diverse economic benefits as well. Municipalities, wastewater treatment facilities, farms and other sources of methane emissions across the country will capture the economic value associated with the use of RNG in the transportation sector while creating jobs and fostering local energy independence and resilience in the process. Catalyzing these marketplace dynamics will allow EPA to reduce these potent GHG emissions in a cost-effective manner, creating a win-win-win-win scenario for methane sources, the transportation sector, consumers, and the climate. [EPA-HQ-OAR-2014-0827-1208-A1 p.2]

3 Communications with David Cox, Director of Operations and General Counsel, RNG Coalition

Response

As pointed out by the Siemens, UPS and VNG comments, renewable natural gas (RNG) substantially reduces the Greenhouse Gas (GHG) emissions by heavy-duty trucks which use RNG. Use of RNG by heavy-duty trucks earns credits under the Renewable Fuels Standard (RFS) nationally, as well as the
Low Carbon Fuel Standard in California. Providing an additional credit for RNG under this rulemaking as suggested by some commenters would be redundant and thus would not be appropriate.

**Organization:** Waste Management (WM)

WM operates the largest natural gas-fueled, heavy-duty truck fleet in North America. Nearly 25 percent of our fleet comprises natural gas vehicles and greater than 90 percent of our new truck purchases each year are compressed natural gas (CNG) vehicles. We have found these trucks to be popular with our customers and communities where we operate, good for our business and good for the environment. Each natural gas truck eliminates the use of 8,000 gallons of diesel fuel per year. The cleaner-burning natural gas vehicles have nearly zero particulate emissions, lower emissions of smog-forming pollutants, and reduce GHG emissions by 20 percent. We are investing in new CNG fueling stations to support our fleet and currently operate 79 facilities of which, more than 36 percent are open to the public or municipal fleets. Our investment in fueling infrastructure has been an important step in promoting municipal adoption of CNG vehicles, as the cost of fueling facilities can present a major barrier for local governments. [EPA-HQ-OAR-2014-0827-1214-A2 p.1-2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.100.]]

While we view natural gas vehicles as a bridge to future, even cleaner vehicles, we expect CNG vehicles to be the predominant vehicle in our fleet for the near future, and quite possibly, into the scope of this rulemaking, which covers MY 2021 through MY 2027. We are therefore focusing many of our comments on the aspects of the rule that affect CNG, heavy-duty vocational trucks. [EPA-HQ-OAR-2014-0827-1214-A2 p.2]

**Response:**

We will highlight and discuss two different pieces of information in the Waste Management comment. First, the commenter stated that compressed natural gas (CNG) engines emit 20% less greenhouse gas emissions (GHG emissions) than diesel trucks. If the natural gas trucks emitted about the same amount of methane emissions as diesel engines, this might be the case. However, the certification data shows that natural gas trucks tend to emit about 1 gram per brake-horsepower-hour of methane, which is about an order of magnitude greater than diesel fuel trucks. We estimate that the higher natural gas truck methane tailpipe emissions combined with the lower thermal efficiency of spark-ignited natural gas trucks makes natural gas trucks about the same in terms of GHG emissions as diesel fuel trucks when assessed on a tailpipe basis. See Preamble Section XI.B.

Second, the commenter reinforced our observation that the installation of CNG and LNG refueling facilities can be a major barrier to the growth in natural gas usage by heavy-duty trucks. This is one reason why we believe that the growth in natural gas usage by heavy-duty trucks in the future will be modest even if natural gas prices return to their large discount to diesel fuel retail prices.

12.2 Natural Gas Engine and Vehicle Technology 1721
12.2.1 General Technology Comments

**Organization:** American Power Group Inc (APG)

Would the EPA consider allowing NG fuel engine/vehicles (either dedicated or Mixed-Fueled) to report only the NMHC values from the appropriate cert tests procedures similarly to how the ARB allows NRCI Mixed-Fuel Tier 1 converted engines to report THC for diesel fueled operation and NMHC for Mixed-Fuel operation? [EPA-HQ-OAR-2014-0827-1197 p.1]
1) Quench volumes within the piston, bore, cylinder head deck configuration: typical HHDD engines are designed to directly inject diesel fuel, aimed into a centrally located re-entrant bowl within the piston crown. Most (if not all), of the diesel fuel is combusted either in or very near this re-entrant bowl. In a Mixed-Fuel configuration, the NG fuel comes into the combustion chamber pre-mixed with the combustion air and this more homogenous NG fuel-air mixture gets compressed throughout the entire volume inside the bore, above the piston and below the cylinder head deck. The NG fuel typically will not compression ignite at compression ratios used by commercial HHDD engines and needs the diesel fuel ignition to act as a pilot ignition source. The further the NG-air mixture is from the diesel fuel pilot ignition source the less chance of complete NG combustion. As you move away from the re-entrant bowl combustion chamber, out near the cylinder bore, the volume between the piston crown edges and the cylinder bore which is above the top compression ring is a 'crevice volume' in which the NG fuel (or most any fuel) will not combust. These crevice volume effects are evident in current OEM HHDD NG engine CH4 emission data that shows 1.04-1.95 g/bhp-h (Cummins 8.8L and 11.95L dedicated NG engines). Even the NG DI injected Westport HPDI technology suffers from 'crevice volume' effects as the NG fuel must be injected much earlier in the compression cycle than the liquid diesel fuel, allowing the NG fuel to mix with the combustion air well before the diesel fuel pilot ignition event. [EPA-HQ-OAR-2014-0827-1197-A1 p.1]

Although S.I. engine OEM's have been studying and employing 'low crevice volume' piston designs to reduce feed-gas HC emissions, the C.I. engine OEM has no compelling reason to employ 'low crevice volume' piston designs for reasons already stated. It would be exorbitantly expensive for a Mixed-Fuel SVM to research 'low-crevice-piston' and top compression ring configurations for all potential HHDD engine applications, and change out all pistons, top rings and head gaskets during the Mixed-Fuel conversion (approx. $10K-$15K/engine incremental variable cost). Any such base engine change would also void the OEM's engine warranty. [EPA-HQ-OAR-2014-0827-1197-A1 p.1]

B. Would the EPA entertain the idea of having a CH4 0.1 g/bhp-h standard for converted Mixed-Fuel engines when running in diesel fuel only operation and report only the NMHC criteria pollutant (or a more flexible CH4 standard) during Mixed-fuel operation? This is patterned after the ARB E.O. certification practice of allowing Mixed-Fuel converted NRCI Tier 1 engines of being certified to Tier 1 standards when running in diesel fuel operation and being certified to Tier 2 standards when running in Mixed-Fuel operation. Please see ARB E.O. Cert # B-59U-2. [EPA-HQ-OAR-2014-0827-1197-A1 p.3]

Organization: Daimler Trucks North America LLC

8. NG Engines

· DFs for NG engines - The agencies request comment on appropriate Deterioration Factors for NG tailpipe emissions. Although we do not have an engine in the US market from which we can measure the NG DF, the agencies' proposed diesel-based assigned deterioration factors seem reasonable. 80 FR 40511. [EPA-HQ-OAR-2014-0827-1164-A1 p.29]

Organization: National Propane Gas Association (NPGA)

Extension of Phase I Standards to 2020

The NPRM permits the current, Phase 1 emission and fuel efficiency standards for natural gas compression ignition engines to continue until 2020. The agencies argue that an extension of the current standards is necessary to allow natural gas engine manufacturers to develop and produce engines
capable of meeting the Phase 2 standards. Presumably, the additional time for such manufacturers is because the agencies seek to encourage production of alternatives. We find it inequitable for the agencies not to extend the same to other alternative fuels, like propane autogas. The rationale for the incongruent treatment is unclear, especially because the agencies’ intend to apply the same emissions standards to all compression ignition engines within the decade. [EPA-HQ-OAR-2014-0827-1272-A1 p.3]

**Organization:** NGVAmerica

**Dual-Fuel Conversions**

NGVAmerica would like to raise several issues related to the application of the greenhouse gas regulations to dual-fuel conversions; specifically, we refer here to the conversion of diesel fueled engines modified to operate on a mixture of diesel and natural gas. It is our belief that compliance with the new greenhouse gas emissions for such engines could be extremely difficult, particularly as it relates to the limits on methane emissions. EPA’s discussion of the methane cap does not indicate that there is technology available for natural gas vehicles to meet these very low limits. The compliance pathway is based on the averaging mechanism and the ability to offset methane emissions with lower carbon dioxide emissions. NGVAmerica and manufacturers of new natural gas engines (SI and CI) support this regulatory approach. [EPA-HQ-OAR-2014-0827-1270-A1 p.7]

Manufacturers of new engines have indicated that they expect to meet the tighter controls on methane through use of credits and averaging. However, natural gas/diesel dual-fuel conversions may not be able to meet the new standards since they are likely to have somewhat higher methane emissions than a fully optimized new natural gas engine. The current practice for converting such engines includes utilizing much of the original engine including the piston crowns. NGVAmerica asks that the EPA work with manufactures to understand the difficulties associated with dual-fuel conversions and develop a compliance strategy that continues to make this option available in the marketplace. The continued ability of small manufacturers to produce such engines, and for businesses to utilize them, is an important part of expanding the use of natural gas and demonstrating to fleets that natural gas is a viable option in heavy duty applications. These engines also may be able to demonstrate lower levels of certain criteria pollutants, with NOx emissions reduced by as much as 25 – 35 percent and therefore do provide environmental benefits that should be encouraged. [EPA-HQ-OAR-2014-0827-1270-A1 p.7]

One approach to regulating such engines might be to adopt a rule similar to CARB regulations for non-road compression ignition engines. CARB allows Dual Fuel (Mixed-Fuel, Bi-Fuel) converted Tier I engines to meet the Tier II NMHC standards when running on Dual Fuel (Diesel/NG), but meet the Tier I THC standard when running on diesel fuel only. We request that EPA allow mixed-fuel (Diesel/NG) applications to meet the proposed 0.1 g/bhp-hr methane standard when running in ‘diesel fuel only’ operation and allow a higher methane level when running in mixed-fuel (Diesel/NG) operation. [EPA-HQ-OAR-2014-0827-1270-A1 p.7-8]

**Organization:**

VNG is developing a nationwide retail compressed natural gas (CNG) fueling network for light-duty and medium-duty vehicles. In contrast to selling CNG at private depots, utility yards, airports, and other locations where drivers don’t normally fuel, VNG collocates public-access CNG fueling facilities at existing gasoline stations in order to provide a convenient and familiar fueling experience. While initially focused on serving commercial fleets – and particularly fleets of the pickups and delivery vans covered by the present rulemaking – VNG’s fueling facilities can also support the adoption of natural gas vehicles (NGVs) by mass-market consumers. [EPA-HQ-OAR-2014-0827-1208-A1 p.1]
NGVs are a critical technology for reducing greenhouse gas (GHG) emissions from medium- and heavy-duty trucks to near-zero levels today. As in the GHG rule for light-duty vehicles for model years 2017-2025, EPA should seek to accelerate NGV adoption by offering advanced technology incentives in the current rulemaking. To this end, an advanced technology multiplier of at least 1.5 should be applied in the Phase 2 program to NGVs as well as electric vehicles (EVs) and fuel cell vehicles (FCVs), and not for waste heat recovery and strong hybrid technologies (since EPA has based the Phase 2 standards on the assumption that these technologies will see widespread deployment). [EPA-HQ-OAR-2014-0827-1208-A1 p.1]

There are two key reasons why such incentives are justified for NGVs alongside EVs and FCVs: the ability of NGVs to achieve near-zero emissions through the use of renewable natural gas (RNG), which delivers GHG reductions of 90% or more compared to diesel and is now providing 25% of NGV fuel consumption nationally, as well as the ability of NGVs to accelerate the deployment of FCVs due to the numerous synergies between these technologies. [EPA-HQ-OAR-2014-0827-1208-A1 p.1]

**Technological Synergies Will Accelerate Development of Hydrogen FCVs**

Natural gas is largely composed of hydrogen, with four hydrogen atoms for every carbon atom in a molecule of methane. Due to the chemical and physical similarities of hydrogen and methane, they share a number of technology synergies, so that the proliferation of NGVs and natural gas fueling infrastructure will facilitate and accelerate the deployment of FCVs. [EPA-HQ-OAR-2014-0827-1208-A1 p.2]

In its rulemaking for light-duty vehicles for model years 2017-2025, EPA acknowledged that “CNG investments have the potential to facilitate the introduction of hydrogen FCVs in several respects,” including innovations in advanced storage materials, innovations in tube trailer designs, improved designs for compressors and fuel dispensers, and on-site production of hydrogen from natural gas feedstock. These and other synergies were discussed in the white paper “Natural Gas Vehicles: An Essential Bridge to Hydrogen,” commissioned by VNG and written by the consultancy Energy Futures, which found that “the synergies start with natural gas as the primary and cheapest feedstock for nearly all hydrogen production today and continue through every step in the fuel supply chain.” [EPA-HQ-OAR-2014-0827-1208-A1 p.3-4]

Research into the link between NGVs and FCVs is ongoing at the Department of Energy, including a recent report by Sandia National Laboratories, Transitioning the Transportation Sector: Exploring the Intersection of Hydrogen Fuel Cell and Natural Gas Vehicles. Synergies on the infrastructure side are especially strong, and the report includes a conceptual design for a multi-fuel station that utilizes a stationary fuel cell to produce both hydrogen and electricity from pipeline natural gas (which could be RNG), thus allowing for fueling of NGVs, EVs, and FCVs. [EPA-HQ-OAR-2014-0827-1208-A1 p.3]

In a variety of ways, increasing adoption of NGVs and the development of CNG fueling infrastructure by companies like VNG will help ensure that the necessary vehicle technologies and fuels will be in place for FCVs, accelerating and lowering the costs of this transition. EPA recognized this linkage by awarding advanced technology multiplier incentives to NGVs in its light-duty rule, and a similar multiplier should be given to NGVs under the current medium- and heavy-duty rulemaking. [EPA-HQ-OAR-2014-0827-1208-A1 p.3]
The Need for Incentives

While NGVs are a relatively established technology compared to EVs and FCVs, they are still a very small part of the market and face significant near-term barriers to adoption with many fleets due to less infrastructure availability and higher up-front costs than petroleum-fueled vehicles. The fall in petroleum-based fuel prices has also reduced the economic case for NGVs, which was expected to drive market development after the shale gas boom. And, from a regulatory perspective, the growing likelihood that NGVs will be fueled by RNG creates positive externalities that are not captured by a focus on tailpipe emissions alone. [EPA-HQ-OAR-2014-0827-1208-A1 p.3-4][This comment can also be found in section 1.4.1 of this comment summary]

While a lifecycle emissions focus could be a possible solution in theory, VNG agrees with Natural Gas Vehicles for America’s (NGVA) position that the incorporation of full lifecycle emissions in the GHG rule would create enormous complications and uncertainty in the accounting for every fuel, including gasoline and diesel as well as alternatives like electricity, hydrogen, and natural gas. Keeping the regulation’s primary focus on tailpipe emissions will greatly simplify compliance planning for OEMs and ensure that emissions are reduced across vehicles of all fuel types. [EPA-HQ-OAR-2014-0827-1208-A1 p.4][This comment can also be found in section 1.4.1 of this comment summary]

At the same time, the continued use of advanced technology incentives could play a distinct but important role in encouraging the development of technologies and fuels that will be able to provide more game-changing emissions benefits in the future. Moreover, because the majority of NGV fueling going forward can be expected to be RNG, the overall emission benefits of the rule are likely to increase instead of being reduced. Thus, it would be most effective – as well as most consistent with the precedent established by the Phase 1 regulation as well as the 2017-2025 light-duty vehicle regulations – to use a simple multiplier of at least 1.5 for NGVs, EVs, and FCVs. [EPA-HQ-OAR-2014-0827-1208-A1 p.4][This comment can also be found in section 1.4.1 of this comment summary]

Regulatory incentives to encourage manufacturers to continue pursuing this vital near-term, near-zero alternative could be critical to sustaining this market during this challenging economic time for non-petroleum fuels, allowing for the long-term investments needed to reduce vehicle costs through higher production volumes. And, beyond the benefits for EPA’s GHG agenda, the promotion of RNG development through greater NGV demand will help EPA achieve its goals for the increase of cellulosic biofuel use under the RFS and the reduction of methane emissions. [EPA-HQ-OAR-2014-0827-1208-A1 p.4][This comment can also be found in section 1.4.1 of this comment summary]

Response:

With respect to the APG and NGV America comments on the methane standard, we are not allowing manufacturers to report only the NMHC values from the certification tests procedures. Nor are we relaxing the methane standards. As described in Section 12.3, methane is a significant greenhouse gas, and the CO2 trading option provides sufficient flexibility for manufacturers unable to meet the methane standard.

The NPGA comment that the agencies are treating propane differently than natural gas appears to result from a misreading of text from the NPRM. The agencies did not propose to do, nor are we finalizing the type of change to which NPGA would object in this context.

Finally, with respect to the VNG comment, we are not adopting advanced technology multipliers for natural gas vehicles. Such vehicles are already available in the marketplace, and do not represent the kind of game-changing technology for which these Phase 2 multipliers are intended.

12.2.2 Natural Gas Emission Control Measures

Organization: California Air Resources Board (CARB)

Oppose/Requested Change Comment

Comment – Tailpipe standards for natural gas vehicles

U.S. EPA and NHTSA state: “For 2014 and later OEM compression ignition natural gas trucks or natural gas conversions of 2014 and later diesel trucks, the trucks must meet a 0.1 g/bhp-hr methane emission standard in the case of a larger truck engine tested with an engine dynamometer, and a 0.05 g/mi methane emission standard in the case of smaller trucks tested on a chassis dynamometer. For spark-ignited engines, the standards take effect in 2016. Natural gas truck manufacturers are allowed to offset methane emissions exceeding the methane emission standard by converting the methane emission exceedances into CO2 equivalent emissions and using CO2 credits. For the initial natural gas engine certifications that U.S. EPA received for 2014, the truck manufacturers chose to continue to emit high levels of methane (around 2 g/bhp-hr) and use CO2 credits to offset those emissions. We don’t know if this practice of will continue in the future; however, for evaluating the lifecycle impacts of natural gas heavy-duty trucks, the 2014 and later natural gas heavy-duty trucks may in fact have an emissions profile more like the pre-2014 trucks and not like the 2014 and later trucks.” [EPA-HQ-OAR-2014-0827-1265-A1 p.163]

CARB staff suggests that U.S. EPA and NHTSA investigate the feasibility of more stringent tailpipe standards for methane and N2O. Considering the high-GWP of methane, a 0.1 g/bhp-hr methane standard is equivalent to 4 to 8 percent of the proposed CO2 standards, depending on vehicle and vocation types. CARB staff also suggests that U.S. EPA and NHTSA consider eliminating or at least phasing out the use of CO2 credits in lieu of compliance with tailpipe methane standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.163]

Support Comment

Also, in 40 CFR 1036.801 (page 40602 of the NPRM), CARB staff supports the clarification that a dual fuel engine can include 2 or more fuels as long as it does not operate on a continuous mixture of those
2+ fuels, and the expanded definition of manufacturer to include those who assemble an engine, vehicle, or piece of equipment. [EPA-HQ-OAR-2014-0827-1265-A1 p.188]

**Organization:** International Council on Clean Transportation (ICCT)

### Natural gas

Delgado and Muncrief (2015) determined that inadequate attention towards limiting methane leakage from heavy-duty natural gas vehicles (NGVs), could diminish the Phase 2 program benefits by as much as 38 percent in 2040, if there was a major breakthrough in NGV sales and using 20-year global warming potential for methane. We recommend that the agencies take every opportunity available within the purview of this regulation to minimize methane emissions throughout the value chain and to promote higher-efficiency natural gas engines. [EPA-HQ-OAR-2014-0827-1180-A4 p.17]

There are a large number of potential locations for methane leakage throughout the natural gas value chain (production, processing, transmission, distribution, storage and transfer, fueling station, refueling events, vehicle tailpipe, vehicle crankcase, vehicle storage tank, vehicle fueling system). The agencies’ proposal addresses two of these by mandating closed engine crankcases and minimum LNG tank hold times for NGVs. We are supportive of these aspects of the proposal. The remainder of the leakage sources are not addressed in any way. One large potential source of methane emissions that would be very practical to address in this rule is the vehicle tailpipe. Emissions levels of methane from the tailpipe are significant, they could be in the range of 0.5% or more (of total fuel consumed) and can be controlled to much lower levels with known aftertreatment control technology (See Dunn et al 2013; Frazier, 2013). There is no incentive in the current proposal to place further controls on these emissions, which means it is likely that they will continue at the current level. In addition, we encourage the agencies to consider whether (a) CO2-CH4 emission trading and (b) exclusion of engine CH4 emissions within the GEM inputs may incentivize the increased deployment of higher-emitting natural gas engines with greater short-term climate forcing impacts in the market. [EPA-HQ-OAR-2014-0827-1180-A4 p.17]

**Organization:** Manufacturers of Emission Controls Association (MECA)

### Methane and PM Emissions from Stoichiometric Natural Gas Engines

Because methane is a potent climate forcing agent with Global Warming Potential (GWP) that is 25 times greater than CO2 over a period of 100 years, we applaud the agencies consideration of both upstream and downstream methane emissions from the growing fleet of natural gas trucks. EPA’s Greenhouse Gas Reporting Program (GHGRP) is an important source for updating the upstream GHG inventories from the production and transportation of this alternate fuel. As the interest in natural gas as a domestic energy source and transportation fuel grows, it leads to expansion of the fuel production and transportation infrastructure. We are encouraged with EPA’s intentions to further regulate methane emissions from natural gas production facilities. The upstream production, distribution and transportation of methane may be a significant contributor to the overall GHG contribution from this fuel sector. [EPA-HQ-OAR-2014-0827-1210-A3 p.13]

MECA is a long supporter of technology and fuel neutral standards and we believe that the proposed provisions to control fugitive methane emissions from natural gas vehicles and engines represent a fair and balanced approach to addressing the CO2-equivalent emissions from the growing natural gas vehicle sector. Because of the low vapor pressure of this alternate fuel, the potential source of emissions...
goes beyond just the tailpipe. Similar to the case of evaporative emissions from gasoline vehicles, it is important to control the non-combustion related emissions from natural gas engines and fuel systems. We support the EPA’s inclusion of boil-off requirements for LNG vehicles in the Phase 2 proposal and to require closed crankcases on all natural gas vehicles. MECA supports the reclassification, starting in 2021 under Phase 2, of natural gas engines according to their primary intended service classes, similar to compression ignition engines. Although MECA lacks the expertise in suggesting the life cycle climate impacts, a number of ongoing studies by California, EPA and others may provide additional insight into how this may be done in the near future. California’s Low Carbon Fuel Standard provides methodology that producers may employ to revise climate impacts of newly developed production pathways and this may serve as a model of how that may be done for upstream methane emissions. If natural gas truck applications continue to grow, as some market analysts predict, EPA should consider developing a separate set of engine efficiency standards that better reflect the full life cycle emissions of natural gas vehicles including leakage and upstream emissions. [EPA-HQ-OAR-2014-0827-1210-A3 p.13]

It is worth noting that stoichiometric, heavy-duty natural gas engines have been shown to emit large numbers of ultrafine particulates that are largely the result of the consumption of lubricant oil during the engine combustion process (see ARB’s funded work published by West Virginia University on particle emissions from stoichiometric natural gas bus engines published in Environmental Science & Technology in June 2014). These stoichiometric heavy-duty engines are currently certified without filters due to their low particulate mass emissions. The mass of metal oxide ash particles from these natural gas engines were an order of magnitude greater than the mass of metal oxide ash emitted from a 2010 technology diesel engine equipped with a DPF and SCR system. The oxidative stress potential (OS) of the PM was also characterized in-vitro through DTT and ROS assays. High correlation coefficients were observed between the mass of lube oil-derived elemental species and both DTT and macrophage ROS, suggesting that the chemical species forcing oxidative stress are metallic in nature. The authors further suggest that, although the PM mass emissions from natural gas vehicles are low, the presence of nucleation mode solid metal particles could pose significant health risks in the alveolar regions of the respiratory system due to the higher surface area of these nanoparticles. Filters on these stoichiometric natural gas engines would significantly reduce the ultrafine particle emissions from these engines and provide additional climate and public health benefits. MECA encourages EPA to investigate the health and climate benefits of applying filters to these engines and enact appropriate policies that force the use of high efficiency filters on these engines to reduce ultrafine metal oxide exposure. [EPA-HQ-OAR-2014-0827-1210-A3 p.13-14]

Response:

The comments describe how natural gas heavy-duty trucks have higher methane emissions than their gasoline or diesel fueled heavy-duty trucks. To reduce the methane emissions from natural gas heavy-duty trucks, the commenters propose to end the CO2 credit trading program and incorporate natural gas trucks into the GEM model. One of the commenters suggested increasing the stringency of the methane emission standard.

Before addressing the various comments, it is useful to review the past and present methane emissions from heavy-duty natural gas trucks, and then discuss what methane emissions might be from future natural gas trucks.

Prior to when the heavy-duty methane emission standards took effect in 2014 for engine compliance (0.1 gram per brake horsepower-hour) and in 2016 for chassis compliance (0.05 gram per mile), natural gas heavy-duty trucks, as well as diesel fuel and gasoline trucks, simply needed to meet a nonmethane hydrocarbon standard. Diesel fuel and gasoline heavy-duty trucks emitted low levels of methane as the
The nonmethane hydrocarbon standard also controlled methane levels. In fact, the phase 1 heavy-duty methane emissions standards that took effect in 2014 and 2016 were set to essentially cap methane emissions at their current levels for diesel and gasoline heavy-duty trucks (the methane emissions standards were established to be two times higher than actual methane emissions). Since natural gas is mostly methane, complying with the nonmethane hydrocarbon standard was not difficult using readily-available aftertreatment technologies. However, methane emissions were high. Our certification data showed that natural gas trucks generally emitted from 2 – 5 gram of methane per brake horsepower-hour, which is approximately two orders of magnitude higher than diesel fuel and gasoline heavy-duty trucks.

A review of our certification data shows that natural gas trucks certified after the methane tailpipe standards took effect average about 1 gram per brake horsepower-hour. This is an improvement over the unregulated levels, but still much higher than the standard. However, when the engine manufacturer exceeds the methane emissions standard (providing that it is a large engine manufacturer, small engine manufacturers are exempt from the phase 1 GHG standards), it must offset the methane emissions above the methane emissions standard with excess carbon dioxide (CO2) emission credits. Because methane is a more potent heat trapping gas than CO2, the engine manufacture must retire more grams of CO2 credits than grams of methane emissions. Under the phase 1 HD GHG standards, 25 grams of CO2 must be used to offset 1 gram of methane emission above the methane emissions standard, and under the phase 2 HD GHG standards, 34 grams of CO2 must be used to offset 1 gram of methane emissions. These CO2 credit trading values are based on methane’s GWP under IPCC’s AR4 and AR5 reports, respectively, over 100 years. Thus, when evaluated over a 100 year timeline, trading CO2 credits for methane emissions will be GHG-neutral based on IPCCs assessment of the relative GHG impacts of these two GHG gasses.

than today’s trucks for several reasons. First, as the CO2 emissions standards become more stringent, the cost of achieving CO2 emission reductions will increase. Therefore, trading CO2 emission credits against methane emissions above the methane emissions standard becomes more expensive. Second, as just explained, when the phase 2 HD GHG emissions standards take effect, the engine manufacturers will have to use even more CO2 credits (34 vs 25) to offset higher methane emissions. This will further increase the cost of offsetting those noncompliant methane emissions and creates an incentive to lower the methane emissions from natural gas trucks. Third, over time, natural gas engine manufacturers will likely be able to dedicate engineering resources to engineer low-cost methods to lower the methane emissions of natural gas trucks. Combining new lower-cost means to achieve lower methane emissions with the higher cost, and higher amount, of CO2 credits will provide an incentive for natural gas engine manufacturers to lower the methane emissions from their natural gas heavy-duty trucks.

One of the commenters suggested increasing the stringency of the methane emission standard for natural gas trucks. Since the methane emissions standard applies to all heavy-duty trucks, if we were to identify a cost-effective means to reduce methane emissions, we would likely consider increasing the stringency of the methane emissions standard for all heavy-duty trucks. For the phase 2 HD GHG rulemaking, we focused on achieving CO2 emission reductions because CO2 is the principal GHG gas and achieving CO2 emission reductions are likely less costly than trying to achieve methane emission reductions. If there is a phase 3 HD GHG standard, we likely will reconsider the stringency of the HD methane tailpipe standard.

Another comment suggested phasing-out the CO2 credit trading program altogether. The agencies typically find that allowing the regulated parties’ flexibility on how to comply with emission control standards is effective for achieving the greatest emission reduction at the lowest cost. If, however, if the agencies makes a finding, or is provided information, that the greater flexibility provided by the CO2 credit trading program is detrimental to achieving GHG emission standards, then EPA may rethink
its strategy. Since the volume of natural gas heavy-duty truck sales is so low at this point in time, EPA would likely wait to make this type of assessment until natural gas heavy-duty trucks begin to comprise a significant portion of the heavy-duty fleet. Based on our projected trend in methane emissions from heavy-duty natural gas trucks described earlier, we believe that some of the concern about high natural gas emissions will diminish.

12.2.3 Crankcase

**Organization:** California Air Resources Board (CARB)

**Comment – Closed crankcase requirement for natural gas engines**

CARB staff supports the Phase 2 proposal to require closed crankcases for all natural gas engines, including those subject to compression ignition standards. An open crankcase has historically been allowed for diesel-fueled engines, as recirculating those crankcase emissions with their high PM levels could potentially foul turbochargers and aftercooler heat exchangers. Natural gas vehicles have low PM emissions, and requiring a closed crankcase is appropriate. The European Union standard currently compels the use of closed crankcase ventilation systems, and Cummins ISL G Euro V engines already have closed crankcase ventilation. [EPA-HQ-OAR-2014-0827-1265-A1 p.165]

**Organization:** Enovation Controls (ENC)

2.3 Crankcase Emissions - Crankcase emissions should be controlled based on system type rather than fuel type, maintaining harmonization with end user focus as specified elsewhere in the proposed rule. CCR Title 13, Section 1971.1 addresses crankcase emissions such that all engines, whether using compression ignition or spark ignition, are subject to monitoring crankcase ventilation (CV) systems depending on whether the engine was certified as an open CV or closed CV system. No delineation is made between fuel type, and we suggest that any crankcase emissions language in the Phase 2 proposal should take a similar fuel-agnostic approach. The current language appears to leave gaps for liquid-fueled engines that certify with a closed CV system. [EPA-HQ-OAR-2014-0827-1203-A1 p.2]

**Organization:** Environmental Defense Fund (EDF)

Account for all on-vehicle methane and require efforts to reduce these emissions

EDF supports the close-crankcase requirement contained in the proposal. This step can significantly reduce methane emissions, as evidenced by the recent CARB certification of the Cummins-Westport ISL G Near Zero engine. With the closed-crankcase, methane emissions were cut 70% compared to the standard ISL G engine. [EPA-HQ-OAR-2014-0827-1312-A1 p.42]

**Organization:** Optimus Technologies

In addition, Optimus applauds the EPA’s provision to require that all natural gas-fueled vehicles have closed crankcases. [EPA-HQ-OAR-2014-0827-1276-A1 p.1]

**Organization:** Union of Concerned Scientists (UCS)

We strongly support the agencies inclusion of controls for crankcase emissions on natural gas vehicles and LNG tank hold times. [EPA-HQ-OAR-2014-0827-1329-A2 p.26]
... We also generally support the addition of the closed crank case requirement and alterations to the agencies’ principal model methodology for natural gas vehicles....

**Organization**: American Gas Association (AGA) et al.

Closed crankcases on HPDI natural gas engines would be ineffective for the following reasons: [EPA-HQ-OAR-2014-0827-1223-A1 p.5]

The contribution of blow-by gases to exhaust methane emissions was measured by comparing the tailpipe out methane to the engine-out methane (measured upstream of the crankcase gases return). These tests were conducted on June 9 and 10, 2014, on an engine that had already accumulated 3340 hours of development, including some durability tests. The engine’s age likely means that the measured blow-by gases were higher than for an average engine. (We note that there is some uncertainty, as the measurement method requires subtracting measurements of already low methane emissions from two different analyzers). [EPA-HQ-OAR-2014-0827-1223-A1 p.6]

[Table 1, 'Exhaust and crankcase methane emissions data', can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1223-A1]

Table 1 shows that the crankcase methane emissions account for approximately 1 percent of the total methane emissions from the engine. Thus, we believe that requiring a closed crankcase to mitigate such a marginal amount of emissions is superfluous. We note our support of the Phase 1 Rule’s provisions on this issue, which allowed for compression-ignition natural gas engines to vent crankcase emissions to the atmosphere as long as the vented emissions were accounted for as part of the engine’s tailpipe emissions. [EPA-HQ-OAR-2014-0827-1223-A1 p.6-7]

**We Support the Proposed Requirement for Closed Crankcases on Natural Gas Engines, but Strongly Recommend that the Agencies Include an Alternative Compliance Pathway for HPDI Engines**

The Proposal includes a requirement that all natural gas-fueled engines have closed crankcases, beginning in model year 2021. This modifies the requirements of the HD Phase 1 Rule, which allowed compression-ignition natural gas engines to vent crankcase emissions to the atmosphere as long as the vented emissions were accounted for as part of the engine’s tailpipe emissions. [EPA-HQ-OAR-2014-0827-1223-A1 p.5]

We understand and agree with the justification for this proposed change for spark-ignited stoichiometric engines, which are the most common engines on the market today. For these engines, returning the ventilation from the crankcase to the intake is an effective strategy to reduce overall methane emissions. We therefore support the agencies’ proposed requirement for closed crankcases on spark-ignited stoichiometric natural gas engines. [EPA-HQ-OAR-2014-0827-1223-A1 p.5]

However, requiring High Pressure Direct Injection (HPDI) natural gas engines to have closed crankcases would be an unnecessary and ultimately ineffective requirement. Further, it would introduce unwarranted complexity, cost, and failure modes. We recommend that the agencies take the following information and data into consideration, and we request the opportunity to discuss the potential for

Closed crankcases on HPDI natural gas engines would be ineffective for the following reasons: [EPA-HQ-OAR-2014-0827-1223-A1 p.5]

- During the compression stroke, the combustion chamber is predominantly filled with air. As a result, the quantity of methane in the blow-by gases is very low, as can be seen in Table 1 below. We note that these levels are different from fumigated engines, which compress a mixture of fuel and air in the combustion chamber, and therefore have a more significant amount of fuel in the blow-by gases. [EPA-HQ-OAR-2014-0827-1223-A1 p.6]
- Because HPDI engines use late-cycle direct injection of the fuel, there is no air-fuel mixture in the combustion chamber crevices. This also reduces the amount of contact between the air-fuel mixture and the cylinder walls. As a result, the in-cylinder methane emissions are much lower than in fumigated engines. This also results in much lower methane in the blow-by gases. [EPA-HQ-OAR-2014-0827-1223-A1 p.6]
- Returning the blow-by gases to the intake is not effective in HPDI engines because these engines operate with excess air, which is similar to diesel engines. Operating with excess air means that returning crankcase emissions (which are already diluted to a great extent) to the intake would form a mixture well below the flammability limit. Thus, a significant fraction of the crankcase methane would simply go through the combustion chamber. Furthermore, the exhaust temperature of a diesel cycle engine is almost always below the catalytic oxidation temperature of methane, so this methane will not be significantly oxidized in the exhaust oxidation catalyst. [EPA-HQ-OAR-2014-0827-1223-A1 p.6]

In support of this, and as summarized in Table 1 below, Westport has extracted representative data from a pre-production HPDI 13L engine. The engine, which has mild EGR quantities, was calibrated for EURO 6 emissions, but was operated over a cold and hot Federal Test Procedure (FTP) drive cycle. In the drive cycle, the crankcase ventilation gas was piped to the exhaust pipe, downstream of the exhaust after-treatment systems (EATS) and upstream of the tailpipe analyzer port. [EPA-HQ-OAR-2014-0827-1223-A1 p.6]

[Table 1, 'Exhaust and crankcase methane emissions data', can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1223-A1]

Further, requiring closed crankcases in HPDI engines may create unintended impacts on safety because closed crankcases can impact the engine’s failure modes. This could lead to unsafe engine operations or engine damage. For example, if a natural gas fuel injector malfunctions, sufficient levels of natural gas may be reintroduced to the cylinder intake air (through the crankcase ventilation system). This would increase the power output of the engine independently from the driver demand before the fault is detected and any mitigating action is taken. We note that stoichiometric engines are less susceptible to this because there is no excess air in the intake. [EPA-HQ-OAR-2014-0827-1223-A1 p.7]

Additionally, we recommend that the final Phase 2 Rule does not mandate specific engine designs or architectures. Notwithstanding the fact that closing the crankcases of spark-ignition natural gas engines resolves the issue of methane emissions from crankcases, we believe that the agencies should maintain their standard approach of setting performance-based emissions standards that allow OEMs to meet the standards in ways that meet their customer needs in the safest, most cost-effective manner possible. Doing otherwise burdens OEMs with potentially avoidable weight, costs, and safety impacts and complicates the task of bringing new products to market. [EPA-HQ-OAR-2014-0827-1223-A1 p.7]
The agencies applied similar reasoning in their assessment of transmission architectures. Transmission improvements create opportunities for fuel consumption improvements and GHG reductions, especially in vocational vehicles’ frequent start-stop operations. Though the agencies noted that “most vocational vehicles currently use torque converter automatic transmissions (AT),” which increases fuel efficiency, the agencies are not requiring that all vocational vehicles use AT in order to meet the Proposal’s emissions and fuel consumption standards. Rather, the agencies are allowing OEMs to bring other products to market that will meet the standards in ways that best meet their customer needs, noting that “other kinds of transmission architectures can meet customer needs, including automated manual transmissions (AMT) and even some manual transmissions (MT).”

For these reasons, we recommend that the agencies explore alternative or additional compliance mechanisms for HPDI engines. Doing so will help ensure that methane emissions from the crankcases of natural gas vehicles are safely and cost-effectively reduced. Towards that end, we request an opportunity to discuss this issue further with you, as well as to provide additional information and data, after the close of the public comment period to assist your efforts to reach the best approach to reducing crankcase emissions.

Organization: NGVAmerica

G. NG Crankcase Emissions. EPA has proposed requiring that natural gas engines have closed crankcases in order to reduce emissions. EPA requests comments on the feasibility and cost effectiveness of requiring closed crankcases.

We support the intent of further reducing emissions from natural gas engines and utilizing all available cost-effective, commercially available technologies to continue to improve upon the emissions of natural gas vehicles. We further support the use of closed crank case technology on spark-ignited engines (i.e., natural gas engines that utilize spark-ignition as part of the combustion process regardless of their classification). However, we have concerns with respect to the inclusion of a hard and fast rule that imposes this requirement in cases where it may not be necessary for regulatory compliance such as where other controls or strategies are able to show compliance with the regulations. We also are concerned that the use of closed crank case systems in some applications may impact the safe operation of natural gas vehicles.

The comments submitted by GNA on behalf of AGA, Clean Energy, and Westport Innovations provide additional information relating to this issue. NGVAmerica supports their comments.

Organization: Cummins, Inc.

*Cummins opposes forcing closed crankcase ventilation (CCV) on HD non-diesel fueled engines* [EPA-HQ-OAR-2014-0827-1298-A1 p.28]

Current HD diesel-cycle engines may discharge emissions such as crankcase gases into the atmosphere as long as the emissions are measured and accounted for during certification and deterioration factor (DF) testing. Since the discharged emissions are accounted for during certification testing, proper technologies must be developed and applied to crankcase ventilation systems to ensure acceptable performance to meet certification and customer requirements. In contrast to diesels, the agencies are proposing to mandate natural gas fueled HD engines use a CCV system, regardless of emissions impact.
of an open crankcase system. Cummins does not support this provision as it mandates a specific technology rather than setting a performance-based standard. Manufacturers should have the flexibility to choose the appropriate technologies to meet standards and customer needs. [EPA-HQ-OAR-2014-0827-1298-A1 p.28]

Also, there is an inconsistency between the regulatory language and the Preamble on the implementation timing. The Preamble (80 FR 40208) indicates this requirement would start in MY2021, while the proposed rule would require “MY2007 and later non-diesel-fueled” engines to have CCV systems. Any regulatory change should provide adequate lead-time for manufacturers to design and validate a reliable system to meet any new requirement. [EPA-HQ-OAR-2014-0827-1298-A1 p.28]

**Organization:** Daimler Trucks North America LLC

- **Crankcase Emissions from Natural Gas Engines** – The agencies request comment on the costs and effectiveness of technologies that we have identified to comply with these provisions involving closing the crankcase and recirculating all crankcase gases for natural gas engines. (80 FR 40208). The EPA asserts that the agency will require closed crankcase on NG vehicles because this presents no problem due to low PM emissions from NG engines. This begs an important question: why is the EPA dictating a solution instead of just requiring a performance level? If the engine can meet the GHG limits with open breather emissions included in the measured results, there is no reason why the agency should require a closed breather. Moreover, we question the EPA’s assertion that closed breathers are not an issue. Aerosols may foul compressor wheels, and the entire discussion of the ease of implementing closed crankcase ventilation ignores the HPDI technology. [redacted] In short, we recommend a performance-based standard, measuring emissions and being required to hit a prescribed level. [EPA-HQ-OAR-2014-0827-1164-A1 p.29]

**Organization:** Securing America's Future Energy

**Closed Crankcase Requirement**

The Proposal requires that all natural gas-fueled engines, beginning in model year 2021, have closed crankcases. We support this requirement for spark-ignited stoichiometric engines, which are the most common on the market today. However, crankcase emissions from High Pressure Direct Injection (HPDI) engines account for approximately 1 percent of the total methane emissions from the engine. Therefore, applying this requirement to HPDI engines is ineffective, unnecessarily adding cost and complexity. [EPA-HQ-OAR-2014-0827-1462-A1 p.9]

SAFE supports the policy of setting performance-based emissions standards, rather than requiring a particular technology approach. This approach creates an innovative environment and generally brings clean technologies to market in the safest, most cost-effective manner. [EPA-HQ-OAR-2014-0827-1462-A1 p.9]

For these reasons, we recommend that the agencies consider not requiring crankcase closure, but instead set equivalent performance standards that allow manufacturers to explore alternative or additional compliance mechanisms for HPDI engines. Doing so will help ensure that methane emissions from natural gas vehicles are safely and cost-effectively reduced. [EPA-HQ-OAR-2014-0827-1462-A1 p.9]
Response:
As described in the proposed rule, we believe that closed crankcases for compression-ignition and spark-ignition engines are both technologically feasible and important for achieving an additional level of emission control. However, we are aware that there are many instances in which secondary engine manufacturers design and certify their engine configurations based on an engine from a different engine manufacturer, and that closing the crankcase depends on proper designs for the engine block, valve cover, and other engine components. As such, this technology change for natural gas would likely require a substantial level of coordination with diesel engine manufacturers. We therefore plan to address this as part of a separate rulemaking, which could require closed crankcases for all compression-ignition engines (including diesel fueled engines) as early as model year 2021.

12.2.4 Emerging Technologies/OBD

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Liquid natural gas (LNG) boil-off warning systems

The NPRM requests comment on the feasibility and appropriateness of a regulatory requirement that LNG-fueled vehicles include a warning system that would notify a driver of a pending boil-off event as one means of reducing the frequency of such events in an effort to limit methane releases to the atmosphere. U.S. EPA and NHTSA have suggested a warning light that would be illuminated once tank pressure exceeded a threshold in addition to an audible, periodic chime. In addition, the RIA notes that the components used as inputs to the boil-off warning system would be required to be monitored by OBD, and the number of boil-off events tracked and reported. CARB staff agrees that it seems valuable to have both a driver notification (so the operator can take action to prevent or mitigate a boil off) and tracking of boil offs that actually occur to help quantify the occurrences and guide development future requirements. However, CARB staff would like to note that tracking the history of boil-off events and the methods used for boil-off would require new communication messages to be defined in both SAE Standards J1939 and J1979 if the information is to be downloaded via scan tool. Because these data are currently not standardized, CARB staff suggests a simpler near term approach such as requiring installation of a dedicated light that would illuminate if the undesired boil-off to the atmosphere event occurred. This light could be designed to only be cleared by a dealership technician. Additionally, the light could provide the same information as the scan tool messages without implementation of new scan tool messages by blinking at key-on engine-off to indicate the exact number of undesired boil-off events that occurred on the vehicle since the memory was last cleared. As the necessary standardization required to obtain boil-off event information is developed, both driver notification and event tracking via OBD could be implemented. [EPA-HQ-OAR-2014-0827-1265-A1 p.106]

Note that if boil offs generally only occur when the vehicle is parked, a warning system would have to be active when the operator has shut down the vehicle. This means either the engine control module (or some other module on the vehicle) has to be kept alive during the vehicle shutdown period or some type of hardware (e.g., latching pressure-based, mechanical switches) has to be incorporated to sense the overpressure condition during the shutdown period. Both of these are feasible and have been done in OBD system implementations. However, it is not clear what the benefit is if the operator is not near the vehicle and is unable to respond. [EPA-HQ-OAR-2014-0827-1265-A1 p.106-107]

Oppose/Requested Change Comment
Comment – Methane leak detection

While CARB staff supports the use of OBD to detect and provide a warning for when methane leaks from the CNG or LNG fuel system occur, staff is not certain if an actual methane leak check is required under the current requirements, or if rationality and functionality of sensors and components is required, or both. If a leak detection monitor is required, staff suggests that the leak size or leak rate be clearly defined. Additionally, it is important to note that simple rationality and functionality of sensors and components, which is what is required by comprehensive component monitoring, do not inherently indicate leaks in the system. A full system check would be required in order to ensure detection of CNG or LNG fuel system leaks. While feasibility of leak detection has not been determined, tank pressure profiles should follow predictable behavior and provide the basis for a monitoring strategy. In reality, the operator might notice a leak in many instances due to odor or a change in fuel level disproportionate to driving before the diagnostic system has adequate time to identify the leak and store a fault code. [EPA-HQ-OAR-2014-0827-1265-A1 p.107]

Organization: Environmental Defense Fund (EDF)

Account for all on-vehicle methane and require efforts to reduce these emissions

Methane is emitted from natural gas trucks at the tailpipe and crankcase, and vented from liquefied natural gas (LNG) fuel tanks. The Phase 2 proposal makes important strides in reducing these emissions. [EPA-HQ-OAR-2014-0827-1312-A1 p.42]

The agencies also took an important step to recognize the significant potential for methane emissions from LNG fuel tanks. EDF supports the agencies’ decision to require a minimum hold time for these tanks. However, the proposed five-day requirement is insufficient. It reflects current industry practice, falling well short of the existing capacity of LNG tank technology. For example, Chart Industries, a leading producer of LNG tanks, brought to market a tank capable of a 10-day hold time in 2013. Westport also claims a 10-day hold time with its existing Ice Pack tank. Given that ten days is achievable today, the final rule should require at least this level of performance in 2021. The agency should consider further strengthening this standard in 2024 and 2027. [EPA-HQ-OAR-2014-0827-1312-A1 p.42]

G. Require on-board monitoring to track boil-off events

The agencies requested comment on the use of on-board monitoring to track boil-off events as well as other methane discharges. EDF believes that requiring this data collection will enhance the ability of manufacturers, fleets, and refueling station owners to quantify the magnitude of methane emissions and take steps to minimize these emissions. Additionally, this data will provide the agencies with improved data quality on which to design effective future policies. [EPA-HQ-OAR-2014-0827-1312-A1 p.46]

179 Preamble at 793-795; 817; 1020-1021.

**Organization:** California Air Resources Board (CARB)

**Comment – More efficient natural gas storage**

The NPRM states that an adsorbent for natural gas (ANG), called metal organic framework (MOF) for storing CNG, has been developed and is being tested for large scale use. The substance stores the same quantity of natural gas in a smaller volume at the same pressure (about 60 percent of the energy density of diesel fuel), or stores the same density of natural gas at a lower pressure. [EPA-HQ-OAR-2014-0827-1265-A1 p.164]

CARB staff believes there is potential in the both adsorbent technology as well as conformable tanks. CARB staff suggests that to the extent that those technologies contribute to lighter weight tanks in the future, U.S. EPA and NHTSA should consider either revising the natural gas weight “penalties” or allow the manufacturers to get credit under the off-cycle technology credits (formerly referred to as “innovative technologies”). [EPA-HQ-OAR-2014-0827-1265-A1 p.164]

**Response:**

We asked for comment on requiring onboard diagnostic (OBD) systems on heavy-duty natural gas trucks to track methane leaks or boil-off events, or for other possible indicator systems to warn vehicle operators about potential impending methane releases to the environment. For a variety of reasons, we did not pursue these ideas for the final rulemaking.

One reason why we did not pursue OBD systems on natural gas heavy-duty trucks is that since the proposed rulemaking there has been a dramatic reduction in crude oil prices, and EIA projects continued low crude oil prices, which further reduces the chance that natural gas will make much headway displacing diesel fuel use by heavy-duty trucks. The low number of natural gas trucks would have an insignificant environmental impact even if there are some high methane emissions from natural gas trucks from time to time. Also it would be burdensome to manufacturers to require the addition of OBD systems on such a low production engine or truck.

Another reason why we did not pursue OBD systems on natural gas heavy-duty trucks is that we do not know the extent of the problem that we would be attempting to fix. We have no data on the number and quantity of methane that boils-off from LNG fueled natural gas trucks.229 We also don’t have any data on the number of trucks which are leaking natural gas fuel and the magnitude of those leaks.

Without data for the number of boil-off events and the quantity of emissions per boil-off event, we still sought a simple, low cost method for detecting and registering a boil-off event with an OBD system. The simplest system we thought of would be to install a position sensor on the boil-off pressure relief valve (PRV) which would mechanically detect whether the PRV opened. If the PRV opened, the OBD system

---

229 The lifecycle analysis contained a sensitivity analysis based on an assumption that a boil-off event occurs during each period between when the truck operator refuels his LNG truck with LNG. The sensitivity analysis, however, was not based on any specific emissions or truck operations data, although it did try to model the impact based on hearsay that some truck operators manually “boil-off” their LNG tanks prior to refueling to lower the tanks pressure to enable faster refueling.
system would register the opening and we could perhaps assume a quantity of methane released to the environment. We shared our idea with a PRV manufacturer which produces at least some of the PRVs used on natural gas trucks. The manufacturer explained that PRV release events most likely would only be very small releases in which the PRV only opens a very small amount allowing the natural gas to only weep from the valve. The manufacturer explained that the very low heat intake in very well insulated LNG tanks would only allow a weeping of natural gas from the PRV for boil-offs from the LNG tank. For this type of release, a position sensor on the valve would likely not be sensitive enough to detect that the valve had in fact opened and had released natural gas as part of a boil-off event. Thus, a change of valve position to indicate boil-off events may not be a viable idea for detecting boil-off events.

We also sought a simple, low cost method for detecting leaks from CNG and LNG tanks that could be registered with the OBD system. For CNG systems, a pressure sensing device could measure whether there is a loss of pressure when the truck is not operating. This loss of pressure could be caused by a leak from the CNG system. The problem with the idea is that decrease in temperature could also cause a reduction in pressure which might be misinterpreted to be a reduction in pressure attributed to a leak. Thus, it would be necessary to measure both pressure and temperature to ensure that decrease in temperature is not responsible for the lowering pressure reading when the truck is not operating. When we ran through the calculations, only a very small change in temperature would be necessary to cause a sufficiently high loss in pressure that could indicate a possible leak. Thus, we would either have to resort to only sensing a fairly large leak, or abandon the idea of trying to detect a leak altogether to avoid indicating false positive leaks from CNG storage on heavy-duty trucks. However, natural gas has an odorant which may be detectable by the vehicle operator before this idea of a pressure/temperature sensors would, and the additional cost of the leak detection system would not be necessary. This sort of idea for detecting leaks from CNG trucks would require much more thought and analysis before being considered. A conceptually more realistic idea would be to set up a leak detecting system in the high pressure piping downstream of the CNG tanks, provided that the high pressure piping was isolated from the CNG tanks by a solenoid operating valve when the truck is not operating. This high pressure piping has a lot of pipe joints and is a more likely location for leaks than the CNG tanks. Again, this sort of idea would need some additional thinking and analysis before it were to be pursued.

The agencies note the ideas by CARB to incentivize the use of ANG as an innovative technology. As we describe in the proposed rulemaking, using ANG in an enclosed CNG system is one possible strategy for reducing the chance for boil-off events, but also have a similar storage density of LNG. As noted by CARB, this is a promising technology that if commercialized, then we will consider such incentives if the technology helps to reduce methane emissions and the industry does not voluntarily opt for the technology on its own. We went through a similar thought process when we considered pressure and temperature sensors for detecting leaks from LNG tanks. There are similar complications to this concept as well. Perhaps a more likely idea would be to measure whether the vacuum seal for the LNG tank has been compromised, which would cause a much faster heat influx into the LNG tank. The LNG tank manufacturer we spoke to stated that a complete loss of vacuum would cause frequent boil-off events to the point that the truck operator would likely immediately seek to have the problem remedied. The PRV manufacturer we spoke to said that there is not an off-the-shelf vacuum pressure detector that could be readily used for this service because of the ultra-cold temperatures involved. While leaks from CNG systems are likely to be detected from the odorant added to natural gas, LNG does not contain odorant after it was liquified. Thus, relying on the odorant to help find leaks is not a viable solution for LNG as CNG, unless if an odorant can be added to LNG after it was liquified. Again, these ideas require additional thought, analysis and perhaps some testing.

---

12.2.5 Aerodynamic Performance of Natural Gas Vehicles

**Organization:** PACCAR, Inc.

It is difficult for PACCAR or any OEM to assess the aerodynamic impact of dealer/body builder installed natural gas fuel tanks. PACCAR conservatively places these vehicles in Bin I for aerodynamics and therefore cannot obtain credits.

**Organization:** Volvo Group

Natural Gas Aerodynamic Impact

Because of the high volume tanks required for on-board compressed natural gas (CNG) fuel storage and the cylindrical shape required to contain high pressure, we are unable to use conventional aerodynamic treatments for CNG fueled tractors. In addition, the extra space required for CNG tanks increases the trailer gap, further increasing the vehicle drag. Under the Phase 1 rule, this has resulted in loss of credits for every CNG tractor sold. With the engine included as part of the vehicle simulation in Phase 2, we expect the lower GHG emissions from the NG engine to help offset the poor aerodynamics, but there is still some risk that this regulation could be detrimental to expansion of natural gas utilization if engine efficiency and methane emissions cannot achieve sufficient GHG advantage over diesel. [EPA-HQ-OAR-2014-0827-1290-A1 p.48]

**Response:**

We do not believe that natural gas vehicles inherently have worse aerodynamic performance. Rather, we believe aerodynamic inefficiency for current vehicles is a result of non-optimized designs. As natural gas comprises a larger portion of the fuels used by the heavy-duty truck sector, we expect that tractor cabs will be optimized to accommodate storage of natural gas without harming aerodynamic performance.

12.3 GHG Lifecycle Analysis for Natural Gas Vehicles

12.3.1 Methane GWP

**Organization:** Center for Biological Diversity

The EPA Must Promulgate Specific Lifecycle-Based Limits on Tailpipe Emissions from Natural Gas Vehicles and Engines

Several groups have undertaken detailed “well-to-wheels” analyses of the climate cost-benefit tradeoff for switching from gasoline or diesel to natural gas in the transportation sector using the most recent, research-based estimates of methane’s global warming potential (“GWP”) and atmospheric lifetime, upstream leakage rates from natural gas operations, and efficiency differences between diesel and natural gas engines. The overarching message is that with current technology switching to natural gas heavy-duty trucks will cause net harm to the climate in the coming decades to centuries. [EPA-HQ-OAR-2014-0827-1460-A1 p.15-16]

**Organization:** Environmental Defense Fund (EDF)

A. A new, more comprehensive lifecycle analysis of NGVs is needed
The agencies’ attempt to quantify the climate impact of natural gas trucks should be strengthened in several ways. The agencies relied exclusively on data from the Greenhouse Gas Inventory (GHGI), leading to a lifecycle analysis (LCA) that likely underrepresents the amount of methane emitted into the atmosphere across the natural gas supply chain. The agencies also relied on outdated Global Warming Potentials (GWPs) for methane, which do not reflect the latest available science on methane’s impact on the climate system. [EPA-HQ-OAR-2014-0827-1312-A1 p.39-40]

In the proposed Phase 2 standards, EPA takes critical steps in providing such an LCA. However, there are a number of areas for improvement, as highlighted in this paper, especially concerning sensitivity analyses related to upstream methane emissions, GWPs, and the carbon dioxide-credit program. [EPA-HQ-OAR-2014-0827-1312-A1 p.40]

B. Use the current and appropriate GWP values for methane emissions

Each greenhouse gas has its own potential to impact the climate, and those impacts can differ over time. To evaluate the climate impact of a non-CO2 greenhouse gas, such as methane, one methodology is to convert those emissions to a unit equivalent to CO2, using the GWP of the gas at issue. GWP is a measure of the climate forcing potential of a gas (such as methane) relative to CO2. [EPA-HQ-OAR-2014-0827-1312-A1 p.41]

The most recent IPCC establishes the 100-year GWP for methane at a figure of at least 28, meaning that methane is 28 times more potent than CO2 over a 100-year period. However, because methane causes greater climate damage over shorter rather than longer time frames, choosing a 100-year GWP will undervalue the short-term impacts of methane. Accordingly, the benefits of methane reductions should also be valued using the most recent 20-year GWP for methane, which is at least 84. [EPA-HQ-OAR-2014-0827-1312-A1 p.41]

These GWP values for methane (28 over 100 years and 84 over 20 years) are conservative because they do not include climate-carbon (“cc”) feedbacks (which are feedbacks between climate change and the carbon cycle). The latest IPCC report concludes that when cc is considered, methane has an even higher GWP on both 100- and 20-year timeframes of 34 and 86, respectively. Other scientific analyses have likewise determined that methane is an even more potent climate forcer. [EPA-HQ-OAR-2014-0827-1312-A1 p.41]

While EPA does consider both 20-year and 100-year GWPs in its LCA, the GWP values it uses should be updated to the estimates referenced above from the latest IPCC report. In addition, the shorter-term impacts of methane are important when comparing emissions from natural gas vehicles to that of diesel vehicles. In recent research, Camuzeaux et al. have found that switching from diesel to natural gas heavy-duty fleets could create damages to the climate for 50 to 90 years before the fuel switch would create any climate benefits, due to the short term impact of methane emitted to the atmosphere across the natural gas value chain. [EPA-HQ-OAR-2014-0827-1312-A1 p.41]

As a direct application of these considerations, we urge EPA to incorporate short-term GWPs when establishing the GHG equivalence value of methane within the rule’s carbon dioxide credit program. [EPA-HQ-OAR-2014-0827-1312-A1 p.41]

Organization: NGVAmerica

J. GWP Values for Methane (CH4) and N2O. EPA has proposed using the GWP values identified in the IPCC Fourth Assessment [EPA-HQ-OAR-2014-0827-1270-A1 p.8]
NGV America strongly supports the continued use of the GWP values used under the Phase 1 rules. These GWP values have long-standing acceptance and are used for purposes of the greenhouse gas regulations covering light and medium duty passenger cars, and also for numerous other EPA rules. Using these values provides consistency and uniformity across a number of regulatory programs and allows efficient comparisons across these regulatory programs. Therefore, we strongly urge EPA to continue to use the GWP values adopted under Phase 1. [EPA-HQ-OAR-2014-0827-1270-A1 p.8]

**Organization:** ICCT

Delgado and Muncrief (2015) determined that inadequate attention towards limiting methane leakage from heavy-duty natural gas vehicles (NGVs), could diminish the Phase 2 program benefits by as much as 38 percent in 2040, if there was a major breakthrough in NGV sales and using 20-year global warming potential for methane. We recommend that the agencies take every opportunity available within the purview of this regulation to minimize methane emissions throughout the value chain and to promote higher-efficiency natural gas engines. [EPA-HQ-OAR-2014-0827-1180-A4 p.17]

**Organization:** American Gas Association

Establishing a global warming potential (GWP) is a critical issue in any GHG program. EPA has wisely adopted a single GWP that it uses consistently in all of its programs and reporting obligations. More specifically, EPA consistently uses a 100-year GWP of 25 for methane. This GWP was established in the IPCC’s Fourth Assessment Report (AR4), which was published in 2007. We strongly support maintaining this approach for the Phase 2 Rule. [EPA-HQ-OAR-2014-0827-1223-A1 p.2]

Examples of EPA’s use of the AR4 GWP include: [EPA-HQ-OAR-2014-0827-1223-A1 p.2]

* The LD Phase 1 Rule, the LD Phase 2 Rule, and the HD Phase 1 Rule;5,6,7 [EPA-HQ-OAR-2014-0827-1223-A1 p.2]
* EPA’s Emissions Factors for Greenhouse Gas Inventories;8 [EPA-HQ-OAR-2014-0827-1223-A1 p.3]
* The recently-announced strategy to reduce methane from the oil and natural gas industry;9 [EPA-HQ-OAR-2014-0827-1223-A1 p.3]
* The national inventory of GHG emissions and sinks.11 [EPA-HQ-OAR-2014-0827-1223-A1 p.3]

In addition to ensuring internal consistency among EPA’s many greenhouse gas programs, maintaining the use of the AR4 GWP also enables EPA to coordinate its data with the data collected by EPA pursuant to its obligations under the United Nations Framework Convention on Climate Change (UNFCCC). Doing so “improves EPA’s ability to analyze corporate, national, and sub-national GHG data consistently, enhances communication of GHG information between programs, and gives outside stakeholders a consistent, predictable set of GWPs to avoid confusion and additional burden.”12 [EPA-HQ-OAR-2014-0827-1223-A1 p.3]

We strongly support the continued use of the AR4 GWP in this Proposal. Furthermore, we believe that changing the GWP should be an agency-wide decision, and not an outcome of any particular sector-specific rule. Anything else could result in a patchwork of inconsistent metrics being used across the array of EPA programs. [EPA-HQ-OAR-2014-0827-1223-A1 p.3]
WM Supports the Use of the Agency-wide GWP Value for Methane

WM supports the use of the global warming potential (GWP) for methane that was published in the Intergovernmental Panel on Climate Change (IPCC) Fourth Assessment Report (AR4). In 2014 revisions to the Federal Greenhouse Gas Reporting Rule program (GHGRP), EPA adopted the IPCC’s AR4 GWP values for selected GHGs and explained their adoption was to “increase the accuracy of the CO2e estimates collected under the GHGRP to better inform EPA policies. The AR4 GWPs will complement the reporting metrics used in other U.S. climate programs, including the Inventory that is submitted to the United Nations Framework Convention on Climate Change (UNFCCC).” [EPA-HQ-OAR-2014-0827-1214-A2 p.5]

Maintaining consistency across EPA climate programs and with the UNFCCC is essential to ensure the comparability and reliability of GHG measurement and reporting. Using consistent GWPs enables the agencies to review more efficiently data collected across multiple domestic climate programs, and to reduce the potential for errors. Use of consistent GWPs also reduce the burden for the regulated community and regulators that would need to track differing GWPs used across multiple federal programs. [EPA-HQ-OAR-2014-0827-1214-A2 p.6]

Parties to the UNFCCC, including the U.S., have agreed to submit annual reports in 2015 and future years using the GWP values from the IPCC AR4. The U.S. government has not agreed to change GWPs pursuant to subsequent IPCC assessment reports. We think it is wholly appropriate and consistent for OTAQ to continue using a methane GWP of 25, based on a 100-year timeframe. Should the Federal government determine that subsequent revisions to GWPs are appropriate; a broader rulemaking that encompasses all the domestic climate programs would be the appropriate mechanism to make that change – not the OTAQ rulemaking, which is narrowly focused on medium and heavy-duty truck emissions. [EPA-HQ-OAR-2014-0827-1214-A2 p.6]

GWP Values for Credit Programs: The agencies ask whether they should continue using the IPCC 4th Assessment Report values for relative global warming potentials on a 100-year timescale to calculate the credits for non-carbon dioxide gases. They should not. Under Executive Orders 12,866 and 13,563, agencies are required to use the “best available science” in rulemaking. The 4th Assessment Report is outdated and no longer reflects the global scientific consensus about relative global warming potentials. At a minimum, the agencies should update the values to reflect the IPCC 5th Assessment Report. Moreover, focusing solely on the 100-year timescale overlooks the more potent effects of some greenhouse gases, like methane, in the short term. The agencies should consider the 20-year timescale estimates. One option to consider might be averaging the 20-year and 100-year estimates.

5 Exec. Order No. 13,563 §1(a) (Jan. 18, 2011).

Response

The Phase 1 GHG rule included a compliance alternative allowing heavy-duty manufacturers and conversion companies to comply with the respective methane or nitrous oxide standards by means of over-complying with CO₂ standards (40 CFR 85.525). More specially, EPA allows manufacturers to use CO₂ credits (generated from the same averaging set) to comply with the methane and nitrous oxide

Organization: Waste Management (WM)

Organization: Institute for Policy Integrity at NYU School of Law
requirements after adjusting the CO\textsubscript{2} emission credits based on the relative GHG equivalents. To establish the GHG equivalents used by the CO\textsubscript{2} credits program, the Phase 1 heavy-duty vehicle rulemaking incorporated the IPCC Fourth Assessment Report GWP values of 25 for CH\textsubscript{4} and 298 for N\textsubscript{2}O, which are assessed over a 100 year lifetime. EPA is largely continuing this allowance for Phase 2.

Since the Phase 1 rule was finalized, a new IPCC report has been released with new GWP estimates. EPA asked for comment on whether the methane GWP used to establish the GHG equivalency value for the CO\textsubscript{2} Credit program should be updated to those established by IPCC in its Fifth Assessment Report (AR5). The IPCC AR5 presents four different potential values for the GWP of methane over a 100 year lifetime, ranging from 28 to 36. These values are the result of slightly different calculation methods. Therefore, we not only requested comment on whether to update the GWP for methane to that of the AR5, but also on which value to use from this report. The GWPs of 28 and 30 are both a result of using a carbon cycle approach consistent with that used in the Fourth Assessment Report. This carbon cycle approach included a climate-carbon feedback when calculating the lifetime of a pulse of carbon dioxide emissions, but did not include any climate-carbon feedback when calculating the impacts of a pulse of non-CO\textsubscript{2} greenhouse gas emissions. As the GWP is the ratio of the impact of a pulse of non-CO\textsubscript{2} GHG emissions relative to a pulse of carbon dioxide emissions, a second approach was presented where the non-CO\textsubscript{2} GHG pulse also included climate-carbon feedbacks. This second approach yields GWP values of 34 or 36. For the purposes of this rule, EPA is choosing the approach that includes climate-carbon feedbacks for both non-CO\textsubscript{2} and CO\textsubscript{2} pulses, as the agency considers this the approach most likely to be adopted by the international scientific community in future assessments on the timescale of this rule. The IPCC presents the value of 34 as the default value for the methane GWP, but also reports a value of 36 for “fossil” methane to take into account the atmospheric CO\textsubscript{2} that would result from the oxidation of methane in the atmosphere.

We received a number of comments on this issue. For the most part, the environmental community favored using the more recent GWP value and even some commented that EPA should use a methane GWP based on a 20 year timeframe. On the other hand, the natural gas industry and natural gas truck manufacturers commented that EPA should not update to the newer GWP values but continue to use the methane GWP value from the AR4 IPCC report because EPA is still using the methane GWP from the AR4 today in other contexts. Although EPA is currently using AR4 values in other contexts, it is unlikely that EPA will still be using AR4 values in 2021 when the Phase 2 requirements begin. Thus, commenters opposing the use the methane GWP from the later IPCC report are not persuasive. EPA will continue to base the credit adjustment on a 100 year timescale because it seems to best balance short-term versus long-term effects of climate change.

Of the possible 100 year methane GWP values presented in the IPCC AR5 report, EPA is choosing to use the value of 34 because it is the primary value presented by the IPCC and because the approach of not accounting for the CO\textsubscript{2} oxidation product within the GWP for methane is consistent with prior IPCC practice.\textsuperscript{231} The use of this GWP for credit adjustments will not begin until 2021, when the Phase 2 engine standards go into effect. The choice of this GWP value for future rules on this timescale does not prejudice the choice of other GWP values for use in regulations and other purposes in the near term.

To be consistent across all its programs and reporting, EPA is using the global warming potentials (GWP) based on the AR4 IPCC report for our analyses in this rulemaking. An important driver for using the AR4 values for GWPs is the United Nations which requires that individual nations report their GHG emissions to the United Nations Framework Convention for Climate Change (UNFCCC) using

\textsuperscript{231} The corresponding N\textsubscript{2}O value from the AR5 report is 298, which is the same as the value used in Phase 1.
GWP values from the AR4 IPCC report and based on 100 year time period. EPA updated to the GWP values in IPCCs AR4 report when the UNFCCC decided to use the GWP values from that report.

The agencies understand that methane’s GWP varies based on the time periods over which the heat trapping impact of methane is evaluated. EPA uses 100 years as the timeframe for evaluating GHG impacts in unity with the reporting requirements to the UN and because it seems to provide the best compromise between the short term and the long term effects of climate change. To show the effect that different GWPs based on different timeframes have on the lifecycle impact, the agencies also provided lifecycle comparisons between natural gas heavy-duty trucks and diesel fuel heavy-duty trucks when methane and nitrous oxide are evaluated over 20 year and 500 year timeframes. See RIA 13.1.4.

12.4 Other Lifecycle Comments

Organization: American Gas Association (AGA) et al.

We recommend that the agencies remove the GHG Lifecycle Analysis for Natural Gas Vehicles

Since the first Clean Air Act regulations were adopted more than forty years ago, EPA has adopted emissions standards for vehicles without considering the upstream impacts of the fuels used in those vehicles. Instead, EPA’s approach has been to regulate upstream emissions at the source. [EPA-HQ-OAR-2014-0827-1223-A1 p.8]

In this Proposal, the agencies have stated that “compliance is based on vehicle fuel consumption and GHG emission reductions, and does not reflect any so-called lifecycle emission properties.” We strongly agree with this approach. [EPA-HQ-OAR-2014-0827-1223-A1 p.8]

Nevertheless, the agencies have asked for comments on including a GHG lifecycle analysis for natural gas vehicles in the Proposal as well as the Draft Regulatory Impact Analysis (DRIA). [EPA-HQ-OAR-2014-0827-1223-A1 p.8]

We recommend that the agencies remove the GHG lifecycle analysis for natural gas vehicles from both the Proposal and DRIA unless they include a GHG lifecycle analysis for all fuels used by trucks to be regulated by the final rule, i.e., gasoline, diesel, natural gas, electric, and fuel cells. We believe that either approach would enable the agencies and the general public to more accurately compare fuels being used in the truck and bus sectors. Including a GHG lifecycle analysis only for natural gas vehicles will be prejudicial to the use of natural gas vehicles in those settings where it is cost-effective to do so, and incorrectly implies that other fuels do not have upstream emissions impacts or other lifecycle impacts that should be considered. [EPA-HQ-OAR-2014-0827-1223-A1 p.8]

If the agencies decide to include a lifecycle analysis in the Proposal and DRIA, we request the opportunity to provide additional data or other materials to the agencies after the close of the comment period, and to continue the dialogue about this issue thereafter. [EPA-HQ-OAR-2014-0827-1223-A1 p.8]

25 Methane may be present in very small amounts if exhaust gas recirculation (EGR) is used.

30 Phase 2 Proposal, page 40159.
B. EPA Must Take a Coherent Approach to Regulating Upstream Emissions from Vehicles

The Proposed Rule extensively analyzes upstream and downstream emissions related to natural gas vehicles. EPA utilizes 2012 methane emission estimates from the most recent GHG Inventory report and ‘[r]ather than attempt to disaggregate [specific emissions from different equipment used in natural gas production] from the rest of process emissions in the GHG Inventory . . . used the estimated emissions for these sources provided by GREET.’ EPA also totaled CO2 and nitrous oxide emissions for the upstream and downstream portions of the natural gas system and converted these values into CO2 equivalents. EPA then compared the life cycle emissions of natural gas against the base fuel it was replacing, diesel. Additional analysis was completed as between different types of natural gas vehicles. Although EPA does not propose provisions to address or account for such emissions, the agency does ask for comment as to ‘[w]ould it be appropriate to adjust the tailpipe GHG emission standard for natural gas vehicles by a factor to reflect the life cycle emissions of natural gas vehicles relative to diesel vehicles?’ [EPA-HQ-OAR-2014-0827-1275-A1 p.12]

The treatment of natural gas vehicles in the Proposed Rule demonstrates two things. First, EPA believes that it is entirely capable of assessing complex information regarding upstream emissions. The agency examined various technologies and made use of existing inventory information and other assessments of the GHG impacts of producing, transporting and using natural gas in medium- and heavy-duty vehicles. Second, EPA believes that the information contained in the Proposed Rule is sufficient to allow for a final rule that addresses such life cycle emissions. Specifically, EPA indicates that ‘we may consider adopting such provisions in the final rule . . .’ [EPA-HQ-OAR-2014-0827-1275-A1 p.12-13]

While AISI takes no position on whether EPA should promulgate such natural gas standards in the final rule, it would be arbitrary for EPA to address some life cycle emissions while ignoring information submitted in our comments and elsewhere regarding the benefits of addressing the life cycle emissions of materials. Such a disparate treatment could not be justified on the basis of the available information. Information regarding energy used (and other life cycle impacts) to produce steel is of high quality and compares favorably with the information that EPA relies on to assess GHG emissions associated with upstream natural gas production. Similar high quality information about other heavy truck materials is available. [EPA-HQ-OAR-2014-0827-1275-A1 p.13]

Organization: American Iron and Steel Institute

Natural Gas Carbon Footprint Should Exclude Upstream Emissions

ATA supports the long-standing practice of only regulating tailpipe emissions as opposed to accounting for the life-cycle carbon footprint associated with natural gas combustion. Assessing and determining upstream emissions is an extremely complicated undertaking. State and federal regulations are, or will soon, address upstream carbon emissions both at production and distribution networks. Therefore, we support the decision not to include upstream emissions in the standards used to regulate motor vehicles and engines. [EPA-HQ-OAR-2014-0827-1243-A1 p.22]
Neutral/Provide Additional Information Comment

Comment – Phase 2 standards apply exclusively at the vehicle tailpipe and do not reflect lifecycle emissions

CARB staff understands the reasoning behind U.S. EPA and NHTSA’s proposal to apply Phase 2 standards exclusively at the vehicle tailpipe (rather than reflecting full lifecycle emissions), in order to better harmonize the fuel efficiency and GHG emission standards. CARB staff also appreciates the inclusion of a lifecycle analysis for natural gas and diesel trucks, even though the proposed standards are tailpipe only, as it illustrates the relative GHG benefits of different vehicle/fuel combinations and the potential reduction in the tailpipe GHG benefits of CNG due to methane leakage during refueling or LNG boil-off as the vehicle sits idle. [EPA-HQ-OAR-2014-0827-1265-A1 p.160]

CARB staff suggests including BEVs and FCEVs in the lifecycle analysis. Those technologies are extremely efficient at utilizing energy for motive power and the lifecycle results are compelling. GVWR are expected to produce significantly less GHG emissions than similar MY conventional diesel fueled trucks on a WTW basis. [EPA-HQ-OAR-2014-0827-1265-A1 p.160]

Oppose/Requested Change Comment

Comment – Natural gas engines must meet the Phase 2 diesel or gasoline tailpipe CO2 standards

According to the NPRM, natural gas engines must meet the Phase 2 diesel or gasoline standards (depending on the service application) and fuel consumption is then calculated according to their tailpipe CO2 emissions. This would likely create a small balanced incentive for natural gas use. A natural gas vehicle that achieves approximately the same fuel efficiency as a diesel powered vehicle would emit 20 percent less CO2; a natural gas vehicle with the same fuel efficiency as a gasoline vehicle would emit 30 percent less CO2. [EPA-HQ-OAR-2014-0827-1265-A1 p.160-161]

CARB staff believes that future natural gas engines, if certified to one of CARB’s optional NOx standards and operated on renewable natural gas, would reduce both NOx and GHG emissions. Many stakeholders are advocating for broad use of natural gas vehicles in California, particularly in the South Coast Air Basin and other areas that need near-term NOx reductions to meet federal ozone ambient air quality standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.161]

However, as shown in U.S. EPA and NHTSA’s lifecycle analysis, if methane emissions from the vehicle and from upstream production and distribution are not well controlled (for example, boil-off from LNG vehicles that are parked for multiple days), natural gas engines have the potential to actually increase GHG emissions. It is important to strengthen natural gas engine and vehicle requirements to ensure we maximize the benefits of the cleaner fuel as well as the most efficient vehicle technology. CARB staff will continue to work with U.S. EPA and NHTSA as well as engine and vehicle manufacturers to require the use of efficient engine and vehicle technology, reduce NOx emissions, and minimize fugitive methane emissions. Additional comments on requirements are also included. [EPA-HQ-OAR-2014-0827-1265-A1 p.161]
Comment – Lifecycle emissions incorporated into the certification level

Based on U.S. EPA and NHTSA’s lifecycle analysis, the impact of leaks and other methane emissions that occur upstream of the vehicle can potentially be large enough to more than offset the CO2 benefit of natural gas vehicles as measured at the vehicle tailpipe. U.S. EPA and NHTSA are considering separate action to control these upstream emissions. U.S. EPA and NHTSA are concerned that the high-GWP of methane makes even small leaks of natural gas of concern. The NPRM requests comment on whether it would be appropriate to adjust the tailpipe GHG emission standard for natural gas vehicles to reflect the relative lifecycle emissions relative to diesel. [EPA-HQ-OAR-2014-0827-1265-A1 p.161-162]

U.S. EPA and NHTSA state that if, for example, they were to determine that the lifecycle climate impacts of natural gas vehicles were 150 percent of the tailpipe GHG emissions, while the lifecycle climate impacts of diesel vehicles were 135 percent of the tailpipe GHG emissions, they could approximate the relative climate impacts by setting the natural gas tailpipe emission standard 10 percent lower than the diesel tailpipe standard. U.S. EPA and NHTSA state “We recognize that there is significant uncertainty in assessing these relative climate impacts, and that they could change as new production methods and/or regulations go into effect. Thus commenters supporting making such an adjustment are encouraged to address this uncertainty. Commenters are also encouraged to address how such an adjustment for GHG emissions would impact the closely coordinated EPA and NHTSA heavy-duty Phase 2 program including how a potential adjustment for upstream methane emissions for natural gas fueled vehicles would impact the coordination of EPA GHG regulations with the NHTSA fuel consumption regulations.” [EPA-HQ-OAR-2014-0827-1265-A1 p.162]

CARB staff believes that future natural gas engines, if certified to one of CARB’s optional NOx standards and operated on renewable fuels, have the potential to reduce both NOx and GHGs and provide needed near term reductions. To ensure those reductions are realized, it is important to strengthen natural gas engine and vehicle requirements to maximize the benefits of the cleaner fuel as well as the most efficient vehicle technology. CARB staff believes it is appropriate to have separate standards for natural gas engines and also important that actions be taken to minimize methane emissions from both the vehicle and the upstream natural gas production and distribution system. Steps to minimize emissions from the vehicle should include requiring a closed crankcase, limiting boil-off from LNG vehicles, and limiting tailpipe methane and N2O. Additional comments on requirements are also included. [EPA-HQ-OAR-2014-0827-1265-A1 p.162]

Neutral/Provide Additional Information Comment

Comment – Supplemental and clarifying information regarding WTW analysis of CNG and LNG and comparison to CARB results.

CARB staff has four main comments regarding the WTW analysis presented in the NPRM: [EPA-HQ-OAR-2014-0827-1265-A1 p.167]
1. The analysis should use GREET’s U.S. diesel result, and should identify the version of GREET used. U.S. EPA and NHTSA use a 2005 NETL analysis to determine the carbon intensity of U.S. diesel. Given that a version of Argonne National Laboratory’s GREET model was used for the majority of U.S. EPA and NHTSA’s WTW natural gas analysis, CARB staff recommends using the result from the same version of GREET for diesel. If they are based on a different baseline, the results should not be expressed in percent reduction from diesel; it would be preferable to use the same U.S. diesel baseline, or just report the carbon intensity directly. Also, the NPRM does not identify the version of the GREET model used in U.S. EPA and NHTSA’s WTW analysis of natural gas fuels (first mention of the use of the GREET model occurs on page 40404). Argonne National Laboratory releases an update nearly every year and 2013-2014 versions included changes to natural gas systems, so it is important to note the model year. [EPA-HQ-OAR-2014-0827-1265-A1 p.167]

2. USEPA accurately portrays CARB’s August 2014 WTW analysis, but we would like to share some updated information based on our work since then. On page 40508-40509, the NPRM presents draft results from CARB’s August 2014 WTW analysis. CARB staff has since finalized its estimates of WTW carbon intensity for CNG and LNG: without adjusting for natural gas vehicle fuel economy, the carbon intensity of CARB’s North American natural gas to CNG pathway is 78.36 gCO2e/MJ, or 76.82 percent of CARB-ULSD WTW emissions and the carbon intensity of CARB’s North American natural gas to LNG pathway is 84.55 gCO2e/MJ, or 82.89 percent of CARB- Ultra Low Sulfur Diesel (ULSD) WTW emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.167-168]

3. U.S. EPA and NHTSA’s WTW analysis results in the NPRM are similar to CARB’s and where they differ, the differences are primarily due to unique California circumstances. CARB staff agrees that the U.S. EPA and NHTSA’s results “are very similar to those estimated by CARB and when there are differences, the differences are as expected.” [EPA-HQ-OAR-2014-0827-1265-A1 p.168]

CARB staff believes that the carbon intensity of CNG determined by U.S. EPA and NHTSA is lower than the result in CARB’s analysis primarily because the transmission distance from Western U.S. natural gas sources to end users in California is greater than the national average. [EPA-HQ-OAR-2014-0827-1265-A1 p.168]

CARB staff estimates the carbon intensity of LNG to be lower than U.S. EPA and NHTSA’s analysis, due to the following factors: [EPA-HQ-OAR-2014-0827-1265-A1 p.168]

- CARB staff assumes a typical liquefaction stage thermal efficiency of 90 percent (resulting in 8.44 gCO2e/MJ for the liquefaction stage), rather than 80 percent (which would result in 18.29 gCO2e/MJ using California grid electricity), reflecting an assumption that most LNG used in California is produced at large centralized facilities. Under the LCFS, each LNG producer must demonstrate the actual efficiency, meaning some individual LNG pathways will result in higher WTW emissions than given in CARB’s illustrative scenario;
- CARB staff does not quantify any venting from the refueling or the vehicle operation stages due to lack of data, but does not disagree with the sensitivity analysis used by U.S. EPA and NHTSA; and
- There may be differences in the mode and distance of LNG transport; the U.S. EPA and NHTSA document does not provide sufficient information to determine the transportation and distribution assumptions or their resulting impacts.

4. CARB staff does not recommend U.S. EPA and NHTSA rely on the U.C. Davis study referenced on page 40509 of the NPRM, as we believe that study is flawed. The U.C. Davis study
used GREET 2014 to explore the role of natural gas in the U.S. trucking industry, and reported that:

(A) CNG has higher WTW GHG emissions than LNG, and [EPA-HQ-OAR-2014-0827-1265-A1 p.169]

(B) CNG and LNG have higher WTW GHG emissions relative to diesel when used in spark-ignited engines (with EER=0.9). [EPA-HQ-OAR-2014-0827-1265-A1 p.169]

CARB staff disagrees with this analysis and finds that under most scenarios, when a methane GWP of 25 is used, both CNG and LNG have a life cycle GHG benefit over diesel. CARB staff believes the UC Davis report reached incorrect conclusions due to using flawed assumptions, including inappropriately using default transport parameters in GREET 2014 (which tend to reduce assumed LNG transport emissions), incorrect assumptions regarding the efficiency of LNG-fueled heavy-duty pilot ignition engines, and not quantifying losses from the LNG vehicle tanks, among others. [EPA-HQ-OAR-2014-0827-1265-A1 p.169]

Oppose/Requested Change Comment

Comment – Supplemental and clarifying information regarding CARB analysis

There is a misprint/typo on page 13-22: [EPA-HQ-OAR-2014-0827-1265-A1 p.169]

For the CARB emissions estimates, we used the estimates made for what it terms purposes” using the 2013 version of the CARB GREET model as published in August, 2014. [EPA-HQ-OAR-2014-0827-1265-A1 p.169]

CARB staff believes this should read: [EPA-HQ-OAR-2014-0827-1265-A1 p.170]

For the CARB emissions estimates, we used the estimates made for what it terms “illustrative purposes” using the 2013 draft version of the CA-GREET2.0 model as published in August, 2014. [EPA-HQ-OAR-2014-0827-1265-A1 p.170]

Regarding the statement comparing CARB and U.S. EPA results on page 13-22, “CARB estimates that CNG engines emit 76 percent of the CO2eq emissions as a diesel truck, while our analysis estimates that CNG engines emit 81 percent of the CO2eq emissions as a diesel truck,” the “percent of diesel emissions” basis does not provide a direct comparison of the CNG results, as CARB and U.S. EPA do not use the same diesel emissions as baseline. In the CA-GREET2.0 analysis, CARB-ULSD was determined to have a carbon intensity of 102.01 gCO2e/MJ, while U.S. EPA and NHTSA appear to use approximately 93 gCO2e/MJ as a baseline (98,000 g/MMBtu, estimated from Figure 13-2 of the RIA). [EPA-HQ-OAR-2014-0827-1265-A1 p.170]

While CARB staff does not object to the value used as a diesel baseline (this value is meant to reflect the national average WTW emissions of diesel fuel and CARB staff can provide no insight on the accuracy of results outside of California), we suggest that CNG, LNG and diesel should be compared using the same model in order to obtain the most robust results. Given that a version of Argonne National Laboratory’s GREET model was used for the majority of U.S. EPA and NHTSA’s WTW natural gas analysis, we recommend using the result from the same version of GREET for diesel. [EPA-HQ-OAR-2014-0827-1267 p.170]
The parameters used to determine methane leakage, LNG boil-off, process energy demand, and the impacts of these inputs are presented clearly and comprehensively; however, the NPRM do not provide information on the transportation and distribution assumptions or resulting impacts modeled for the CNG or LNG pathways. These transport modes and distances are a major driver of the difference between the GREET and CA-GREET2.0 model results. If default transport parameters from GREET 2014 were used in U.S. EPA and NHTSA’s analysis, the following table provides a breakdown and contrast of the differences in the two models. [EPA-HQ-OAR-2014-0827-1265-A1 p.170]

[Table 17 can be found on p.171 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

65 This is because natural gas has lower carbon content than either diesel or gasoline.

66 See http://www.arb.ca.gov/msprog/onroad/cert/mddehdhv/2016/cummins mhd 0210630 8d9 0d20-0d01 ng.pdf and http://www.arb.ca.gov/msprog/onroad/cert/mddehdhv/2016/cummins ub 0210629 8d9 0d20-0d01 ng.pdf for Cummins natural gas certification on 8.9L engines to 0.02 g/bhp-hr NOx standard, September 2015.

67 CARB staff finds the WTW emissions of California ULSD to be 102 g CO2e/MJ, approximately 9 gCO2e/MJ higher than the value U.S. EPA uses to represent the WTW emissions of average U.S. diesel (approximately 93 gCO2e/MJ or 98,000 g/MBtu, which we estimate from Figure 13-2 of the RIA). This lack of common baseline confounds the comparison between the NPRM’s and CARB’s results for natural gas fuels.

**Organization:** Center for Biological Diversity

**The EPA Must Promulgate Specific Lifecycle-Based Limits on Tailpipe Emissions from Natural Gas Vehicles and Engines**

As currently proposed, the Phase 2 standards tailpipe methane would be maintained at Phase 1 levels (0.1 g/bhp-hr or 0.5 g/mi) and CO2 emissions limits for natural gas vehicles and engines would be the same as those that apply to diesel engines. The only difference would be the requirement for closed crankcases on natural gas engines. This is an important step as it can reduce the amount of methane that is emitted during operation of the engine. But closure of crankcases is only one of a number of technology options that should be considered to reduce methane emissions during operation, including more effective methane catalysts and elimination of dynamic venting. [EPA-HQ-OAR-2014-0827-1460-A1 p.15]

The EPA is proposing to require manufacturers to follow the industry standard of a 5-day or less holding limit for LNG vehicles, which we support. The EPA also requested comment regarding other measures to limit boil-off events and associated emissions from LNG vehicles. The Center urges the EPA to require on-board monitoring and warning systems. In addition, we support the EPA in its intention to reduce fugitive methane emissions during refueling. [EPA-HQ-OAR-2014-0827-1460-A1 p.15]
On the other hand, we have grave concerns with the EPA’s proposal to allow natural gas vehicles to be treated as diesel engines for the purpose of tailpipe emissions. The EPA notes that per unit of fuel consumed, natural gas vehicles are able to meet the same tailpipe efficiency standard more easily than a gasoline or diesel engine, creating an “incentive” for natural gas vehicles. The Proposed Rule asserts that this is an “appropriate” balance between climate and energy security, but the Center strenuously disagrees. [EPA-HQ-OAR-2014-0827-1460-A1 p.15]

A single tailpipe standard does not account for the difference in upstream emissions between natural gas and diesel; nor does it account for the reduced work efficiency of natural gas as opposed to diesel engines. The large difference in upstream emissions and the potency of methane as a global warming pollutant necessitates a separate natural-gas specific standard. [EPA-HQ-OAR-2014-0827-1460-A1 p.15]

The Proposed Rule and Draft Regulatory Impacts Analysis (“RIA”) also include a lifecycle analysis for natural gas and diesel engines. The EPA performed a sensitivity analysis for differing thermal (work) efficiencies as well as for different methane global warming potentials. One of the largest influences comes from choice of GWP, which we address below. Another key predictor is whether the vehicle is in compliance with the 2014 and beyond methane tailpipe standards. [EPA-HQ-OAR-2014-0827-1460-A1 p.16]

The question of compliance with methane tailpipe standards is particularly relevant to the Proposed Rule. Post-2014 vehicles theoretically must comply with the Phase 1 methane tailpipe standards, although over 90 percent of vehicles on the road are older vehicles that do not have to comply with the standard. Furthermore, due to credits and trading provisions, manufacturers of new engines can – and do – avoid complying with the standard by applying credits generated from conventional engines. As the Proposed Rule indicates, manufacturers to date are solely applying credits and continuing to build natural gas engines that have high methane emissions: 2 g/bhp-hr as opposed to the 0.1 g/bph-hr 2014 standard. This is a massive and unacceptable volume of excess methane. As such, the trading provisions that allow the application of CO2 credits to methane should be abolished, or in the alternative, credits should be translated using an accurate 20-year methane GWP that includes carbon cycle feedbacks (see discussion below). [EPA-HQ-OAR-2014-0827-1460-A1 p.16]

The EPA’s sensitivity analysis for lifecycle methane emissions also failed to include a key parameter: natural gas methane leakage rates. The recent literature indicates that the leakage rates assumed by the EPA are significant underestimates. If the leakage rates were appropriately adjusted to reflect current data, the lifecycle emissions for natural gas vehicles would be well above those of diesel engines. These data are reviewed below. [EPA-HQ-OAR-2014-0827-1460-A1 p.16]

The Proposed Rule does raise the possibility of a standard that is weighted by the difference between upstream and downstream emissions for natural gas as opposed to diesel vehicles. We support a weighted standard so long as the most current research findings are used to assess the life-cycle emissions for each fuel. In the sections below we review the current research. [EPA-HQ-OAR-2014-0827-1460-A1 p.16]

The Upstream Methane Emissions from Natural Gas Are Larger than Current EPA Emission Factors

The other key factor in determining climate impacts from the use of natural gas is upstream methane emissions, i.e., leaking and venting during extraction, processing, storage and transmission of natural gas. The EPA has standard emission factors of 1.14 percent for conventional gas and 1.2 percent for
shale gas. These are based on “bottom up” estimates of leakage and venting. The recent literature, however, is rife with top down and analytical studies of methane leakage that show significantly higher levels of methane leakage from natural gas operations – two-fold or more. [EPA-HQ-OAR-2014-0827-1460-A1 p.17-18]

For instance, Miller and colleagues recently used atmospheric measurements to estimate that actual methane emissions are about 1.5 times larger than EPA estimates. Observations from oil and gas operations in Colorado indicate that inventories underestimate methane emissions by at least a factor of two. Leakage rates over a Utah gas field were recently estimated at 6.2 to 11.7%, well above the rates assumed by national inventories. A study of leakage rates in the Barnett Shale region of Texas indicated that leakage rates were 1.5 to over 4 fold higher than EPA estimates, especially at gathering compressor stations. A more detailed study of methane emissions from natural gas gathering and processing found that methane leakage rates were double the rate EPA assumes for the U.S. Greenhouse Gas Inventory, resulting in a volume of methane that is one-third the total emissions estimated for all natural gas operations. This discrepancy was due primarily to large rates of leakage from gathering stations, which are not subject to separate emissions quantification for the purposes of the EPA’s U.S. Greenhouse Gas Inventory. [EPA-HQ-OAR-2014-0827-1460-A1 p.18]

Moreover, EPA’s data for oil and combined oil/gas wells omit the impact of hydraulic fracturing. A recent white paper from Environmental Defense Fund summarizes findings from a number of studies to conclude that emissions factors used in EPA’s current inventory underestimate methane emissions from oil wells that employ hydraulic fracturing. Hydraulic fracturing and associated techniques are widespread and continue to expand at a rapid pace, making it all the more necessary that EPA update its emission factors, which were developed for conventional wells. [EPA-HQ-OAR-2014-0827-1460-A1 p.18]

Another major source of methane emissions from the oil and gas sector is leaks from pneumatic devices. A recent study calculated emission factors for pneumatic devices to find that national emissions from this source are likely at least twice the amount predicted using the emission factors in the U.S. Greenhouse Gas Inventory. [EPA-HQ-OAR-2014-0827-1460-A1 p.18-19]

Recent reports have also substantiated an alarming rate of leaks from decaying gas pipeline systems across the country, creating the need for systematic, on-the-ground data collection to obtain an accurate quantification of emissions from this source. For example, according to a recent study, the two distributors of natural gas in New York City and Westchester County reported 9,906 leaks in their combined system for 2012 alone, and gas distributors nationwide reported an average of 12 leaks per 100 miles of the 1.2 million miles of gas main pipes across the country. More than 5,800 leaks were detected from aging gas pipelines underneath the streets of Washington, D.C. These samples indicate that EPA’s data are incomplete, and we urge the EPA to note this fact. [EPA-HQ-OAR-2014-0827-1460-A1 p.19]

Finally, a recent study raised the possibility that sensors used to measure methane leakage for the purpose of “bottom-up” inventories, such as those compiled by the EPA, may have fundamental flaws such that methane will be consistently under-estimated. [EPA-HQ-OAR-2014-0827-1460-A1 p.19]

The EPA has requested input regarding the treatment of uncertainty related to methane emissions. At the outset, it should be noted that there is now such a large body of evidence that EPA’s emission factors underestimate actual fugitive methane from natural gas operations that the “uncertainty” surrounds not the discrepancy between the emission factors and actual leakage, but the magnitude of said discrepancy. With regard to selecting new emission factors, the Center advocates for an approach that raises the
emission factors by a multiplier that harmonizes the peer-reviewed literature, giving particular emphasis
to top-down studies and selecting a multiplier in the range most often reported in the literature. On a
longer-term basis, we recommend that the EPA undertake an independent, detailed and reliable study of
methane leakage rates that could be used to modify and verify the current best available values. [EPA-

In sum, a complete and accurate well-to-wheels analysis is absolutely crucial to ensure that natural gas
gases, which are increasing in market share, do not undermine the potential benefits of the proposed
standards. Multiple studies have come to the conclusion that switching to natural gas transportation can
hasten climate change, especially in the near term. One study found that climate benefits could be
eroded by as much as 39 percent.97 This robust result underscores the need to ensure that from this point
forward natural gas engines are not incentivized, but rather placed on an even playing field with

Organization: Clean Energy

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p.251.]

Lastly, we appreciate the scope of the rule, which looks more at the tailpipe emissions, rather than lifecycle emissions, which we believe should be addressed but in other regulatory frameworks.

Organization: Enovation Controls (ENC)

2.1 Lifecycle Analysis for GHG - It is inaccurate to suggest any significant impact to the overall GHG impact of Natural Gas production resulting from use in on-highway vehicles. First, natural gas combustion results in less CO2 than traditional fossil fuel per unit of usable energy. The chemical makeup of natural gas, which is mostly CH4, readily lends itself to producing more water and less CO2 as a result of the combustion process when compared to diesel and gasoline. Second, fugitive methane emissions result from both oil and natural gas production process from well to end user - excluding any naturally-occurring methane production. [EPA-HQ-OAR-2014-0827-1203-A1 p.1]

Considering only natural gas production, vehicle-specific natural gas usage is a small fraction of total US natural gas use. As of 31-July-2015, the US Energy Information Administration tracked that in 2014, 0.12% of natural gas consumption in the US is consumed in vehicle power (32,850 Mmcf for vehicle power compared to total consumption of 26,818,618 Mmcf). Figure 1 shows the trend of vehicle-related natural gas consumption in the US. Even the most aggressive extrapolation of the trend would result in minor impact to overall natural gas consumption by vehicles. [EPA-HQ-OAR-2014-0827-1203-A1 p.1-2]

[Figure 1 can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-1203-A1]
ENC submits that lifecycle analysis for GHG focused on methane emissions does not belong in the Phase 2 proposal. It is sufficiently and appropriately addressed in EPA-HQ-OAR-2010-0505-4776 with a holistic approach to all fugitive methane emissions. [EPA-HQ-OAR-2014-0827-1203-A1 p.2]

**Organization:** Environmental Defense Fund (EDF)

Based on evaluation of these options against the guiding principles stated above, the best overall options appear to be Option 1 or 2 (without refueling and boil-off emissions), in conjunction with Option 5 (to account for refueling and boil-off emissions). Option 1 or 2 can be implemented based on the precedent of the EV compliance factor used in the LD GHG rules. Following this precedent provides a lot of benefits in considering an upstream compliance approach for the Phase 2 rule. Under Options 1 or 2, an upstream compliance factor would be established as part of the compliance framework, providing regulatory stability to manufacturers for product planning. The tailpipe standard would be left intact, preserving consistency with the NHTSA fuel economy rule. These options can be applied to any of the fuels, and provide incentive to reduce upstream emissions where higher than those for conventional diesel. The primary difference between Options 1 and 2 is the focus on natural gas; Option 1 would consider only methane, and while applying to all fuels it would clearly be most stringent for natural gas trucks, out of concern that upstream methane emissions will undercut lower tailpipe CO2 emissions.

Option 2 provides a more fuel-neutral option, in that upstream emissions for all GHGs would be assessed, allowing more tradeoff between CH4, CO2 and N2O, which will help level the playing field more across different fuels.[EPA-HQ-OAR-2014-0827-1312-A3 p.9]

In conjunction with Options 1 or 2, Option 5 then provides a means to incentivize reductions in refueling and boil-off emissions on LNG trucks. This option can be designed off of the A/C credit program used for LD vehicles, which provides a template for successful implementation. A challenge will be establishing a test procedure or model to determine credits for emission reduction technologies, and verify these emission reductions. Test procedures in place for evaporative and refueling emissions from gasoline vehicles may be adaptable to natural gas vehicles. The physical nature of vapor emissions also lends itself well to development of a compliance model, similar to GEM.[EPA-HQ-OAR-2014-0827-1312-A3 p.9]

Overall, our assessment finds that upstream emissions can be accounted for in the Phase 2 rule, following the precedents established in the LD GHG rules. Concerns with the potential magnitude of GHG emissions in lifecycle emissions, especially for natural gas trucks, suggests that these emissions should be directly accounted for in some way in the Phase 2 rule.[EPA-HQ-OAR-2014-0827-1312-A3 p.9][See EPA-HQ-OAR-2014-0827-1312-A2]

**B. EDF supports accounting for upstream methane emissions from natural gas**

The agencies have requested comment on accounting for upstream emissions in the standards for natural gas and other trucks, and we urge the agencies to finalize a rule that includes such accounting. Reducing upstream emissions from natural gas trucks is integral to ensure the final program delivers on its climate protection goals. A recent ICCT study found that “inadequate attention to technologies designed to limit methane leakage ... would diminish the program benefits by as much as 38 percent.”73 By including the upstream emissions from natural gas trucks in the final program, the agencies will strengthen the integrity of the program. We provide recommendations for improving the methodology in Section VII below. [EPA-HQ-OAR-2014-0827-1312-A1 p.16]

**Final rule must ensure fuel savings and greenhouse gas reductions from natural gas vehicles**
Diesel is the current dominant fuel for heavy trucks. While it is likely to remain the most widely used fuel throughout the Phase 2 proposal, gasoline and natural gas are each making inroads in different market segments. EPA should ensure that these other technologies are likewise subject to rigorous environmental standards. [EPA-HQ-OAR-2014-0827-1312-A1 p.39]

EDF is particularly concerned about the ability of natural gas trucks to deliver real-world greenhouse gas reductions. Given the significant impact of upstream methane emissions, a recent ICCT study found that “inadequate attention to technologies designed to limit methane leakage ... would diminish the program benefits by as much as 38 percent.” [EPA-HQ-OAR-2014-0827-1312-A1 p.39]

The finding from ICCT is consistent with other leading research. A recent study by Camuzeaux et al in Environmental Science & Technology found that switching heavy-duty truck fleets from diesel to natural gas could lead to worse climate impacts over the next 50 to 90 years than remaining with diesel because of the powerful effect that methane has on global warming in the near-term. [EPA-HQ-OAR-2014-0827-1312-A1 p.39][Attachment 1 can be found in docket number EPA-HQ-OAR-2014-0827-1312-A2]

While natural gas trucks lead to increased climate damage for decades compared to diesel trucks today, over the course of the Phase 2 program these vehicles have the potential to provide immediate, sizable climate benefits. Camuzeaux et al found that – with improvements to the vehicles and the natural gas supply chain – “fuel switches have the potential to produce climate benefits on all time frames.” Similarly, ICCT found that natural gas trucks could “increase the Phase 2 regulatory program’s 2040 benefits by 11 million tons of CO2e, or 7 percent” if best practices to reduce methane emissions on-vehicle and across the supply chain are adopted. With improvements to the proposal, the final Phase 2 program could avoid an unintended consequence of additional climate damage from a switch to natural gas trucks and instead enhance the climate benefits of the program by enabling natural gas trucks to deliver on their climate potential. [EPA-HQ-OAR-2014-0827-1312-A1 p.39]

A. A new, more comprehensive lifecycle analysis of NGVs is needed

The agencies’ attempt to quantify the climate impact of natural gas trucks should be strengthened in several ways. The agencies relied exclusively on data from the Greenhouse Gas Inventory (GHGI), leading to a lifecycle analysis (LCA) that likely underrepresents the amount of methane emitted into the atmosphere across the natural gas supply chain. The agencies also relied on outdated Global Warming Potentials (GWPs) for methane, which do not reflect the latest available science on methane’s impact on the climate system. [EPA-HQ-OAR-2014-0827-1312-A1 p.39-40]

The GHGI estimates U.S. natural gas methane emissions based mainly on bottom-up estimates of methane emissions. It is based heavily on data collected in the 1990s and recent data suggest that the Inventory likely underestimate actual emissions and does not fully include important sources like those found in the gathering and boosting segment. For example, new research conducted in Texas’ Barnett Shale, one of the country’s largest production areas, finds methane emissions are 50% higher than GHGI estimates. Other recent studies have made similar conclusions, predicting the underestimation is in the range of 25-75% below actual emissions. [EPA-HQ-OAR-2014-0827-1312-A1 p.40]

In addition, the LCA in the proposal predicts that methane emissions will only rise by 4% from 2012 levels by the year 2025, while natural gas production is expected to increase by about 22%. However, the most recent GHGI, which was not available for this LCA, shows a 3% increase in methane emissions over 2012-2013, which suggests these projections may be understated. Accordingly, we recommend EPA develop a sensitivity analysis to the existing LCA using the numerous recent field
studies conducted over the past few years aimed at better characterizing national methane emissions from the oil and natural gas sector. [EPA-HQ-OAR-2014-0827-1312-A1 p.40]

EPA recognizes a number of other gaps in the LCA that have not been addressed. For compressed natural gas (CNG) trucks, due to lack of quantifiable data, EPA does not estimate emissions from refueling or small leaks in the CNG fuel storage system. The LCA also does not include estimations for fugitive emissions from fuel piping for either CNG or LNG trucks. Furthermore, there is a significant amount of uncertainty in the estimation for the quantity of boil-off and venting emissions from LNG trucks. [EPA-HQ-OAR-2014-0827-1312-A1 p.40]

In the proposed Phase 2 standards, EPA takes critical steps in providing such an LCA. However, there are a number of areas for improvement, as highlighted in this paper, especially concerning sensitivity analyses related to upstream methane emissions, GWPs, and the carbon dioxide-credit program. [EPA-HQ-OAR-2014-0827-1312-A1 p.40]

E. Adopt a full fuel cycle accounting approach for alternative fuels

While on-vehicle methane emissions are an important factor, it is the methane emissions associated with the production, processing and distribution of natural gas that largely determine the amount of climate damage natural gas fleets cause compared to diesel fleets. In order for the Phase 2 program to accurately reflect the climate impact of natural gas trucks, the final standards must reflect the full lifecycle impact of using these and other trucks. Therefore, an upstream emissions analysis should be incorporated into efficiency standards in some capacity. [EPA-HQ-OAR-2014-0827-1312-A1 p.43]

The agencies have used this approach before. In the historic light-duty standards, the agencies developed an upstream compliance factor to reflect the upstream impact of electric vehicles. While these vehicles emit much less CO2 at the tailpipe, the compliance factor takes into account the generation or production of the fuel source upstream of the tailpipe. This strategy could be applied in a parallel manner to NGVs to account for the full impact of their CO2 and methane emissions. An upstream compliance factor could be calculated given current estimates of the upstream impact for a respective NGV, and later adjusted accordingly based on improved GHGI estimates. [EPA-HQ-OAR-2014-0827-1312-A1 p.43]

The agencies asked for comments about including lifecycle emissions in the final program, as well as the feasibility of doing so while maintaining the linkage between the EPA standards and the NHTSA standards. Eastern Research Group has examined the options (Attachment 2), concluding, “upstream emissions can be accounted for in the Phase 2 rule, following the precedents established in the LD GHG rules. Concerns with the potential magnitude of GHG emissions in lifecycle emissions, especially for natural gas trucks, suggests that these emissions should be directly accounted for in some way in the Phase 2 rule.” Given the viability of this pathway, EDF urges the agencies to adopt full lifecycle accounting in the final standards. [EPA-HQ-OAR-2014-0827-1312-A1 p.43]

Organization: Institute for Policy Integrity at NYU School of Law

**Upstream Emissions and Electric and Natural Gas Vehicles:** The agencies propose phasing-out the advanced technology credits. In our comments on the Phase 1 rulemaking, Policy Integrity explained the problems of treating advanced electric vehicles as if they had zero emissions, especially in combination with applying a 1.5 multiplier to electric vehicle credits. Phasing out the credits partly addresses this concern. However, the agencies continue to treat electric vehicles as if they have zero emissions, focusing only on the tailpipe and ignoring upstream emissions from electricity generation. Somewhat contradictorily, the agencies are also considering a lifecycle approach to natural gas vehicles that would count upstream emissions. [EPA-HQ-OAR-2014-0827-1195-A1 p.2]

To accurately compare the greenhouse gas emissions associated with different vehicle types, the agencies must consider lifecycle emissions for all power sources. By contrast, limiting the analysis to downstream emissions or considering upstream emissions for only some power sources will undermine the efficacy of the standards by irrationally favoring vehicles whose climate impacts occur upstream. See our previous comments on lifecycle emissions analysis in the context of efficiency standards.  

[EPA-HQ-OAR-2014-0827-1195-A1 p.2] (arguing that ignoring upstream emissions “arbitrarily tips the scales in favor of power sources with superior downstream efficiency over those with superior upstream efficiency”)

**Organization:** National Waste & Recycle Association
We are pleased that the agencies declined to propose any provisions that would adjust the compressed natural gas or the liquid natural gas vehicle standard to account for upstream emissions of methane that occur from natural gas production, processing, transmission and distribution. We wholeheartedly support this approach. [NHTSA-2014-0132-0071-A1 p.4]

**Organization:** NGVAmerica

E. Consideration of Upstream Emissions. The proposal includes an extensive discussion of upstream emissions and full fuel cycle energy use and emissions. However, the proposal leaves in place a regulatory approach that applies the long-standing practice of only regulating tailpipe emissions and those emissions immediately associated with the vehicle. [EPA-HQ-OAR-2014-0827-1270-A1 p.3]

NGVAmerica supports the agencies’ approach to regulating vehicle and engine emissions. Assessing and determining upstream emissions is highly complicated, a moving target subject to changes as new upstream emission rules and voluntary efforts are implemented. Including upstream emissions would greatly complicate the adoption of final rules for this program. As EPA has noted, upstream emissions are addressed by a host of other statutory-mandated programs and are best addressed by regulations that focus on, and control the source of emissions. We further believe that it is inefficient to require manufactures to address emissions through vehicle controls that will soon be reduced or even eliminated by new regulatory controls. Therefore, we support the decision not to include upstream emissions in the standards used to regulate motor vehicles and engines. [EPA-HQ-OAR-2014-0827-1270-A1 p.3-4]

With respect to upstream emissions, the Preamble includes an extensive discussion related to natural gas vehicles. We respectfully request that this information not be included in the final rule given that similar attention to, and discussion of, other fuels has not been provided in the rule. If the full fuel cycle benefits and attributes of natural gas are to be included, a detailed discussion of the emissions of other fuels should also be included and commenters should be provided an opportunity to review this information and comment on the attributes of all fuels. In addition, any discussion of upstream emissions should carefully consider what percentage of natural gas in each state is or would be used as motor vehicle fuel, so that the total upstream emissions associated with the production and transportation of natural gas are discounted and adjusted accordingly when calculating upstream emissions for natural gas as a motor vehicle fuel. Finally, the introduction of renewable natural gas (RNG) into the motor-vehicle fuel market should also be included as many pathways for production of RNG have very low carbon intensity values and some are actually carbon-negative. An example of use of RNG for transportation fuel is California’s Low-Carbon Fuel Standard. As of 2014, RNG accounts for up to twenty-five percent of California’s natural gas transportation fuel. [EPA-HQ-OAR-2014-0827-1270-A1 p.4]

**Organization:** Optimus Technologies

With respect to upstream emissions, the Preamble includes an extensive discussion related to natural gas vehicles. We respectfully request that this information not be included in the final rule given that similar attention to, and discussion of, other fuels has not been provided in the rule. If the full fuel cycle benefits and attributes of natural gas are to be included, a detailed discussion of the emissions of other fuels should also be included and commenters should be provided an opportunity to review this information and comment on the attributes

**Lifecycle Emissions**
From Optimus’ review of the proposed rule as well as discussion with employees at the EPA, the EPA does not currently incorporate lifecycle emissions into the process of engine/vehicle certification. One of the bases for this decision seems to be the assumption that EV HD vehicles will not enter the market during the regulatory period: “we project very limited adoption of all-electric vehicles into the [heavy-duty] market” (see 80 FR 40159, Column 1). This assumption seems to neglect the fact that other alternative fuel technologies (besides EV) exist. Optimus Technologies believes that the EPA should begin to evaluate engines/vehicles on a lifecycle emissions basis, especially when evaluating technologies that allow engines/vehicles utilize alternative fuels. For instance, a natural-gas engine may show reduced CO2 tailpipe emissions when compared to its diesel counterpart. However, the same natural-gas engine may show increase CO2 lifecycle emissions. One example of this is a recent Argonne National Laboratory study completed on transit buses. An excerpt and chart from that study are below: [EPA-HQ-OAR-2014-0827-1276-A1 p.1-2]

““The GHG emissions per VMT for transit buses are illustrated in Figure 5. The emissions per VMT for CNG transit buses are not statistically different from those of diesel buses with a 100-year GWP horizon. However, when considering a 20-year GWP horizon, CNG buses emit significantly more GHGs than do their petroleum-fueled counterparts, with emissions that are 34% higher for conventional NG and 20% higher for shale NG. To reduce GHG emissions, CNG buses will need to exceed our Base Case fuel economy assumptions.” [EPA-HQ-OAR-2014-0827-1276-A1 p.2]

The already excellent GREET model should serve as a way to evaluate various engines/vehicles/fuels in a non-biased and consistent manner. For instance, using unmodified GREET 2014 data, a car fueled with ultra-low sulfur diesel emits (on a well-to-wheel basis) 391.276 g/mi. A dedicated CNG car emits (again on a well-to-wheel basis) 406.277 g/mi (an increase of 14.951 g/mi). [EPA-HQ-OAR-2014-0827-1276-A1 p.2-3]

The EPA has objected to a lifecycle emissions approach in the past for multiple reasons including the belief that including lifecycle GHG emissions would disrupt the harmonization of EPA and NHTSA rulings and the belief that the RFS properly incentivizes alternative fuels (see 77 FR 51701). [EPA-HQ-OAR-2014-0827-1276-A1 p.3]

On the first belief, Optimus sees no reason why the addition of lifecycle GHG emissions would upset or go against the dual goals outlined in Phase I (see 76 FR 57109, Column 2) of reduction of dependence on oil, achievement of energy security, and amelioration of global climate change. [EPA-HQ-OAR-2014-0827-1276-A1 p.3]

Regarding the second belief, RFS does an excellent job of incentivizing the production alternative fuels but fails to directly incentivize the use of alternative fuels and associated technologies by engine/vehicle OEMs. The regulatory environment surrounding the RFS (including the RIN program and tax credits) has been in constant flux recently so that producers of alternative fuels rarely pass those incentives on to consumers. RINs and tax credits essentially assist in holding alternative fuel producers above water during periods of regulatory uncertainty and low petroleum prices. The proposed rule should consider incentivizing technologies that integrate alternative fuels at the OEM level and push the market towards a low carbon fuel economy in a way that RFS cannot. [EPA-HQ-OAR-2014-0827-1276-A1 p.3]
The EPA argues (in 77 FR 51701) that “the tailpipe performance measurement of alternative fuels provides sufficient incentives for their use” and integration with engine/vehicle OEMs. Optimus Technologies argues that the full lifecycle emissions and the use of the off-cycle technology credit (see section below) should be used by the EPA to further incentivize, or in some cases, disincentivize the use of alternative fuels and their associated technologies by vehicle/engine OEMs (in the event that they produce vehicles with higher lifecycle GHG emissions). [EPA-HQ-OAR-2014-0827-1276-A1 p.3]

Organization: Securing America’s Future Energy

Specifically, we recommend that EPA and NHTSA equilibrate the treatment of non-petroleum fuels across the light- and heavy-duty sectors by: (1) extending 49 USC §32905 manufacturing incentives into the medium- and heavy-duty sector and (2) implementing advanced technology credits for medium- and heavy-duty natural gas vehicles. We also provide comments on the agency's considerations related to upstream natural gas vehicle emissions below. [EPA-HQ-OAR-2014-0827-1282-A1 p.1-2]

At the same time, SAFE believes the regulation of upstream emissions is more appropriately addressed under separate regulatory frameworks that hold those upstream entities directly accountable. [EPA-HQ-OAR-2014-0827-1462-A1 p.4]

Specifically, SAFE recommends that the agencies equilibrate the treatment of non-petroleum fuels across the light- and heavy-duty sectors by: (1) extending 49 USC §32905 manufacturing incentives into the medium- and heavy-duty sector and (2) implementing advanced technology credits for medium- and heavy-duty natural gas vehicles and reinstating them for technologies that qualify for the credit under Phase I. Finally, comments on the considerations related to upstream natural gas vehicle emissions (as requested in the proposed Phase 2 rule) are offered. [EPA-HQ-OAR-2014-0827-1282-A1 p.6]

Treatment of Upstream Natural Gas Emissions

Traditionally, with the limited exception of vehicles powered by energy sources that are recharged through off-board fuel combustion, emissions associated with the upstream production and distribution of vehicular fuels have been regulated independently of established motor vehicle GHG and fuel economy standards.\(^27\) There is fundamentally sound rationale behind such an approach since vehicle manufacturers have no authority over the production and distribution of vehicular fuels. Fuel producers and distributors are separately regulated entities subject to controls established for their respective industries. [EPA-HQ-OAR-2014-0827-1282-A1 p.9]

Nevertheless, the EPA and NHTSA have requested comment on whether it would be appropriate to adjust the tailpipe GHG emission (and, by extension, fuel consumption) standards for natural gas vehicles by a factor to reflect the lifecycle emissions of natural gas vehicles relative to diesel-powered vehicles. While the benefits of such an approach might possibly be rationalized in a more static and certain world, it is difficult to envision any type of a practical and equitable system. [EPA-HQ-OAR-2014-0827-1282-A1 p.9]
Vehicle manufacturers have no control over upstream fuel production and distribution, yet under a lifecycle approach vehicle manufacturers would be required to discount motor vehicle technology impacts for the actions (or inactions) of independently regulated entities or the agencies that regulate them, even as they vary across time or regions. Would vehicle manufacturers suffer the consequences of upstream regulatory stringency decisions over which they have no control? Given that production methods and associated controls are continually evolving, how would upstream evolutionary impacts be reflected in regulated downstream adjustments in a timely fashion? Lifecycle adjustments would have to be dynamically applied to previously certified vehicles since the upstream emissions performance of fuels being utilized in both new and existing vehicles would be equally affected. Further, since any adjustment would be based on the ratio of upstream performance for two fuels, how would differences in the uncertainty of a generalized lifecycle estimate for each fuel be resolved? Clearly, there are a number of complex issues that would need to be address before equitable upstream adjustments could even be practically considered. [EPA-HQ-OAR-2014-0827-1282-A1 p.10]

Even ignoring practicalities, a lifecycle approach would, at a minimum, require an adjustment factor to be developed for all fuels, not simply natural gas, as well as for all vehicle sectors. Adopted standards applicable to light-duty natural gas (or any other alternatively-fueled) vehicles are not subject to lifecycle adjustment. Given that such adjustments would be fuel, not vehicle, specific, there is no basis for establishing an adjustment that is isolated to the heavy-duty sector. In recognition of these various issues, and given the diversity of fuel portfolios and carbon emissions at utilities around the country (which will also change over time), SAFE believes that the appropriate approach to regulating carbon emissions throughout the economy is to regulate them at the point of combustion and not at the point where the power is consumed. SAFE recommends that the EPA and NHTSA abandon any potential lifecycle approach and focus on adopting cost effective control strategies for regulating vehicle and upstream entities separately. [EPA-HQ-OAR-2014-0827-1282-A1 p.10]

27 Note: Generally, vehicles powered by energy sources that are recharged through off-board fuel combustion are all-electric or plug-in electric hybrid vehicles whose batteries are recharged using energy generated through upstream fuel combustion. Upstream combustion and distribution losses for such vehicles are considered in determining light-duty vehicle fuel economy and will be considered beginning as early as model year 2020 in determining light-duty vehicle CO2 emissions. Prior to model year 2020 and for some period thereafter until a specified vehicle production threshold is exceeded, all-electric vehicle operation is assumed to emit zero CO2. Upstream emissions for all-electric heavy-duty vehicles are not considered throughout the proposed Phase 2 period (i.e., CO2 emissions and fuel consumption for such vehicles are assumed to be zero).

Organization: Union of Concerned Scientists (UCS)

Alternative fuels

While diesel and gasoline vehicles currently represent the vast majority of new heavy-duty vehicles sold today, advances in technology, favorable differences in alternative fuel prices, and state and national policies supporting alternative fuel trucks will lead to a growing number of alternative fueled vehicles being deployed during the timeframe of the rule. However, evaluating only tailpipe emissions from natural gas and electric vehicles underestimates the climate impacts of these vehicles compared to gasoline and diesel vehicles raising concerns about the real benefits of the standards under different market projections. For example, analysis by the ICCT shows that natural gas fueled trucks could represent as much as 20 percent of the new truck sales under favorable market conditions. In that case,
they found as a result of methane leakage both on the vehicle and upstream of the vehicle, the climate benefits of the proposed rule could be diminished by as much as 38% in 2040 using a 20-year global warming potential for methane (Delgado and Muncrief 2015). While the likelihood of this scenario is uncertain, it illustrates the importance of looking beyond simply tailpipe emissions in evaluating vehicle emissions. [EPA-HQ-OAR-2014-0827-1329-A2 p.26]

We strongly support the agencies inclusion of controls for crankcase emissions on natural gas vehicles and LNG tank hold times. [EPA-HQ-OAR-2014-0827-1329-A2 p.26] [This comment can also be found in section 12.5, 12.7 and 13.2.3 of this comment summary.]

However, these do not fully capture the sources of methane emissions from natural gas trucks. In addition, electric trucks are evaluated as have 0 g/mile emissions, which does not fully reflect this vehicle technology's actual climate impact. While the current low volumes of electric trucks do not present a significant concern, the market for these vehicles will likely increase over the time frame of the regulation, and when they make up a substantial part of the market, real benefit erosion will occur. [EPA-HQ-OAR-2014-0827-1329-A2 p.26-27]

To ensure the program produces the estimated benefits and to accurately capture the climate impact of vehicles regulated under the standards, the agencies should consider a phase-in of requirements to include the upstream emissions for natural gas and electric trucks, relative to diesel and gasoline vehicles, in vehicle certification. [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

Organization: VNG

NGVs are the Primary Driver of Renewable Natural Gas Development

Renewable natural gas (RNG) is methane captured from renewable sources like landfills, dairy farms, and sewage treatment plants, then processed to be chemically identical to fossil natural gas and transported through the same pipeline system. Because methane is a powerful greenhouse gas and RNG captures methane that would otherwise escape into the atmosphere, its use achieves lifecycle GHG reductions of 90% or more compared to diesel in CO2-equivalent terms — and even greater positive impacts in the near term since methane is a potent short-lived climate pollutant (SLCP) that both EPA and the California Air Resources Board are beginning to target more aggressively in their climate policies. [EPA-HQ-OAR-2014-0827-1208-A1 p.1]

Organization: Waste Management (WM)

WM Supports Maintaining the Phase 1 Compliance Flexibility Framework in Phase 2

In the Phase 1 rule, EPA provided a compliance approach, which allows OEMs to certify their engines, using carbon dioxide (CO2) credits to meet the nitrous oxide (N2O) and methane standards. OEMs may convert all measured emissions to CO2 equivalent credits using the global warming potentials (GWP) of
N2O and methane. An OEM may offset excess methane or N2O emissions with the appropriate number of CO2 reduction credits. [EPA-HQ-OAR-2014-0827-1214-A2 p.2]

Continuing this compliance framework in the Phase 2 rule is particularly important to the future compliance of natural gas (NG) vehicles. Since NG vehicles generate higher methane emissions, but lower CO2 emissions, the flexibility afforded by continuing the Phase 1 offset provisions will allow their continued compliance under Phase 2. We support the agencies’ inclusion of this flexibility allowing OEMs to balance emissions among the three GHGs in the proposed Phase 2 rule. [EPA-HQ-OAR-2014-0827-1214-A2 p.2]

WM works closely with our manufacturing partners and over the last decade, we have seen steady improvements in heavy-duty natural gas technology. Our OEM partners are already working on technologies for future model years that will enable significant reduction of fugitive emissions from NG vehicles – making an already clean technology even more environmentally beneficial. Extension of the Phase 1 compliance framework into Phase 2 will also support further adoption and use of vehicles fueled with renewable natural gas (RNG). NG vehicles may employ RNG with no changes to either the vehicle or fueling infrastructure. Use of RNG results in even greater GHG reductions on a lifecycle basis (upwards of 90%) than the already significant GHG reductions achieved with use of fossil NG. A flexible Phase 2 compliance framework will allow EPA to achieve lower GHG emissions from medium and heavy-duty trucks while also supporting continued growth of in production and use of renewable transportation fuel. [EPA-HQ-OAR-2014-0827-1214-A2 p.2-3] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.101.]

We note that the agencies are taking comment on adoption of provisions that would “adjust the GHG emission standard for NG vehicles by a factor to reflect lifecycle emissions of NG vehicles relative to diesel vehicles.” However, there is no explanation or fully formed regulatory concept describing how those provisions might be applied, how lifecycle emission factors would be established, or how lifecycle accounting would affect other vehicle fuels. We find that the language is not sufficiently descriptive to enable commenters to understand the “adjustment factor” that the agencies are contemplating and provide meaningful comments and information. As a result, the agencies have no basis for using any input on this topic in a final rule. Should the agencies determine that lifecycle emission factors are appropriate, we believe it would be incumbent upon the agencies to issue a new proposal to ensure the regulated and affected stakeholders are afforded appropriate notice and an opportunity to provide comment. [EPA-HQ-OAR-2014-0827-1214-A2 p.3]

Were the agencies to consider developing regulatory provisions featuring a “lifecycle approach” for natural gas, they would completely upend the basic architecture of the Phase 1 rule. Furthermore, the EPA would be forced, under this new framework, to develop lifecycle analyses of all vehicle fuels, as all vehicle fuels – including gasoline, diesel and electricity – have upstream emissions. Undertaking such an analysis would significantly complicate and delay final promulgation of the Phase 2 rule with no additional GHG benefits beyond those that are, or will be accomplished through other EPA programs. [EPA-HQ-OAR-2014-0827-1214-A2 p.3]

As a next step to further reducing the GHG footprint of our NG fleet, we are using the gas produced by our landfills to power our trucks with biomethane. We fuel 380 refuse trucks in California with RNG from our Altamont Landfill and we will be fueling several hundred more vehicles with RNG produced at our Milam, Illinois landfill. We are also working with other landfill owners to purchase RNG to fuel additional vehicles. WM plans to fuel as many of its NG trucks with renewable fuel as we can. The RFS program has helped facilitate this switch to even lower GHG emitting fuels than fossil natural gas. NG vehicles are also a technology pathway to lower NOx emissions. While this rule is focused on fuel
efficiency and GHG reductions, EPA should think holistically and recognize co-benefits of other pollutant reductions that a technology can offer. [EPA-HQ-OAR-2014-0827-1214-A2 p.4-5] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.101.]]

The recent proposals complement the Agency’s 2012 standards. In addition to reducing both VOCs and methane from hydraulically fractured oil wells, the new proposals extend emission reduction requirements further downstream, covering equipment in the natural gas transmission segment of the industry not regulated by the 2012 rule. EPA has also proposed to require owner/operators to find and repair leaks, a significant source of VOC and methane emissions. These new standards are expected to achieve additional reductions of up to 400,000 short tons of methane in 2025, the equivalent of reducing 7.7 to 9 million metric tons of CO2 equivalent. These rules, along with the Agency’s proposed voluntary Natural Gas STAR Methane Challenge Program, and upcoming actions from the Department of Interior’s Bureau of Land Management, will help ensure significant methane reductions from the oil and gas sector. Given the significant work already underway to reduce lifecycle emissions of fossil fuel and methane and VOC emissions from the natural gas sector, there is no reason for EPA’s Office of Transportation and Air Quality to use the Phase 2 rule to require methane reductions from vehicles to offset upstream NG sources. [EPA-HQ-OAR-2014-0827-1214-A2 p.5]

Organization: Waste Management (WM)

WM, therefore, strongly recommends the agencies abstain from incorporating lifecycle GHG emissions accounting in the Phase 2 rule. [EPA-HQ-OAR-2014-0827-1214-A2 p.4]

**EPA’s Renewable Fuel Standard Already Addresses Lifecycle Emissions of Fossil Fuel**

EPA already implements a regulatory program, the Renewable Fuel Standard (RFS), the goal of which is to achieve reductions in lifecycle GHG emissions associated with replacing transportation diesel with increasing volumes of certain renewable fuels. Further, the Administration and EPA are addressing upstream methane emissions associated with natural gas through a host of regulatory programs that will significantly reduce methane emissions from the oil and gas sector. Any attempt to regulate trucks with the goal of mitigating upstream emissions would be redundant and far less effective. [EPA-HQ-OAR-2014-0827-1214-A2 p.4]

The EPA Renewable Fuel Standard (RFS) program is designed to ensure that transportation fuel sold in the U.S. contains a minimum volume of renewable fuel, and thus achieves a lower fossil carbon content. The RFS program requires EPA to evaluate the GHG lifecycle emissions associated with each category of renewable fuel to assess the GHG reductions that will be realized from its use as a replacement for diesel fuel. The transportation fuels market is required to increase its use of renewable fuels over time to both reduce sector GHG emissions, and to promote production and use of homegrown, clean fuel alternatives to imported petroleum fuels. [EPA-HQ-OAR-2014-0827-1214-A2 p.4]

The RFS program has helped stimulate the production and use of renewable natural gas (RNG) as a transportation fuel. Historically, RNG from landfills, wastewater treatment plants and anaerobic digesters has been beneficially used to produce electricity. On a GHG lifecycle basis, RNG as a cellulosic biofuel is among the lowest carbon intensive renewable fuels available, with GHG reductions of nearly 90% as compared to the diesel fuel it replaces. Due in large part to the RFS program and the California Low Carbon Fuel Standard, WM is increasing its production and use of RNG as a transportation fuel. [EPA-HQ-OAR-2014-0827-1214-A2 p.4]
The Administration’s Methane Strategy Will Achieve Significant Upstream Methane Reductions from the Oil & Gas Sector

The Administration’s Methane Strategy is a key component of the President’s Climate Action Plan, with a goal of achieving reductions in methane emissions from the oil and gas sector of 40 to 45 percent below 2012 levels by 2025. EPA began with an April 17, 2012 New Source Performance Standard (NSPS) for natural gas wells, along with requirements for several other sources of volatile organic compounds (VOCs) from storage tanks and other gas production equipment. A key component of the 2012 rules was a requirement to capture emissions from hydraulically fractured and re-fractured natural gas wells – a step estimated to yield a 95 percent reduction in VOCs, and a similar methane reduction co-benefit. Although VOCs are the regulated pollutant, EPA estimated significant reductions of 1.0 to 1.7 million short tons of methane (about 19 to 33 million tons of CO2 equivalent). Following upon this first rule, EPA proposed a suite of rules August 18, 2015 to reduce further methane emissions from a broader array of sources within the oil and gas industry. [EPA-HQ-OAR-2014-0827-1214-A2 p.5]

Organization: Center for Biological Diversity

NATURAL GAS ENGINES MUST BE HELD TO A MEANINGFUL STANDARD THAT PREVENTS METHANE EMISSIONS FROM UNDERMINING CLIMATE BENEFITS

It is essential that the EPA use its full authority to address “well-to-wheels” methane emissions associated with natural gas vehicles and engines. Methane is a potent greenhouse gas with a radiative forcing of approximately 0.48 W/m², and, at least as importantly, its comparatively short atmospheric lifetime means that its emissions over the next few decades will exert an even larger warming influence than will CO2 emissions over this period. This dual nature of methane’s influence mean that aggressive methane mitigation will be critical in slowing the near-term rate of climate change, avoiding climatic tipping points, and moderating current climate impacts such as Arctic sea-ice loss, ice sheet melt, permafrost thaw, and declining seasonal snowpack.[EPA-HQ-OAR-2014-0827-1460-A1 p.14]

The extraction, processing, storage and transmission of natural gas is the second largest source of fugitive methane emissions in the United States according to the EPA’s U.S. Greenhouse Gas Inventory, and may be the largest source if updated leakage factors are used. The Obama Administration has targeted methane emissions as an important component of climate mitigation and meeting international climate commitments.[EPA-HQ-OAR-2014-0827-1460-A1 p.14]

It is important to address methane emissions from heavy duty natural gas vehicles and engines due to the potential for market expansion. Natural gas vehicles are currently a small part of the medium- and heavy-duty engine fleet: about one percent. But the EIA expects this market share to rise rapidly, with growth rates up to 14 percent per year. One report placed market share for new tractors at 50 percent in 2025. Overall heavy-duty fleet expectations have been placed around 20 percent by both the National Resource Council and the National Petroleum Council. All of these forecasts underline the importance of setting meaningful standards for natural gas vehicles in this rulemaking as the impacts will be much multiplied relative to the existing fleet. [EPA-HQ-OAR-2014-0827-1460-A1 p.14]

As proposed, the Phase 2 standards for natural gas vehicles and engines could result in significant and unintended climate harm. The Center appreciates that the EPA recognizes the potential for methane leakage from natural gas systems and vehicles to offset the CO2 reductions of the standards. We respond below to a number of EPA’s requests for comment related to the treatment of methane from natural gas vehicles. [EPA-HQ-OAR-2014-0827-1460-A1 p.14]

The proposed free pass for natural gas engines must also be eliminated. Natural gas engines currently make up a small portion of the truck-engine market, but that market share is predicted to rise rapidly. We simply can’t afford the methane leakage from natural gas production and transmission, nor the harm to our communities and wildlife if the standards incentivize more fracking for natural gas. [EPA-HQ-OAR-2014-0827-1167-A1 p.1]

Organization: Optimus Technologies

However, as Optimus has stated above, the company believes that the proposed rule is lacking and requires additional consideration to achieve the goals the EPA set out to do. If the intended rule was written to address climate change, lifecycle greenhouse gas emissions must be taken into account. The proposed rule is intended to be fuel-neutral, but Optimus believes the standards do not reflect that intention. The effects of the proposed rule on alternative fuel technologies (especially small volume alternative fuel engine converters) needs additional clarification and consideration. [EPA-HQ-OAR-2014-0827-1276-A1 p.4]

Response:

The agencies are aware of methane’s potency as a heat trapping gas. The heat trapping potency of methane, coupled with several projections which showed rapid penetration of natural gas fuel into the heavy-duty truck sector, are the primary reasons why, for this rulemaking, the agencies conducted a lifecycle analysis comparing natural gas heavy-duty trucks to diesel heavy-duty trucks and projected the growth of natural gas use by heavy-duty trucks.
Substantial amounts of new information on methane emissions from oil and gas systems have become available recently from a number of channels, including EPA’s GHG Reporting Program, industry organizations, and research studies by government, academic, and industry researchers. Separate from this analysis, as part of the annual development process for EPA’s GHG Inventory, this year EPA reviewed the substantial body of new studies, and conducted early and extensive engagement and communication with stakeholders on updates to oil and gas sector emission estimates. Based on this review of new information and stakeholder input, EPA revised its estimates of methane emissions from natural gas and petroleum wells, natural gas processing plants and the natural gas transmission, storage and distribution systems for the 2016 U.S. GHG Inventory report to the United Nations Framework Convention for Climate Change (UNFCCC). Comparing the most recent GHG Inventory estimate for 2013 to the previous GHG Inventory estimate for 2013, methane emissions are about one-third higher for the aggregated natural gas systems than the previous estimate. These revised methane emissions estimates are incorporated in the final rule natural gas heavy-duty truck lifecycle analysis.

Recognizing the contribution of U.S. methane emissions to climate change, in 2015, the Obama Administration announced a goal of reducing methane emissions from the oil and gas sectors by 40 to 45 percent from 2012 levels by 2025. EPA has been taking steps, and intends on taking additional steps, to reduce the methane emissions from the natural gas and petroleum sectors. In 2012, EPA finalized New Source Performance Standards (NSPS) which require that emissions from natural gas wells that are hydraulically fractured be controlled using flaring or reduced emission completions (RECs). Starting in 2015, RECs are required for natural gas well completions and workovers. The NSPS also regulates the emissions from certain new petroleum and natural gas production, processing, and transmission and storage equipment. EPA continues to promote Natural Gas Star, a flexible voluntary partnership that encourages oil and natural gas companies to adopt proven, cost-effective technologies and practices that improve operational efficiency and reduce methane emissions. Further, EPA launched the Methane Challenge program in March of 2016 in which oil and gas companies make and track ambitious commitments to reduce emissions. On May 12, 2016, EPA finalized regulations (2016 NSPS OOOOa) which, among other things, include methane emission standards for oil and gas equipment used across oil and gas sources previously regulated in the 2012 NSPS OOOO for VOCs, and require the use of RECs at hydraulically fractured oil wells. In addition, in March of 2016, EPA and Canadian Environment and Climate Change Canada (ECCC) announced plans to align with the US goal for 40 to 45 percent reductions of methane from the oil and gas sector relative to 2012 emissions.

The goal of the various actions is to achieve an aggregated 40 to 45 percent reduction in methane emissions relative to methane emissions in 2012.

The agencies are also taking action to further limit the GHG emissions from natural gas heavy-duty trucks. Starting with the 2021 model year, if a heavy-duty truck manufacturer uses carbon dioxide (CO2) credits to offset methane emissions above the methane tailpipe emissions standard, EPA is requiring that the truck manufacturer must use 34 grams of CO2 to offset 1 gram of methane emissions (based on the relative GWPs from IPCC AR5) which is increased from today's CO2 credits standard which is 25 grams of CO2 to offset 1 gram of methane emissions (based on the relative GWPs from IPCC AR4). While the EPA is continuing the flexibility of the CO2 credit trading program, the EPA is taking appropriate action to update the credit trading program to reflect the recent update to the methane GWP. The agencies are also putting in place a 5 year hold time requirement for liquefied natural gas (LNG) storage tanks on LNG-fueled heavy-duty trucks which must be met throughout the truck's useful life. A warranty requirement applies to LNG heavy-duty storage tanks as well.

The various upstream and vehicle emission standards being pursued by EPA is expected to improve the lifecycle performance of natural gas trucks.
Some commenters stated that the agencies should use a full lifecycle assessment of the greenhouse gas emissions of natural gas heavy-duty trucks for this rulemaking. Other commenters stated that only the tailpipe emissions of heavy-duty natural gas trucks should be considered and actions to limit methane emissions from the upstream sector should be pursued separately. As our analysis in the Preamble and RIA shows, the sales volume of natural gas trucks is projected to be very low during the period that the Phase 2 HD GHG standard apply; thus, it is not important to assess and regulate the GHG performance of natural gas heavy-duty trucks on a full lifecycle basis because any impact on GHG emissions, whether natural gas trucks are higher or lower emitting in GHG emissions, would be very small. However, if we ignore the projected sales volume of natural gas heavy-duty trucks and review the full lifecycle performance of natural gas heavy-duty trucks compared to diesel heavy-duty trucks on their face value, the lifecycle analyses leads us to conclude that natural gas heavy-duty trucks may in fact have about the same lifecycle impact as diesel heavy-duty trucks. See Preamble section XI.B. Therefore, evaluating GHG emissions of natural gas heavy-duty trucks based solely on their tailpipe emissions would be adequate. Finally, EPA regards it as a rational strategy to control upstream emissions by directly regulating upstream emission sources, rather than by attempting indirect control through lifecycle-based standards for natural gas heavy duty vehicles. EPA also takes the commenters’ point that it would be arbitrary to establish lifecycle-based standards for only one vehicle fuel, and not all of the others. See also 77 FR 51702 (Aug. 27, 2012) and Section 1.8 of this RTC further explaining various reasons why it is reasonable for the heavy duty standards to be tailpipe based.

Reviewing Figure 13.2 of the RIA which is based on GWPs evaluated over a 100 year time period, our assessment of CNG heavy-duty trucks show them to be lower emitting in CO2-equivalent emissions than diesel fuel heavy-duty trucks, while our analysis shows LNG heavy-duty trucks to be higher emitting in CO2-equivalent emissions. The primary reason why LNG trucks are higher emitting in GHG emissions is because we assume that LNG will be produced by smaller, less efficient liquefaction plants. If LNG trucks source their LNG from a much more efficient LNG export facility (which is the case in California), the lifecycle emissions of LNG heavy-duty trucks is much like that of CNG heavy-duty trucks. If our boil-off sensitivity analysis for LNG trucks is reflective of actual natural emissions, then LNG trucks would be much higher emitting than diesel fuel trucks, although we would not base a lifecycle analysis on a sensitivity analysis – we would need actual boil-off emissions data which we do not have. See also the similar analysis in Preamble section XI.B and Figure 1 to that chapter.

Some commenters stated that we should conduct our lifecycle analysis using methane’s global warming potential based on 20 years. While EPA continues to use 100 year GWPs as the primary metric to evaluate the relative climate impact of different greenhouse gas emissions, EPA has also used 20 year GWPs in sensitivity analysis in the RIA. Reviewing Figure 13.4 of the RIA which is based on 20 year GWPs, our lifecycle assessment shows CNG heavy-duty trucks to be higher emitting in CO2-equivalent emissions than diesels, and LNG heavy-duty trucks even higher emitting (based on a low-efficiency LNG liquefaction plant). However, there are two large uncertainties in our lifecycle analysis which makes our lifecycle GHG emissions analysis of natural gas versus diesel fuel heavy-duty trucks tentative. First, there is uncertainty in the diesel fuel lifecycle analysis. As noted above, EPA reassessed GHG emissions from the petroleum sector as part of the 2016 GHG inventory and EPA’s updated methane emissions from the sector are estimated to be much higher than previous estimates. However, the updated GHG emissions analysis of the petroleum sector are not yet integrated into the GREET model which converts aggregated GHG emissions to fuel-specific emissions (this sort of fuels-specific analysis cannot be easily determined from the GHG Inventory; thus, we were not able to revise the diesel fuel lifecycle GHG analysis ourselves). This change will likely increase the calculated lifecycle GHG emissions of diesel fuel heavy-duty trucks which would make natural gas- fueled heavy duty vehicles look relatively better. However, the 2016 NSPS requires emissions reducing activities at new and modified petroleum production sites including reduced emission completions (RECs) of new oil wells completed with hydraulic fracturing which will then reduce those higher diesel fuel-associated emissions.
GHG emissions. We don’t know the net effect of these two changes. Second, EPA has committed to further regulate the methane emissions from existing natural gas and petroleum sources. Assuming that these future regulations are put into place, it would improve the relative lifecycle GHG impacts of natural gas heavy-duty trucks. However, since these rules have not yet even been proposed, it is virtually impossible to project the lifecycle GHG emissions of natural gas heavy-duty trucks relative to that of diesel heavy-duty trucks.

The identified uncertainties in the GHG emission profile of both natural gas and diesel fuel would make establishing a full lifecycle assessment for natural gas heavy-duty trucks uncertain and speculative. In the future, the agencies may pursue additional steps to reduce lifecycle methane emissions from natural gas heavy-duty trucks, or choose to assess the GHG performance of natural gas heavy-duty trucks on a full lifecycle basis, for example, it becomes clear that natural gas truck sales begin to increase significantly above today's levels, or if new data and analyses related to natural gas and diesel fuel lifecycle emissions indicate a need for further action, and it proves possible to rationally develop lifecycle-based standards for gasoline, diesel, and other heavy duty vehicle fuels. The Energy Information Administration's (EIA's) most recent Annual Energy Outlook (AEO 2015) projects that crude oil prices will remain relatively low compared to natural gas prices for the next 15 years. Thus, natural gas heavy-duty truck fuel consumption is not projected by EIA to exceed 1 percent of total heavy-duty trucks fuel consumption until after 2035 which is well after the phase 2 GHG standards are phased-in. Thus, even if the GHG emissions impact of natural gas heavy-duty trucks is higher or lower than diesel heavy-duty trucks, if natural gas truck sales remain very low as forecasted by EIA, then there would be little impact on the US GHG inventory.

12.5 Projected Use of LNG and CNG

Organization: Environmental Defense Fund (EDF)

F. Revisit projected growth of natural gas vehicles in heavy-duty sector

The agencies improperly characterize the potential use of natural gas trucks in its proposal and draft regulatory impact assessment. Specifically, the agencies concluded, [EPA-HQ-OAR-2014-0827-1312-A1 p.43]

“... based on our review of the literature and external projections we believe that the use of natural gas is unlikely to become a major fuel source for medium and heavy-duty vehicles during the Phase 2 time frame. Thus, since we project natural gas vehicles to have little impact on both overall GHG emissions and fuel consumption during the Phase 2 time frame, the agencies see no need to propose fundamental changes to the Phase 1 approach for natural gas engines and vehicles.” [EPA-HQ-OAR-2014-0827-1312-A1 p.43-44]

Both findings are incorrect and could undermine the benefits of the final Phase 2 standards. [EPA-HQ-OAR-2014-0827-1312-A1 p.44]

The agencies’ finding that “natural gas is unlikely to become a major fuel source for medium and heavy-duty vehicles during the Phase 2 time frame” is based on U.S. Energy Information Administration (EIA) market projections. As EPA notes, the EIA projections are an outlier among other projections and are flawed. Most significantly, the projections account only for high-pressure direct injection engines (HPDI). Yet, in 2013, the only manufacturer of HPDI engines discontinued their production, citing high-costs compared to spark-ignited natural gas engines. [EPA-HQ-OAR-2014-0827-1312-A1 p.44]
Moreover, the EIA projections fail to accurately reflect current sales. The market for natural gas-fueled heavy-duty trucks expanded by 20% in 2014 with 10,480 units sold. These trucks are Class 8 heavy trucks including tractor-trailers, transit buses, and refuse trucks. Transit buses and refuse trucks saw the highest levels of natural gas adoption at 30% and 43% respectfully. The significant increase in market share for natural gas trucks is consistent with industry forecasts by ACT research and the National Petroleum Council (‘‘NPC’’). Current sales volumes are 4.5 times greater than recent projections of sales from the EIA. [EPA-HQ-OAR-2014-0827-1312-A1 p.44]

The discrepancy between market data and EIA projections continue in 2015. Recent industry data suggest total sale volumes of on-highway applications are expected to be 3,300 units in 2015. These numbers, which do not include the refuse trucks and transit buses units that are leading NGV sales, are triple EIA projections. [EPA-HQ-OAR-2014-0827-1312-A1 p.44]

The agencies discount ACT, NPC and others by noting, [EPA-HQ-OAR-2014-0827-1312-A1 p.44]

‘‘[t]he first observation we can make about all these reports is that they start out assuming that natural gas use is 2 percent of the Class 8 heavy duty truck fleet in 2012. However, that level of natural gas vehicle penetration of the heavy-duty fleet is not supported by other data sources.’’ [EPA-HQ-OAR-2014-0827-1312-A1 p.45]

This is a misreading of the projections, which represent new vehicle sales and not total penetration of the existing fleet. As we note above, new trucks sales in 2014 were consistent with NPC projections. [EPA-HQ-OAR-2014-0827-1312-A1 p.45]

The agencies also claim that NGVs are likely to drive less than diesel trucks, citing dated information from the Vehicle Inventory and Use Survey (VIUS) comparing light and medium heavy-duty trucks with diesel heavy trucks. Given the fact that the agencies failed to break out low-mileage duty cycles, such as refuse trucks and transit buses that have significantly embraced natural gas engines, it is not surprising the agencies found that NGVs travel fewer miles than heavy diesel trucks. [EPA-HQ-OAR-2014-0827-1312-A1 p.45]

This conclusion is counter to how fleets operate over-the-road trucks. Palmer Trucks puts over 200,000 a year on its natural gas trucks. In reference to its NGVs, Dillon Transport recently noted “we want to run those trucks 1,000 miles per day if we can.” Saddle Creek has run its NGV trucks 34 million miles since 2012 while growing fleet size from 40 to 175 trucks. Companies that buy NGVs for over-the-road duty maximize the mileage on these vehicles. It is core to the business case for choosing these trucks. [EPA-HQ-OAR-2014-0827-1312-A1 p.45]

The conservative EIA projections fail to account for another critical market development: new natural gas trucks are increasingly able to offer significant NOx reduction benefits compared to diesel trucks. The California Air Resources Board certified the Cummins-Westport 8.9-liter ISL G engine at 0.02 grams NOx per brake horsepower-hour. Given the ability of this engine to deliver lower NOx, its adoption is likely to benefit from the deployment of public funds to mitigate local air pollution concerns. [EPA-HQ-OAR-2014-0827-1312-A1 p.45-46]

Response:

For the final rulemaking, the agencies further reviewed the economics of purchasing and using natural gas trucks. Based on this additional review, the agencies have the following responses to the comments raised by EDF.

First, we continue to support the conclusion we reached for the proposed rulemaking which is that it is unlikely that natural gas will become a major (major defined as 5% of the total fuel consumed) fuel source for medium and heavy-duty vehicles during the Phase 2 timeframe. This is further supported by the fact that crude oil prices started to decline during 2014 and continued their decline during 2015. While crude oil prices increased during the spring of 2016, as of early summer of 2016 they are still about half of what they were during the first part of 2014 when crude oil prices averaged at or above $100 per barrel. Speaking to one LNG station owner, they explained that they shut down one LNG retail station because the LNG trucks that normally refuel at that LNG retail station were "parked" because LNG was priced relatively higher than diesel fuel. EIA projects that crude oil prices will remain low for the foreseeable future, and at these crude oil prices, purchasing natural gas-fueled heavy-duty trucks is not a cost-effective option for most fleet operators. Another factor influencing low natural gas usage by heavy-duty trucks is that natural gas prices are projected to be higher in the latest Annual Energy Outlook (AEO 2015) compared to AEO 2014.

Despite the lower crude oil prices, natural gas truck sales are continuing. We believe that this does not raise serious questions about our payback analysis, but instead reflects upon certain special circumstances for truck fleets for the use of natural gas. For example, a fleet owner that signed a contract to purchase the natural gas trucks based on earlier fuel prices.

There are likely special cases where the purchase of natural gas trucks make sense, even in today's poor pricing environment. For example, some states offer subsidies for the purchase of natural gas trucks, or for the construction of CNG or LNG refueling facilities. These subsidies explain why EIA fuel sales data shows such high natural gas sales to the transportation sector for those states which offer these subsidies. However, states may have little tolerance for continuing these subsidies over the long term, particularly if the sales of natural gas trucks begin to increase.

Another favorable market for using natural gas trucks are the trucks which transport petroleum or natural gas liquids out from a fossil-fuel producing region. For example, the Eagle Ford shale play produces natural gas liquids and also produces a significant amount of natural gas. Providing that the natural gas can be made clean enough out in the field, it could be compressed and distributed to CNG trucks at a much lower price point than the natural gas which must be moved into and out of storage and be transported through both the natural gas transmission and distribution systems.

Some natural gas trucks and urban buses are purchased because of their desirable emissions profile, such as low NOx emissions, and these purchases are more likely to continue for air quality issues and not just for economic reasons. These trucks purchased for low NOx are likely urban buses purchased by municipalities which likely are driven short distances in stop-and-go driving consuming only a modest amount of natural gas.

---

232 Conversation with Jon Wadsworth of BLU on May 2, 2016.
Another category worth mentioning are the refuse trucks which use landfill gas, which may be quite cheap since it is available free at landfills and it receives a renewable fuels credit. See the comments of Waste Management. But landfill gas poses almost no greenhouse gas risk to the environment.

Finally, there are trucks which driven an ultra-high mileage, such as the 200,000 mile per year class 8 trucks referred to by EDF. These trucks likely could pay down the higher purchase price of natural gas trucks more quickly. The problem with this argument is that these trucks are estimated to comprise less than 1% of the total population of heavy-duty trucks, and other trucks cannot simply be driven more -- their driving profile (i.e., stop-and-go urban driving and limited use) limits their mileage accumulation and increases the time it takes to pay-off the higher cost of purchasing a natural gas truck.

While these various situations can provide sales opportunities for natural gas trucks, their sales are likely to comprise a very small fraction of the heavy-duty truck fleet. Unless natural gas prices are substantially lower than diesel fuel prices the longer pay off of the higher upfront purchase cost of a natural gas truck is likely to slow the adoption of natural gas as a heavy-duty truck fuel.

12.5.1 Applying Standards to Natural Gas Vehicles

Organization: NGVAmerica

NGVAmerica supports the decision to continue the practice of measuring the fuel economy of all fuel types based on CO2 emissions. The preamble states that fuel consumption is based on a “one-to-one relationship between fuel efficiency and tailpipe CO2 emissions.” This practice provides regulatory certainty for all fuel types and is consistent with previous rules for light and heavy duty motor vehicles. Moreover, it provides a reasonable incentive for natural gas manufacturers, since natural gas vehicles with the same efficiency as gasoline or diesel fueled vehicles produce less CO2 emissions. EPA indicates that this benefit is about 20 – 30 percent, which we believe is a reasonable incentive given that natural gas powered vehicles in most cases offset 100 percent of the petroleum that would otherwise be used and one of the goals of the fuel economy rules is to reduce petroleum reliance. [EPA-HQ-OAR-2014-0827-1270-A1 p.4]

Organization: Enovation Controls (ENC)

3.1 Contradictory Statement - Section XI on Natural Gas Vehicles and Engines states that “…since we project natural gas vehicles to have little impact on both overall GHG emissions and fuel consumption during the Phase 2 time frame, the agencies see no need to propose fundamental changes to the Phase 1 approach for natural gas engines and vehicles.” (P. 775, EPA Phase 2 Proposal) It is unclear if this statement supersedes all discussion of natural gas regulation proposals for Phase 2. We respectfully request clarification on whether or not Phase 1 carryover for natural gas engines and vehicles is indeed the approach proposed by the document. [EPA-HQ-OAR-2014-0827-1203-A1 p.3]

3.2 Lean-Burn vs Stoichiometric Combustion - Also within Section XI on Natural Gas Vehicles and Engines, the statement that a diesel-fueled engine converted “to run on natural gas by adding a spark plug and changing calibration strategy to rely on stoichiometric combustion” implies that stoichiometric combustion is required to run a natural gas engine using spark ignition. (P. 776, EPA Phase 2 Proposal) This statement is misguided because, absent of emissions requirements, the spark-ignited natural gas engine can indeed run lean-burn combustion, and does so in EU4 and lower
emissions levels for heavy-duty applications. At EU6 and US standards for 2018, the decision to use Stoichiometric combustion with EGR is driven by cost and the likely desire to use a three-way catalyst rather than using a diesel aftertreatment solution. It is technically feasible to use a lean-burn solution with SCR, but at significantly higher system cost and with higher end-customer maintenance. [EPA-HQ-OAR-2014-0827-1203-A1 p.3]

**Organization:** Securing America’s Future Energy

Reconsider Application of 49 USC §32905 Manufacturing Incentives

The manufacture of non-petroleum fueled light-duty vehicles is incentivized through the application of volumetric adjustment factors under 49 U.S.C. §32905. Generally one gallon of non-petroleum fuel consumption is treated as 15 percent of one gallon, so that regulatory fuel economy is 6.67 times higher than measured fuel economy. This incentive, originally established under the Alternative Motor Fuels Act of 1988, has been renewed and expanded many times over the intervening years, including as recently as 2014 when expanded allowances for dual fuel natural gas vehicles were added. In short, there is a long legislative history that affirmatively demonstrates congressional intent to facilitate the production and widespread use of alternative fuel vehicles (AFVs). [EPA-HQ-OAR-2014-0827-1282-A1 p.6]

In the absence of similarly explicit statutory requirements for heavy-duty vehicles, EPA and NHTSA elected not to extend the §32905 allowances to such vehicles when the Phase 1 GHG and fuel economy rules were developed, and to maintain this restriction in the Phase 2 proposal. Although there is no supporting discussion in the Phase 2 proposal, it is clear from discussion included in the final Phase 1 rule that both EPA and NHTSA understand quite clearly the implications of this decision—both in terms of promoting alternative fuels and decreasing manufacturer flexibility—affirmatively stating that the adopted approach of not applying light-duty-equivalent incentives ‘could have the disadvantage of not doing more to encourage some cost-effective means of reducing petroleum consumption by trucks, and the accompanying energy security costs’ and that adopting distinct GHG and fuel economy standard incentives ‘might enable manufacturers to achieve the twin goals of reducing greenhouse gas emissions and decreasing consumption of petroleum-based fuels in a more cost-effective manner.’ The Phase 1 discussion also affirms that EPA and NHTSA will reconsider the non-expansion of the light-duty-equivalent incentives in establishing future heavy-duty requirements (76 FR 57125). [EPA-HQ-OAR-2014-0827-1282-A1 p.6]

SAFE is specifically requesting that EPA and NHTSA undertake such reconsideration and formally expand the §32905 incentives to heavy-duty vehicles. Such expansion will make available to heavy-duty vehicle manufacturers the same incentives that are available to their light-duty counterparts, as well as introduce provisions into the heavy-duty rule that are fully consistent with the statutorily established goal of promoting non-petroleum fuels. From a fueling perspective, there is no rational reason to treat heavy-duty manufacturers differently than their light-duty counterparts. If introducing an AFV into the light-duty fleet is deemed important for national and economic security, and explicit incentives are provided to promote such introduction, introduction of an AFV into the heavy-duty fleet should contribute to the same goal and be worthy of the same incentives. Any other determination is arbitrary, as it effectively results in differential treatment of the same fuel. [EPA-HQ-OAR-2014-0827-1282-A1 p.6-7]

We recognize that EPA and NHTSA are proposing a fuel economy determination for heavy-duty AFVs that takes advantage of the differential carbon contents of such fuels relative to gasoline and diesel. However, the resulting fuel economy benefit for a fuel such as natural gas is equivalent to a multiplier of 1.25 to 1.5, versus the 6.67 multiplier available to light-duty natural gas vehicle manufacturers. EPA and NHTSA should adopt the same fuel economy incentives for alternative fuels across both sectors. [EPA-HQ-OAR-2014-0827-1282-A1 p.7]
Note: Since fuel economy is measured as $X$ miles per $Y$ gallons, adjusting $Y$ gallons to $0.15Y$ gallons effectively increases fuel economy by $1$ divided by $0.15$ (i.e., by a factor of $6.66$).

Note: Intent of legislative action derived from the 'Purpose' clause of the Alternative Motor Fuels Act of 1988.

Note: As used in these comments, the terminology 'heavy-duty' is intended to include both medium and heavy-duty vehicles as included in the EPA and NHTSA Phase 2 GHG and fuel economy proposal.

See, e.g., Phase 1 discussion at 76 FR 57123 through 76 FR 57125.

Note: EPA and NHTSA 'justify' such differential treatment in their discussion of the Phase 1 rule by citing the benefits of reduced reporting and compliance determination requirements, coupled with the possibility that providing the § 32905 incentives might lead to little increased production of alternative fueled vehicles or that alternative fuels may be imported. However, all of these 'justifications' are independent of market sector and would apply equally to light- and heavy-duty manufacturers. Clearly, such rationales were rejected when statutory requirements were established to provide incentives in the light-duty sector so it is not at all clear why they would carry more weight in rejecting these same incentives for the heavy-duty sector.

Response:

We continue to believe that a CO$_2$ standard is the most effective way for EPA to set efficiency standards for heavy-duty engines and vehicles under the Clean Air Act. With respect to SAFE’s comments, EPA notes that we are adopting our Phase 2 standards to control greenhouse gas emission as allowed under the Clean Air Act, including the authority to set fuel-neutral performance standards.

The agencies noted in the NPRM Preamble that we are not adopting fundamental changes to the Phase 1 program, but noted elsewhere that we are adopting Phase 2 standards for all engines in this rule, including those fueled by natural gas. Readers are encouraged to read the regulatory text to fully understand the requirements being adopted.

We agree that spark-ignition natural gas engines can rely on lean-burn fueling strategies and have revised the Preamble accordingly.

12.5.2 Converters and Dual-Fuel Conversions 1776

Organization: NGVAmerica

The Preamble provides little discussion of the coverage of aftermarket alternative fuel conversions. In communications with EPA staff, however, NGVAmerica has learned that EPA is proposing to regulate all alternative fuel conversions as part of these Phase 2 regulations. This is noteworthy because it is a change from the Phase 1 rules that according to EPA exempted small businesses from having to comply with the medium and heavy duty greenhouse gas emission standards. Since most alternative fuel conversions are produced by small businesses, this change is expected to impact most of the businesses that produce alternative fuel conversions for medium and heavy duty vehicles, and it will have a major impact on this industry segment. [EPA-HQ-OAR-2014-0827-1270-A1 p.5]

NGVAmerica supports EPA’s efforts to ensure that alternative fuel conversions are clean and efficient and comply with the Clean Air Act. NGVAmerica members are committed to complying with
certification and compliance requirements for aftermarket conversion systems, and are on record as advocating that federal and state incentives such as tax credits and grant programs only go to systems that comply with EPA regulations. NGVAmerica members are sometimes placed at an economic disadvantage and lose out on business to companies that opt not to comply with the current EPA regulations for aftermarket systems. Adding another layer of regulatory compliance will only exacerbate this situation for those companies that are committed to following the law. [EPA-HQ-OAR-2014-0827-1270-A1 p.6]

NGVAmerica appreciates that EPA over the years has recognized the unique status of aftermarket conversion companies and has adopted compliance pathways that include regulatory flexibility and exemptions where appropriate. We therefore support the proposed flexibilities and delayed compliance schedule for aftermarket converters proposed in the Phase 2 proposal. We would urge EPA however to go further and provide several additional changes and clarifications to the proposal as indicated here. [EPA-HQ-OAR-2014-0827-1270-A1 p.6]

NGVAmerica requests that EPA clarify that compliance for alternative fuel conversion systems manufactured by small businesses under Phase 2 is not mandatory until 2023. It is our understanding that this was intended, and that the reference to 2019 in section 1819-14 was not. In any case, we would urge EPA to amend the regulatory text so that compliance for conversion manufactures under Phase 2 starts no sooner than it does for new engines produced by small manufactures (i.e., 2022), and provides the additional year indicated for alternative fuel systems (i.e. 2023). It would be helpful if this were expressly stated in Part 85 Subpart F which includes specific requirements for alternative fuel conversions. We also urge EPA to clarify that for small business manufacturers, who produce alternative fuel aftermarket conversion systems, regulatory coverage shall only extend to the modification of engines that were originally manufactured in 2022 or later. This additional clarification is necessary to ensure that aftermarket systems installed on 2021 and earlier engines, or vehicles by small manufacturers, are not covered when they occur post-2021. Since those engines were covered under Phase 1 and not Phase 2, the regulation of conversions on such systems should continue to be regulated under Phase 1 rules. [EPA-HQ-OAR-2014-0827-1270-A1 p.6]

Effect on Small Volume Alternative Fuel Engine Converters

Optimus Technologies requests clarity regarding how the proposed rule will affect small volume alternative fuel engine converters that install alternative fuel conversion systems into vehicles after the first retail sale (or introduction into retail commerce). Optimus is aware of the one-year delays available for increases in stringency. Clarity around what those increases are would be helpful. Reading the proposed rule, it is unclear which proposed regulations apply strictly to OEMs and which also apply to small volume alternative fuel engine converters. For instance, will small volume alternative fuel engine converters be required to submit fuel economy data when submitting engine certification packages? Will small volume alternative fuel engine converters need to use the GEM software? [EPA-HQ-OAR-2014-0827-1276-A1 p.3]

NGVAmerica agrees with the [Preamble] statement and supports the agencies’ decision. The one area of potential clarification would be for aftermarket conversion systems (not new engines or vehicles) where the practice has been to retain the original classification of the vehicle/engine undergoing conversion. This would mean that an in-use medium duty diesel engine converted so that it retains the diesel cycle,
would continue to be classified as a diesel engine. The conversion manufacturer would then have to certify or demonstrate compliance with the standards originally applied to the vehicle/engine undergoing conversion. Similarly, if a heavy-duty gasoline engine used in a vehicle rated at 19,500 lbs. GVWR or higher were converted to operate on natural gas, and the engine continued to be an Otto-Cycle engine, the conversion systems would be subject to the Otto-cycle standards, not the compression-ignition standards. Clarifying the treatment of aftermarket conversion would help avoid any possible confusion concerning this issue. [EPA-HQ-OAR-2014-0827-1270-A1 p.3]

Response:

It is apparent from the comments that we need to provide an overview of EPA’s policy regarding aftermarket fuel conversions as that relates to the prohibitions in the Clean Air Act. As a starting point, EPA requires that manufacturers of new engines and new vehicles obtain certification to allow them to sell their engines and vehicles in the United States. If manufacturers sell new engines or new vehicles without certifying, they would be in violation of CAA section 203(a)(1).

Companies that modify a certified engine or a certified vehicle are subject to the tampering prohibition in CAA section 203(b)(1). The statute broadly prohibits removing or rendering inoperative emission controls. This applies in a straightforward way for modifications such as removing aftertreatment devices or reprogramming an engine’s ECU for high-performance applications. This is not straightforward for fuel conversions. EPA has therefore adopted regulations at 40 CFR part 85, subpart F, to provide a path for companies performing aftermarket fuel conversions to demonstrate that their conversions do not remove or render inoperative emission controls. If a company performing conversions meets all the specified requirements, their conversions are exempt from the tampering prohibition. A company performing aftermarket fuel conversions without certifying under 40 CFR part 85, subpart F, is not in violation of the introduction-into-commerce violation of CAA section 203(a)(1).

The one-year delay in emission standards applies for manufacturers of new engines or vehicles certifying to standards under 40 CFR part 86, 1036, or 1037. This means that those manufacturers are exempt from the introduction-into-commerce prohibition under CAA section 203(a)(1) during that time, which means that they do not need to certify their engines or vehicles to the GHG standards that would otherwise apply for that year.

Companies performing aftermarket fuel conversions are subject to the tampering prohibition in CAA section 203(b)(1), with no one-year delay. The whole premise of the conversion provisions in 40 CFR part 85, subpart F, is that the tampering exemption applies where the company is able to make a demonstration that the modified engines and vehicles continue to operate at a level of emission control that is consistent with the original certified configuration. The expectation is that conversions are preserving the level of performance also for GHG emissions as established for the certified configuration when operating on the alternative fuel. This same approach applies for both Phase 1 and Phase 2 GHG standards. We would have no basis under the statute to allow conversions that increase emission levels above those of the original certified configuration.

If companies performing aftermarket fuel conversions would choose to act as a manufacturer and certify the engines or vehicles to the criteria emission standards that apply under 40 CFR part 86, subpart A or S, respectively, they would then qualify for the one-year delay in complying with GHG standards.

We agree with NGV America that the 2019 date is incorrect. We have revised that to state that small manufacturers are exempt from GHG standards until January 1, 2022. The one-year delay for
conversions is not in addition to the one-year delay for other small manufacturers; rather, the one-year delay for alternative-fuel engines applies for each new standard as it applies to new model years.

If any engines or vehicles are not yet certified to GHG standards (from small or non-small manufacturers), the GHG requirements do not apply for conversions of those engines or vehicles. Similarly, if any engines or vehicles are certified to Phase 1 GHG standards, the Phase 2 GHG requirements do not apply for conversions of those engines or vehicles. Standards for conversions never exceed the stringency of standards corresponding to the certified configuration.

Companies performing aftermarket fuel conversions must test engines or vehicles and submit information as specified in 40 CFR part 85, subpart F. This generally involves emission measurements to show that modified engines or vehicles continue to meet applicable emission standards. This would never involve using GEM.

Aftermarket fuel conversions involving a change from, for example, compression-ignition to spark-ignition engine technology continues to be subject to the same standards. Since the aftermarket requirements relate to the statutory tampering prohibition, the modified engines or vehicles are judged relative to the original certified configuration, regardless of the operating characteristics of the modified engines or vehicles.
13 Amendments to Phase 1 Standards

13.1 General Comments

Organization:  Daimler Trucks North America LLC

Changes to Phase 1: There should be no changes to Phase 1. 80 FR 40519. It is too late for us to revise aero numbers or our delegated assembly procedures, given the agencies’ lead time requirements, which require four years’ lead time for NHTSA and require a joint program for the EPA (see Massachusetts v. EPA 549 U.S. 497, 532, 2007, where the Supreme Court stated that “there is no reason to think the two agencies [EPA and NHTSA] cannot both administer their obligations and yet avoid inconsistency”). We are busy working on Phase 2, to go back and adjust computer systems or delegated assembly at this point in time is too much for our limited groups. [EPA-HQ-OAR-2014-0827-1164-A1 p.111] [Comment is also in 1.4.4 for delegated assembly.]

Response:
The final rule mostly includes only a variety of minor changes to the Phase 1 program. In most of these cases, we add options and flexibility, either to reduce burden or to align with the Phase 2 program. There are also several technical amendments where we make corrections or adjustments to testing or compliance procedures for more effective implementation. We are specifically not making changes to the Phase 1 emission standards, GEM simulations, aerodynamic bins, or other aspects of the regulation that define stringency. We have also taken steps to ensure that the Phase 1 amendments do not substantially alter data collection and submission requirements. The rest of this Section 13 describes the specific amendments to the Phase 1 program in greater detail. Section 1.4.4 describes our approach to delegated assembly.

13.2 EPA Amendments

13.2.1 Pickups and Vans

Organization:  California Air Resources Board (CARB)

The CARB staff supports the language added to 40 CFR 86.1819-14 clarifying that the CO2 standards must be met over the full useful life. CARB staff supports the addition of language setting broad applicability and pulling out specific further requirements. This approach by U.S. EPA and NHTSA will close potential loopholes for engines/vehicles that are difficult to fit into existing language. [EPA-HQ-OAR-2014-0827-1265-A1 p.189]

For non-medium-duty passenger vehicle heavy-duty vehicles, the emissions standards in 40 CFR 86.1819 apply for the currently defined useful life of 11 years, 120,000 miles though MY 2020, then increase to 150,000 miles/15 years with MY 2021 and beyond. Under 40 CFR 1036.108 (d), a 150,000 mile/15 year useful life over which compliance must continue is also specified (page 40585 of the NPRM). CARB staff supports the increased useful life for vocational class 2b through 5 vehicles from 110,000 miles/10 years to 150,000 miles/15 years as specified in 40 CFR 1037.105 (e)(1). [EPA-HQ-OAR-2014-0827-1265-A1 p.189]

Organization:  Daimler Trucks North America LLC

Part 86 Changes - We agree with all the changes done in Part 86.
Response:

We are adopting the provisions as proposed and as supported by the commenters.

13.2.2 Differentiating Spark-Ignition and Compression-Ignition Engines

Organization: Power Solutions International (PSI)

One area of the proposed rule seems to discriminate against spark-ignition engines while favoring compression ignition engines. We are specifically concerned with the language pertaining to spark-ignition engines that operate on fuels other than gasoline and are “engines that qualify as medium heavy-duty or heavy heavy-duty and do not operate on gasoline.” The proposed rule would require such spark-ignition engines to comply with standards applicable to compression-ignition engines. [EPA-HQ-OAR-2014-0827-1161-A1 p.1]

We feel this language will put some spark-ignition engines at a disadvantage and will potentially “regulate” these engines out of the market. In turn, this language seems to give an advantage to diesel derived spark-ignition alternative fueled engines (all of which are fueled by CNG fuel only) and may “regulate” these engines into the market. The language in the proposed rule appears to be derived from the diesel engine manufacturer sector, specifically from those manufacturers that offer diesel derived spark-ignition engines that operate on CNG fuel. [EPA-HQ-OAR-2014-0827-1161-A1 p.1]

Diesel engine derived spark-ignition engines are converted from compression-ignition engines. In some cases up to 80% of the diesel derivative components are used in converting the spark-ignition engine variant. Cummins Westport advertises the commonality between their NG ISX/ISL/ISB engines and their Cummins diesel derivatives. These diesel derived spark-ignition engines are generally turbocharged with CAC, have high compression ratio and are specifically targeted for CNG or LNG fuel. These engines are typically not targeted or sold to applications that use LPG, which requires compression ratios similar to what is used for gasoline fuel. These diesel derived spark-ignition engines are design for rebuild and can be sold into Class 8 line haul applications and down into medium heavy-duty vocational markets. [EPA-HQ-OAR-2014-0827-1161-A1 p.2]

Our company supplies spark-ignition engines into the heavy duty on highway vocational vehicle sector. We supply engines into markets classified as light heavy-duty and medium heavy-duty. Our engines are “fuel agnostic” and are capable of being fueled by gasoline, LPG or CNG. Our engine long blocks are similar regardless of fuel type. Our engines are derived from the automotive sector, some of which are supplied by General Motors Powertrain and some are PSI/internally produced engine blocks. All of our on highway heavy duty spark-ignition engine products are derived and carried over from the automotive market. Our engines do not have cylinder liners and are not designed for rebuild. Our on highway heavy duty engines are all designed as spark-ignition and do not have a compression-ignition derivative. Our engines are can be sold to the light heavy duty and up into the medium heavy-duty market. [EPA-HQ-OAR-2014-0827-1161-A1 p.2]

The current proposed rule, as written, will put our spark-ignition engine products at a distinct disadvantage as compared with “diesel derived” spark-ignition alternatively fueled engine products. Diesel derived spark ignition engines are designed for heavy heavy-duty and are sold down to medium heavy-duty. They carry over 80% of the diesel content, are specifically targeted for CNG fuel and are designed for rebuild. These engines are designed to have an identical interface/foot print as the diesel derivative. [EPA-HQ-OAR-2014-0827-1161-A1 p.2]
A better approach to this regulatory language is presented below. Either approach presented would provide a more level playing field for engine manufacturers supplying non-gasoline fueled spark-ignition engines into the heavy duty vocational vehicle market. [EPA-HQ-OAR-2014-0827-1161-A1 p.2]

**Proposal for non-gasoline spark-ignition language:**

Option 1:

Unless other specified, spark-ignition engines that qualify as medium heavy-duty or heavy heavy-duty and operate on LPG or CNG must meet all the emission standards and other requirements of this part that apply for compression-ignition engines, if a manufacturer has derived the spark-ignition engine from a similar compression-ignition base engine block. If an engine qualifies as medium heavy-duty or heavy heavy-duty and operates on LPG or CNG and is derived from a similar gasoline fueled spark-ignition engine block, the engine must meet all emission standards and other requirements of this part that apply to spark-ignition engines. [EPA-HQ-OAR-2014-0827-1161-A1 p.2]

Option 2:

Alternatively, the language for Phase 2 could be such to keep all spark ignition engines, regardless of fuel type, regulated the same as gasoline (627 g/hp-hr standard). This would eliminate any biasing toward the higher BMEP “diesel derived” spark ignited engines that exists in the Phase 2 NPRM today, and would effectively put all spark ignited engine on equal footing regardless of fuel type and design origin. Diesel derived spark ignited CNG fueled engines could still have the option to comply with the compression ignition standard, should they choose (as they do today in Phase 1). [EPA-HQ-OAR-2014-0827-1161-A1 p.3]

We feel that the language we are proposing in Option 1 will sufficiently distinguish between dedicated spark-ignition engines and diesel derived spark-ignition engines and will not discriminate either. We feel it would also be acceptable to regulate all spark ignited engines to the 627 g/hp-hr standard, regardless of gasoline or alternative fuel. We are hopeful that the significant nature of this issue is taken into consideration so the final rule can specify requirements that are fair and appropriate for all manufacturers. [EPA-HQ-OAR-2014-0827-1161-A1 p.3]

**Organization:** ROUSCH CleanTech

We are concerned about the proposed changes to the standards applying to spark-ignited engines using clean alternative fuels for MHD/HHD. Two specific paragraphs are included here for reference (emphasis added): [EPA-HQ-OAR-2014-0827-1007-A1 p.2]

> “We are also proposing that these provisions would apply equally to engines fueled by any fuel other than gasoline or ethanol, should such engines be produced in the future. Given the current and historic market for vehicles above 19,500 lbs GVWR, EPA believes any alternative fueled vehicles in this weight range would be competing primarily with diesel vehicles and should be subject to the same requirements as them. We request comment on all aspects of classifying natural-gas and other engines for purposes of applying emission standards. See Sections XI and XII for additional discussion of natural gas fueled engines.” [EPA-HQ-OAR-2014-0827-1007-A1 p.2]
We believe that this discussion is problematic on several levels: [EPA-HQ-OAR-2014-0827-1007-A1 p.2]

The “current and historic market for vehicles above 19,500 GVWR” includes a wide variety of non-diesel engines. Gasoline engines are offered in commercial stripped chassis and RV chassis up to 26,000# GVWR, and chassis-cab chassis up to 33,000# GVWR. Propane autogas engines are currently offered in all Type C school bus chassis, accounting for approximately 10% of the market, and both CNG and gasoline options have recently been announced for introduction in the next year. [EPA-HQ-OAR-2014-0827-1007-A1 p.2]

The treatment of “alternative fuels” here is unique to any other context we are aware of. In all other regulatory framework, and in all practical market consideration, natural gas, ethanol, and propane are all considered clean alternative fuels to gasoline. The sole exception to this is the traditional exception that EPA has given diesel engine manufacturers who converted their engines to spark ignition natural gas—those manufacturers were allowed to certify under the compression ignition standards if it was to their benefit. We find it hard to imagine any context in which EPA would encourage the use of gasoline as a substitute for diesel, but discourage those same engines operating on natural gas or propane—but this is exactly what the regulation proposes. Propane is simply not a diesel replacement fuel in any relevant context—its octane and burn characteristics do not allow it to be easily used on a CI-based engine, and there are no current propane engines that are based on CI designs. Natural gas has several historic advantages here—very high knock resistance, and the exclusion of methane from historic pollutant standards—that has allowed its use on CI-based engines, but there is very little penetration of these engines below 33,000#. [EPA-HQ-OAR-2014-0827-1007-A1 p.2-3]

“We are not aware of any currently certified engines that would change from compression-ignition to spark-ignition under the proposed clarified approach. Nonetheless, because these proposed standards implicate rules for criteria pollutants (as well as GHGs), the provisions of CAA section 202 (a)(3) (C) apply (for the criteria pollutants), notably the requirement of four years lead time. We are therefore proposing to continue to apply the existing interim provision through model year 2020.110 Starting in model year 2021, all the provisions would apply as described above. Manufacturers would not be permitted to certify any engine families using carryover emission data if a particular engine model switched from compression-ignition to spark-ignition, or vice versa. However, as noted above, in practice these vehicles are already being certified as CI engines, so we view these changes as clarifications ratifying the current status quo.” [EPA-HQ-OAR-2014-0827-1007-A1 p.3]

The paragraph above is technically correct, in that it should only apply to engines that are currently certified as compression-ignition. However, the proposed regulatory change doesn’t only apply to those engines—it applies to all SI engines “other than gasoline or ethanol.” Therefore, the logic presented is simply wrong. Using the last complete HD certification data available on the EPA website (2014), it shows spark-ignited engines, certified to SI standards, from BAF, Bi-Phase Technologies, Clean Fuel USA, Greenkraft, ICOM, Landi Renzo, NGV Motori, Roush, Westport, and IMPCO; these engines are all offered in vehicles above 19,500# GVWR (school bus, straight truck, stripped chassis). The only SI engines listed as certified to CI standards are those from Cummins; to the best of our knowledge these engines have little or no market acceptance below 33,000# GVWR. This change would have significant impact to the market below 33,000#. [EPA-HQ-OAR-2014-0827-1007-A1 p.3]

We also believe that the proposed change would cause an unintended distortion of the Class 6/7 market. As proposed, an engine manufacturer which supplies propane or CNG engines, based on conventional SI engine technology, to chassis OEM’s (including at least ROUSH CleanTech and PSI/PTI currently)
would be required to meet the compression ignition standards. These same engines, if certified as conversions, would only be required to meet the spark ignition (gasoline) standards. This makes no sense—it is the same engine, used by the same customer in the same way. Encouraging these engines (which the customer always intends to use on the clean alternative fuel) to circumvent the full OEM certification procedure and move into the conversion standards is a clear market distortion, and will likely reduce the environmental benefits that would be accomplished from a complete OEM certification. Requiring the conversion manufacturers to certify under the CI standard would be even worse; the changes to useful life alone would be prohibitively expensive for a conversion manufacturer. Therefore, we think that this is another strong justification for keeping the certification standards the same for gasoline and clean alternative fuels used on gasoline-based engine technologies (whether they were conversions or not). [EPA-HQ-OAR-2014-0827-1007-A1 p.3]

In general, we believe that the proposal appears to have been developed primarily focused on the Class 8 (over 33,000#) GVWR market, and because of this, that the only alternative fuel that was studied in any detail was natural gas. We believe that the proposed changes below 33,000# would harm consumer choice; are not supported in the text; and are not consistent with actual market conditions. However, we understand the agencies’ concern about the potential “loophole” in Class 8 applications which could result in CI manufacturers achieving a competitive advantage through use of the SI standard for natural gas engines which are otherwise fully capable of meeting the CI standard. Therefore, we propose the following revisions: [EPA-HQ-OAR-2014-0827-1007-A1 p.3-4]

- Keep the Phase 1 GHG compliance logic in place for all engines certified for use in vehicles up to 33,000# GVWR (LHD/MHD). Spark-ignited engines certify to the proposed SI standards, regardless of fuel type, and vehicles using these engines will certify to the proposed SI vehicle standards. CI engine manufacturers may choose to certify their SI engines under the CI standards; engines certified in this manner will be considered CI for the purposes of averaging, banking, and trading. [EPA-HQ-OAR-2014-0827-1007-A1 p.4]
- Engines fueled partially or wholly by natural gas, used in vehicles above 33,000# GVWR, must certify to the CI standards, regardless of ignition type. Spark-ignited engines using gasoline must be certified to the SI standards; SI engines using clean alternative fuels other than natural gas may be certified as SI engines or CI engines at the choice of the manufacturer. [EPA-HQ-OAR-2014-0827-1007-A1 p.4]

We believe that this approach protects the consumer choice in the existing Class 6/7 market; eliminates a potential incentive to use gasoline instead of propane/natural gas in these products; and still ensures there is no incentive for Class 8 engine manufacturers to certify as spark-ignited to take advantage of the higher GHG standard. In this way, we think it is fully consistent with the stated intention of Phase 2, and protects all of the proposed environmental benefits better than the original proposal. In the long run, we think that accounting for full life-cycle emissions for all fuels, and ensuring a robust credit trading marketplace between manufacturers, will hopefully eliminate the need for the split SI/CI standards altogether. [EPA-HQ-OAR-2014-0827-1007-A1 p.4]

**Organization:** American Automotive Policy Council

**Classification of Spark Ignited CNG Engines**

The agencies requested comment (80 Federal Register 40207) on re-classifying natural-gas engines for purposes of emission and GHG regulations. AAPC does not agree with EPA’s proposal to reclassify all natural gas and propane fueled vehicles > 19,500 lbs. GVWR from “spark ignition” to “compression ignition” status. While liquid natural gas storage systems and large displacement turbo charged engines
with spark ignition and three way catalysts are an emerging competitor to urea/SCR diesel technology, naturally aspirated spark ignited CNG and propane engines serve entirely different needs and segments much closer to their gasoline powered SI counterparts. [EPA-HQ-OAR-2014-0827-1238-A1 p.30]

AAPC proposes that Phase 2 compressed natural gas / propane emissions classification be subject to the following three criteria: (1) Is the GVWR > 37,000lbs? (2) Is the engine boosted? (3) Is advertised / certified peak torque of the engine > 15 bar BMEP? Only if the answer to any of these questions is “yes” should the engine/vehicle be subjected to the compression ignition standards. [EPA-HQ-OAR-2014-0827-1238-A1 p.30]

Organization:  California Air Resources Board (CARB)

Support Comment

Comment – Natural gas engines and vehicles certifying according to intended service class

CARB staff supports the Phase 2 proposal to require any natural gas engine qualifying as a medium heavy-duty (19,500 to 33,000 lbs GVWR) or heavy heavy-duty (over 33,000 lbs GVWR) natural gas engine to be subject to all the emission standards (GHG and criteria pollutant) and other requirements, including the longer useful life and warranty provisions, that apply to compression ignition engines. [EPA-HQ-OAR-2014-0827-1265-A1 p.164-165]

CARB supports the proposal to require medium heavy-duty and heavy heavy-duty engines to meet compression ignition requirements (useful life, warranty, not-to-exceed limits, criteria pollutant standards) because they are more stringent and protective of air quality compared to the comparable spark-ignited requirements. [EPA-HQ-OAR-2014-0827-1265-A1 p.165]

CARB believes there are some 6.8 to 9 liter natural gas engines (produced by BAF, Greenkraft, Impco, Landi Renzo, and Power Solutions) that are currently being certified to the Otto-cycle requirements that may be offered in the future in medium heavy- and even heavy heavy-duty vehicle configurations, and thus could ultimately be impacted by the proposed requirements. Many of these natural gas “converters” offer vehicles primarily in the light heavy-duty classes, and there is some possibility that with the additional requirements they may no longer choose to offer medium heavy-duty and heavy heavy-duty natural gas vehicles. However, this should have minimal market impact as Cummins is already certifying their spark-ignited natural gas engines to the compression ignition requirements. [EPA-HQ-OAR-2014-0827-1265-A1 p.165]

40 CFR1036.150 (e) Alternate phase-in standards (page 40587 of the NPRM) states “[w]here a manufacturer certifies all of its model year 2013 compression-ignition engines within a given primary intended service class to the applicable alternate standards of this paragraph (e), its compression ignition engines within that primary intended service class are subject to the standards of this paragraph (e) for model years 2013 through 2016.” Then follows an untitled table, the last line of which is labeled “Model Years 2016 and later,” and provides standards of 576 g/hp-hr for light heavy-duty and medium heavy-duty engines, and 555 g/hp-hr for heavy-duty diesel engines. CARB staff believes this last line of the table should be labeled “Model Years 2016 through 2020.” The presumably unintended implication in this table as written is that if a manufacturer follows this alternate phase-in schedule, the manufacturer may continue to certify engines to the same standard after 2016 and throughout Phase 2. [EPA-HQ-OAR-2014-0827-1265-A1 p.190]
C. Classification of NG Engines. The notice indicates that the agencies plan to continue the practice of regulating most heavy duty natural gas engines as compression ignition engines. NGVAmerica supports the decision to retain the current regulatory framework used to classify natural gas engines. We are not aware of any manufacturers who have requested a change in classification.

Organization: NGVAmerica

C. With regard to Chuck Moulis note 6 August 2015 stating the following:

- No delay in the applicable standards under §85.525.
- That small converters showing compliance with the applicable part 1036 engine standards under §85.525 would not be required to separately show compliance with the part 1037 vehicle standards as long as the pre-conversion vehicle was certified to the part 1037 standards and the converter does not modify certified vehicle components such as tires, axles, and transmissions.

Trying to understand the implications of the above statements to a non-new fully OEM certified HHDD engine (before conversion) and how it would relate to a HHDD (>26K #s) mixed-fuel converted engine.

- GHG standards would apply to mixed-fuel engine emissions under 85.525 and 1036.108

[Table from NPRM under 1036.108 greenhouse gas emissions standards can be found on p.3-4 of docket number EPA-HQ-OAR-2014-0827-1197-A1]

It would appear the CO2, CH4 and N2O standards for HHDD engine Mixed-Fuel conversion in a tractor for a SVM starting in Jan 2023 would be CO2.

Organization: American Power Group Inc. (APG)

Oppose/Requested Change Comment

Comment – Definitions

The definition of compression ignition in 40 CFR1036.801 has been expanded to include gas turbines and ‘certain’ spark-ignited engines. CARB staff believes it would be appropriate to either state here which spark-ignited engines are to be treated like compression ignition and subject to the requirements of compression ignition or to provide a reference to the appropriate section so describing, which would appear to be 40 CFR1036.140. 40 CFR 1036.140 (a) states that medium heavy-duty and heavy heavy-duty engines that do not run on gasoline must meet compression ignition standards, even if they are
spark-ignited engines. Gasoline-fueled (including dual fuel) medium heavy-duty and heavy heavy-duty meet spark-ignited standards. Light heavy-duty spark-ignited engines meet spark-ignited requirements regardless of fuel. Thus, CARB staff suggests the following modification to the definition of compression ignition in 40 CFR 1036.801: [EPA-HQ-OAR-2014-0827-1265-A1 p.188]

Compression ignition means relating to a type of reciprocating, internal-combustion engine that is not a spark-ignited engine. Note that 40 CFR 1036.1 also deems gas turbine engines and other engines to be compression-ignition engines. Note also that certain spark-ignited engines are subject to the requirements for compression-ignition engines, specifically, per 40 CFR 1036.140(a), medium heavy-duty and heavy heavy-duty engines that do not operate on gasoline, even if they are spark-ignited engines. [EPA-HQ-OAR-2014-0827-1265-A1 p.189]

The CARB staff supports the lengthening of the useful lives of class 2b through 8 engines and vehicles to more properly reflect their actual use. [EPA-HQ-OAR-2014-0827-1265-A1 p.189]

Response:

As noted in the proposed rule, EPA’s objective in setting standards for alternative-fuel engines is to adopt requirements that create a level playing field for competitive products. For Class 5 and smaller vehicles for example (light heavy-duty), it is clear that there is a substantial market position for gasoline-fueled engine. On that basis, we proposed an approach that would allow alternative-fueled spark-ignition engines to meet the same standards that apply for other spark-ignition engines. For bigger vehicles, it was not so clear that there was enough of a market position for gasoline-fueled or other spark-ignition engines to justify setting less stringent standards for alternative-fueled spark ignition engines. The outcome to avoid is one in which an alternative-fueled engine gains a competitive advantage in a market that is dominated by compression-ignition engines, which are subject to more stringent CO₂ standards.

We have concluded that Class 8 vehicles (heavy heavy-duty) are clearly dominated by compression-ignition engines. As such, alternative-fueled engines, whether they are derived from gasoline or diesel engines or created as a new engine design, should be subject to the same emission standards as all the other engines competing in that market.

The situation for engines used in Class 6 and Class 7 vehicles (medium heavy-duty) is less clear-cut. Most of these vehicles use compression-ignition engines, but there is a viable market niche for gasoline-fueled engines. For the final rule, we are opting not to adopt the proposed approach. We are instead setting the standards for medium heavy-duty engines to correspond to the actual engine type, with all spark-ignition engines subject to the same standards that apply for gasoline-fueled engines. Given that some of these engines are already certified to standards for compression-ignition engines, we are also adopting a provision allowing manufacturers to opt into the more stringent compression-ignition standards.

In order to balance our concerns about alternative-fueled engines certifying as spark-ignition, but competing with compression-ignition engines, we are finalizing a restriction against medium heavy-duty alternative-fueled engines generating emission credits relative to the spark-ignition standards. Manufacturers of such engines may generate emission credits only if they choose to certify the engines to the compression-ignition Aftermarketstandards. Aftermarket fuel conversions are certified to meet the specified standards to gain an exemption from the tampering prohibition. As such, converted engines are generally required to meet the same standards that applied to the engine when it was new. The final rule includes a one-year delay for small businesses with respect to meeting new emission standards adopted in this rule.
We revised the final rule to no longer state that spark-ignition engines are subject to the standards that apply for compression-ignition engines. We instead have made the emission standards for heavy heavy-duty engines to be universal, applying equally to both spark-ignition and compression-ignition engines. This approach prevents the confusion addressed by the comment from California ARB.

We have revised the applicability dates for the phase-in standards in §1036.150 as suggested by California ARB.

We are adopting the useful-life provisions for engines as proposed and supported by California ARB.

13.2.3 Evaporative Emission Testing for LNG Vehicles

Organization: American Gas Association (AGA) et al.

Industry is Better Situated to Determine LNG Tank Hold-Times

EPA has proposed adopting industry standard SAE J2343 which requires a 5-day hold-time for natural gas tank boil-off on vehicles powered by LNG. ATA supports the decision of EPA to defer to, and reference, industry standards relating to hold-times for LNG tanks. The current standards address concerns related to emissions from natural gas vehicles that could be parked for long periods of time without use. Concerns related to vehicles that are parked and unused for longer periods of time can, and should be addressed by operational practices such as starting up the vehicle for a short period of time to relieve pressure, or scheduling to ensure that vehicles do not remain parked for long periods of time. Compliance demonstrations of the 5-day hold-times should be the responsibility of tank manufacturers or fuel system packagers. [EPA-HQ-OAR-2014-0827-1243-A1 p.23]

We Support the Proposed Requirement for Industry to Adhere to the Recommended Practices as Defined in SAE J2343 for Evaporative Emissions from LNG Vehicle Fuel Systems

We support the proposed inclusion of the requirement to adhere to SAE J2343 as a means of demonstrating compliance with the five-day hold time requirement. [EPA-HQ-OAR-2014-0827-1223-A1 p.4]

However, in the final rule, we strongly recommend that the agencies clarify that SAE J2343 applies to a vehicle’s fuel system, rather than the engine or vehicle itself. This is an important distinction and one that is not clearly made in the Proposal. Engines and vehicles, as required under the Phase 1 Rule and the Phase 2 Proposal, demonstrate compliance through engine bench or chassis dynamometer tests, as well as simulation in the Greenhouse Gas Emissions Model (GEM). However, demonstrating compliance with SAE J2343 cannot be performed using any of those tests or simulations. Thus, we are providing recommend language below, which will help the agencies better reflect the difference applications of SAE J2343 and the Phase 2 Proposal. [EPA-HQ-OAR-2014-0827-1223-A1 p.4]

The SAE J2343 standard specifies a minimum five-day hold time. However, as the agencies noted, the standard provides little description regarding the procedure for determining the amount of time between a refueling event and initial venting. We provide the following three recommendations to help the agencies clarify the application of SAE J2343: [EPA-HQ-OAR-2014-0827-1223-A1 p.4]

- We recommend that the agencies revise the existing language that “the vehicle must remain parked...” to state clearly that “the tank must remain immobile...” This reflects a more accurate
description of SAE J2343’s application to the vehicle’s fuel system, rather than the engine or vehicle. [EPA-HQ-OAR-2014-0827-1223-A1 p.4]

- We recommend that the agencies either expand the proposed ambient temperature range of 20-30°C to 10-30°C, or include a temperature correction factor. This revision would provide OEMs and integrators located in northern U.S. states and Canada a more equitable opportunity to conduct fuel systems compliance tests. Further, we note that this broader temperature range of 10-30°C will have minimal impacts as the inner tank temperature is roughly -140°C. [EPA-HQ-OAR-2014-0827-1223-A1 p.4]

- We recommend that the agencies revise the existing language that “This standard and procedure are consistent with Section 9.3.5 of NFPA 52, except that NFPA specifies a three-day hold time” to become “This standard and procedure are consistent with Section 9.3.5 of NFPA 52, except that NFPA specifies a three-day hold time and requires a stabilization period not otherwise required in SAE J2343.” [EPA-HQ-OAR-2014-0827-1223-A1 p.5]

Organization: Daimler Trucks North America LLC

Request for Comment on Extending the 5 Day Hold Time for LNG Vehicles - [redacted] [EPA-HQ-OAR-2014-0827-1164-A1 p.110]

LNG venting test: The agencies discuss an LNG venting test but fail to clarify: is the test at any temperature between 20 and 30°C that the EPA chooses on an audit? In other words, if the system is designed, tested, and demonstrated to pass on a series of 5 days with ambient temperatures varying naturally between 20 and 30°C but the EPA audits by taking the vehicle to a controlled-temperature shed and testing at exactly 30°C for five straight days, under which test the system fails, is that a failed audit? [Redacted], we think that the proposed change to the test procedures is acceptable. [EPA-HQ-OAR-2014-0827-1164-A1 p.110]

L. 5 Day Hold Time for LNG Vehicles. EPA has proposed adopting industry standards per SAE J2343 that address natural gas boil off on vehicles powered by LNG. This standard requires a 5-day hold time but EPA has requested comments on extending this to 10-days. EPA has requested comment on who should be responsible for certifying compliance with these requirements and how this responsibility could be delegated. [EPA-HQ-OAR-2014-0827-1270-A1 p.9]

NGVAmerica supports the decision of EPA to defer to, and reference, industry standards relating to hold times for LNG tanks. At this time, we are unable to support modifying requirements for natural gas tanks to extend hold times beyond what is currently recognized by natural gas safety standards. We appreciate EPA’s concerns relating to hold times and its interest in understanding whether additional hold times are feasible or necessary. The current hold times are based on a 4-day weekend that includes allowance for holidays. We believe that the current standards address concerns related to emissions from NGVs that could be parked for long periods without use. Any additional concerns related to vehicles that are parked and unused for longer periods of time can and should be addressed by operational practices such as starting up the vehicle for a short period of time to relieve pressure, or scheduling to ensure that vehicles do not remain parked for long periods of time. [EPA-HQ-OAR-2014-0827-1270-A1 p.9]

In terms of responsibility for demonstrating compliance with these standards, it is likely that only tank manufacturers or fuel system packagers would be able to demonstrate this compliance. The existing vehicle regulations, such as chassis testing and engine dynamometer testing, would not be sufficient to demonstrate compliance. [EPA-HQ-OAR-2014-0827-1270-A1 p.10]
NGV America welcomes additional discussion of this issue with EPA and affected industry. [EPA-HQ-OAR-2014-0827-1270-A1 p.10]

M. Other Issues Related to LNG Vehicles: LNG Boil-Off Warning Systems; Capturing and/or Converting Methane Refueling or Boil-Off Emissions; On-Board Monitoring Requirements for Boil-Off Events and Venting at Refueling. [EPA-HQ-OAR-2014-0827-1270-A1 p.10]

EPA discusses a host of other issues relating to LNG vehicles and possible emissions. With respect to these issues, we reiterate our support for EPA’s decision to rely on existing industry standards for LNG vehicles. We are unable to endorse new requirements or additional regulations when it is not clear what technologies exist to address these issues or how they would impact the safety of operating natural gas vehicles. We welcome additional discussion with EPA on how these standards can be revised or expanded to address issues of concern. [EPA-HQ-OAR-2014-0827-1270-A1 p.10]

Organization: Truck & Engine Manufacturers Association (EMA)

In addition, the proposed evaporative emission requirements for LNG vehicles need to be modified to be more consistent with the longstanding and accepted industry guidelines that are incorporated by reference into the proposed regulatory requirements. Proposed section 1037.103(e) incorporates SAE Recommended Practice J2343 and NFPA 52 into the mandated LNG vehicle leak requirements. However, SAE J2343 and NFPA 52 each specify LNG tank requirements, while the agencies’ proposed requirements would apply to a vehicle that is built with an LNG tank. For the reasons stated above, and to be consistent with SAE J2343 and NFPA 52, the evaporative emission standard should apply to the tank itself, not the vehicle, regardless of whether it is installed by the vehicle manufacturer or some subsequent manufacturer.2 [EPA-HQ-OAR-2014-0827-1269-A1 p.44-45]

[T]he proposed changes to the Phase 1 requirements for LNG venting should not be finalized, as those changes also would amount to retroactive amendments to the overall stringency and cost of the Phase 1 program in violation of administrative due process and the CAA’s leadtime and stability provisions. Moreover, the proposed LNG venting process is ill-defined, lacks a sufficiently definite test temperature and pressure, and fails to include the necessary audit parameters and procedures. In sum, there is no reason to pull those proposed provisions forward, especially when to do so would disrupt the implementation and feasibility of Phase 1. [EPA-HQ-OAR-2014-0827-1269-A1 p.22]

2 If vehicle manufacturers are to be made responsible for testing LNG tanks, better clarity will be required with respect to the starting conditions for such testing, including with respect to LNG tank temperature and pressure.

Organization: Union of Concerned Scientists (UCS)

We strongly support the agencies inclusion of controls for LNG tank hold times. [EPA-HQ-OAR-2014-0827-1329-A2 p.26]

Organization: Volvo Group

LNG Tank Venting
Volvo Group supports the agencies’ efforts to establish hold time requirements for Liquid Natural Gas (LNG) tanks. These are vital since venting is the largest source of evaporative emissions on LNG vehicles, and controlling emissions from tank venting was not addressed in the Tier 3 rulemaking of April 28, 2014. Since the 100 year Global Warming Potential (GWP) of CH4 is 28-36 times greater than CO2, it is appropriate that precautions are taken to limit tank venting and its greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1290-A1 p.46]

The requirements proposed in 1037.103(e) (Evaporative and refueling emission standards) are vague and ambiguous. They make indirect reference to two industry recommended practices without specifying how these conflicting recommended practices should be specifically applied. The Agency stipulates a vehicle test to demonstrate LNG tank hold times, whereas SAE J2343 and NFPA 52 specify “tank only” hold time requirements. Demonstration tests performed by tank manufacturers today according to these recommended practices are “tank-only” tests conducted in controlled environments. Volvo Group believes that since LNG tank hold time is dependent on tank design, and has little or no dependence on vehicle installation conditions, fulfillment of any hold time requirements should be met with tank-only demonstrations. Demonstration tests conducted on the tank itself, complete with associated valves, vents and other plumbing, can be conducted in a more controlled environment than is possible after the tanks are installed on the vehicle. This also avoids multiple tests of the same tank design by various vehicle manufacturers, which would unnecessarily add cost, especially given that LNG is today a low volume segment of the vehicle market. [EPA-HQ-OAR-2014-0827-1290-A1 p.46-47]

Section 1037.103(e) specifies the hold time measurement is to start after a “conventional refueling event” without a clear definition of the event itself, or what is meant by a “conventional” event. SAE J2343 (section 4.2) and NFPA 52 (section 9.3.5) each specify unique yet incomplete procedures for the filling/refueling event. A robust test should specify the starting temperature and/or pressure, and quantity of LNG already in the tank, as well as the amount of fuel to be added or tank fill level, and the temperature and/or pressure of the LNG added during the refueling event. Without this specificity concerning starting conditions, the requirements are an incomplete assessment of tank performance, and leave far too much to the discretion of the manufacturer. The Agency also specifies the hold time to start “without a stabilization event” (section 1037.103(e)) which also needs to be defined, as it is not mentioned in SAE J2343. On the other hand, NFPA 52 requires that the LNG be stabilized at the start of the hold time test, which contradicts the agencies’ proposed requirements. EPA should clarify their expectations with respect to these conflicting requirements. In addition section 1037.103(e), SAE J2343, and NFPA 52 all specify different ambient temperature requirements for the duration of the hold time test; EPA should specify a single allowable ambient temperature range. [EPA-HQ-OAR-2014-0827-1290-A1 p.47]

Volvo Group supports the EMA comments that propose that the tank manufacturer certify the tank hold time performance with the agencies. This is necessary when considering the fact that LNG tanks are frequently installed by secondary manufacturers and the aforementioned inefficiency in requiring each vehicle manufacturer to repeat the testing. [EPA-HQ-OAR-2014-0827-1290-A1 p.47]

The Agency requested comments as to whether they should increase the LNG tank hold time requirement beyond the current SAE J2343 hold time of 5 days. Volvo Group supports the interest to prolong tank hold times, but only cautions that the agencies consider the technical feasibility of a longer hold time requirement, especially recognizing that the requirement must be fulfilled for the useful life of the vehicle. [EPA-HQ-OAR-2014-0827-1290-A1 p.47]
Again, the Volvo Group supports the agencies actions to promulgate improved procedures to limit the venting of high global warming potential (GWP) methane into the atmosphere. The proposal can be improved by clarifying, beyond the details in the industry recommended practices today, the refueling procedures and starting conditions for the refueling event. EPA should also consider additional requirements for fueling station equipment and refueling practices. [EPA-HQ-OAR-2014-0827-1290-A1 p.48]

Organization:  PACCAR, Inc.

PACCAR should not be further burdened with the responsibility for determining leakage [from LNG vehicles]. [EPA-HQ-OAR-2014-0827-1204-A1 p.30]

Oppose/Requested Change Comment

Comment – Proposed evaporative emissions testing provisions for LNG vehicles

The NPRM requests comment on all aspects of the proposed provisions for LNG vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.120]

CARB staff supports regulatory action encouraging long hold times before boil off emissions are emitted, but suggests clarifying the requirements. The draft Phase 2 regulatory language states, “Liquefied natural gas vehicles must meet the requirements in Section 4.2 of SAE J2343 (incorporated by reference in § 1037.810), which specifies that vehicles meet a five-day hold time after a refueling event before the fuel reaches the point of venting to relieve pressure.” [EPA-HQ-OAR-2014-0827-1265-A1 p.120]

SAE Standard J2343 states the following regarding LNG venting and tank design: “Vehicle LNG Tanks shall have a design hold time (build pressure without relieving) of 5 days after being filled net full and at the highest point in the design filling temperature/pressure range.” (Section 4.2 of SAE Standard J2343) [EPA-HQ-OAR-2014-0827-1265-A1 p.120-121]

The SAE Standard J2343 covers the test initial conditions adequately: 1) fill level and 2) thermal energy in the tank as expressed in either temperature or pressure of the fuel, and the draft Phase 2 regulatory language specifies that the vehicle must remain parked away from direct sun with ambient temperatures between (20 and 30) degree Celsius throughout the measurement procedure. [EPA-HQ-OAR-2014-0827-1265-A1 p.121]

However, the SAE Standard J2343 does not give detail about how fill level, thermal energy in tank, or venting would be measured. For example, the fuel flow rate threshold or minimum fuel mass emission that defines a venting event needs to be specified. [EPA-HQ-OAR-2014-0827-1265-A1 p.121]

CARB staff recommends specifying the required measurement techniques for determining hold time. [EPA-HQ-OAR-2014-0827-1265-A1 p.121]

There is also need for durability requirements for LNG tanks. At present the NPRM proposal is for 5 days for new vehicles only with no restriction on subsequent degradation of vacuum insulated tanks. A minimum durability of the insulation is imperative to controlling boil off emissions over the life of the vehicle. CARB staff recommends the following language be added: “vehicle mounted LNG tank
insulation shall continue to meet SAE Standard J2343 hold time standards through the emissions warranty period of the vehicle.” [EPA-HQ-OAR-2014-0827-1265-A1 p.121]

Support Comment

Comment – Proposal to require 5-day hold time for LNG vehicles

CARB supports the Phase 2 proposal to require a 5-day hold time for LNG vehicles, to reduce the potential for an LNG boil-off event. Manufacturers would have to follow current industry recommended practice, SAE Standard J2343 for 5-day hold time to limit boil-off emissions from LNG vehicles. Boil-off events occur when a LNG truck is parked or driven very little, the fuel vaporizes, and the pressure inside the tank increases to a maximum of 230 pounds per square inch (psi) and a safety release valve releases the methane gas to vent excess pressure. CARB staff concurs that the venting characteristics inherent in LNG vehicles are an emissions concern, and recommends adoption of this requirement. CARB staff believes this is a good step towards limiting the release of methane from natural gas fueled vehicles, and that this will better standardize the requirements. CARB may consider similar requirements in the future. [EPA-HQ-OAR-2014-0827-1265-A1 p.166]

Organization: NGV America, et al

Additional Comments

EPA had additional communications with industry representatives to further work out the test procedures associated with LNG venting. Most of these additional comments were related to EPA’s suggested secondary in-use test based on vehicle testing to establish an allowable pressure rise corresponding to the five-day hold time requirement. Manufacturers suggested a standard of 25 kPa per hour instead of EPA’s specified 9 kPa per hour. This greater allowance was largely intended to account for a high degree of variability from operators and other third parties performing tests with a wide range of experiences for refueling, parking, and reading pressure gauges. The accuracy and readability of the pressure gauges themselves were a substantial consideration. Manufacturers also suggested revising the in-use procedure to (1) more closely mimic the refueling event used for tank testing, (2) include a short drive after refueling to help stabilize fuel temperature and pressure inside the tank, and (3) define a window of tank pressures (345 – 900 kPa) to establish a proper starting condition for testing.

Organization: Enovation Controls (ENC)

3.3 Fuel Tank Safety - Safety references are made on page 779 with respect to Natural Gas vehicles. Fuel systems for natural gas vehicles are thoroughly vetted in the Heavy Duty market and are subject to extensive, thoughtfully-considered federal regulations, ISO standards and ANSI guidelines. Applicable U.S. Federal Motor Vehicle Safety Standards include: 49 CFR 571.303 Fuel System Integrity of Compressed Natural Gas Vehicles, ISO 15500-9:2012; 49 CFR 571.304 Compressed Natural Gas Fuel Container Integrity; and 49 CFR 393.68 Compressed Natural Gas Fuel Containers. Additional guidelines include: National Fire Protection Association (NFPA) 52 Vehicular Gaseous Fuel Systems Code, 2013; ANSI/IAS NGV 2 Standard for Compressed Natural Gas Fuel Containers; and ANSI/AGA NGV3.1/CGA 12.3 Fuel System Components for Natural Gas Powered Vehicles. We submit that no change is required to existing regulations, and that any future modification to fuel tank regulation should be contained within existing regulatory framework. The section in question in the Phase 2 proposal regarding fuel tank safety is not value-added and should be removed from the Phase II proposal. [EPA-HQ-OAR-2014-0827-1203-A1 p.3]
Organization: Quantum Technologies

XIII. Amendments to Phase 1 Standards

(3) EVAPORATIVE EMISSION TESTING FOR LNG VEHICLES [EPA-HQ-OAR-2014-0827-1154-A1 p.2]

Heavy-duty vehicles fueled by natural gas have for many years been subject to evaporative emission standards and test procedures. While fuel systems containing gasoline require extensive design features to handle vented fuel, fuel systems containing natural gas generally prevent evaporative losses by remaining sealed. In the case of compressed natural gas, there is a voluntary consensus standard, ANSI NGV1-2006, that is designed to ensure that there are no leaks or losses during a refueling event. Since compressed natural gas systems remain sealed indefinitely once the refueling event is complete, we understand that complying with the ANSI refueling standard is sufficient to demonstrate that the vehicle also complies with all applicable evaporative emission standards. The Light-Duty Tier 3 final rule included provisions to clarify that compressed natural gas systems meeting the applicable ANSI standard are deemed to comply with EPA's evaporative emission standards. [EPA-HQ-OAR-2014-0827-1154-A1 p.2]

Quantum proposes the following alternative to the XIII. Amendments to Phase 1 Standards [EPA-HQ-OAR-2014-0827-1154-A1 p.2]

(3) EVAPORATIVE EMISSION TESTING FOR LNG VEHICLES [EPA-HQ-OAR-2014-0827-1154-A1 p.2]

Although the ANSI NGV1-2006 specified CNG refueling device is the correct choice for light duty applications, Quantum believes that specifying only ANSI NGV1-2006 limits better options for refueling heavy duty CNG trucks. The ANSI NGV1-2006 CNG refueling device is very low in flow capability for a heavy duty application. It is common for heavy duty applications to have CNG fuel capacities between 40 to 280 diesel gallon equivalent (DGE). This heavy duty CNG tank capacity is far greater than the typical light duty CNG tank capacity (less than 20 DGE). The small ANSI NGV1-2006 CNG refueling device would cause excessive fill times on heavy duty applications with no benefit to evaporative refueling emissions. Commonly used higher flow CNG refueling devices for heavy duty vehicles meet the requirements of ECE R110 Annex 4F 4.2, and have greater than twice the cross sectional flow area of an ANSI NGV1-2006 device. ECE R110 Annex 4F is comparable to ANSI NGV1-2006 from an evaporative and refueling emissions performance requirement. Like ANSI NGV1-2006, ECE R110 Annex 4F is also designed to ensure that there are no leaks or losses during a refueling event. [EPA-HQ-OAR-2014-0827-1154-A1 p.2]

By allowing the alternative ECE R110 Annex 4F 4.2 in addition to ANSI NGV1-2006 specified CNG refueling devices, the intent of meeting all applicable evaporative emissions is still maintained, and faster filling rates needed for larger heavy duty CNG tank capacities is allowed. [EPA-HQ-OAR-2014-0827-1154-A1 p.2]

Response:

We are retaining the five-day hold time described in SAE J2343 for the final rule, as supported by most commenters. We agree to some extent with commenters expressing a concern that technological feasibility has not been established for achieving hold times longer than five days throughout a vehicle’s useful life.

Before describing detailed responses to the comments, it is important to clarify the context of the proposed hold-time requirement. EPA’s evaporative emission standards for heavy-duty vehicles apply
equally to gasoline-fueled and gaseous-fueled vehicles. As such, LNG vehicles are today subject to the
current evaporative emission standards and test requirements, even though those standards and test
procedures were designed around the technologies associated with gasoline-fueled vehicles. The hold-
time requirement is intended to create a parallel compliance demonstration that applies in lieu of the
conventional evaporative emission standards. The objective of pursuing a hold-time standard is to
capture the current best practices for manufacturers of LNG fuel systems to ensure that vehicles and
their fuel tanks are properly designed and manufactured to contain fuel during normal operation (and
non-operation) to the greatest degree that can be achieved with available technology.

Because the hold-time standard is an alternative means of demonstrating compliance with an existing
standard, the minimum lead-time requirement does not apply. In fact, while we specify a start date of
January 1, 2020, we are specifically creating an allowance for manufacturers to certify based on the
SAE J2343 protocol directly upon completion of the final rule. It is also the case that the existing
framework of requirements that apply under voluntary consensus standards adopted by industry and
other associations does not address the concerns associated with EPA’s evaporative emission standards,
which requires that we adopt provisions to allow for certifying LNG vehicles.

We have revised the measurement procedure for the hold-time test to be focused on the vehicle’s fuel
tank as the test article. We have similarly revised the certification protocol to allow either vehicle
manufacturers or tank manufacturers (or assemblers) to certify with respect to the hold-time standard for
evaporative emissions, even if a different company certifies the vehicle with respect to exhaust
emissions. We agree with AGA that operational practices play an important role in managing LNG
boil-off; however, we understand those practices to be supplemental to adopting a performance standard
in line with current industry practice to establish a certain level of performance for LNG systems. This
is especially true given that the reference to SAE J2343 allows us to rely on that industry standard for
hold-time performance as a means of demonstrating compliance with existing evaporative emission
standards.

We have revised the test procedure to address the concerns raised by AGA: (1) We specify that the fuel
tank must be at rest, rather than requiring that the vehicle be parked. (2) We allow for ambient
temperatures down to 10° C to allow for more flexibility to account for varying temperature control over
the 120 hours it takes to complete the test. We would not expect such testing to often go below 20° C,
but agree with the comment this this has a minor effect on cryogenic behavior. It is also the case that the
vehicles remain subject to the hold-time standard at the high end of the temperature range. (3) We have
removed the reference to the analogous hold-time protocol adopted by the National Fire Protection
Association to avoid confusion.

The proposed approach to allow for valid tests at ambient temperatures ranging from 20 to 30° C is
identical to what has applied for almost all engine and vehicle testing for the last 40 years. It means that
a test is valid if temperatures remain within the specified window. This means that a test is valid if
ambient temperatures stay at 30° C throughout the measurement procedure. We emphasize this by
specifying the temperature range as being between (20 and 30)° C rather than 25±5° C, which means
that there is no expectation that testing involves a targeted setpoint at any specific temperature within
the specified range. As noted in the previous paragraph, we are expanding the specified temperature
range, largely based on the reasoning that this still allows for testing at 30° C and therefore does not
compromise the stringency of the standard.

We agree with Volvo that LNG refueling station operators and upstream suppliers should properly
manage LNG delivery and storage to allow for consistent refueling at proper temperatures and
pressures. Many stations are able to receive fuel vented from vehicle tanks, which is a good and
effective way to avoid venting to the atmosphere. We do not have the authority to require such systems,
or to require certain financial arrangements for the exchange of vented fuel. We believe market forces
are adequate to address the concern.
We have revised the measurement procedures to address the concerns expressed by California ARB and Volvo. We specify a refueling event to automatic shutoff, which adequately addresses the tank fill level and quantity of dispensed fuel. We address the starting point for the hold-time measurement based on the tanks stabilized pressure after refueling to address thermal energy level and the temperature and fill level of the tank before refueling. The time to pressure relief is as simple as operating a clock or stopwatch. We specify the start time based on tank pressure, and we identify pressure venting as the event that defines the end of the test. We allow manufacturers to devise their own method to establish the time at which pressure venting occurs, consistent with good engineering judgment.

We agree with California ARB’s concerns about system durability and the proposal, in fact, described the hold-time standards as being subject to warranty and useful life requirements. We have revised the final rule to state directly that the warranty and useful-life provisions apply for the LNG venting standards.

Regarding the in-use test, we have revised the specified procedure to incorporate all the items identified by the industry group. However, we continue to believe that 9 kPa per hour is the appropriate standard to allow for in-tank pressure increases corresponding to the five-day hold time. This allows for a 20 percent margin beyond the 7.5 kPa per hour that correlates directly with a five-day hold time. The 20 percent margin accounts for the possibility of nonlinear pressure increases over time, variability from different starting conditions and ambient temperatures, and the accuracy of measurement equipment. The pressure reading for comparing to the standard is a difference between two measurements, which greatly reduces concerns about accuracy and readability. Any inaccuracy or imprecision in one measurement would generally be canceled out in the second measurement. Manufacturers can also take steps to improve the precision and readability of installed pressure gauges. A digital readout, for example, would eliminate variability associated with reading pressure values from an analog gauge. Manufacturers can also take steps to provide clear instructions on proper preconditioning and measurement procedures. Finally, if there is a dispute regarding proper measurements, manufacturers can arrange for further testing with more carefully controlled conditions and practices to ensure that the test results are reliable.

We recognize the concern described by Optimus for heavy-duty refueling rates. However, we learned that the recommended European protocol is based on systems up to 3000 psi and is therefore not valid for most heavy-duty CNG vehicles in the United States. Representatives of the natural gas industry responded to the comment suggesting the European protocol by recommending that we instead reference a recently published supplement to ANSI NGV1, which accommodates the higher flow rates corresponding to heavy-duty vehicles and current refueling technology. We are accordingly revising the regulation to reference this additional ANSI document, which is known as CSA IR-1-15, “Compressed Natural Gas Vehicle (NGV) High Flow Fueling Connection Devices.”

13.2.4 Additional LNG Technology Considerations

Organization: American Gas Association (AGA) et al.

We Recommend that the Agencies Conduct Additional Research on Boil-Off and Refueling Emissions

We commend the agencies on their efforts to collect information on monitoring and warning systems. However, we caution that such technologies are not well known or researched today. We also note that the boil-off emissions themselves are the result of a critical safety feature used to avoid catastrophic failure of the LNG tanks in the case of over-pressurization. We thus recommend that any efforts to incorporate boil-off monitoring or warning systems into the onboard diagnostics should not
interfere with the critical boil-off release system, especially in emergency cases such as collisions. [EPA-HQ-OAR-2014-0827-1223-A1 p.11-12]

Due to the lack of currently available solutions and the concern that any proposed solution may impinge on the key safety components of the boil-off system, we recommend that the agencies conduct additional technical research on this issue. We would welcome the opportunity to work with the agencies to research, evaluate, and demonstrate the appropriate methods to monitor, quantify, and prevent boil-off releases. [EPA-HQ-OAR-2014-0827-1223-A1 p.12]

In response to the agencies request for additional information, we are also providing the following data on the quantification of vapor released during boil-off events. The Phase 2 Proposal states that each event has the potential of releasing 5,300 – 15,800 grams of methane, which translates to 132,000 – 400,000 grams CO2e. However, from a GHG perspective, the amount of vapor released in one event is much less important than the amount of vapor released over a given period – such as the day after the hold time has been exceeded, for example. The amount of vapor is highly dependent on the dynamics of the pressure release valve (PRV) – some PRVs release relatively larger quantities at less frequent intervals while other PRVs release smaller quantities at more frequent intervals. For reference, we consider that, when a natural gas tank has reached its maximum pressure set point, it will boil off between 2 – 3% of its maximum content per day. As an example, a 150 gallon LNG tank contains 240,000 grams of LNG that may boil off 5,000 grams of methane during the course of a whole day. We would be pleased to discuss with the agencies any further data needs to better quantify boil off emissions. [EPA-HQ-OAR-2014-0827-1223-A1 p.12]

We also caution the agencies that the market for certain emissions capture technologies, such as methane canisters, combustion, or conversion via a catalyst, is still very early in its development and many of these technologies are still demonstrating proof-of-concept. Westport has studied experimentally the concept of returning methane vapor to the engine intake, and has identified a number of challenges and opportunities in doing so. We are currently reviewing the specific technologies and strategies identified in the Proposal (methane canisters, combustion, or conversion via a catalyst), and would welcome the opportunity to work with the agencies on further research. [EPA-HQ-OAR-2014-0827-1223-A1 p.12]

It is worth noting that we do see potential value in developing a standardized method to return natural gas tank vapors to the station, perhaps through the integration of technology installed on vehicles’ natural gas tanks and natural gas refueling stations. We recommend that the agencies continue to maintain an open dialogue with industry representatives on this issue. [EPA-HQ-OAR-2014-0827-1223-A1 p.12]

Further, we provide the following recommendations regarding how the agencies can improve the explanation of the LNG fuel system, including guidance on the terms “supercooled” and “vacuum.” “Supercooled” refers to the process of lowering the temperature of a liquid or gas below its freezing point without it changing phases (i.e., without the liquid or gas becoming solid). Additionally, we have never found a vacuum condition in an LNG tank, because the LNG fuel system always operates above atmospheric pressure – a condition rendering the creation of a vacuum inside the LNG tank impossible. [EPA-HQ-OAR-2014-0827-1223-A1 p.12-13]

We also find that the agencies’ language “that the pressure of the LNG is well below the pressure at which the natural gas vent valve would relieve the LNG pressure” does not correctly explain the physics of the system. We provide the following language as a suggestion to guide the agencies and request
that the agencies follow up directly for any further information: [EPA-HQ-OAR-2014-0827-1223-A1 p.13]

*LNG must be kept below -161°C to stay in its liquid state.* Even if an LNG tank is well insulated, a small amount of heat from the atmosphere will still be able to transfer from the exterior tank to the LNG fuel inside the tank. As the temperature of LNG in the tank increases, the density decreases and the pressure increases. When the vehicle is in operation, liquid or vapor is withdrawn from the tank to fuel the engine, which helps maintain the pressure within the operating range of the tank. When the tank is refueled, the introduction of new LNG fuel from the station also decreases the temperature and pressure to the desired level. Thus, under normal operation of an LNG truck, the pressure is maintained within the design operating range and there is no release to the environment. However, if a vehicle is left unused for several days, the pressure inside the tank will eventually increase above the design operating range and some vapor will be released from the tank to prevent over-pressurization of the tank. This vapor is referred to as boil-off. [EPA-HQ-OAR-2014-0827-1223-A1 p.13]

Finally, we object to the statement that “an LNG truck is inherently high emitting since if the truck were to be parked long enough its entire contents would be emitted to the environment.” We note that, while it is true that a truck parked for a long time will vent, LNG truck owners are incentivized by the low cost of LNG as a fuel to use these vehicles at high utilization rates – in other words, they are unlikely to sit more than 5 days unused in normal operation. [EPA-HQ-OAR-2014-0827-1223-A1 p.13]

**We Recommend that the Agencies Conduct Additional Research on Extended Hold Time Length for LNG Vehicle Fuel Tanks**

On the issue of hold times, the agencies noted that SAE J2343’s five-day hold time will only apply to new LNG vehicles. This understandably causes the agencies concern over the treatment of aging vehicles, which may have diminished insulating properties that could result in shorter hold times. Though we are unable to submit data at this time, we support the agencies’ efforts to research the availability and feasibility of tank technologies that would enable a 10-day hold time and recommend that the agencies continue to maintain an open dialogue with industry representatives. [EPA-HQ-OAR-2014-0827-1223-A1 p.13]

We would also like to draw the agencies’ attention to the potential for extending hold time and limiting boil-off through the use of LNG fuel temperature management along the distribution chain, at the LNG station, and on the vehicles. When LNG is produced, the fuel temperature is -280°F and stored at near atmospheric pressures (~15 psi). During transportation to the fueling station and storage in the station typically, the fuel temperature rises marginally to around -260°F and the corresponding pressure (referred to as saturation pressure) of the LNG rises to ~30 psi. [EPA-HQ-OAR-2014-0827-1223-A1 p.14]

LNG, if introduced to the LNG vehicle tank at this temperature and saturation pressure, could enable 10-day hold times. However, LNG stations customarily add heat energy to the fuel. Typically, this results in the LNG fuel temperature rising to ~220°F at 120 psi. The additional pressure is required by many vehicle fuel systems to move the fuel out of the fuel tank, through the vaporizer, and into the engine’s injectors. This “warm” fuel serves as the basis for the 5-day hold time under SAE J2343. [EPA-HQ-OAR-2014-0827-1223-A1 p.14]

We are aware of LNG storage systems currently available on the market from multiple manufacturers that can receive “cold” fuel (~260°F at ~30 psi) instead, thereby enabling extended hold times. We would therefore welcome a dialogue with the agencies on further research into truck and station systems
and processes that could make further use of “cold” LNG fuel to increase hold times and reduce the risk of boil-off emissions occurring. [EPA-HQ-OAR-2014-0827-1223-A1 p.14]

**Organization:** Volvo Group

The Agency also requested comment on a proposed LNG vehicle boil-off warning system. The cost and complexity of a system needs to be weighed against its benefit. Most venting events occur when a vehicle is not used for an extended period of time, particularly for engine systems that can pull vapor from the LNG tank (typical for SI engines) to lower the pressure via evaporative cooling. During such down time when the vehicle is not in use, a message/warning cannot be observed by the operator to take the appropriate action. A warning system would be more useful if it provided an estimated time to a venting event (assuming vehicle is parked) and also a warning if the LNG tank needs maintenance by detecting deterioration of insulating properties. This could be done by evaluating LNG warming (or pressure increase) rate in relation to fill level and ambient conditions. [EPA-HQ-OAR-2014-0827-1290-A1 p.47]

A final area the Agency should address is the high variability of LNG temperature and pressure at retail fuel delivery stations. This variability can be caused by the temperature and pressure of the LNG as delivered to the refueling station, throughput of LNG in the dispensing equipment, design of the station’s tanks and dispensing equipment, use of systems to maintain LNG temperature and pressure, and other factors. This variability can force vehicle operators to vent the vehicle’s tank(s) to the atmosphere to reduce tank pressure to enable refueling. The agencies should require that refueling stations be equipped with recovery systems that allow operators to vent the vehicle’s tank(s) back into the station’s fuel supply. In addition, the stations should be required to credit the operator for the quantity of fuel returned to the station, so as to incentivize this action on the part of the operator. This would allow for more complete tank filling, potentially improved vehicle hold times, and reduced venting to the atmosphere. [EPA-HQ-OAR-2014-0827-1290-A1 p.47-48]

**Organization:** California Air Resources Board (CARB)

The NPRM also requests comments on other potential requirements to control LNG boil-off emissions. These include control technologies like methane canisters, a methane burner, a catalyst to convert the methane to CO2, an on-board monitoring requirements to track boil-off events, and other ways to reduce emissions from LNG refueling. CARB staff has not made final determinations on the efficacy of those technologies at this time, but will further investigate their effectiveness. [EPA-HQ-OAR-2014-0827-1265-A1 p.166]

As estimated in U.S. EPA and NHTSA’s lifecycle analysis, each boil-off event has the potential to release from 3 to 9 gallons of LNG for each boil off event, depending on the fill level of the LNG tank. And because methane has a global warming potential that is 25 times higher (assessed over 100 years) than CO2, that equates to 132,000 to 140,000 grams of CO2 equivalent emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.166]
Response:

We recognize that manufacturers and vehicle operators are motivated to prevent both catastrophic and incidental venting of LNG, for safety and economic reasons. We are nevertheless interested in exploring further ideas of diagnostics, monitoring, control, and refueling practices to provide further assurance that the industry will reduce the frequency and severity of venting. The information provided is a good step in that direction.

13.2.5 Stockpiling Provisions for Heavy-Duty Highway Engines

Organization: Daimler Trucks North America LLC

- **Stockpiling:** The EPA's proposal for years when emission standards change, allowing three months to use of a prior year's engine in the year that the standards change and an additional several engines upon a showing of hardship, is a good proposal as it gives vehicle manufacturers the clarity we need and is realistic in its three month changeover date. What is problematic is the number of engines allowed past the three month date on showing of hardship. In particular, fifty engines is much less than one day's production; if a manufacturer has a hardship, fifty engines will only allow the manufacturer to weather a portion of day. The number should be at least 1,000 engines, which would better help us in the event of unexpected circumstances. [EPA-HQ-OAR-2014-0827-1164-A1 p.120]

- The EPA proposes redundant yet conflicting changeover and stockpiling rules. In 1037.601(a)(1) the EPA proposes to prohibit using an engine from a prior year, which means that engines built in December or November are essentially unusable (given our current engine model year changeovers), but the agency modifies that requirement in 1037.601(a)(2). The EPA should eliminate the duplicative and overly constrictive rules in (a)(1), given that in the very next subparagraph (a)(2) the agency erodes the rule. Moreover, in (c), the EPA proposes to apply 1068.101, which invokes 1068.105(a), which has different changeover and stockpiling rules than the EPA concurrently proposes in 1037. The EPA has proposed mutually conflicting rules and needs to be consistent. A better approach would be simply to write that it is a violation of the regulations to sell a tractor or vocational vehicle with an engine from the previous calendar year installed in the vehicle any later than three months into the next year, except 1) in years when there are no changes to the emission regulations in which case the three month limitation does not apply or 2) when the manufacturer successfully petitions the agency for the fifty engine flexibility (which, as we note above, should be several times greater). 1037.601(a)(1) [EPA-HQ-OAR-2014-0827-1164-A1 p.120]
Organization:  GILLIG LLC

GILLIG requests the agencies review the proposed March 31 end date for installing engines built before the date of any new or changed standard. GILLIG does not build stock transit buses. As previously mentioned, each bus is custom built to unique customer specifications. There is one engine manufacturer in our market segment and the engines are limited to one diesel, one CNG and one diesel/hybrid offering. If the engine manufacturer has an unforeseen delay in certification or production of the new model year engines, and this delay occurs late in the prior model year, as a vehicle manufacturer we cannot order more of last year's engines and have them built and delivered in time, we cannot substitute other like engine models because there are none, and we cannot move up production buses using other certified engines because of other long lead time parts availability. At that point, getting written permission from EPA to use prior year's engines past the March 31 date, as provided for in the rule, provides no remedy. Having no engines with which to build vehicles would bring transit bus production at GILLIG to a standstill, delay delivery of replacement buses to municipalities responsible for sustaining transportation services, impact jobs at those municipalities, inconvenience those who travel and depend on public transportation, and be financially devastating for our business and our employees. GILLIG has long had the production philosophy to build no more than one bus for a customer in any given day. This helps reduce risks from production issues arising from design problems, parts availability, etc. Additionally, transit buses are typically purchased in fleet quantities to maintain commonality for drivers, spare parts and maintenance. Building out a fleet for a customer can require many months of production time. For the above mentioned reasons, GILLIG would request the agencies allow for installing engines built before the date of any new or changed standard through June of the new emissions standard year. [EPA-HQ-OAR-2014-0827-1156-A1 p.5-6]

Organization:  PACCAR, Inc.

PACCAR supports the proposed 90-day window after the end of the engine Model Year to address the issue of stockpiling. [EPA-HQ-OAR-2014-0827-1204-A1 p.30]

Revisions to Stockpiling Provisions

As a general matter, Volvo Group supports the codification and clarification of existing guidance designed to prevent the unnecessary stockpiling of engines by vehicle and engine manufacturers during years when emissions standards change. Volvo Group further supports EPA’s recognition of particular challenges manufacturers may face during years when new emissions standards take effect. While the rule should account for the need by manufacturers for some flexibility in transitioning to new technology, however, it also must provide objective, clear and unambiguous rules for manufacturers to follow. To remain in accord with the spirit and intent of the Clean Air Act, the rule also must create a level playing field (i.e. one that does not effectively punish manufacturers who comply in a timely manner with new EPA standards, while rewarding those who do not), and must ensure that cleaner engines are introduced into the marketplace as quickly as possible, taking into account the need for flexibility in transition to the use of new, often very complex technologies. [EPA-HQ-OAR-2014-0827-1290-A1 p.72]

Volvo Group believes that the intent of both the Clean Air Act and EPA’s existing guidance15 is to ensure there is a level playing field among vehicle and engine manufacturers subject to new emissions standards. Additionally, the Act and the guidance are intended to ensure that the introduction of new
engines into the market is not unnecessarily delayed, while taking into account the need by manufacturers for flexibility in transitioning to often complex new technologies. Volvo Group supports EPA’s efforts to bring law and order to manufacturers’ product transition schedules when new standards come into effect, as represented in the amendments proposed in the NPRM. In fact, Volvo Group has been a strong proponent for clear rules that prohibit the stockpiling of engines and that ensure timely transition. Volvo Group does have concern, however, that EPA’s proposal did not give full consideration to certain business entities that have relatively low volumes, but for whom many orders are by municipalities for a large quantity of vehicles, often delivered at one time, and for which one of the basic requirements is that all vehicles be of identical specification and even of the same model year. [EPA-HQ-OAR-2014-0827-1290-A1 p.73]

EPA’s rule must maintain a level playing field during the transition to new emissions standards, and must ensure technology is introduced into the marketplace expeditiously. [EPA-HQ-OAR-2014-0827-1290-A1 p.73]

This principle is in keeping with the spirit and intent of the Clean Air Act, which requires manufacturers who are unable to introduce compliant technologies due to technological challenges to pay nonconformance penalties (NCPs) designed to remove any competitive advantage they might realize by continuing the sale of older engines. The statute requires that EPA establish such NCPs through a rulemaking that ensures the penalties are “increased periodically in order to create incentives for the development of production vehicles or engines which achieve the required degree of emission reduction” and which “remove any competitive disadvantage to manufacturers whose engines or vehicles achieve the required degree of emissions reductions...” CAA § 206(g), 42 U.S.C. § 7525(g). [EPA-HQ-OAR-2014-0827-1290-A1 p.73]

Left unchecked, a manufacturer’s stockpiling practices could have precisely the effect Congress intended to avoid. With the increasing stringency of new emissions standards for heavy-duty diesel engines, engine manufacturers are employing more complex, more expensive engine technologies. Due to their increased cost and complexity, engines that comply with the most recent emission limits are generally less desirable to customers than those compliant to the former standard – thus creating an incentive for manufacturers to stockpile older engines, and a disincentive for them to initiate introduction of new ones. Even with the advent of fuel efficiency standards, which on their face might be perceived as driving the introduction of products more desirable to commercial vehicle customers due to an anticipated reduction of fuel consumption costs, purchasers are often skeptical of products that introduce new technologies not formerly known in the marketplace. Vehicle and engine manufacturers that have prepared for timely introduction of new technology, therefore, are placed at a competitive disadvantage to manufacturers that will delay introduction and rely on continued sale of the engines and vehicles compliant to the previous standards for a longer period of time. [EPA-HQ-OAR-2014-0827-1290-A1 p.73]

There is unfortunate historical evidence of these forces at work. During the months following the new 2010 standards, the mere hint of availability of 2009 engines was generating a chill in market demand for 2010 engines, with customers refusing to place orders for the new technology as long as they knew the older technology was still available. As a result, vehicle manufacturers offering 2010 technologies were already finding the need to discount their vehicles significantly to generate interest from customers, if interest could be generated at all. The result of an ineffective anti-stockpiling policy, therefore, is precisely the opposite of what the Clean Air Act envisions – it imposes a penalty on the leader as opposed to the laggard. In addition, although all manufacturers eventually had to transition to 2010 engines at some point – and thus the manufacture of vehicles using 2009 engines was temporary – the operation of these higher emitting engines will continue for many years. As such, excessive
stockpiling, although a temporary practice, can result in considerable additional emissions when total emissions over the lifetime of the engine are considered. [EPA-HQ-OAR-2014-0827-1290-A1 p.73-74]

Volvo Group believes that EPA’s intentions to fortify their stockpiling provisions are an important step forward to securing, at times of transition to new engine or vehicle standards, that stockpiling abuses do not occur, and that the playing field is leveled to avoid disadvantaging manufacturers who establish timely product transition schedules. Volvo Group is quite concerned, however, that EPA’s proposed language leaves too much room for creative interpretation that gives license to abuses, and will continue to leave manufacturers who seek to work to the spirit and intent of the regulations at the mercy of those willing to push all limits to gain an unfair market advantage. In fact, given the customer desire for lower cost and less complex engines, the marketplace essentially forces each manufacturer to build and utilize older engines to the regulated limits or be boxed out of the market until competitors exhaust their supply. This practice is costly due to high inventory costs and production disruptions that impact manufacturers, suppliers, and employees. Volvo Group recommends that EPA consider more robust bright line provisions that ensure a level playing field and that better account for the business practices of certain low volume manufacturers. [EPA-HQ-OAR-2014-0827-1290-A1 p.74]

While Volvo Group supports the implementation of the current provisions of 40 CFR 1068 as proposed, we believe there is room for improvements that would better protect against unlawful stockpiling while also addressing some of the nuances of the heavy-duty, on-highway sector. To the extent additional amendments to the current provisions require additional rulemaking, Volvo Group supports implementation of the current provisions as an interim measure. They are an improvement to the current prohibitions to stockpiling that currently exist for heavy-duty highway engines. We believe, however, that additional refinements to the current provisions are necessary and urge EPA to consider such improvements either in the current rulemaking process, or in a follow-up process shortly following the adoption of the current provisions. Volvo Group is willing to work with the Agency to that end. [EPA-HQ-OAR-2014-0827-1290-A1 p.74]

EPA’s rule must be unambiguous and apply the same objective standards to all manufacturers. [EPA-HQ-OAR-2014-0827-1290-A1 p.74]

Volvo Group supports EPA’s adoption of the Part 1068 provisions that designate the “date of manufacture” of an engine as the date the crank is installed in the block. This convention has been used in the industry for many years, and has become a settled process within the manufacturing scheduling and record systems for many manufacturers. [EPA-HQ-OAR-2014-0827-1290-A1 p.74]

The provisions at 40 CFR 1068.103(j) as proposed to now apply to heavy-duty highway engines state: [EPA-HQ-OAR-2014-0827-1290-A1 p.74]

You may not circumvent the provisions of § 1068.101(a)(1) by stockpiling engines with a date of manufacture before new or changed emission standards take effect by deviating from your normal production and inventory practices. [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

The term “normal production and inventory practices” is vague and needs to be better defined and delineated to provide clear and consistent guidance on acceptable practices. This language appears to focus primarily on the practices of individual manufacturers without setting a clear, industry-wide standard. Moreover, what EPA considers to be “normal inventory” is subject to multiple possible interpretations and variations, depending on the idiosyncrasies of any one company. It is therefore ripe for abuse. EPA must clarify what it intends by this term through the use of objective standards that will apply equally to all manufacturers. The terms, though now appearing in CFR provisions rather than
guidance, still do not provide for the kind of bright line criteria that are necessary to ensure a level playing field. [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

Volvo Group appreciates that EPA has attempted to achieve greater clarity by expanding on the language in Section 1068.103(j), but remains concerned that it is unacceptably vague. The additional language provides: [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

For most engines you should plan to complete the assembly of an engine of a given model year into its certified configuration within the first week after the end of the model year if new emission standards start to apply in that model year. [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

Once more, the term “most” is ambiguous and will lead to inconsistent interpretation. EPA should better define what qualifies as an acceptable number of engines in this regard. EPA also should objectively define what it means to “complete” an engine. The language continues: [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

For special circumstances it may be appropriate for your normal business practice to involve more time. [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

The manufacturing environment, especially in the transition period of a standards change year, is fraught with challenges that might be considered “special circumstances,” but should not justify stockpiling. Volvo Group is concerned that this provision will be abused in attempts to justify the opportunity to push production practices in ways that otherwise would be deemed stockpiling. It appears that 1068.103 leaves this “special circumstances” determination, and the additional freedom that comes with it, up to the manufacturer. Under this condition, the manufacturer is given a deadline to complete the remainder of engines (of displacement less than 2.5 liters per cylinder): [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

For engines with per-cylinder displacement below 2.5 liters, if new emission standards start to apply in a given year, we would consider an engine not to be covered by a certificate of conformity for the preceding model year if the engine is not assembled in a compliant configuration within 30 days after the end of the model year for that engine family. [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

According to this provision, we see that the first bright line requirement is introduced. Unfortunately, the example that follows in the text weakens, or at minimum confuses, the earlier text: [EPA-HQ-OAR-2014-0827-1290-A1 p.75]

For example, in the case where new standards apply in the 2010 model year, and your normal production period is based on the calendar year, you must complete the assembly of all your 2009 model year engines before January 31, 2010, or an earlier date consistent with your normal production and inventory practices. [EPA-HQ-OAR-2014-0827-1290-A1 p.76]

[Note: The 30 day provision seems to be inconsistent with the January 31 deadline posed in the example][EPA-HQ-OAR-2014-0827-1290-A1 p.76]

In the example, there’s no mention of “special circumstances,” and the “or” proposition seems to leave the choice to the manufacturer. [EPA-HQ-OAR-2014-0827-1290-A1 p.76]
Volvo Group is of the opinion that bright line provisions must be the backbone of anti-stockpiling provisions, not simply the backstop. It’s on this basic principle that we will base our recommendations [EPA-HQ-OAR-2014-0827-1290-A1 p.76]

The Agency should effectively define what they mean by “most” when defining the required completion date of an engine manufacturer’s prior model year engines that are not complete as of December 31. The requirements should be quantified and scheduled in a way that is controllable and auditable. We would propose eliminating the “normal production and inventory practices” criteria, and provide for specific deadlines. An example of such a provision might look like this: [EPA-HQ-OAR-2014-0827-1290-A1 p.76]

Of the engines having a date of manufacture before the first day of a model year in which new standards apply, and that are not completed by the end of the prior model year, 80% of those that are certified to the prior model year’s standards must be completed within 7 days of the new model year. The remainder of the prior model year engine builds must be completed by January 31 of the new model year. [EPA-HQ-OAR-2014-0827-1290-A1 p.76]

There is certainly room for discussion in setting the language to determine the most appropriate dates and percentages, but this kind of language accomplishes two things. First, it restrains build practices tightly enough to avoid that a manufacturer generates a high quantity of stockpiled “crank in block” partial engines, because the manufacturer could not “work off” a large inventory in such a limited timeframe. Second, it provides much greater certainty, and hence ensures a level playing field. Even if the Agency settles on parameters which are slightly more “forgiving” than they might prefer, at least they can be confident of the outcome in any given standards change event, and if there is a small degree of “play” in the provision, each manufacturer can use that play according to his needs. This is especially true of the provision to complete the remainder (20%, in the framework proposal above) of engines by January 31, whereby each manufacturer can deal with its own “special circumstances” as needed, but without Agency review and without uncertainty. In fact, there need not be any special circumstances present to complete the builds by January 31, yet every manufacturer would have identical rules to play by, with a reasonably tight control on engine quantities from the prior model year. The outcome will certainly be far better than what has been witnessed during, and long following, past standards changes. [EPA-HQ-OAR-2014-0827-1290-A1 p.76]

The Volvo Group also believes that there need not be, and therefore should not be, any provisions that sets distinct deadlines on the basis of the size of the engine, whether absolute displacement or per-cylinder displacement. The reason the deadline for completion was conditioned to displacement per cylinder in the original Part 1068 language was because the production volumes of such engines, in the non-road sector, for example, were low, and it was deemed appropriate to allow additional time for the completion of such engines. Volvo Group believes that this is not the case for heavy-duty highway engines, and therefore completion dates should not be conditioned to a displacement or displacement per cylinder basis. If, however, the Agency decides to retain this discriminator, it should clarify which deadline applies to engines having a displacement of 2.5 liters per cylinder (the current language addresses only engines greater than or less than 2.5 liters per cylinder). [EPA-HQ-OAR-2014-0827-1290-A1 p.76-77]

Turning to vehicle assembly controls, Volvo Group finds the language of 40 CFR 1068.105 to be similarly flawed. [EPA-HQ-OAR-2014-0827-1290-A1 p.77]

If new engine-based emission standards apply in a given model year, your equipment produced in that calendar year (or later) must have engines that are certified to the new standards, except that you may
continue to use up normal inventories of earlier engines that were built before the date of the new or changed standards. For purposes of this paragraph (a), normal inventory applies for engines you possess and engines from your engine supplier’s normal inventory. [EPA-HQ-OAR-2014-0827-1290-A1 p. 77]

[Note: At a technical level, the following language would be preferable: “..you may continue to use up normal inventories of engines certified to the prior model year standards.” The term “earlier engines” is somewhat vague and undefined, and some engines “built before the date of the new or changed standards” can be installed without restriction if they’re certified to the new standards]. [EPA-HQ-OAR-2014-0827-1290-A1 p. 77]

Again, terminology like “normal inventories” is vague and ambiguous, and ripe for abuse, though it is correct that EPA makes it clear that this includes engines in the engine manufacturer(s)’ inventories as well. It should also include engines “in transit,” or better define “possession.” [EPA-HQ-OAR-2014-0827-1290-A1 p. 77]

The provision of 1068.105 continues: [EPA-HQ-OAR-2014-0827-1290-A1 p. 77]

You may not circumvent the provisions of § 1068.101(a)(1) by stockpiling engines that were built before new or changed standards take effect. Similarly, you may not circumvent the provisions of § 1068.101(a)(1) by knowingly installing engines that were stockpiled by engine suppliers in violation of § 1068.103(f). [EPA-HQ-OAR-2014-0827-1290-A1 p. 77]

...and is further limited by 40 CFR 1037.601: [EPA-HQ-OAR-2014-0827-1290-A1 p. 77]

The provisions of 40 CFR 1068.105(a) apply for vehicle manufacturers installing engines certified under 40 CFR part 1036 as further limited by this paragraph (a)(2). If new engine emission standards apply in a given model year, you may install engines built before the date of the new or changed standards under the provisions of 40 CFR 1068.105(a) through March 31 of that year without our approval; you may not install such engines after March 31 of that year unless we approve it in advance. Installing such engines after March 31 without our prior approval is considered to be prohibited stockpiling of engines. In a written request for our approval, you must describe how your circumstances led you and your engine supplier to have normal inventories of engines that were not used up in the specified time frame. We will approve your request for up to three additional months to install up to 50 engines under this paragraph (a)(2) if we determine that the excess inventory is a result of unforeseeable circumstances and should not be considered circumvention of emission standards. [EPA-HQ-OAR-2014-0827-1290-A1 p. 77]

The requirements in this section are in fact, clearer than in the previous sections with respect to installing prior model year engines. While they are noted as further limiting the provisions of 1068.105(a), the provisions in the subject section seem to lose the limitation of “normal inventory,” and address directly a hard-stop completion date. Some manufacturers would take this to be the predominant limiting provision, with little regard for normal inventory practices. In the case of the subject language, at least, there is a requirement to lay out the “unforeseeable circumstances” that EPA could consider before granting an approval for “up to three additional months to install up to 50 engines” [EPA-HQ-OAR-2014-0827-1290-A1 p. 77-78]

Once again, the Volvo Group finds these provisions to be unacceptably ambiguous; they must be shored up so as to have all manufacturers working to the same clear requirements and limitations. Any manufacturer’s actions should be objectively auditable. [EPA-HQ-OAR-2014-0827-1290-A1 p. 78]
One of the problems is that “normal inventory” can be variable according to market conditions. What is normally held constant, however, is the number of engines “in float” relative to the rate of vehicle production rate. There is nothing out of the ordinary, for example, about a manufacturer ramping up production of the “pre-buy” engines and vehicles being phased out at the end of the model year. In this case, vehicle production would increase as the end of the year approaches. As long as vehicle production is ramped up at the same rate as engine production so as not to proliferate the inventory of prior model year engines, and the engine production provisions that protect against stockpiling as discussed above are respected, there should be no real cause for concern about stockpiling. It’s for this reason that Volvo Group suggests that the Agency might consider using a calculation of the ratio of the engines in float (total number of complete engines in the possession of the vehicle manufacturer, and in the possession of the engine manufacturer, or in transit to the vehicle manufacturer) to the weekly vehicle build quantity, as a control parameter. This “float ratio” may differ from one manufacturer to the next, but should be relatively constant for any given manufacturer. The control parameter may have to incorporate a “lag function” to accommodate delivery lead times, the lag being duration of each manufacturer’s choosing within a limited range. Manufacturer-specific variations and production issues can be smoothed out by setting the control parameters on a four-week rolling average basis. The process may require some weekly accounting and reporting of engine quantities and build rates, but in the end may be a reliable parameter to monitor, or to request of manufacturers as an audit mechanism. Specific allowable limitations could be placed on the maximum degree of variation of such a control parameter. The period of control could be pre-defined in the regulation, for example, during the 6 months before and 6 months after a standards change. Alternatively, there could be an “observation period” of 6 months prior to the end of the model year, followed by a control period in the new model year. [EPA-HQ-OAR-2014-0827-1290-A1 p.78]

The methodology as outlined is merely an example of what might be several possible objective, controllable and auditable means to ensure that engines are not being stockpiled and that the playing field is leveled. The Volvo Group is willing to explore other bright line options. [EPA-HQ-OAR-2014-0827-1290-A1 p.78]

The last concept that the Volvo Group thinks the Agency must consider is linked to the production practices of low volume vehicle manufacturers. Typically, low volume manufacturers have much more variation in their processes, and take an extended period of time, perhaps as much as a year or more, to complete a customer order from the first vehicle built to the last. This is sometimes the case for low volume manufacturers that sell large orders to municipalities, wherein the contract has a strong demand that all vehicles be built of exactly the same specification. In these cases, there will be a need to continue to install the prior model year engines into vehicles for an extended period of time. Though the time period may be extended, the volume of engines remains low by the nature of the business. Accommodating this need among low volume manufacturers could be managed in different ways. First, the Agency might consider a unique set of requirements for low volume manufacturers. The “float ratio” example is likely not well suited to low volume manufacturers, given the mathematical variability that naturally comes from lower volumes, but also because there’s less of a refined “rhythm” to the assembly process in such production environments. So, the Agency could consider allowing a certain “carry-over” volume, either in the absolute, or as a percentage of annual production volumes. Another possibility is that the set carry-over engine quantity could be applied also to the higher volume highway market, such that that volume is not included in the float ratio calculation. This would serve as another mechanism to provide flexibility necessary for changes to the industrial setup or component supply issues that often arise in a model year changeover or a high demand pre-buy market, while applying flexibility evenly with all manufacturers. [EPA-HQ-OAR-2014-0827-1290-A1 p.78-79]
Volvo Group would be very willing to bring proposals and to take part in any discussions to develop sound, workable concepts that meet industry’s needs and ensure the goals of the Agency are met in the transition to a new standard. The key is to set specific bright line requirements that provide certainty, require a minimum of Agency approvals or interventions, and ensure a level playing field. [EPA-HQ-OAR-2014-0827-1290-A1 p.79]

As a final note, the Volvo Group believes stockpiling prohibitions will, as a practical matter, be a matter for necessary controls only with respect to changes to engine standards. Concerning changes to vehicle standards, we don’t think there will be issues of concern with respect to stockpiling. This is largely due to the fact that the Phase 2 GHG standards as proposed tie standards changes to the model year of the vehicle. Because manufacturers routinely introduce the new model year vehicles many months before the calendar year of applicability (for example, most manufacturers introduced 2012 model year vehicles in the first quarter of 2011), the vehicles compliant to the new standards are introduced well ahead of the regulated effective date. To the extent that a manufacturer might modify this convention by delaying introduction of the new model year to a date much closer to the “latest January 1” effective date, any actions by the manufacturer to build a large number of the prior model year vehicles before years’ end should not be construed as stockpiling, so long as all those vehicles were completed by the end of the year. In such a case, the agencies may have to modify the definition of “date of manufacture” for vehicles, to ensure that it is clear and deterministic, and void of opportunity for gaming. [EPA-HQ-OAR-2014-0827-1290-A1 p.79]

Revisions to Stockpiling Provisions

While not addressed in the NoDA, EPA’s NPRM proposed to apply certain non-road prohibitions against stockpiling to highway heavy-duty engines and vehicles when new emissions standards take effect. As a general matter, Volvo Group supports the codification and clarification of existing guidance designed to prevent the unnecessary stockpiling of engines by vehicle and engine manufacturers during years when emissions standards change. Volvo Group further supports EPA’s recognition of particular challenges manufacturers may face during years when new emissions standards take effect. While the rule should account for the need by manufacturers for some flexibility in transitioning to new technology, however, it also must provide objective, clear and unambiguous rules for manufacturers to follow. To remain in accord with the spirit and intent of the Clean Air Act, the rule also must create a level playing field (i.e. one that does not effectively punish manufacturers who comply in a timely manner with new EPA standards, while rewarding those who do not), and must ensure that cleaner engines are introduced into the marketplace as quickly as possible, taking into account the need for flexibility in transition to the use of new, often very complex technologies. [EPA-HQ-OAR-2014-0827-1928-A1 p.25-26]

The Volvo Group submitted extensive comments to EPA’s proposed changes to heavy-duty highway engine and vehicle stockpiling provisions in the July 13, 2015 NPRM. Our comments were supportive of EPA’s intention to clarify acceptable practices with respect to timely completion of engines compliant to prior standards in a standards change year, and timely installation of said engines into vehicles. In fact, Volvo seriously questioned the strength of EPA’s reliance on “normal production and inventory practices,” and lack of clarity as to what might constitute “special circumstances.” We made suggestions as to how the stockpiling prohibitions should be improved to provide bright line, auditable requirements by which all manufacturers could reliably be measured, so as to avoid the abuses that have been witnessed in previous standards change years. The Volvo Group insists that such improvements are necessary to ensure a level playing field. [EPA-HQ-OAR-2014-0827-1928-A1 p.26]
In our NPRM comments, we also expressed concern that EPA’s proposal did not give full consideration to certain business entities that have relatively low volumes, but for whom many orders are by municipalities for a large quantity of vehicles, and for which one of the basic requirements is that all vehicles be of identical specification and even of the same model year. [EPA-HQ-OAR-2014-0827-1928-A1 p.26]

Anticipating that EPA will determine that some of the recommendations made by the Volvo Group are too extensive to be completed in this rulemaking, we would like to take this opportunity to reinforce some of our earlier comments to the NPRM. We support the implementation of the provisions of 40 CFR 1068 as proposed, but we believe some changes to the proposal are necessary to ensure successful implementation in the heavy-duty highway sector. [EPA-HQ-OAR-2014-0827-1928-A1 p.26]

Volvo Group supports EPA’s adoption of the Part 1068 provisions that designate the “date of manufacture” of an engine as the date the crank is installed in the block. This convention has been used in the industry for many years, and has become a settled process within the manufacturing scheduling and record systems for many manufacturers. [EPA-HQ-OAR-2014-0827-1928-A1 p.26]

In our NPRM comments, we incorrectly cautioned that the example cited in 40 CFR 1068(g) was in contradiction with previous language. We cited the text “…we would consider an engine not to be covered by a certificate of conformity for the preceding model year if the engine is not assembled in a compliant configuration within 30 days after the end of the model year for that engine family” as being contradicted later by “For example, in the case where new standards apply in the 2010 model year, and your normal production period is based on the calendar year, you must complete the assembly of all your 2009 model year engines before January 31, 2010….” (italics ours, in both cases). Since our comments were submitted, we’ve determined that there is no contradiction. [EPA-HQ-OAR-2014-0827-1928-A1 p.26-27]

Further to the provisions of Part 1068, the Volvo Group also believes that there need not be, and therefore should not be, any provisions that set unique deadlines on the basis of the size of the engine, whether absolute displacement or per-cylinder displacement. The proposed provisions provide greater flexibility for completing engines having a “per-cylinder displacement at or above 2.5 liters.” The reason the deadline for completion was conditioned to displacement per cylinder in the original Part 1068 language was because the production volumes of such engines, in the non-road sector, for example, were low, and it was deemed appropriate to allow additional time for the completion of such engines. Volvo Group believes that this is not the case for heavy-duty highway engines, and therefore completion dates should not be conditioned to a displacement or displacement per cylinder basis. [EPA-HQ-OAR-2014-0827-1928-A1 p.27]

Finally, the Volvo Group thinks the Agency must consider the production practices of low volume vehicle manufacturers. Typically, low volume manufacturers have much more variation in their processes, and take an extended period of time, perhaps as much as a year or more, to complete a customer order from the first vehicle built to the last. This is sometimes the case for low volume manufacturers that sell large orders to municipalities, wherein the contract has an absolute demand that all vehicles be built of exactly the same specification. In these cases, there will be a need to continue to install the prior model year engines into vehicles for an extended period of time. Though the time period may be extended, the volume of engines remains low by the nature of the business. [EPA-HQ-OAR-2014-0827-1928-A1 p.27]

Accommodating this business critical need among low volume manufacturers could be managed in different ways. First, the Agency might consider a unique set of requirements for low volume
manufacturers. For example, the Agency could consider allowing a certain “carry-over” volume, either in the absolute, or as a percentage of annual production volumes for these low volume manufacturers. Another possibility is that an absolute carry-over engine quantity could be applied also to the higher volume highway market, such that that volume is not included within the volume considered according to other prohibition controls the Agency has proposed. This would serve as another mechanism to provide flexibility necessary for changes to the industrial setup or component supply issues that often arise in a model year changeover or a high demand pre-buy market, while applying flexibility evenly with all manufacturers, and accommodating the unique needs of the low volume manufacturers. The Volvo Group would be very willing to work with the Agency to determine appropriate carry-over volume limitations. [EPA-HQ-OAR-2014-0827-1928-A1 p.27]

Response:

Volvo’s comments effectively capture the logic, rationale, and objectives underlying the proposed limitations on stockpiling and inventory practices in the transition to new, more stringent emission standards.

Daimler’s concern about engine volumes seems to indicate an expectation that the proposed limits apply for ongoing engine production in the year that new emission standards start to apply. This is not the case. The stockpiling provisions of 40 CFR 1037.601 describe how vehicle manufacturers may continue to install previous-tier engines in the year that new emission standards have already started to apply. Vehicle manufacturers must plan their engine orders to comply with emission standards. For the high-volume production described by Daimler, we would expect manufacturers to order engines on a weekly basis, with engine installations proceeding at the same pace. Such a vehicle manufacturer would not find itself several months after the transition to new emission standards with a need to install thousands of additional previous-tier engines. We believe the proposed provisions properly establish the need to continue with established ordering and build practices, subject to clear deadlines for installing previous-tier engines.

We have revised the language in 40 CFR 1037.601(a)(1) to more broadly establish the principle that heavy-duty vehicles need to have certified engines to avoid violating statutory prohibitions. We have also reduced the risk of noncompliance related to mismatched model years between engines and vehicles by identifying the vehicle’s model year as being dependent on the engine’s model year in Phase 2. Specifically, starting with vehicles built on or after January 1, 2021, the vehicle’s model year is the same as the calendar year corresponding to the vehicle’s build date, though we also allow the vehicle’s model year to be one year previous to match the engine’s model year. The provisions in 40 CFR 1068.105 do not conflict with the proposed provisions in 40 CFR 1037.601; rather, the highway-specific provisions add clarity and further limitations that go beyond what applies under 40 CFR 1068.105.

Gillig describes a production scenario that closely matches the proposed stockpiling provisions of 40 CFR 1037.601. As a low-volume manufacturer, they have a normal practice of managing engine inventories for an extended interval requiring installation of a common engine platform over a several-month production run. This will generally be complete within three months after new emission standards take effect, but EPA approval can accommodate further use of previous-tier engines for three additional months. A further flexibility implied by Gillig’s comments is that we should perhaps allow engine manufacturers to produce new previous-tier engines after the new emission standards already apply. This would introduce a host of problems for EPA oversight, enforceability, level playing field, etc.; we are therefore not pursuing that option. We believe the provisions as proposed adequately address the concerns of low-volume vehicle manufacturers as expressed by Gillig.

Volvo’s comments address inventory and stockpiling practices for both vehicle manufacturers (40 CFR 1037.601 and 1068.105) and engine manufacturers (40 CFR 1037.103). We first address comments related to inventory and stockpiling practices for vehicle manufacturers.
The final rule at 40 CFR 1037.601 restates the provision from 40 CFR 1068.105 describing as a starting point that we disallow departing from normal inventory practices, even if that does not cross the “bright-line” dates in the regulation. We believe the combined approach of accommodating normal inventory practices, subject to a firm deadline, appropriately balances the need for a clear, objective, and enforceable requirement with the variety of industry build practices and the unpredictability of building vehicles for an uncertain market.

We agree that the term “earlier engines” in 40 CFR 1068.105(a) is not helpful. Since the rest of that sentence already describes those engines as being built before the date of new or revised emission standards, we believe it is best to simply delete the word “earlier.”

We believe that the regulation allowing for “inventory” to include engines both at the equipment manufacturer and “from the engine supplier’s normal inventory” clearly also allows for engines in transit.

Volvo’s suggested approach would add a significant complexity to tighten inventory practices in the three-month transition period specified in the regulation. We believe the proposed provisions, as modified for the final rule, establish clear deadlines with a reasonable accommodation for varied production volumes and market uncertainty. We will monitor manufacturers’ behavior in the coming transition to new emission standards, and will consider further refining the inventory and stockpiling provisions based on that experience.

Volvo also commented on the stockpiling provisions for engine manufacturers in 40 CFR 1068.103. Volvo objected to referencing “normal production and inventory practices” for engine manufacturers. As with the vehicle-manufacturer provisions described above, we believe it is necessary to combine a flexible approach with a bright-line date to accommodate varied production volumes and market uncertainty. This is profoundly applicable for the provisions in 40 CFR part 1068, which apply to sectors ranging from lawnmowers and snowmobiles to locomotives and ocean-going vessels. We adopted more specific requirements for heavy-duty vehicle manufacturers, and can consider more specific requirements for heavy-duty highway engine manufacturers in the future; however, in the current rule, we believe the general approach that already applies under 40 CFR 1068.103 appropriately addresses the issue for heavy-duty highway engines. In particular, the one-month backstop specification applies as an objective standard for all sizes and power ratings of heavy-duty highway engines, since they all have per-cylinder displacement well below 2.5 liters. Applying the more subjective “normal inventory” standard for most engines and applying the objective one-month deadline for all engines properly balances the need to accommodate varied production volumes and market uncertainty.

We believe Volvo’s suggested approach of requiring 80 percent of engines completed after effective date of new standards is arbitrary, unnecessary, and contrary to our expectation that there will be numerous circumstances where such an objective criterion would inappropriately limit a manufacturer’s ability to manage their transition to the new standards.

We believe the example cited for compliance with 2010 standards properly describes the balance between the subjective and objective compliance criteria. We also believe “completing engine assembly” has a plain meaning. Ready to ship. It is not clear why Volvo wants us to revise the regulation to address engines with per-cylinder displacement of exactly 2.5 liters, since the existing CFR text already references engines “at or above 2.5 liters.”

13.2.6 Compliance and Other General Provisions

Organization: American Trucking Associations (ATA)

Clean Air Act Section 203 Tampering Provisions will Cause Hesitation for Fleets
Fuel-efficient, add-on equipment on a tractor or trailer is now considered to be emission control devices subject to the provisions under Clean Air Act Section 203. In the past it was abundantly clear that modifications made to an EPA-certified “engine” that increased emission levels was considered tampering and subject to an enforcement action. It would be a stretch to envision that Congress’ original intent was to characterize mismatched tires with different levels of rolling resistance, pieces of plastic, or non-functioning tire inflation systems as being subject to enforcement actions under Section 203’s tampering provisions. [EPA-HQ-OAR-2014-0827-1243-A1 p.13-14]

Fleets continue to express concerns over the potential for future enforcement actions involving such mundane matters by either the agencies or states. If such actions do indeed occur, fleets will seriously decide whether to specify fuel-efficient equipment when they place their orders with OEMs. In the alternative, fleets will invest in fuel-efficient equipment in the aftermarkets which will not benefit OEMs in meeting their targets or the agencies’ objectives. [EPA-HQ-OAR-2014-0827-1243-A1 p.14]

Section 207 of the Clean Air Act states that compliance by vehicles and engines “in use” is done through manufacturer warranties that are provided to purchasers. Several of the equipment maintenance concerns under Phase 2 will therefore be addressed under appropriate warranty claims. Once such warranties expire, it follows that enforcement burdens will likely shift onto fleets. An overriding presumption must be recognized that fleets purchasing expensive, fuel-efficient technologies have both the interest and intent to use and maintain such equipment. To do otherwise would be economically counter-productive and ill-conceived. Therefore, ATA strongly recommends that any enforcement actions that may be directed at fleets (beyond engine alterations) be addressed with “fix-it” tickets versus financial penalties. [EPA-HQ-OAR-2014-0827-1243-A1 p.14]

Organization: National Automobile Dealers Association (NADA)

The final Phase 2 rule should not impose downstream “tampering” liabilities related to fuel economy and GHGs. While Section 203(a)(3)(A) of the Clean Air Act makes it unlawful for “any person to render inoperative any such device or element of design after such sale and delivery to the ultimate purchaser,” that provision makes no sense in the context of fuel use and GHG reduction controls (42 USC 7522). If anything, commercial vehicle customers are economically incentivized to maintain and operate their vehicles with the goal of maximizing, not reducing fuel efficiency (and thus GHG emissions performance). Since similar incentives have not historically existed with respect to criteria emissions, EPA’s tampering policies have made sense when applied to components related to such emissions. Notably, changes to aerodynamics or tires, for example, are expected in the normal course of truck or tractor operations, and in some cases, may be done for safety reasons (winter tires, skirt and fairing modifications, etc.). [EPA-HQ-OAR-2014-0827-1309-A1 p.11]

Organization: Daimler Trucks North America LLC

Rewording in 1037.241(was b, now a): the EPA changes the regulations to say that a vehicle is noncompliant if its GEM score is above the applicable standard, but the EPA needs to add in something like 'unless the vehicle's exceedance is covered by credits accumulated from some other vehicle.' 1037.241 [EPA-HQ-OAR-2014-0827-1164-A1 p.131]

Organization: California Air Resources Board (CARB)
The definition of basic vehicle frontal area in 40 CFR 1037.801 (page 40661 of the NPRM) would be enhanced by an illustration. The language states that “basic vehicle frontal area means the area enclosed by the geometric projection of the basic vehicle along the longitudinal axis onto a plane perpendicular to the longitudinal axis of the vehicle, including tires but excluding mirrors and air reflectors.” [EPA-HQ-OAR-2014-0827-1265-A1 p.189]

Neutral/Provide Additional Info Comment

Comment - Manufacturer data submittal

The NPRM discusses ways to streamline the submittal of manufacturer data, avoid unnecessary duplication, and allow timely access to the data by both U.S. EPA and NHTSA, for example by allowing manufacturers to submit compliance data to U.S. EPA's VERIFY database system for use by both U.S. EPA and NHTSA. When CARB staff proposes its California’s Phase 2 regulations, we will seek ways to similarly allow CARB staff timely access to Phase 2 compliance data, potentially by requiring all manufacturers who wish to certify in California to submit data to CARB simultaneous with submittal to U.S. EPA and NHTSA. CARB staff looks forward to finding the most efficient way to allow this access. [EPA-HQ-OAR-2014-0827-1265-A1 p.191]

Organization: Chemours Company FC, LLC

Chemours recommends that imported Medium- and Heavy-Duty vehicles should also comply with this new standard. [EPA-HQ-OAR-2014-0827-1231-A1 p.1]

Organization: PACCAR, Inc.

Wording Change to 1036.130(b)(5)

The words “steady-state” should be deleted. In this subsection of 1036, EPA states, “Describe how your certification is limited for any type of application. For example, if you certify heavy heavy-duty engines to the CO2 standards using only steady-state transient FTP testing, you must make clear that the engine may not be installed only in tractors.” The section is referring to the FTP transient test but calls out...

“...steady-state transient FTP testing,” which are opposite conditions. [EPA-HQ-OAR-2014-0827-1204-A1 p.31]

Response:

With respect to tampering and certified configurations, we note that the CAA prohibits—

“for any person to remove or render inoperative any device or element of design installed on or in a motor vehicle or motor vehicle engine in compliance with regulations under this title prior to its sale and delivery to the ultimate purchaser, or for any person knowingly to remove or render inoperative any such device or element of design after such sale and delivery to the ultimate purchaser.”

Because this is a statutory requirement, NADA’s position that it “makes no sense in the context of fuel use and GHG reduction controls” is not relevant to this rulemaking. The plain meaning of this provision leads us to conclude that we have no alternative other than to apply the tampering prohibition to the range of parts and specifications that vehicle manufacturers rely on to establish their certified configuration. This is not so different from applying this same principle to fuel injectors or catalytic converters. The emission standards are premised on manufacturers producing their vehicles in a certified
configuration, and specifying maintenance that allows for a reasonable expectation that in-use vehicles will continue to operate consistent with that original certified configuration. See Section 1.4 of this RTC for additional discussion of permissible modifications.

We disagree with ATA that “Section 207 of the Clean Air Act states that compliance by vehicles and engines “in use” is done through manufacturer warranties that are provided to purchasers.” The Act includes many provisions directly addressing, including the prohibition against tampering. In fact, section 207(c)(3)(A) specifies how the manufacturers must inform operators of proper maintenance. A vehicle manufacturer’s certification includes a review of those maintenance instructions, which is intended to address the manufacturers’ burden to demonstrate that the specified maintenance will occur with in-use vehicles. While we may pursue a case against fleet operators or other vehicle owners that violate the tampering prohibition by installing tires or other replacement components that do not conform to the manufacturer’s original certified configuration, consistent with the statute, we could also focus on the manufacturer’s role to ensure that in-use vehicles are getting anticipated maintenance as described in the application for certification. Thus, actions against the manufacturer would not excuse an operator from a tampering violation under the Act. ATA “recommends that any enforcement actions that may be directed at fleets (beyond engine alterations) be addressed with “fix-it” tickets versus financial penalties” but provides no legal basis for EPA to do so.

We address Daimler’s concern about demonstrating compliance in the context of an averaging program in two ways. The proposed rule already described that an individual vehicle or family is compliant or noncompliant based on its performance relative to the “applicable standard,” which we note as being the Family Emission Limit in cases involving generation or use of emission credits. For the final rule, we are expanding this discussion to provide more clarity. In addition, the regulations at 40 CFR 1037.750 describe the manufacturer’s obligation to determine at the end of each model year whether there is a deficit credit balance for the year, and to describe plans for resolving any existing credit deficit.

“Basic vehicle frontal area” has been part of the EPA regulation for several decades. We may pursue an illustration that clarifies the meaning of the term, but believe this is not needed in the regulation.

We expect to work with California ARB as part of the effort to coordinate data management as part of our respective compliance programs.

The new standards apply to all new engines and vehicles, with specific standards applying based on the applicable model year, consistent with the Clean Air Act. This applies to both domestically produced and imported products.

We have corrected the typographical error of including “steady-state” in 40 CFR 1036.130(b)(5).

13.2.7 Compliance Provisions for Tires

Organization: Truck Trailer Manufacturers Association (TTMA)

Requirements of Tire & Component Manufacturers:

On page 40278 and in footnote 246, the rule mentions that EPA is considering adopting regulatory text addressing obligations for tire manufacturers. Specifically, the EPA asks that, in the event they discover tires on certified trailers that do not conform to the regulations, that they require the tire manufacturer to recall and replace the nonconforming tires. TTMA supports this concept and suggests that when and if regulatory authority is granted, if possible, it be extended in two specific ways. First, that the recall and replace provisions not be limited to tire manufacturers, but to all suppliers of regulated trailer components including Automatic Tire Inflation Systems and Aerodynamic Components. As EPA alludes to in footnote 246, the industry would be uniquely challenged by recall and replace provisions if
a tire manufacturer is found to be out of compliance, but the same situation would apply if an aerodynamic skirt were also found to be out of compliance. Second, if the agency insists on collecting data for every trailer made, that the agency tracks the relevant performance figures from component manufacturers (CRR for tires, Delta CDA for aero-devices) and allows the manufacturers to select the actual component they fitted when filing with the Agency so that it will auto populate with the correct figure. This would have two major advantages. [EPA-HQ-OAR-2014-0827-1172-A1 p.16]

First it would prevent transcription errors as manufacturers filed with the agency. Second, it would provide the Agency with a database of trailers that may have been fitted with a given tire or aero-device in the event that they determine that a recall is required. Provision would still be needed for trailer manufacturers to enter their own data in the event they are using components of their own manufacture or their own testing of particular device combinations as the Agency is encouraging. [EPA-HQ-OAR-2014-0827-1172-A1 p.17]

Organization: Rubber Manufacturers Association (RMA)

EPA Should Not Add Regulatory Text Giving the Agency Authority to Recall Trailer Tires

In the Preamble, EPA requested comment on whether it should add regulatory text that would essentially give the agency authority to recall trailer tires that do not conform to the regulations. As support for this idea, EPA points to section 207(c)(1) of the Clean Air Act, the Act’s recall provision. Section 207(c)(1) notes that: [EPA-HQ-OAR-2014-0827-1304-A1 p.21-22]

If the Administrator determines that a substantial number of any class or category of vehicles or engines, although properly maintained and used, do not conform to the regulations ... of this title, when in actual use throughout their useful life ... [the Administrator] shall require the manufacturer to submit a plan for remedying the nonconformity of the vehicles or engines...[EPA-HQ-OAR-2014-0827-1304-A1 p.22]

Section 216 of the Clean Air Act defines manufacturer as “any person engaged in the manufacturing or assembling of new motor vehicles ... or [any person] who acts for and is under control of any such person.” The plain language of these provisions seems to provide EPA with recall authority over manufacturers of vehicles and engines only, not over other part manufacturers. [EPA-HQ-OAR-2014-0827-1304-A1 p.22]

The legislative history provides additional evidence that Congress did not intend to give EPA recall authority over other part manufacturers. The portions of the U.S. House Committee Report and the Conference Report that covered section 207 only mention vehicles and engines as the products that could be recalled under that section of the Clean Air Act. The House Committee also envisioned testing of vehicles and engines to be quick, easy, and uniform, which seems incongruous to the testing process for tires. [EPA-HQ-OAR-2014-0827-1304-A1 p.22]

Additionally, tires are a consumable item, not a durable component of the trailer and EPA has historically focused on durable components of vehicles for recall purposes. In addition, unlike many other emissions-related vehicle components, a tire’s efficiency improves (tire rolling resistance decreases) as a tire wears, thus improving the tire’s contribution to fuel economy. In the most recent and publicly available guidance document on recalls, EPA tracked vehicle and engine recalls by problem category and none of the categories seem comparable to tires. For example, EPA recalls have primarily been related to the catalytic system, the fuel delivery system, or the computer system based on their
direct impact on emissions. A tire’s impact on emissions is more attenuated. [EPA-HQ-OAR-2014-0827-1304-A1 p.22-23]

If EPA’s recall regulations were applied to tires, it is unclear how they would be enforced. The agency has acknowledged that insignificant defects do not warrant recalls. In the proposal, EPA does not discuss tolerances or other policies to account for manufacturing or testing variability. Similar issues have been addressed in Europe, where regulations setting rolling resistance performance thresholds set a regulatory allowance of 0.3 kg/T to accommodate sources of variability. [EPA-HQ-OAR-2014-0827-1304-A1 p.23]

Other global regions that have adopted the allowance of +0.3 kg/t allowance for conformity of production testing include: [EPA-HQ-OAR-2014-0827-1304-A1 p.23]

**EPA Should not Expand Authority to Include Tire Recalls.** In part because there is no reference laboratory, and to be consistent with the Clean Air Act, its legislative history, and EPA’s past practice, EPA should not add regulatory text giving the agency authority to recall trailer tires. [EPA-HQ-OAR-2014-0827-1304-A1 p.2]

**Rolling Resistance Machine Alignment.** RMA renews its call for the agencies to establish a reference laboratory for use in correlating rolling resistance data generated in support of this rule and to provide a clear and unambiguous guide to the compliance tests that the agencies may conduct to enforce this regulation. [EPA-HQ-OAR-2014-0827-1304-A1 p.2]

**Tire Rolling Resistance Testing.** The agencies **Should Specify a Procedure for a Tire Rolling Resistance Reference Machine, Consistent with ISO 28580**

**i. A reference machine is necessary to limit the effects of machine-to-machine variation.**

In the NPRM, the agencies have proposed to continue to allow use of either STL or Smithers in testing based on their conclusion that lab-to-lab variability is very small and would not significantly affect RRc values. Consistent with its comments during Phase I of this regulation, RMA advocates that EPA/NHTSA establish a reference machine, pursuant to the requirements of ISO 28580. Establishing a reference machine in this regulation would be consistent with NHTSA’s approach in the consumer tire information rulemaking. In its final rule on its Tire Fuel Efficiency Consumer Information Program, NHTSA states, “NHTSA must specify [a reference laboratory] for the purposes of implementing this rule so that tire manufacturers know the identity of the machine against which they may correlate their test results.” [EPA-HQ-OAR-2014-0827-1304-A1 p.5]

In the final rule for Phase I of this regulation, the agencies recognized the value of machine alignment in measuring rolling resistance consistently across multiple machines in multiple locations. However, the agencies stated that “Because the test procedure has not been finalized and heavy-duty LATs [Laboratory Alignment Tires] are not currently defined, the agencies are postponing the use of these elements of ISO 28580 to a future rulemaking.” International Standard ISO 28580:2009, together with
its accompanying TR 16377:2012\(^8\) specifies an alignment method using a set of two predetermined tires measured by both the candidate and reference machines (Clause 3.10 of ISO28580:2009). The standard provides criteria for any user of the standard, such as a government agency or its designated alignment lab to select alignment tires for alignment purposes. In particular, alignment tires must meet the criteria of clause 10.4, which provides specifications for (a) the minimum range of tire rolling resistance values between the alignment tires, (b) alignment tire section width, (c) alignment tire outer diameter, (d) load index values and (e) the number of alignment tires (two). [EPA-HQ-OAR-2014-0827-1304-A1 p.5-6]

The fact that the ISO 28580 standard does not list specific alignment tires should not be viewed as a barrier to establishing a reference machine for purposes of this rule. In the case of Passenger Car Tires, ISO identified alignment tires in a letter submitted to the NHTSA docket (NHTSA-2010-0036-0016).\(^9\) No manufacturer or lab has volunteered to provide specific alignment tires for Truck Bus tires. However, the operator of a selected reference machine could simply select regular production tires that meet the specifications for alignment tires in the ISO standard and sell them to candidate laboratories as part of a RR alignment service. [EPA-HQ-OAR-2014-0827-1304-A1 p.6]

ii. RMA challenges the Agencies’ assertion that the machine variability is very small and does not vary over time.

In the NPRM, the agencies conclude that lab-to-lab variability is very small and would not have a significant impact on R Rc values. RMA member company experts continuously study rolling resistance measurements, relative machine performance and machine-to-machine correlations. Two RMA members have provided correlation studies for inclusion in these comments. [EPA-HQ-OAR-2014-0827-1304-A1 p.6]

The first RMA member company (“Company A”) provided data showing rolling resistance measurements from 19 tires, three replicates each, with tires tested at both Smithers and STL. A summary of that data is included in Figure 1. These data show that while the measurements taken at both labs are similar, they are not identical, and highlight the need for a reference machine. Company A also shows in Figure 2 that the laboratories can be correlated, with an R2 value of 0.9029. [EPA-HQ-OAR-2014-0827-1304-A1 p.6-7]

[Figure 1, ‘Company A RRc Data for Truck/Bus Tires, Measured at STL and Smithers (kg/T)’, and Figure 2, ‘Company A Rolling Resistance Correlation data between STL and Smithers (kg/T)’, can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

The second RMA member company (“Company B”) has studied the correlation between Smithers and STL over time. Included is an illustration from that work. Figure 3 contains comparisons among several tires tested at both STL and Smithers in 2011 and 2014. Company B also correlated its own machine to both Smithers and STL. [EPA-HQ-OAR-2014-0827-1304-A1 p.8]

These data show several important reasons why machine alignment is critical. First, while Smithers and STL are well correlated, they do not produce the same results. It is important to understand that differences in measured rolling resistance coefficient (R Rc), even small percentage differences, can be very meaningful to a tire company, particularly in business and auditing or compliance contexts. Second, this analysis shows that the percent difference in tested values at the two labs is not the same for all tires tested. In fact, some tires perform better at one lab, while others perform better at the other. The example comparison at the bottom of Figure 3 shows this phenomenon. Third, the values at each lab drift over time. In Figure 3, tires 1A, 3C and 4B were tested in 2011 and 2014. The values for each
of these tires changed from 2011 to 2014. Further, the values correlated between the two labs but did not remain constant across the two testing periods. [EPA-HQ-OAR-2014-0827-1304-A1 p.8]

iii. A reference machine is necessary to limit the effects of measurement drift over time.

Establishing a reference machine is important to limit the effects of machine-to-machine variation and manage machine drift over time. Even accepting the view the agencies state in the NPRM that “agencies believe the lab-to-lab variation for the STL and Smithers laboratories would have very small effect on measured rolling resistance values,” this analysis only addresses one aspect of the alignment – machine-to-machine variation. 80 Fed. Reg. at 40283. The other aspect, management of machine drift over time, should also be addressed in the regulation. The effect of drift and how to manage it can be evaluated by comparing rolling resistance measurements from a tire company’s machine to results for the same tires using the machines at STL and Smithers. To illustrate this point, Company B has conducted such an evaluation and presents measurements of the tires it compared in Figure 4. [EPA-HQ-OAR-2014-0827-1304-A1 p.8]

Company B also provided Figure 5 and Figure 6, below, which illustrate the correlation among Smithers, STL and Company B in 2011 and 2014. These two figures show that while Company B’s machine was well-correlated with both Smithers’ and STL’s machines in 2011, the correlation equations are different for each machine. The same phenomenon was observed in 2014. In addition, the correlations shifted from 2011 to 2014, which indicate measurement drift. Measurement drift can be managed by periodic re-correlation. While this illustration shows management of drift for certification and compliance measurement purposes, the agencies should also address drift from the perspective of rolling resistance target-setting or compliance auditing. [EPA-HQ-OAR-2014-0827-1304-A1 p.10]

Two AIAG manuals speak to the management of drift, specifically for automotive parts, which evolve with measurement. Measurement Systems Analysis (MSA)\[9\] and Statistical Process Control (SPC)\[10\] are both good manuals for guidance on how to apply statistics in real applications. In the MSA manual see Chapter IV, Sections A and C, particularly V7 and V8. In the SPC manual, Chapter III on Regression Charts and Residual Charts are helpful. Generally, the recommendation is that the next rolling resistance value should be predicted based on the known evolution and the statistical analysis should be conducted based on the error to the predicted value. These manuals can be ordered from www.aiag.org. [EPA-HQ-OAR-2014-0827-1304-A1 p.12]

The agencies also have invited comment on whether “tire testing facilities are interested in and willing to commit to developing a reference machine.”\[11\] Of course, in considering whether to establish a reference machine, it is critical that a testing firm agree to serve to develop and maintain that machine. In order to gauge interest among those in the tire testing community, RMA recommends that the agencies create a request for proposal (RFP) and post it to www.FedBusOpps.gov, as NHTSA did when it established its National Alignment Lab for passenger car tire rolling resistance testing. Using this process would be the one true mechanism to gauge interest among testing firms. It is unlikely that a
testing firm would telegraph its business plans in the context of a rulemaking. [EPA-HQ-OAR-2014-0827-1304-A1 p.12]

12 Id.

Response:

As discussed in Section I.C(1)(f) of the FRM preamble, CAA section 207(c)(1) requires “the manufacturer” to remedy certain in-use problems. The remedy process is to recall the nonconforming vehicles and bring them into conformity with the standards and the certificate. The regulations for this process are in 40 CFR part 1068, subpart F. EPA is also adopting regulatory text addressing recall obligations for component manufacturers and other non-certifying manufacturers. Under EPA regulations, we can require any person meeting the definition of manufacturer for a nonconforming vehicle to participate in a recall. However, we would normally presume the certificate holder to have the primary responsibility.

We agree with that the Rubber Manufacturers Association that CAA section 207(c)(1) effectively assigns recall liability to manufacturers of motor vehicles and motor vehicle engines. However, EPA remains of the view that in the event that vehicles (e.g. trailers) do not conform to the standards in-use due to nonconforming tires, tire manufacturers would have a role to play in remediating the problem. In this (hypothetical) situation, a tire manufacturer would not only have produced the part in question, but in the case of a trailer manufacturer or other small vehicle manufacturer, would have significantly more resources and knowledge regarding how to address (and redress) the problem. Accordingly, EPA would likely require that a component manufacturer responsible for the nonconformity assist in the recall to an extent and in a manner consistent with the provisions of CAA 208 (a). This section specifies that component and part manufacturers “shall establish and maintain records, perform tests where such testing is not otherwise reasonably available under this part and part C of this subchapter (including fees for testing), make reports and provide information the Administrator may reasonably require to determine whether the manufacturer or other person has acted or is acting in compliance with this part and part C of this subchapter...” Any such action would be considered on a case-by-case basis, adapted to the particular circumstances at the time.
We also encourage manufacturers of tractors, trailers, and vocational vehicles to pursue their own business arrangement with their suppliers to address the in-use performance of products from those suppliers. This applies equally to tires, tire-pressure systems, aerodynamic devices, and any other components needed for demonstrating compliance with emission standards. This is also no different than arrangements that are presumably already in place for a wide range of engine and vehicle components, especially aftertreatment devices, where the component supplier bears a disproportionate responsibility for the overall compliance of the engine or vehicle relative to applicable emission standards.

Moreover, in the case of tires meeting a certain performance level as part of GEM simulation, vehicles manufacturers can declare their FELs so that measured rolling resistance slightly above the Tire Rolling Resistance Level (TRRL) used for certification would not alone cause the vehicle to exceed the emission standard (and thereby fail to conform to the regulation). On the other hand, where we specify TRRL levels as design standards (such as for non-box trailers, and non-aero box vans), a tire that is shown to exceed the specified TRRL would be a direct finding of not conforming to the regulation. In such a case, we would expect to work with all affected trailer manufacturers to arrange for a remedy to address the problem in a way that involves the tire manufacturer, in line with statutory limitations. For example, the regulation identifies the tire manufacturer’s statement reporting TRRL values to vehicle manufacturers as a submission to EPA, which means that we have a role in determining the truthfulness of that information if subsequent test results show that production and in-use tires do not meet reported TRRL values.

There is a potential for future enhancements to our certification program to allow for real-time information management and auto-populating data fields. This is currently more than we are able to do.

We intend to determine whether tires comply with emission standards the same way we have always handled compliance with exhaust emission standards. We establish standards based on specified measurement procedures. In the case of tires, we reference ISO 28580 and identify several clarifying provisions in 40 CFR 1037.520. As a general matter, any testing meeting the published specifications is considered a valid test for verifying TRRL values, either in the context of GEM inputs, or for demonstrating compliance with design standards. Manufacturers are expected to account for this variability when selecting TRRL values for compliance purposes. In fact, the (proposed and final) regulation specifies that tire manufacturers may select TRRL values that are identical to measured rolling resistance, or any higher value. This option to select a higher TRRL value is intended, among other things to account for measurement variability when performing tests according to the procedure specified in the regulation. In addition, the feasibility assessment for the Phase 2 standards is effectively an extension of what was already established under the Phase 1 program, with manufacturers continuing to incorporate compliance margins needed to meet standards.

We did not identify a reference laboratory for measuring tire rolling resistance by regulation. Individual manufacturers may ask us to identify a laboratory to correlate their results to. EPA invites manufacturers to do any amount of in-house or round-robin testing to better understand measurement variability, whether that is from variability to account for the various tolerances within the specified procedure, or lab-to-lab variability, variability from aging equipment, or variability from any other source.
13.3 Other Compliance Provisions for NHTSA
13.3.1 Standards and Credit Alignment

**Organization:** Daimler Trucks North America LLC

**Standards and Credit Alignment** - The agencies request comment on whether optional compliance should be allowed. We agree with the addition of significant digits to align the credit calculations. 80 FR 40521. [EPA-HQ-OAR-2014-0827-1164-A1 p.118]

**Response:**

The final rule includes the provisions as proposed and as supported by the commenters.
14 Other Regulatory Provisions

14.1 General Comments

Organization: Alliance of Automobile Manufacturers and Association of Global Automakers

The Alliance and Global Automakers (referred to jointly as “Automakers” in these comments) appreciate the opportunity to provide comments on the light-duty (LD) vehicle issues contained within the Phase 2 heavy duty (HD) greenhouse gas (GHG) and fuel efficiency proposed rule (the “HD NPRM”). We would like to also thank the agencies for supplying the redline-strikeout version of all the regulatory changes. This saves both agencies and automotive manufacturers review time and focuses limited resources to important changes, thereby allowing a more extensive review. [EPA-HQ-OAR-2014-0827-1271-A1 p.3]

This HD NPRM, in addition to containing new HD requirements, unexpectedly also contains several proposals and requests for comments on significant regulatory changes specific to LD. Also, neither the Preamble nor the Regulatory Impact Analysis (RIA) contained discussions of the rationale or background underlying many of these changes. While the Automakers agree that some of these changes are minor in nature and do not need significant evaluation, some of the proposals are substantive. In particular, the emission defect reporting and related provisions, and proposals to change the global warming potential values for certain compounds are of significant concern. These proposals would benefit from a fulsome discussion and analysis, and therefore we request that they be removed from this rulemaking and addressed in a separate rulemaking. [EPA-HQ-OAR-2014-0827-1271-A1 p.3]

In addition to comments on the substantive light-duty issues described above, the Automakers also provide comment on the agencies’ approach to other light-duty issues contained within or related to this rulemaking. [EPA-HQ-OAR-2014-0827-1271-A1 p.3]

Organization: Truck & Engine Manufacturers Association (EMA)

Proposed Technical Amendments

EPA is proposing numerous technical amendments as part of the NPRM process. EMA is in agreement with most of the proposed amendments, and, in general, is not providing comments on those changes. There are, however, certain proposed changes where EMA feels it is important to offer comments, and those comments are set forth in detail below. [EPA-HQ-OAR-2014-0827-1269-A1 p.73]

Response:

We note and agree that there are several noteworthy and substantive amendments in addition to the wide range of minor amendments. We address those amendments receiving specific comment in Section 13 and the rest of this Section 14.
14.2 Amendments Affecting Gliders and Glider Kits

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Glider Kits

ACEEE fully supports EPA’s proposal to establish GHG and criteria emissions standards for engines in glider kits and NHTSA’s proposal to include glider kits under its Phase 2 standards. The Phase 2 proposal will allow only engines that have been certified to meet current standards to be installed in new glider vehicles (p.40174). The agencies have observed sharp increase in glider kit production (p.40529) recently, which suggests that gliders are being used more and more as a loophole to avoid purchasing engines that meet 2010 EPA emission standards, and potentially to avoid NHTSA safety regulations.

These vehicles, unless regulated, will emit significantly higher NOx and PM emissions than from equivalent vehicles being produced with new engines. [EPA-HQ-OAR-2014-0827-1280-A1 p.29]

- Adopt standards for Glider vehicles in order to prevent them from using older engines with high criteria emissions. [EPA-HQ-OAR-2014-0827-1280-A1 p.30]

Organization: American Lung Association

The American Lung Association offers the following recommendations to strengthen the stringency and timing of the proposal and address several key elements of California’s commitment to protecting public health and air quality. [NHTSA-2014-0132-0087-A1 p.2]

The American Lung Association urges that the glider kit loophole be closed. Glider kits sales have grown significantly. Many of the engines have substantially greater emissions of NOx and particulate matter than current emissions standards allow. Glider kit manufacturers must no longer be able to exploit this loophole leading to more health-threatening pollution. We urge you to finalize the provisions that would close the glider kit loophole. [NHTSA-2014-0132-0087-A1 p.3]

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Gliders: Proposed amendment to U.S. EPA and NHTSA vehicle and engine standards

CARB staff supports U.S. EPA’s proposal to end Phase 1 provisions in 40 CFR part 1037 that: a) allow used, remanufactured or rebuilt engines certified to pre-Phase 1 emission standards to be installed in glider kits; and b) exempt glider kits and glider vehicles produced by small businesses from the requirement to obtain a vehicle certificate for GHG emissions compliance. Since the adoption of the federal 2007/2010 emission standards for PM and NOx, glider sales have significantly increased, and
the Phase 1 provisions affecting glider kit and glider vehicle production did not inhibit the accelerated growth in the glider market. [EPA-HQ-OAR-2014-0827-1265-A1 p.133]

U.S. EPA believes, and CARB staff concurs, that the proposed changes in the Phase 2 rulemaking are necessary to curb the nearly 10-fold increase in the sale of glider vehicles with older engines (used, remanufactured, or rebuilt), and the associated increase in emissions that has occurred since the implementation of the 2007/2010 NOx and PM standards. While criteria pollutant increases due to the sale of glider vehicles with older engines is somewhat constrained in California as a result of CARB’s Truck and Bus Regulation, which required the installation of DPFs on heavier trucks (GVWR over 26,000 lbs) starting in 2012, and engine upgrades to at least 2010 NOx and PM emission levels starting in 2015 for lighter trucks (with GVWR under 26,000 lbs), CARB staff supports U.S. EPA’s proposal to limit the production and sale of glider vehicles with older, higher-emitting engines for the nationwide protection of human health and the environment and to close potential enforcement loopholes. [EPA-HQ-OAR-2014-0827-1265-A1 p.133-134]

Glider kits and glider vehicles are currently exempt from NHTSA’s Phase 1 fuel consumption standards. Unlike U.S. EPA, NHTSA defines glider kits as motor vehicle equipment, not as motor vehicles, and therefore is only considering the inclusion of completed glider vehicles in its proposed Phase 2 requirements which will be similar in effect to U.S. EPA’s proposal, including special provisions for small business manufacturers. NHTSA is seeking comments from the glider industry regarding its intent to include glider vehicles in its Phase 2 requirements. CARB staff supports NHTSA’s intent to apply Phase 2 requirements to completed glider vehicles and strongly encourages it to develop provisions that align, to the extent possible, with U.S. EPA’s proposed requirements. [EPA-HQ-OAR-2014-0827-1265-A1 p.134]

46 “Glider kit” typically refers to a chassis and cab assembly produced by a manufacturer without a new engine, transmission, or rear axle. “Glider vehicle” or “glider” typically refers to the completed assembly of the glider kit with a used, remanufactured, or rebuilt engine, a transmission, and/or rear axle. U.S. EPA considers “glider kits” to be incomplete motor vehicles, and, under the Clean Air Act, has the authority to regulate incomplete motor vehicles, including un-motorized chassis.

47 Under Phase 1, U.S. EPA requires glider kits and gliders to obtain a vehicle certificate, except those produced by small businesses. The engine installed in the glider kit is not required to certify to the Phase 1 engine standards. Thus, depending on the size of the business producing the glider kit or glider vehicle, some are exempt from the requirement to obtain a Phase 1 vehicle certificate prior to introduction into commerce as a new vehicle.

Organization: Capacity Trucks, Inc.

A terminal truck is a purpose-built truck: its only purpose is to move trailers in-yard more efficiently and effectively than can be done with a traditional heavy-duty over-the-road truck. Seventy percent of terminal trucks are built for off-road use only, operating only in yards. The terminal tractor industry is very small with only 4,000-6,000 terminal trucks built per year, and is primarily comprised of small businesses. Fifty percent of our competitors are small businesses and will be exempt from the proposed Phase 2 regulations governing glider kits and glider vehicles because of their size. This will likely cause a shift in the market and negatively impact our business. [EPA-HQ-OAR-2014-0827-1303-A1 p.1]
EPA should exempt engines that are still within their useful life—as measured by miles only, not years—from the proposed regulations governing glider kits and glider vehicles. Terminal trucks take a beating on the outside, while the powertrains remain intact. Capacity chassis are typically rebuilt or refurbished due to severe duty and use, with terminal trucks operating two and three shifts per day at an average speed of 20 mph. At the time of rebuilding/refurbishment, these trucks may be 5 years old or 25 years old, depending on the customer's use of the vehicle, but typically have limited miles on them.

Terminal trucks are rebuilt and refurbished due to their operating environment: a small confined area, numerous impacts to trailers and docks or other obstructions, and corrosion from weather exposure. When a truck couples to a trailer parked against a dock door, as much as 7-8 gs of force is transmitted through the chassis. [EPA-HQ-OAR-2014-0827-1303-A1 p.1-2]

Vehicles with powertrains that are still within their mile and/or hour useful life should be exempted from the rule. EPA should not use the years component of the useful life definition because customers frequently bring in terminal trucks that are greater than ten years old but have very limited miles. Reusing these powertrains with rebuilt/refurbished or new chassis and vehicle components has no effect on overall emissions or negative environmental impacts, but results in important cost savings to our customers, many of whom are small businesses. [EPA-HQ-OAR-2014-0827-1303-A1 p.2]

Organization: Clarke Power Services

I. Amendments Affecting Gliders

A. Glider Definition Proposed Rules and Past Practices

1. **Giders and Glider Kits**: The EPA has defined a Glider as a Motor Vehicle in the proposed rules and as a Motor Vehicle, Gliders would be subject to the Model Year (MY) Phase 2 GHG requirements. Reviewing past practices, the trucking industry over the last decade has worked under the NHTSA guidance that a glider is a repair part not dissimilar to any rebuilt part that is used in the repair and maintenance of heavy duty trucks and not a Motor Vehicle. The rebuilt engine in the Glider, as a repair part, complies to the criteria pollutant rules for the MY of the engine that is rebuilt. As a repair part, Gliders have been used by fleets to refresh or refurbish an “older” heavy duty truck that is beyond its useful life (defined as a greater than 435,000 miles). Trucks beyond useful life often have rebuilt engines, transmissions, and rear axle differentials installed to lengthen the miles and years a chassis can be utilized to haul freight. Fleets move the rebuilt engine, transmission, and/or the rear axle differentials from the “older” truck to the Glider after which the remainder of the “old” truck is salvaged removing it from service. Trucking fleets that have made this truck repair process using a Glider repair part an ongoing method for maintaining their fleet have dramatically changed the safety profile of their fleet. Glider repaired trucks now have “new” cab, electronics, controls, brakes, and air conditioning along with rebuilt engines, transmissions, and/or real axle differentials. The engine, transmission and axles are supplied from the “older” truck, often called a “donor” truck in the industry, and are usually rebuilt. For a fleet that does not have adequate capital (usually smaller fleets with less than 1000 heavy duty trucks in service) to purchase new equipment utilizing a Glider as a replacement part gives a freshly refurbished truck that has the following positive impacts: [EPA-HQ-OAR-2014-0827-1005-A1 p.1-2]

a) Improved operating costs with less down time for maintenance which improves utilization and reduces the number of trucks required to haul the same tonnage of freight.

b) Improved safety with the same braking, lane drift devices, dynamic cruise control, and blind spot detection devices found on current MY heavy duty trucks.
c) The new cab and controls improve driver skill level and safety.

d) Improved particulate, NOx, and GHG emissions of a newly rebuilt engine compared to worn oil burning engine which is beyond its useful life. The engine is returned to the MY standard of the “donor” truck.

e) New air-conditioning components reducing GHG emission compared to hydrofluorocarbon leakage from the old components. Also the latest standard for refrigerant can be used on Glider equipment with new air-conditioning components part of the kit.

This commenter recommends that used engines be eliminated as an option when assembling gliders. A rebuilt engine that has been brought back to the original MY EPA emission standard is always a cleaner option than a used engine installed in a Glider chassis. [EPA-HQ-OAR-2014-0827-1005-A1 p.2]

2. Phase-out and Exemptions for Small Trucking Fleets: It is the opinion of this commenter that the intentions of trucking fleets using gliders as described in this paragraph are not motivated by circumventing the EPA policies, but are most interested in being more efficient by removing old equipment from service and introducing a significantly improved heavy duty truck in its place. This being said, the agencies proposing the rule change should carefully access the impact on small trucking companies. A delay of the rules with an “appropriate” phase-out of the oldest engines to ease the burden on the small trucking fleets is needed. Also as part of the phase-out and to encourage the oldest engines to continue to be retired, a hard look at and consideration of the 2010 engine specification for the small fleet use in Glider equipment is also merited. A recommended schedule for Phase-out of older engines in Gliders follows: [EPA-HQ-OAR-2014-0827-1005-A1 p.2]

<table>
<thead>
<tr>
<th>MY EPA Standard</th>
<th>Phase out in Gliders by</th>
</tr>
</thead>
<tbody>
<tr>
<td>1998 – 2003</td>
<td>2021</td>
</tr>
<tr>
<td>2004 – 2007</td>
<td>2023</td>
</tr>
<tr>
<td>2008 – 2009</td>
<td>2025</td>
</tr>
<tr>
<td>2010</td>
<td>2027</td>
</tr>
</tbody>
</table>

Further, with the potential impact being severe on small trucking companies that have adopted the Glider repair part business model, exempting small trucking companies that have a history of assembling gliders for their own use should be considered. The agencies should use similar logic on exempting small fleets as other users of Gliders (Vocational Fleets) to limit the total number of Gliders. For example each small trucking company’s exemption could be the lesser of the average number of Gliders built annually over the past 3 years or 150 units/year. This would limit the impact on GHG emissions because of small numbers of Gliders and aid small fleets in remaining competitive providing trucking capacity and driver jobs as transition is made. [EPA-HQ-OAR-2014-0827-1005-A1 p.3]

3. Assemblers/Manufacturers of Gliders: There are two type of Glider Assemblers that have been defined as Manufacturers by the agency’s proposed new rules:[EPA-HQ-OAR-2014-0827-1005-A1 p.3]

a) Type 1 is an assembler/manufacturer that builds Gliders to sell directly to the industry either as a retail or wholesale completed truck [EPA-HQ-OAR-2014-0827-1005-A1 p.3]
b) Type 2 is an assembler/manufacturer that is contracted as a third party to assemble a complete truck. This type of assembler never owns the glider and is not building to resell the final product to an end user. [EPA-HQ-OAR-2014-0827-1005-A1 p.3]

As defined above, Type 2 assemblers/manufacturers are often hired by small trucking company customers to assemble the parts, components, and glider repair part into a completed truck. This type of assembler also has several small businesses that are dependent upon it for a small quantity of Glider assemblies each year. Further exemption should be evaluated for manufacturers dedicated to assembly only with no intent or history of retail or wholesale selling of the completed truck. The logic is that exempt Gliders for small businesses, vocational truck fleets, and off-highway and oil field operators can all benefit from the synergies of a quality manufacturer that is hired to complete the exempt Glider. The main qualification for this exemption would be that the Glider is never owned by the assembler/manufacturer and is not intended for retail sale or wholesale to the end user of the truck. The end user in this case owns the Glider and donor components throughout the assembly process. [EPA-HQ-OAR-2014-0827-1005-A1 p.3]

4. Impact of Section XIV.B: The proposing agencies need to assess carefully the impact of the proposed rules in light of past practice and the impact on small trucking companies and the assemblers that support them. There were four impacted groups identified by the agencies; Trailer Manufacturers, Alternative Fuel Converter, Vocational Chassis Manufacturer, and Glider Vehicle Assemblers. However, one of the most impacted groups was not identified by the agencies, small trucking companies. This commenter strongly recommends more diligent review of the impact on small trucking companies as part of the small business initial impact study as required by the SBREFA. [EPA-HQ-OAR-2014-0827-1005-A1 p.3]

5. Cap of Glider Assemblies: This commenter believes that the trucking company’s decision to utilize Gliders will rationalize itself based on economic factors. As newer MY engines have become more fuel efficient, the demand for Gliders with cleaner engines will become the choice. Additionally, there is growing shortages of older engines, since diesel engine blocks have limited life and can only be rebuilt 3 times. This industry is currently considering MY 2010 engines as the choice for Gliders moving forward. So as the trucking industry transitions, this commenter recommends caps on non-exempt Gliders based on three years of production as recommended by the Panel Report, c, subsection xi, page 40545; however, instead of using production years 2010-2012 to establish peak levels use production years 2015-2016. [EPA-HQ-OAR-2014-0827-1005-A1 p.4]

B. Gliders for Special Purpose Vocational Trucks Proposed Rules

1. Vocational Trucks related to Gliders: Throughout the proposed rules beginning with the Executive Summary at Section D.(2) page 40142, the agencies discuss vocational trucks and define them as “a wide variety of truck and bus types (e.g. delivery, refuse, utility, dump, cement, transit bus, shuttle bus, school bus, emergency vehicles, and recreational vehicles.” Clarity from the agencies in relating vocational trucks to Gliders would be helpful. [EPA-HQ-OAR-2014-0827-1005-A1 p.4]

a) 1037.630 Special Purpose Tractors states: “Vocational tractors are treated as vocational vehicles and are exempt from the standards of § 1037.106....This allowance is intended only for vehicles that do not typically operate at highway speeds, or would otherwise not benefit from efficiency improvements designed for line-haul tractors. This allowance is limited to the following vehicle and application types: [EPA-HQ-OAR-2014-0827-1005-A1 p.4]
1. Low-roof tractors intended for intra-city pickup and delivery, such as those that deliver bottled beverages to retail stores.
2. Tractors intended for off-road operation (including mixed service operation), such as those with reinforced frames and increased ground clearance.
3. Model year 2020 and earlier tractors with a gross combination weight rating (GCWR) over 120,000 pounds...."

b) This commenter recommends the agencies provide clarity which is specificity related to Gliders in the case of Special Purpose Tractors or Vocational Trucks. While exemptions from Phase 2 have been suggested in the proposed rules the definition of Vocational Trucks should clearly include trucks that are heavily modified for a vocational application. While heavy duty chassis, limited speeds when on-highway, and predominately off-highway application were called out by the agencies there are several vocational applications that the agencies intend to include in the proposed exclusions that are not clear. For example many utility, dump, and concrete applications are supported by Vocational Gliders that have mixed pattern of use i.e. stop and go city driving, urban highway driving, and/or rural highway driving where speed may be in excess of 55 MPH but the truck is clearly a special use vocational truck. The speed only test and/or the predominately off road test do not always apply to these types of vocational trucks or the Gliders that support their industries. [EPA-HQ-OAR-2014-0827-1005-A1 p.4-5]

2. Special Use Trucks: Other special use trucks for which Gliders are used and that need to brought to the attention of the agencies are: [EPA-HQ-OAR-2014-0827-1005-A1 p.5]

a) Auto Hauling Tractors: This is a special use tractor that is heavily modified with a substantially lower roof than even a day cab. This low roof requires a modification that is not performed by a major OEM but is contracted to a fabrication/modification “shop” The resulting vehicle is low in height and also to the ground with low ground clearances. This low configuration is necessary to haul the number of automobiles on a single load required to be cost, fuel consumption and therefore emissions per delivered car effective. The auto hauling tractor has limited suppliers in the market place. Modified Gliders assembled for this purpose is one of only two acceptable suppliers today. This commenter recommends including auto hauling Gliders in the exemption rules being proposed for vocational equipment. [EPA-HQ-OAR-2014-0827-1005-A1 p.5]

b) Safety Issues with Auto Hauling Tractors: Trucks conforming to MY 2014 emission requirements have proven to be not-fit-for the purpose of auto hauling. There have been reported cases in the auto hauling industry of fires that result from the regeneration cycle of MY 2014 and newer equipment that have been modified to haul automobiles. Because of the low ground clearances of the auto hauler the heat that is produced during the regen cycle has caught dry combustible material (grass and leaves) that may be under the truck when it is parked. This has damaged equipment and the automobiles that were being hauled. Using a Gilder with pre MY 2014 rebuilt engine solves this problem and is further evidence that Auto hauling Gliders need be included as a vocational truck in the proposed rules. [EPA-HQ-OAR-2014-0827-1005-A1 p.5]

c) Ultra-Light Weight Gliders: This is a Special Use Glider Truck that has been heavily modified to lower the overall weight of the Truck by 1,500 lbs. These modifications allow certain products to be transported more efficiently by loading more product into the trailer while conforming to the total vehicle weight limit required by the DOT. A lighter truck means more freight per load, therefore less loads are required to haul the same tonnage of product. A Glider can be produced that is the lightest heavy duty truck on the road today and is well received by carriers hauling products like beverages;
bulk powdered or liquid starches, syrups, and other bulk food grade products; and dry bulk and liquid chemicals. [EPA-HQ-OAR-2014-0827-1005-A1 p.5]

3. **1031.631 Exemption of vocational vehicles intended for off-road use**: The chassis of vehicles in the vocational industries in general and the off-road vehicles take a tremendous amount of load and torque (twisting). This kind of use guarantees that the chassis will be worn out prior to the modifications that were used to prepare the vehicle to be a vocational truck. The work box, crane, hydraulic lifts, etc. that are required in the vocational application are expensive and are transferred to the next chassis. When the replacement chassis is a Glider, then this commenter believes that the flexibility should be granted with regard to the engine choice. This commenter recommends that one sentence should be struck from 1031.631; that sentence being “This section does not exempt engines used in vehicles from the standards of 40 CFR part 86 or part 1036” atop of page 40655. Striking this sentence will give maximum flexibility once the agencies realize the vocational equipment being described may be older than MY 2014. [EPA-HQ-OAR-2014-0827-1005-A1 p.5-6]

1. **Impact Study of number of Gliders**: The agencies proposing the Phase 2 GHG gas rules have not adequately defined the impact of the current number of Gliders which are assembled each year (XIV.B.3, page 40528), since no production numbers are reported to the EPA. Since the total is unknown, the impact on pollutants is also unknown; therefore additional studies need to be made to adequately define the “right” number of Gliders allowed. [EPA-HQ-OAR-2014-0827-1005-A1 p.6]

2. **Vocational Caps**: It is clear that the agencies propose to exempt vocational gliders, however, a cap is also being considered in the rules; proposed as not more than 21,000 in any three year period. This 7,000 average per year can be limiting to certain major U.S. industries and does not allow for growth and replacement for all transportation segments. This commenter recommends with regard to vocational trucks that no cap be mandated: [EPA-HQ-OAR-2014-0827-1005-A1 p.6]

   a) The in-service life of a vocational truck exceeds 10 years and the equipment on the truck can be moved from one chassis to the next. So capping the number of gliders will adversely impact the moving of the very equipment needed to make the replacement Glider able to do the vocational work. The investment to modify a Glider chassis for vocational applications is large and every time vocational equipment can be moved to a new chassis it will be done. Caps become overly complicated when replacement and growth Gliders are considered. [EPA-HQ-OAR-2014-0827-1005-A1 p.6]

   b) As the agencies have noted in their vocational definitions several different transportation segments and major industries are using vocational equipment. Limiting or capping vocational trucks can have the unintended effect of giving one transportation segment or industry access to Glider equipment over another. This can drive cost up as availability is limited and offer a favored advantages to a selected few U.S. industries that can pay. [EPA-HQ-OAR-2014-0827-1005-A1 p.6]

   c) As the agencies commented the over-all volume of vocational is relatively low so the need to cap vocational is also low. So allowing each industry to rationalize the number of vocational vehicles necessary each year is more prudent that trying to regulate an artificial cap. [EPA-HQ-OAR-2014-0827-1005-A1 p.6]

1. **EPA Regulatory Status Quo Proposed Rules**: Section XIV.B.(3) page 40529 This commenter is also concerned about the economic impacts on small businesses that assemble gliders and build glider kits. The agencies are correct in assuming that the activities of these small manufacturers are for non-circumvention purposes. The proposed rules that maintains the regulatory status quo for existing small businesses is supported. The additional point this commenter would make is to expand the small businesses impacted to include small trucking companies that have a history of assembling gliders in lieu of operating used equipment. Regulatory relief for this group would also be appropriate with reasonable caps.

2. **Cap of Gliders Allowed**: The agencies ask for comment with regard to the methodology and total number of Gliders allowed to be assembled by small businesses. It is the opinion of this commenter that the number of small businesses engaged in Glider assembly is likely to decrease with the rule changes being proposed. If this is accurate then using the history of total production as the basis for establishing the limit on total production may disallow an otherwise efficient small business from acquiring additional customers as other assemblers cease business. A more equitable method would be to allow any small business assembler that has built a minimum of 100 gliders within the last three years be granted an exemption for gliders being built in any given year up to a cap of 300 gliders/year. This allows for competition and for high quality small business assemblers to secure business from lesser assemblers. Additionally, the vocational exemptions the agencies are proposing should also be made available to small business assemblers and it is recommended that this cap would also be 300 vocational units based on the definition of the final rules. The maximum cap with Gliders and Vocational Gliders would be 600/year.

3. **Timing**: The EPA has solicited comment with regard to the timing of implementation of the proposed rules. The proposed date of January 1, 2018 is tight to transition all of the stake holders in the Glider industry. It is the opinion of this commenter that Phase 2 should be postponed until January 1, 2020 assuming there has been adequate assessment of the impact on the impacted groups including small trucking companies.

**Organization**: Cummins, Inc.

*Cummins supports limitations on the use of glider kits* [EPA-HQ-OAR-2014-0827-1298-A1 p.41]

Glider kits are a necessary option for replacing damaged vehicles that still have usable powertrain components. However, glider kits should not be used to circumvent the purchase of a currently certified engine and aftertreatment system. Cummins urges the agencies to work with the industry to develop a workable solution for glider kits.

**Organization**: Daimler Trucks North America and Detroit Diesel Company

We submitted separately to the docket a letter going into detail on the EPA’s memorandum. [This letter can be found in docket number EPA-HQ-OAR-2014-0827-1926-A1][EPA-HQ-OAR-2014-0827-1918-A2 p.9]

**Organization**: Daimler Trucks North America LLC
I. Legal Issues with Glider Provisions

As DTNA expressed in its comments to the Phase 2 Proposed Rule, DTNA has concerns with EPA's proposed regulation of 'glider kits' and 'glider vehicles,' including EPA's legal authority for regulating them. EPA's Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act ('CAA'), which does not provide EPA authority to regulate the sale of motor vehicle components. The CAA only provides EPA with authority to regulate 'new motor vehicles' and their engines, defined as 'self-propelled' vehicles 'the equitable or legal title to which has never been transferred to the ultimate purchaser'—not non-motorized frames, cabs, and axles. 42 U.S.C. §§ 7522(a), 7550(3). In turn, any regulation of glider kits is beyond the agency's authority. Further, glider vehicles when constructed retain the identity of the donor vehicle, such that the title has already been exchanged, making the vehicles not 'new' under the CAA. Thus, EPA lacks authority to regulate glider vehicles. And even if the EPA had authority to regulate, the CAA requires 4-years' lead-time for new or revised NOx and PM requirements and for regulations governing engine rebuilding practices, which has not been met under the proposed regulations. [EPA-HQ-OAR-2014-0827-1926-A1 p.2] [[This comment can also be found in section 1.3.1 of the Comment Summary.]]

A. Distinction Between 'Glider Kit' and 'Glider Vehicle'

As DTNA explained in its comments to the Phase 2 Proposed Rule, EPA has proposed two overlapping and potentially confusing definitions: 'Glider kit means any of the following: (1) A new vehicle that is incomplete because it lacks an engine, transmission, or axle; (2) A new vehicle produced with a used engine (including a rebuilt or remanufactured engine); (3) Any other new equipment that is intended to become a motor vehicle with a previously used engine (including a rebuilt or remanufactured engine); and 'Glider vehicle means a new vehicle produced with a used engine.' As EPA has proposed these definitions, 'glider vehicle' is a subset of 'glider kit,' whereas under industry usage and understanding, the two are separate, and should remain so under the regulations. A 'glider kit' should instead be defined as 'an assemblage of new vehicle components, including at a minimum the chassis, cab and front axle, but lacking a new engine, transmission, and rear axle.' Once the glider kit is used to rebuild a truck, EPA would consider it a 'glider vehicle.' [EPA-HQ-OAR-2014-0827-1926-A1 p.2]

EPA should clarify when a glider vehicle becomes a 'new motor vehicle' subject to regulation, as NHTSA has done, by adopting a provision similar to 49 C.F.R. § 571.7(e). Under its regulations, NHTSA considers a truck to be 'newly manufactured' and subject to Federal Motor Vehicle Safety Standards when a new cab is used in its assembly, 'unless the engine, transmission, and drive axle(s) (as a minimum) of the assembled vehicle are not new, and at least two of these components were taken from the same vehicle.' 49 C.F.R. § 571.7(e) (emphasis added). In other words, as long as the engine, transmission, and drive axle(s) are remanufactured and not new, and at least two of these components were taken from the same vehicle, the resulting glider vehicle would not be a new motor vehicle subject to regulation, and the glider kit used to build the glider vehicle could contain the third component (remanufactured engine, remanufactured transmission, or remanufactured drive axle(s)). This harmonization would be consistent with the agencies' commitment to establish a national GHG program. [EPA-HQ-OAR-2014-0827-1926-A1 p.2]

B. EPA Lacks Authority to Regulate 'Glider Kits' and 'Glider Vehicles'

The distinction between 'glider kits' and 'glider vehicles' is important because EPA lacks authority to regulate vehicle parts, including assemblages of parts (without an engine) such as glider kits. EPA's Phase 2 Proposed Rule is being carried out under the authority of the CAA, and the CAA does not provide EPA authority to regulate the sale of motor vehicle components, which is all that glider kits are.
The CAA only authorizes EPA to set emission standards for 'new motor vehicles' and 'new motor vehicle engines,' 42 U.S.C. § 7521(a)(1), and to prohibit the sale of uncertified 'new motor vehicles' and 'new motor vehicle engines,' see 42 U.S.C. § 7522(a)(1). 'New motor vehicles' are defined under the CAA as 'self-propelled' vehicles 'the equitable or legal title to which has never been transferred to an ultimate purchaser'—not non-motorized frames, cabs, and axles. 42 U.S.C. § 7550(2), (3). Because glider kits do not contain engines, transmissions, and drive axles, and have no motive power, the CAA does not authorize EPA to regulate the sale of glider kits. [EPA-HQ-OAR-2014-0827-1926-A1 p.2-3] [This comment can also be found in section 1.3.1 of the Comment Summary.]

EPA's examples of CAA provisions that address certain vehicle components are inapplicable. EPA cites to three CAA provisions granting it authority to regulate evaporative emissions, including from certain components, and concludes from those specific provisions that it has authority to regulate all vehicle components, whether or not they produce emissions in any form. Specifically, EPA cites to 'CAA section 202(a)(6) (standards for onboard vapor recovery systems on 'new light-duty vehicles,' and requiring installation of such systems); section 202(a)(5)(A) (standards to control emissions from refueling motor vehicles, and requiring consideration of, and possible design standards for, fueling system components), 202(k) (standards to control evaporative emissions from gasoline-fueled motor vehicles). EPA Legal Memo, at 3. From these examples, EPA concludes that it has authority to regulate all vehicle components, a conclusion that is not justified under the language, of the Act. First, the fact that the CAA lists specific components that EPA may regulate suggests that EPA lacks authority to regulate other components that are not specifically listed, particularly given the broader dictate that EPA may set emission standards only for 'new motor vehicles' and 'new motor vehicle engines,' 42 U.S.C. § 7521(a)(1), and may prohibit only the sale of uncertified 'new motor vehicles' and 'new motor vehicle engines,' 42 U.S.C. § 7522(a)(1). Second, all of the examples cited by EPA relate to evaporative emissions. Although EPA might be able to argue that it has authority to regulate evaporative emissions from those specific components, and exhaust emissions from 'new motor vehicles' and 'new motor vehicle engines,' it is a stretch to say that EPA has authority to regulate all motor vehicle components. This is particularly true where, as with glider kits, the components do not produce emissions on their own. EPA itself recognizes that it cannot extend its argument to the smallest vehicle component—'This is not to say that the Act authorizes emission standards for any part of a motor vehicle, however small,' EPA Legal Memo, at 3—but nonetheless believes it has the authority to draw the line to include glider kits and trailers. In fact, Congress drew the line in the CAA at 'new motor vehicles' and 'new motor vehicle engines,' and EPA may not extend its authority further than Congress allowed. [EPA-HQ-OAR-2014-0827-1926-A1 p.3] [This comment can also be found in section 1.3.1 of the Comment Summary.]

EPA also lacks authority to regulate glider vehicles. When constructed, glider vehicles retain the identity of the donor vehicle, such that the title has already been exchanged, making the vehicles not 'new' under the CAA and not subject to EPA's regulatory authority. EPA's argument that glider assemblers market their finished products as 'new trucks' is unavailing. A company's marketing materials have no bearing on the statutory definition that governs EPA's authority. Although the CAA may not reference Vehicle Identification Numbers as determinative of new motor vehicle status, the Act does contain an express definition of 'new motor vehicles'—'self-propelled' vehicles 'the equitable or legal title to which has never been transferred to an ultimate purchaser,' 42 U.S.C. § 7550(2), (3)—which EPA is not free to disregard. Glider vehicles incorporate not just a used engine, as EPA suggests, but the engine, transmission, and rear axle—the entire powertrain that comprises a significant portion of a vehicle's cost and identity—from a previously owned vehicle. The glider kit, which may be considered to be 'new' vehicle parts, is not self-propelled. The glider becomes self-propelled only when the powertrain components are added, but cannot be a 'new motor vehicle' because the equitable or legal title of those powertrain components has previously been transferred to an ultimate purchaser. [EPA-
C. Regulation of 'Glider Vehicles' Targets NOx/PM Emissions and Must Meet Statutory Lead-Time Requirement

In addition, the proposed regulation of 'glider vehicles' actually targets NOx/PM emissions rather than GHG emissions, as EPA concedes, and is therefore inappropriate for inclusion in a GHG rule. Glider sales actually create the potential to reduce GHG emissions by incorporating used and rebuilt engines in newer, more aerodynamic vehicles. Rebuilt engines used in glider vehicles emit fewer GHGs, and new cabs and low rolling resistance tires are more efficient than what they replace. Because regulation of glider vehicles targets NOx/PM emissions, it should be done only in a separate rulemaking, if at all. [EPA-HQ-OAR-2014-0827-1926-A1 p.4]

In addition, this separate rulemaking should be carefully drafted to meet statutory lead-time requirements for NO and PM regulations as required by statute. NO and PM emissions standards are subject to an express CAA lead-time requirement under which new or revised NOx and PM requirements cannot take effect sooner than the model year commencing 4 years after a new or revised standard is promulgated. 42 U.S.C. § 7521(a)(3)(C). As currently proposed, with an effective date of January 1, 2018, the proposed glider regulations violate the 4-year lead-time requirement under the CAA. Assuming the Phase 2 rule is finalized in early 2016, the earliest that the regulations governing glider vehicles could take effect would be 2020, in compliance with the CAA lead-time requirement. [EPA-HQ-OAR-2014-0827-1926-A1 p.4]

For its proposed glider provisions, EPA purports to rely on its authority to regulate the 'practice of rebuilding heavy-duty engines.' 42 U.S.C. § 7521(a)(3)(D). However, EPA is not regulating engine rebuilding practices, as evidenced by the lack of relevant proposed amendments to its engine rebuilding regulations (40 C.F.R. §§ 86.004-40, 1068.120). Instead, EPA is attempting to regulate vehicle rebuilding, which it clearly does not have the authority to do under the CAA. Congress granted EPA authority to regulate 'new motor vehicles' and 'new motor vehicle engines' only, and while Congress granted EPA authority to regulate engine rebuilding, it did not grant EPA similar authority to regulate vehicle rebuilding. EPA's reliance on (3)(D) is misplaced with respect to its proposed regulation of glider vehicles. Even if EPA were properly regulating heavy-duty engine rebuilding practices with its proposed glider provisions, it would be subject to the same four-year statutory lead-time requirement. [EPA-HQ-OAR-2014-0827-1926-A1 p.4]

As currently proposed, EPA is attempting to regulate NO and PM in the GHG rule in a way it could not undertake in a proper NOx and PM rulemaking. Under the CAA, EPA must allow four years of lead time, at a minimum, before its proposed glider provisions would take effect. [EPA-HQ-OAR-2014-0827-1926-A1 p.4]

II. Alternative Provisions Proposed by EPA

In its draft legal memorandum, EPA proposes several alternative provisions for comment. These include alternative provisions governing glider kit manufacturers, engine remanufacturers, and glider vehicles using newer engines. [EPA-HQ-OAR-2014-0827-1926-A1 p.5]

A. Alternative Provisions for Glider Kit Manufacturers as Manufacturers of Motor Vehicle Parts
EPA proposes alternative provisions governing glider kit manufacturers that would apply in the event that its primary implementation provisions are held inapplicable. EPA asserts that a glider kit sold in a configuration that would not meet the tractor emission standard when the specified engine, transmission, and axle are installed would 'cause' a violation of that standard in violation of 42 U.S.C. § 7522(a)(1), or could be considered a prohibited defeat device under 42 U.S.C. § 7522(a)(3)(B). Under 42 U.S.C. § 7522(a)(1), a manufacturer is prohibited from distributing in commerce, selling or offering for sale, or introducing or delivering for introduction into commerce, a 'new motor vehicle' or 'new motor vehicle engine' that is not covered by a certificate of conformity. As explained above, neither a glider kit nor a glider vehicle meet the definition of 'new motor vehicle.' As a result, EPA's assertion that the sale of a glider kit could 'cause' a violation of an emission standard applicable to a new motor vehicle fails for the same reason that EPA does not have authority to regulate glider kits and glider vehicles—they are not 'new motor vehicles.' [EPA-HQ-OAR-2014-0827-1926-A1 p.5]

With respect to 'defeat devices,' the CAA prohibits 'any person' from manufacturing or selling or offering to sell or installing 'any part or component intended for use with, or as part of, any motor vehicle or motor vehicle engine, where a principal effect of the part or component is to bypass, defeat, or render inoperative any device or element of design installed on or in a motor vehicle or motor vehicle engine in compliance with regulations under this subchapter, and where the person knows or should know that such part or component is being offered for sale or installed for such use or put to such use.' 42 U.S.C. § 7522(a)(3)(B). It is difficult to see how a 'principal effect' of a glider kit is to 'bypass, defeat, or render inoperative any device or element of design installed on or in a motor vehicle or motor vehicle engine.' Because the engines installed in glider vehicles are typically older model year engines subject to less stringent emission standards, a glider kit generally improves the GHG emissions performance of the engine/vehicle. It is unclear how a glider kit could be said to 'bypass, defeat, or render inoperative any device or element of design installed on or in' these older model year engines, let alone for that to be the glider kit's 'principal effect.' [EPA-HQ-OAR-2014-0827-1926-A1 p.5]

EPA proposes an alternative rule which would require glider kit manufacturers to do one of two things: either a) affix a label on the glider kit stating that the 'glider kit is not to be used in combination with tractors certified to the applicable phase 2 GHG standard,' or b) 'conduct testing (including aerodynamic and tire testing) to show that the glider kit is consistent with the glider vehicle's final certified condition.' EPA Legal Memo, at 8. Both of these alternatives still assume that EPA has authority under the CAA to regulate glider kits as 'new motor vehicles' or as motor vehicle components and to regulate glider vehicles as 'new motor vehicles,' which as explained above, EPA does not. [EPA-HQ-OAR-2014-0827-1926-A1 p.5]

If EPA moves forward with regulating gliders, it should pursue a variation on the proposed cap rather than these alternative rules. As DTNA explained in its comments to the Phase 2 Proposed Rule, a cap of 300 vehicles is too low given the abrupt change this regulation brings to the 50-year-old glider industry and the disproportionate impact it will have on small businesses. A more reasonable approach would be to begin with a higher initial cap and gradually reduce it over time to allow large and small businesses in the glider industry to adapt to EPA's new requirements. Specifically, if EPA decides to implement a certification requirement for glider vehicles, the small business exemption should start with a cap of 1,500 vehicles in 2020 (complying with the statutory lead-time requirement) and then reduce the cap by 250 each year for the next 3 years to 1,250 in 2021, to 1,000 in 2022, and finally to 750 vehicles in 2023. Such a phase-down would allow these small manufacturers to transition to other lines of business and to move their employees to other types of work without extensive layoffs. Many small manufacturers will already be limited by their highest annual sales volume and will not be affected by the cap, while for those that are, the initial 1,500 vehicle cap and subsequent phase-down represents a substantial reduction. [EPA-HQ-OAR-2014-0827-1926-A1 p.5-6]
Further, EPA should clarify that the proposed glider provisions apply only to the final assembler of the glider vehicle, as that is the only entity that knows what the final vehicle configuration will be. There is no need for a glider kit manufacturer to label the assemblage of parts that it sells in accordance with the delegated assembly provisions. It is obvious that the glider kit requires further assembly as it lacks an engine, transmission, and/or rear axle. The regulations should require that only the glider vehicle, once assembled and ready to drive, be labeled by the assembler. [EPA-HQ-OAR-2014-0827-1926-A1 p.6]

B. Alternative Provisions for Engine Remanufacturers

EPA is also considering alternative provisions for engine remanufacturers if the primary implementing provisions are held to apply only to the glider vehicle assembler. Relying on its section 202(a)(3)(D) authority, EPA would require any rebuilt/remanufactured motor vehicle engines to meet current model year engine standards if they are intended to be installed in new motor vehicle chassis. [EPA-HQ-OAR-2014-0827-1926-A1 p.6]

If EPA proposes to amend its heavy-duty engine rebuilding provisions (40 C.F.R. §§ 86.004-40, 1068.120), it must do so in a separate rulemaking subject to public notice and comment, rather than making such a proposal in a draft legal memorandum entered into the Phase 2 Proposed Rule docket and not proposed or explained in the Federal Register. Further, if EPA intends to rely on its authority to regulate the 'practice of rebuilding heavy-duty engines' under 42 U.S.C. § 7521(a)(3)(D) to amend the heavy-duty engine rebuilding regulations, such amendment would be subject to the four-year statutory lead-time requirement. The four-year lead-time and three-year stability requirements of 42 U.S.C. § 7521(a)(3)(C) are applicable to all of paragraph 3, which includes the engine rebuilding provision contained in (3)(D). It is not enough for EPA to opine that the January 1, 2018 implementation date for the glider provisions allows 'sufficient time to permit the development and application of the requisite control measures' under 42 U.S.C. § 7521(a)(3)(D) to amend the heavy-duty engine rebuilding regulations, such amendment would be subject to the four-year statutory lead-time requirement. The four-year lead-time and three-year stability requirements of 42 U.S.C. § 7521(a)(3)(C) are applicable to all of paragraph 3, which includes the engine rebuilding provision contained in (3)(D). It is not enough for EPA to opine that the January 1, 2018 implementation date for the glider provisions allows 'sufficient time to permit the development and application of the requisite control measures' under 42 U.S.C. § 7521(a)(3)(D). The four-year lead-time and three-year stability requirements of (3)(C) provide an absolute minimum, even for engine rebuilding regulations, and then EPA must determine whether additional time is required above and beyond that based on its determination under the standard contained in (3)(D). [EPA-HQ-OAR-2014-0827-1926-A1 p.6]

C. Glider Vehicles Using Newer Engines

Assuming EPA moves forward with its proposal to regulate glider kits and glider vehicles, EPA solicits comment on certain potential flexibilities for glider vehicles using newer engines: (1) raising or eliminating the cap on sales for engines that were certified to meet the 2010 NOx and PM standards, as opposed to pre-2010 engines; (2) for vehicles using engines meeting the 2010 NOx and PM standards, raising or eliminating the cap on sales for glider vehicles using engines still within their regulatory useful life; and (3) for Class 8 vehicles, treating engines with high years/low mileage or low years/high mileage (e.g., engines that are more than 10 years old but have fewer than 100,000 miles or that are less than 3 years old regardless of mileage) as still within their useful life. EPA Legal Memo, at 9-10. DTNA would support all of these potential flexibilities. [EPA-HQ-OAR-2014-0827-1926-A1 p.6-7]

EPA should eliminate the cap on sales for engines that were certified to meet the 2010 NOx and PM standards. As EPA recognizes, the potential for adverse environmental effects from these engines is significantly reduced when compared to pre-2010 engines that have higher criteria pollutant emissions. This alternative would cover all 2010 and later engines without regard to their useful life and would provide manufacturers with necessary flexibility going forward. [EPA-HQ-OAR-2014-0827-1926-A1 p.7]
EPA should also eliminate the cap on sales for glider vehicles using engines that are still within their regulatory useful life, including treating Class 8 engines with high years/low mileage or low years/high mileage as being within their useful life. For Class 8 engines to be within their useful life under current regulations, they must be both less than 10 years old and have fewer than 435,000 miles of use. As EPA recognizes, some vehicles in very low use applications may have less than 100,000 miles after 10 years, while other vehicles may reach 435,000 miles within a few years. EPA should treat these engines as being within their useful life and eliminate the cap on sales for glider vehicles using these engines.

III. NHTSA Exemption

As DTNA expressed in its comments to the Phase 2 Proposed Rule, DTNA supports NHTSA’s current proposal to maintain its existing regulations with respect to glider kits and glider vehicles, under which NHTSA does not consider glider kits to be motor vehicles, and not to include gliders under its Phase 2 program. Since at least 1975, NHTSA has recognized that ‘use of a new ‘glider kit’ [typically a cab, frame rails, and front suspension]’ in combination with the valuable components from an existing vehicle’ is ‘common practice’ in the industry. 40 Fed. Reg. 19,485 (proposed May 5, 1975). In response to this common industry practice, NHTSA finalized a regulatory provision clarifying what it does and does not consider to be a ‘new vehicle,’ striking an appropriate balance between common-sense, cost-effective reuse of vehicle components and the need for adequate safety regulation of new vehicles. 40 Fed. Reg. 49,340 (Oct. 22, 1975). Under its regulations, NHTSA considers a truck to be ‘newly manufactured’ and subject to Federal Motor Vehicle Safety Standards when a new cab is used in its assembly, ‘unless the engine, transmission, and drive axle(s) (as a minimum) of the assembled vehicle are not new, and at least two of these components were taken from the same vehicle.’ 49 C.F.R. § 571.7(e) (emphasis added). DTNA supports the continuation of this long-standing regulatory provision. To the extent that NHTSA has concerns about compliance, it should issue guidance and engage in outreach to glider assemblers rather than revising its regulations. Further, NHTSA should not pursue inclusion of gliders under its Phase 2 program.

8. Gliders

- **Legal Issues with Glider Provisions** - DTNA has concerns with EPA’s proposed regulation of “glider kits” and “glider vehicles,” including EPA’s legal authority for regulating them. EPA’s Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act (“CAA”), which does not provide EPA authority to regulate the sale of motor vehicle components. Moreover, the CAA only provides authority to regulate “new motor vehicles” and their engines, defined as “self-propelled” vehicles “the equitable or legal title to which has never been transferred to the ultimate purchaser”—not non-motorized frames, cabs, and axles. CAA §§ 203(a), 216(3). In turn, any regulation of glider kits is beyond the agency’s authority. Further, glider vehicles, when constructed retain the identity of the donor vehicle, such that the title has already been exchanged, making the vehicles not “new” under the CAA. So the EPA may not regulate them either. And even if the EPA had authority to regulate, the CAA requires 4-years’ lead-time for new or revised NOx and PM requirements and for regulations governing engine rebuilding practices, which has not been met under the proposed regulations.

- **Proposed Definitions of ‘Glider Kit’ and ‘Glider Vehicle’** - EPA has proposed two overlapping and potentially confusing definitions: “Glider kit means any of the following: (1) A new vehicle that is incomplete because it lacks an engine, transmission, or axle; (2) A new vehicle produced with a used engine (including a rebuilt or remanufactured engine); (3) Any other new equipment that is intended to become a motor vehicle with a previously used engine (including a rebuilt or remanufactured engine)”;

Page 1836 of 2127
and “Glider vehicle means a new vehicle produced with a used engine.” As EPA has proposed these definitions, “glider vehicle” is a subset of “glider kit,” whereas under industry usage and understanding, the two are separate, and should remain so under the regulations. A “glider kit” should instead be defined as “an assemblage of new vehicle components, including at a minimum the chassis, cab and front axle, but lacking an engine, transmission, and rear axle.” Once the glider kit is used to rebuild a truck, EPA would consider it a “glider vehicle.” The EPA-proposed definitions are confusing because they conflate the two, which are typically sold by separate businesses. DTNA manufactures and sells glider kits, while most glider assemblers sell glider vehicles but do not manufacture glider kits. The third part of the proposed “glider kit” definition is simply too broad and vague to be workable: “Any other new equipment that is intended to become a motor vehicle with a previously used engine (including a rebuilt or remanufactured engine)” could potentially encompass any number of vehicle parts. Any other assemblages of parts that EPA considers to be “new equipment that is intended to become a motor vehicle “ could potentially be regulated as a glider kit, down to the wiring that constitutes a single headlight, or the glass and metal parts that together comprise a side mirror. This part of the proposed definition should be deleted. [EPA-HQ-OAR-2014-0827-1164-A1 p.122]

**EPA Lacks Authority to Regulate 'Glider Kits'** - The distinction between “glider kits” and “glider vehicles” is important because EPA lacks authority to regulate vehicle parts, including assemblages of parts (without an engine) such as glider kits. EPA’s Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act (“CAA”), and the CAA does not provide EPA authority to regulate the sale of motor vehicle components, which is all that glider kits are. The CAA only authorizes EPA to prohibit the sale of uncertified “new motor vehicles” and “new motor vehicle engines.” See 42 U.S.C. § 7522(a)(1). “New motor vehicles” are defined under the CAA as “self-propelled” vehicles “the equitable or legal title to which has never been transferred to an ultimate purchaser”—not non-motorized frames, cabs, and axles. 42 U.S.C. § 7550(2), (3). Because glider kits do not contain engines, and have no motive power, the CAA does not authorize EPA to regulate the sale of glider kits. [EPA-HQ-OAR-2014-0827-1164-A1 p.122-123] [This comment can also be found in section 1.3.1 of this comment document]

**Regulation of 'Glider Vehicles' Targets NOx / PM Emissions and Must Meet Statutory Lead Time Requirement** - In addition, the proposed regulation of “glider vehicles” actually targets NOx/PM emissions rather than GHG emissions, as EPA concedes, and is therefore inappropriate for inclusion in a GHG rule. Glider sales actually create the potential to reduce GHG emissions by incorporating used and rebuilt engines in newer, more aerodynamic vehicles. Rebuilt engines used in glider vehicles emit fewer GHGs, and new cabs and low rolling resistance tires are more efficient than what they replace. Because regulation of glider vehicles targets NOx/PM emissions, it should be done only in a separate rulemaking, if at all. [EPA-HQ-OAR-2014-0827-1164-A1 p.123] [This comment can also be found in section 1.3.1 of this comment document]

In addition, this separate rulemaking should be carefully drafted to meet statutory lead-time requirements for NOx and PM regulations as required by statute. NOx and PM emissions standards are subject to an express CAA lead-time requirement under which new or revised NOx and PM requirements cannot take effect sooner than the model year commencing 4 years after new or revised standard is promulgated. 42 U.S.C. § 7521(a)(3)(C). As currently proposed, with an effective date of January 1, 2018, the proposed glider regulations violate the 4- year lead-time requirement under the CAA. Assuming the Phase 2 rule is finalized in early 2016, the earliest that the regulations governing glider vehicles could take effect would be 2020, in compliance with the CAA lead-time requirement. [EPA-HQ-OAR-2014-0827-1164-A1 p.123] [This comment can also be found in section 1.3.1 of this comment document]
For its proposed glider provisions, EPA purports to rely on its authority to regulate the “practice of rebuilding heavy-duty engines.” 42 U.S.C. § 7521(a)(3)(D). However, EPA is not regulating engine rebuilding practices, as evidenced by the lack of relevant proposed amendments to its engine rebuilding regulations (40 C.F.R. §§ 86.004-40, 1068.120). Instead, EPA is attempting to regulate vehicle rebuilding, which it clearly does not have the authority to do under the CAA. Congress granted EPA authority to regulate “new motor vehicles” and “new motor vehicle engines” only, and while Congress granted EPA authority to regulate engine rebuilding, it did not grant EPA similar authority to regulate vehicle rebuilding. EPA’s reliance on (3)(D) is misplaced with respect to its proposed regulation of glider vehicles.[EPA-HQ-OAR-2014-0827-1164-A1 p.123] [This comment can also be found in section 1.3.1 of this comment document]

Even if EPA were properly regulating heavy-duty engine rebuilding practices with its proposed glider provisions, it would be subject to the same four-year statutory lead-time requirement. The four-year lead-time and three-year stability requirements of 42 U.S.C. § 7521(a)(3)(C) are applicable to all of paragraph 3, which includes the engine rebuilding provision contained in (3)(D). It is not enough for EPA to opine that the January 1, 2018 implementation date for the glider provisions allows “sufficient time to ‘permit the development and application of the requisite control measures’” under 42 U.S.C. § 7521(a)(3)(D). The four-year lead-time and three-year stability requirements of (3)(C) provide an absolute minimum, even for engine rebuilding regulations, and then EPA must determine whether additional time is required above and beyond that based on its determination under the standard contained in (3)(D). [EPA-HQ-OAR-2014-0827-1164-A1 p.123] [This comment can also be found in section 1.3.1 of this comment document]

Additional Considerations with Glider Provisions - Although EPA states that it considered impacts on small businesses in drafting the Phase 2 Proposed Rule, the glider provisions particularly impact small businesses and it is not clear that EPA fully considered the consequences the proposed regulations will have or how they could be minimized. As EPA notes, the Small Business Advocacy Review Panel process—which EPA undertook to meet its legal requirements under the Regulatory Flexibility Act and Small Business Regulatory Enforcement Fairness Act—included only one glider assembler. As a result of this oversight, if EPA moves forward with regulation of glider vehicles in its Phase 2 rule, which would not be appropriate under the CAA, there are a number of additional ways that the proposal should be modified to mitigate the impacts of any glider regulation on small businesses, jobs, and the economy in general. [EPA-HQ-OAR-2014-0827-1164-A1 p.124]

'Glider Vehicle' Exemption Cap - EPA has proposed that small manufacturers would be eligible for an exemption from EPA’s proposed glider vehicle certification requirements under 40 C.F.R. § 1037.635 that would allow them to continue selling a limited number of glider vehicles. This cap would be based on the manufacturer’s highest annual sales volume for calendar years 2010 through 2014 up to a maximum of 300 exempt glider vehicles. A cap of 300 vehicles is too low given the abrupt change this regulation brings to the 50-year-old glider industry and the disproportionate impact it will have on small businesses. A more reasonable approach would be to begin with a higher initial cap and gradually reduce it over time to allow large and small businesses in the glider industry to adapt to EPA’s new requirements. Specifically, if EPA decides to implement a certification requirement for glider vehicles, the small business exemption should start with a cap of 1,500 vehicles in 2020 (complying with the statutory lead-time requirement) and then reduce the cap by 250 each year for the next 3 years to 1,250 in 2021, to 1,000 in 2022, and finally to 750 vehicles in 2023. Such a phase-down would allow these small manufacturers to transition to other lines of business and to move their employees to other types of work without extensive layoffs. Many small manufacturers will already be limited by their highest annual sales volume and will not be affected by the cap, while for those that are, the initial 1,500 vehicle cap and subsequent phase-down represents a substantial reduction. The adjustment of the cap
Applicability to glider assemblers, coupled with the additional lead-time required under the CAA, is also critical to saving as many as 1,000 jobs at Detroit Reman, where a substantial portion of the business is driven by glider kit sales. [EPA-HQ-OAR-2014-0827-1164-A1 p.124]

- **Applicability to Engine Model Years** - As EPA recognizes, “the environmental impacts of gliders using 2010 and later engines would be much smaller,” and as a result, EPA’s proposed regulations should govern glider vehicles using pre-2010 engines only. As stated above, EPA’s glider regulation is intended to address NOx and PM emissions, which are primarily a concern with pre-2010 engines rather than 2010 and later engines. Based on engine core availability, glider vehicles using pre-2010 engines will naturally decrease over time. While 2010 and later engines are not currently being used in glider vehicles in large numbers, their future use would enable many of the benefits to the U.S. economy from glider kit usage to continue, without the potential environmental impacts associated with the use of pre-2010 engines. EPA should incentivize, rather than limit, the rebuilding and reuse of 2010 and later engines in glider vehicles because such use would generate all of the benefits of rebuilding the engines and installing them in newer, more aerodynamic vehicles detailed above, including using 85% less energy than manufacturing the engines new, without the potential drawbacks of higher NOx and PM emissions. In the Phase 2 Proposed Rule, EPA proposes a requirement that glider vehicles incorporate engines certified to meet standards applicable for the engine model year corresponding to the vehicle’s date of assembly but allows that earlier model year engines may be used “if the standards were identical.” 40 C.F.R. § 1037.635. EPA does not offer a definition of “identical standards,” which creates uncertainty. For example, new on-board diagnostics (“OBD”) requirements may be introduced in a model year where otherwise emissions standards remained the same. It is unclear whether, under EPA’s proposed regulations, an earlier model year engine could be used in a glider vehicle assembled in a year when new OBD requirements are in effect. EPA should instead allow the use of any 2010 or later engine in a glider vehicle, or at a minimum, define what it means by “identical standards.” Although EPA recognizes that “salvaging powertrains from vehicles otherwise destroyed in accidents” is a “legitimate” purpose for producing glider vehicles, its requirement that glider vehicles incorporate engines certified to meet standards applicable for the engine model year corresponding to the vehicle’s date of assembly could prevent this “legitimate” purpose from being met. As one example, under EPA’s proposal, a new truck built to meet current emission standards and purchased in December that is then wrecked in February of the next year when new engine standards took effect, would require a brand-new engine due to the new engine standards, even though the salvageable engine was only a few months old. On a larger scale, if a fleet of more than 300 vehicles becomes wrecked—for example, in a flood—but the engines are salvageable, EPA should not prevent a company, no matter its size, from restoring the vehicles to service cost-effectively with glider kits and remanufacturing processes. EPA should provide sufficient exemptions for “legitimate” rebuilds of wrecked vehicles. [EPA-HQ-OAR-2014-0827-1164-A1 p.124-125]

- **Eligibility for Small Manufacturer Exemption** - EPA has proposed that only those small businesses that sold glider vehicles in 2014 (under the provisions of 40 C.F.R. § 1037.150(j)) are eligible for the exemption under 40 C.F.R. § 1037.635 that would allow them to continue selling a limited number of glider vehicles. This is too narrow a window for sales and associated exemption eligibility, and ignores business practices common to the industry. While some glider assemblers sell glider vehicles each year, others may not, depending on the extent of their glider assembly operations and their customers’ demands. Some fleets order a few glider vehicles every year while others order every other year or every few years. In addition, due to delays associated with manufacturing and assembly, a customer might order a glider kit and not receive it for 12 months or more, with vehicle assembly taking additional time. As a result, EPA’s current proposal unfairly penalizes those small businesses that did not sell gliders in 2014, but might have sold them in 2013 or 2015. Instead, EPA should allow small businesses that sold any glider vehicles in the calendar year 2010-2014 time period to be eligible for the exemption up to the highest annual sales volume from those years. This
modification would still have the effect of preventing new market entrants (in 2015 and later), thereby limiting future glider vehicle production as EPA intends with its proposal, but not unfairly put a company out of business in year one simply because it did not sell a glider vehicle in 2014. [EPA-HQ-OAR-2014-0827-1164-A1 p.125-126]

- **NHTSA Exemption** - DTNA supports NHTSA’s current proposal to maintain its existing regulations with respect to glider kits and glider vehicles, under which NHTSA does not consider glider kits to be motor vehicles, and not to include gliders under its Phase 2 program. Since at least 1975, NHTSA has recognized that “use of a new ‘glider kit’ [“typically a cab, frame rails, and front suspension”] in combination with the valuable components from an existing vehicle” is “common practice” in the industry. 40 Fed. Reg. 19,485 (proposed May 5, 1975). In response to this common industry practice, NHTSA finalized a regulatory provision clarifying what it does and does not consider to be a “new vehicle,” striking an appropriate balance between common-sense, cost-effective reuse of vehicle components and the need for adequate safety regulation of new vehicles. 40 Fed. Reg. 49,340 (Oct. 22, 1975). Under its regulations, NHTSA considers a truck to be “newly manufactured” and subject to Federal Motor Vehicle Safety Standards when a new cab is used in its assembly, “unless the engine, transmission, and drive axle(s) (as a minimum) of the assembled vehicle are not new, and at least two of these components were taken from the same vehicle.” 49 C.F.R. § 571.7(e) (emphasis added). DTNA supports the continuation of this long-standing regulatory provision. To the extent that NHTSA has concerns about compliance, it should issue guidance and engage in outreach to glider assemblers rather than revising its regulations. Further, NHTSA should not pursue inclusion of gliders under its Phase 2 program. [EPA-HQ-OAR-2014-0827-1164-A1 p.125]

2 The CAA does authorize the EPA to regulate engine rebuilding practices, so in that limited respect the agency can regulate non-new products. But engine rebuilding is not at issue here. Moreover, given that Congress authorized regulation of engine rebuilding and could have similarly authorized vehicle rebuilding but did not, Congress made clear its intent not to authorize regulation of vehicle rebuilding.

**Organization:** Diesel 2 Gas, Inc.

Glider Kit Trucks are the only means by which hundreds of thousands of Class 8 Trucks can have access to natural gas as an engine fuel. Several EPA approved dual fuel conversion systems are currently being applied to heavy duty engines 2009 and older allowing trucks to operate with up to 60% natural gas. [EPA-HQ-OAR-2014-0827-1198 p.1]

Modern 2010 and newer Class 8 Truck engines cannot be converted efficiently to dual fuel mode with any known technology. The electronics associated with these modern engines makes adaptation of dual fuel conversions not achievable in the foreseeable future. [EPA-HQ-OAR-2014-0827-1198 p.1]

Dedicated gas fired engines fail to meet the operating requirements of U.S. Class 8 Truck fleets in many operating applications. The lower horsepower and torque, lower efficiency and range limitations of dedicated gas engines prohibit many fleets from using them in their operating applications. Trucks carrying heavy loads and trucks operating in mountainous terrains cannot use the gas fired engines. [EPA-HQ-OAR-2014-0827-1198 p.1]
Without the availability of dual fuel conversion systems, these trucking applications cannot use natural gas as an engine fuel and will continue to be limited to diesel as a fuel. Operators of these trucks rebuild old engines of their old trucks that are less energy efficient than that of new Glider models. The effects of this rule change will stop the progress of natural gas use in these trucking applications. [EPA-HQ-OAR-2014-0827-1198 p.2]

The effect of this rule change will have a detrimental effect on the development of dual fuel technologies for Class 8 Trucks. Dual Fuel technologies have not been embraced by heavy duty engine OEMs. Therefore the current EPA approved dual fuel technologies have been developed by small and midsized and mostly U.S. companies. Owners of older trucks find it difficult to justify the expense of converting their depreciated older trucks to dual fuel. Gliders have provided the best platform to deploy these dual fuel systems allowing U.S. dual fuel manufactures to lead the world in heavy duty dual fuel technologies. 'Dual Fuel Gliders' have allowed these U.S. companies to continue prove and improve their technologies in the field. These sales provide resources for these companies to work on finding technology improvements that may lead to the eventual conversion of modern heavy duty engines. Without Gliders many of these technologies will fail to advance into reaching new post 2010 engines. [EPA-HQ-OAR-2014-0827-1198 p.2]

Without Gliders many of the current U.S. manufacturers of dual fuel conversion systems will fail. This will give foreign companies an advantage in deploying their own inferior dual fuel technologies overseas in countries where trucks are not required meet EPA standards. The effect of the proposed rule will have a detrimental effect on U.S. companies leading the world in availing natural gas as a means to lower the emissions of heavy duty engines. This rule will have a chilling effect on lowering U.S. and global emissions from heavy duty truck engines. [EPA-HQ-OAR-2014-0827-1198 p.2]

EPA's own previous rulings in 2011 state the beneficial environmental impact of dual fuel aftermarket conversion systems in many Class 8 Truck applications. The proposed rule is in conflict with EPA's previous ruling. [EPA-HQ-OAR-2014-0827-1198 p.2]

Organization: E-ONE

E-ONE would like to take this opportunity to comment on the proposed Phase 2 of the Heavy Duty Greenhouse Gas rule 40 CFR 1037. More specifically E-ONE would like to comment on the proposal that gliders will be required to meet current emission standards for the year in which they are produced. [EPA-HQ-OAR-2014-0827-1185-A1 p.1]

Gliders are an important product in the emergency vehicle industry. An emergency vehicle, while critical to saving lives in the event of an emergency; typically does not drive very many miles over the lifetime of the vehicle. The industry standard of the lifetime of an emergency vehicle is 10 to 20 years in which an emergency vehicle may only have traveled 10-50,000 miles, although it is not uncommon for an emergency vehicle of 30+ years of service to have the same amount of miles. E-ONE has found that the durability of engines in class 8 emergency vehicles far surpass the longevity of the chassis that they power, this can be attributed to the extreme environment that these vehicles have to endure. Having the ability to purchase a glider allows municipalities with limited financial resources capable of maintain a fleet that is required to save lives. [EPA-HQ-OAR-2014-0827-1185-A1 p.1]

E-ONE’s stance is that it would be advantageous to allow gliders, given that the donor engine is still within its useful life based on mileage but not based on age. Doing so will allow the EPA to limit the amount of gliders produced enough to make a significant difference in the emissions of heavy duty
vehicles while still creating a standard that requires vehicles over time to continually increase in emission standards. [EPA-HQ-OAR-2014-0827-1185-A1 p.1]

With ever changing technology and the need for increased safety and efficiency of fire protection it can become a challenge for a community to determine when to replace a piece of fire apparatus. There is a large financial burden to a community when a new fire apparatus is purchased. This being said, every option needs to be explored to make the best financial decision for the community. While many large communities have a replacement program in place for their apparatus where the impact of this cost can be spread out, many smaller communities do not. [EPA-HQ-OAR-2014-0827-1253-A1 p.1]

In our service shops we offer a glider kit program to extend the life of a fire truck for communities with limited budgets. Fire trucks are historically extremely low mileage with many units as old as 10, 15 and 20 years with 10,000, 25,000 and 50,000 miles. The diesel engines and transmissions used in the fire service are designed to perform for a minimum of 300,000 to 1,000,000 miles. This gives the communities fire departments the ability to reuse these components, extending the life of the apparatus. This thus gives them the ability to increase the safety and efficiency of the apparatus while reducing the financial impact. [EPA-HQ-OAR-2014-0827-1253-A1 p.1]

Glider kits provide a new cab and chassis with the option to reuse the engine, transmission, axles, fire pumps and apparatus bodies or any combinations of these components (components that have considerable useful life remaining). This gives the small community department a piece of apparatus that will provide several years of additional service without the cost of a new apparatus. [EPA-HQ-OAR-2014-0827-1253-A1 p.1]

If the ability to 'glider' fire apparatus is prohibited it will have a serious impact on many communities and their fire departments across the country. When departments cannot afford to purchase new fire apparatus their only option is to repair or refurbish their existing apparatus. Most fire departments across the country are volunteer with limited budgets and sometimes purchase only one new truck and strive to maintain that unit for as long as possible. We need to give these communities as many options as possible. [EPA-HQ-OAR-2014-0827-1253-A1 p.1]

I believe it would be a financial burden for many of these departments. With only one or two trucks and no other options, most would have to disband and close for lack of funds to support new apparatus. This could seriously affect the personal safety of lives in those communities. [EPA-HQ-OAR-2014-0827-1253-A1 p.1]

I have attached some letters for existing fire department so you can see firsthand their financial situation. [EPA-HQ-OAR-2014-0827-1253-A1 p.1]

**Organization:** Environmental Defense Fund (EDF)

**EDF supports closing the loophole for dirty glider kits**

EDF fully supports EPA’s proposal to establish GHG and criteria emissions standards for engines in glider kits and NHTSA’s proposal to include glider kits under its Phase 2 standards. These provisions are important to close the current loophole for glider kit manufacturers – which currently allows an older dirtier engine to be installed in a new body and certified as a new vehicle. EPA estimates significant growth in glider kit production. And glider vehicles using pre-2007 engines have in-use NOx and PM emissions tenfold the emissions from equivalent vehicles being produced with new
engines. This combination could result in a significant increase in criteria emissions from in-use trucks if the current loophole is not addressed. [EPA-HQ-OAR-2014-0827-1312-A1 p.16]

The proposal does not limit the use of glider kits or rebuilt engines – it simply requires that engines be certified to the same standards (for both GHG and criteria standards) as apply for the calendar year of the glider vehicle assembly. As noted in the Preamble, there has been adequate time for glider manufacturers to transition to a compliance regime. And the agencies have determined that removing the exemption for these glider vehicles will be cost-effective. The agencies should finalize these important provisions to level the playing field and bring glider kits in line with all new truck standards. [EPA-HQ-OAR-2014-0827-1312-A1 p.16]

Organization: Fitzgerald Truck Sales

Fitzgerald Truck Sales appreciates the opportunity to submit its comments on the Phase 2 Proposed Rule. In section I we speak to the underestimated and under investigated economic impact to small businesses and misconceptions about gliders and there part in a “Green” environment. In section II we see some key elements making gliders part of this Phase 2 proposal, in our opinion, lacking a comprehensive investigation and frankly confronting some legal challenges. [EPA-HQ-OAR-2014-0827-1134-A1 p.1]

EPA and NHTSA have specifically requested comment on their proposed regulation of “gliders” as part of the Phase 2 Proposed Rule. As used in the industry, a “glider kit” is a new cab, front axle, and frame rail/chassis that uses existing or rebuilt drivetrain components (engine, transmission, and rear axle) to repair or extend the life of a used truck. Fitzgerald Truck Sales rebuilds tractors using these OE supplied glider kits, and has been building kits since 1989. Rebuilding tractors with glider kits drives a significant volume and business to local economies especially in the smaller communities of Tennessee, like Byrdstown, Crossville and Jamestown. [EPA-HQ-OAR-2014-0827-1134-A1 p.1]

Glider History and its Economies - Glider kits have been around for almost 50 years and are used for a number of reasons. Gliders are less expensive than new trucks and offer a more economical option for smaller fleets and owner/operators to maintain the reliability of their commercial trucking operations. The reused drivetrain components constitute approximately 30-50% of the value of a new truck, which generates significant cost savings for small businesses and owner-operators. Rebuilding an engine and transmission uses 85% less energy than manufacturing them new, and results in engines and transmissions that are more reliable and efficient that pre-rebuild. With improved aerodynamics and low rolling resistance tires on trucks assembled from glider kits, these rebuilt vehicles actually have better fuel efficiency than when they were new. The engines most commonly used in gliders actually have better fuel economy and greenhouse gas (“GHG”) emissions than today’s ultra-low NOX engines (pre-EGR EPA98 S60s). Wrecked or otherwise damaged trucks can be put back on the road economically by placing the undamaged powertrain components in a new cab/chassis. In addition to the use of glider kits for rebuilds, many CNG fleet operators prefer to buy glider kits and power them themselves, often recycling the fuel system or saving money on CNG system installation. Hundreds of small businesses have come to rely on gliders over the past 50 years as a cost-effective way of doing business. These businesses include glider distributors, glider assemblers, small fleets, owner/operators, and other small businesses in the commercial trucking industry. [EPA-HQ-OAR-2014-0827-1134-A1 p.1-2]
Additional Considerations with Glider Provisions

Although EPA states that it considered impacts on small businesses in drafting the Phase 2 Proposed Rule, the glider provisions particularly impact small businesses and it is not clear that EPA fully considered the consequences the proposed regulations will have or how they could be minimized. As EPA notes, the Small Business Advocacy Review Panel process—which EPA undertook to meet its legal requirements under the Regulatory Flexibility Act and Small Business Regulatory Enforcement Fairness Act—including only one glider assembler. As a result of this oversight, there are a number of additional ways that the proposal should be modified to mitigate the impacts of any glider regulation on small businesses, jobs, and the economy in general. [EPA-HQ-OAR-2014-0827-1134-A1 p.2]

Economic Impacts

- Gliders as a whole represent over 10,000 units annually. While this is insignificant as compared to new trucks sold it does support a very significant number of jobs both locally and nationwide.[EPA-HQ-OAR-2014-0827-1134-A1 p.2]
- Fitzgerald Employs 285 employees locally, predominately in areas historically economically challenged in recent years. [EPA-HQ-OAR-2014-0827-1134-A1 p.2]
- Fitzgerald supports 137 vendor/suppliers not including the OEM’s and their downstream support. [EPA-HQ-OAR-2014-0827-1134-A1 p.2]
- The end user of Gliders is the smaller business owner and employer who may not be economically competitive and is definitely at risk if such rulings were to attempt to force them to rely solely on new equipment. [EPA-HQ-OAR-2014-0827-1134-A1 p.2]
- The independent truckers buying one or a few gliders does not have the purchasing power to buy new trucks at the same acquisition costs as a large fleet placing them at a disadvantage. [EPA-HQ-OAR-2014-0827-1134-A1 p.2]
- Beyond Fitzgerald, the Supporting OEM’s like Daimler (DTNA) and Peterbilt and Kenworth (PACCAR), employ hundreds of men and women in the creation, support and manufacture of the base Glider chassis. [EPA-HQ-OAR-2014-0827-1134-A1 p.2]
- Detroit Diesel, is the largest supplier of rebuilt engines and engine parts in support of gliders and maintains an entire manufacturing facility in Ohio that would be devastated by the current proposal. [EPA-HQ-OAR-2014-0827-1134-A1 p.2]

“Glider Vehicle” Exemption Cap

EPA has proposed that small manufacturers would be eligible for an exemption from EPA’s proposed glider vehicle certification requirements under 40 C.F.R. § 1037.635 that would allow them to continue selling a limited number of glider vehicles. This cap would be based on the manufacturer’s highest annual sales volume for calendar years 2010 through 2014 up to a maximum of 300 exempt glider vehicles. A cap of 300 vehicles is too low given the abrupt change this regulation brings to the 50-year-old glider industry and the disproportionate impact it will have on small businesses. A more reasonable approach would be to begin with a higher initial cap and gradually reduce it over time to allow large and small businesses in the glider industry to adapt to EPA’s new requirements. Specifically, if EPA decides to implement a certification requirement for glider vehicles, the small business exemption should start with a cap equal to the 2015 sales levels of vehicles in 2020 (complying with the statutory lead-time requirement) and then reduce the cap annually in levels that give business time to adjust. Such a phase-down would allow these small manufacturers to transition to other lines of business and to move their employees to other types of work without extensive layoffs. Many small manufacturers will already be limited by their highest annual sales volume and will not be affected by the cap. The adjustment of the cap applicable to glider assemblers, coupled with the additional lead-time required
under the CAA. is also critical to saving literally thousands of jobs. [EPA-HQ-OAR-2014-0827-1134-A1 p.3]

**Legal Issues with Glider Provisions**

We are not alone in our concerns with EPA’s proposed regulation of “glider kits” and “glider vehicles,” including EPA’s legal authority for regulating “glider kits.” EPA’s Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act (“CAA”), which does not provide EPA authority to regulate the sale of motor vehicle components. Moreover, the CAA requires 4-years’ lead-time for new or revised NOx and PM requirements, which has not been met under the proposed regulations. [EPA-HQ-OAR-2014-0827-1134-A1 p.3]

**Proposed Definitions of “Glider Kit” and “Glider Vehicle”**

EPA has proposed two overlapping and potentially confusing definitions: “Glider kit means any of the following: (1) A new vehicle that is incomplete because it lacks an engine, transmission, or axle; (2) A new vehicle produced with a used engine (including a rebuilt or remanufactured engine); (3) Any other new equipment that is intended to become a motor vehicle with a previously used engine (including a rebuilt or remanufactured engine)” and “Glider vehicle means a new vehicle produced with a used engine.” As EPA has proposed these definitions, “glider vehicle” is a subset of “glider kit,” whereas under industry usage and understanding, the two are separate, and should remain so under the regulations. [EPA-HQ-OAR-2014-0827-1134-A1 p.3]

A “glider kit” should instead be defined as “an assemblage of new vehicle components, including at a minimum the chassis, cab and front axle, but lacking an engine, transmission, and rear axle.” Once the glider kit is assembled using existing or rebuilt drivetrain components (engine, transmission, and rear axle), then it becomes a rebuilt truck, which EPA would consider a “glider vehicle.” The EPA-proposed definitions are confusing because they conflate the two, which are typically sold by separate businesses. DTNA sells glider kits but not glider vehicles, while most glider assemblers sell glider vehicles but do not manufacture glider kits. The third part of the proposed “glider kit” definition is simply too broad and vague to be workable: “Any other new equipment that is intended to become a motor vehicle with a previously used engine (including a rebuilt or remanufactured engine)” could potentially encompass a single headlight or side mirror as a “glider kit.” This part of the proposed definition should be deleted. [EPA-HQ-OAR-2014-0827-1134-A1 p.3-4]

**Regulation of “Glider Vehicles” Targets NOx/PM Emissions and Must Meet Statutory Lead-Time Requirement**

In addition, the proposed regulation of “glider vehicles” actually targets NOx/PM emissions rather than GHG emissions, as EPA concedes, and is therefore inappropriate for inclusion in a GHG rule. Glider sales actually create the potential to reduce GHG emissions by incorporating used and rebuilt engines in newer, more aerodynamic vehicles. Rebuilt engines used in glider vehicles emit fewer GHGs, and new cabs and low rolling resistance tires are more efficient than what they replace. Because regulation of glider vehicles targets NOx/PM emissions, it should be done only in a separate rulemaking, if at all. In addition, this separate rulemaking should be carefully drafted to meet statutory lead-time requirements for NOx and PM regulations as required by statute. NOx and PM emissions standards are subject to an express CAA lead-time requirement under which new or revised NOx and PM requirements cannot take effect sooner than the model year commencing 4 years after new or revised standard is promulgated. 42 U.S.C. § 7521(3)(C). As currently proposed with an effective date of January 1, 2018, the proposed glider regulations violate the 4-year lead-time requirement under the CAA. Assuming the Phase 2 rule
is finalized in early 2016, the earliest that the regulations governing glider vehicles could take effect would be 2020, in compliance with the CAA lead-time requirement. As currently proposed, EPA is attempting to regulate NOₓ and PM in the GHG rule in a way it could not undertake in a proper NOₓ and PM rulemaking. [EPA-HQ-OAR-2014-0827-1134-A1 p.4]

**Organization:** GATR Truck Center

GATR Truck Center strongly supports the agencies’ proposal to impose new requirements on companies assembling and offering for sale vehicles produced by installing used driveline components into new glider kits. EPA and NHTSA should require that manufacturers of these glider-based vehicles comply with all applicable and current greenhouse gas and criteria emissions standards. NHTSA should also enforce the existing regulations that require manufacturers of glider-based vehicles to comply with all applicable safety standards. [EPA-HQ-OAR-2014-0827-1010-A2 p.1]

Dealers such as ours have been subject to a growing unfair competition from this rapidly expanding market of non-compliant vehicles. Over the past few years, an increasing number of our customers have purchased these non-compliant glider vehicles at prices that are 25% less than our comparable new compliant trucks. [EPA-HQ-OAR-2014-0827-1010-A2 p.2]

GATR Truck Center supports the application of glider kits as a means to repair badly damaged vehicles, while taking advantage of the remaining useful life in the damaged vehicle’s driveline components. When conducted within the requirements of 49 CFR 571.7(e), which sets forth NHTSA’s rules for re-use of driveline components for installation into a glider kit, we have no specific concerns with such legitimate applications of glider kits. It’s when these rules are violated, however, in an effort to offer for sale an essentially new vehicle whose production costs and total cost of ownership may be tens of thousands of dollars less than the fully compliant new products sold by our dealership that we strongly object to such an unfair disruption of market competition. Unfortunately, this practice has become widespread without consequence to the glider-based vehicle manufacturers, and it is unfairly and negatively impacting our business. In many cases, the manufacturers of glider-based vehicles are not collecting the 12% federal excise tax (‘FET’) that normally applies to new vehicle sales, giving customers even further financial incentive to purchase glider vehicles rather than fully compliant new vehicles. This abusive application of glider kits must be stopped; we strongly support the agencies’ efforts to do so through appropriate new regulations and enforcement of existing regulations. EPA and NHTSA should seek to remedy this situation as soon as practicable, while protecting for the continued use of glider kits for legitimate purposes as we have described. [EPA-HQ-OAR-2014-0827-1010-A2 p.2]

We refer you to the comments of the Volvo Group North America for a more complete analysis and set of recommendations with respect to the regulation and enforcement of glider-based vehicles. GATR Truck Center supports the comments submitted by Volvo Group North America. [EPA-HQ-OAR-2014-0827-1010-A2 p.2]

The rapidly expanding glider-based vehicle market is seriously undermining the significant gains EPA, NHTSA, and the heavy-duty vehicle industry have made to reduce criteria and greenhouse gas emissions, reduce fuel consumption, and improve roadway safety. The market availability of these non-compliant engines and vehicles poses an unfair competitive disadvantage to manufacturers that have undertaken the enormous effort and investment necessary to comply with all applicable emissions, fuel efficiency, and safety standards, and likewise an unfair competitive advantage to the dealer network representing those OEM’s. It is therefore imperative that the agencies follow through by finalizing regulations that prohibit the production of glider-based vehicles for anything other than legitimate
purposes, and that the agencies actively ensure compliance to those requirements. [EPA-HQ-OAR-2014-0827-1010-A2 p.2]

**Organization:** Harrison Truck Centers

EPA and NHTSA have specifically requested comment on their proposed regulation of “gliders” as part of the Phase 2 Proposed Rule. As used in the industry, a “glider kit” is a new cab, front axle, and frame rail/chassis that uses existing or rebuilt drivetrain components (engine, transmission, and rear axle) to repair or extend the life of a used truck. Harrison Truck Centers rebuilds tractors using these glider kits, and has for over fifteen years. Rebuilding tractors with gliders kits drive a significant volume and business to our area. [NHTSA-2014-0132-0059-A1 p.1]

Glider kits have been around for almost 50 years and are used for a number of reasons. Gliders are less expensive than new trucks and offer a more economical option for smaller fleets and owner/operators to maintain the reliability of their commercial trucking operations. The reused drivetrain components constitute approximately 30-50% of the value of a new truck, which generates significant cost savings for small businesses and owner-operators. Remanufacturing an engine and transmission uses 85% less energy than manufacturing them new, and results in engines and transmissions that are more reliable and efficient that pre-rebuild. With improved aerodynamics and low rolling resistance tires on trucks assembled from glider kits, these rebuilt vehicles actually have better fuel efficiency than when they were new. The engines most commonly used in gliders actually have better fuel economy and greenhouse gas (“GHG”) emissions than today’s ultra-low NOX engines (pre-EGR EPA98 S60s). Wrecked or otherwise damaged trucks can be put back on the road economically by placing the undamaged powertrain components in a new cab/chassis. In addition to the use of glider kits for rebuilds, many CNG fleet operators prefer to buy glider kits and power them themselves, often recycling the fuel system or saving money on CNG system installation. Hundreds of small businesses have come to rely on gliders over the past 50 years as a cost-effective way of doing business. These businesses include glider distributors, glider assemblers, small fleets, owner/operators, and other small businesses in the commercial trucking industry. [NHTSA-2014-0132-0059-A1 p.1-2]

Harrison Truck Centers also repeated comments summarized above for Daimler.

**Organization:** International Council on Clean Transportation (ICCT)

**Potential regulatory loophole**

The ICCT recommends that the agencies ensure there are no regulatory loopholes whereby increasing unforeseen numbers of trucks exploit regulatory exemptions to avoid deploying emission reduction and efficiency technology. The ICCT spends a considerable amount of time investigating gaps between policy objectives and their market outcomes. The U.S. exemption for gliders (i.e., “glider kits,” “gliders,” or “glider vehicles”) in the criteria pollutant heavy-duty vehicle regulations is among the more egregious and high-risk regulatory gaps. The glider kit provision that was previously used to assist in bringing hundreds of repaired vehicles per year is now creating an entirely new market with tens of thousands of sales per year, now with multiple suppliers competing in the space. This glider market is predicated upon reduced costs from vehicles that are not regulated and not certified through the full process that most modern tractors are. This is a clear distortion of the market and the exploitation of a regulatory provision that was not foreseen to be used in such a way. We recommend that the agencies’ include glider kit-manufactured vehicles within the greenhouse gas emission and efficiency regulations, as well as criteria pollutant emission regulations as soon as possible. Exemptions, if granted, would ideally be restricted to a number that is consistent with pre-emission-regulation glider production – on
the order of hundreds of units per year industry wide – and only those with legally or insurance-verified evidence of inoperably damaged tractor frames. [EPA-HQ-OAR-2014-0827-1180-A4 p.16]

**Organization:** Manufacturers of Emission Controls Association (MECA)

**Heavy-Duty Glider Kits and Glider Vehicles**

MECA strongly supports the agency’s proposal to require that the engines installed in glider vehicles meet the same criteria and GHG emission requirements as new engines certified in the same model year. The recent rapid growth in the number of glider vehicles sold since 2007 to over 5,000 vehicles a year shows the large emissions impact that this category of high emitters has on the overall contribution of PM and NOx from heavy-duty engines. As new engines become cleaner in the future the contribution from glider vehicles will continue to grow. Glider vehicles are classified as “new motor vehicles” because they use a new chassis, although they can continue to use engines that are 10-15 years old and emit 20-40 times more pollution than vehicles equipped with a new engine. The existing exemption of glider vehicles from the latest pollution requirements represents a huge loophole in the regulation. Using this “new motor vehicle” designation under the clean air act, glider vehicles could potentially qualify for clean air incentive funding under some state in-use fleet programs while not meeting the intent or emission reduction goals of those programs. Glider vehicles, equipped with old diesel engines, or converted to alternative fuels could potentially compete for funding with newly manufactured trucks, replacement engines or retrofit emission control devices. The proposed glider kit and glider vehicle provision in this proposal takes an important step towards closing this loophole and MECA supports inclusion of this provision in the final regulation and moving the implementation date ahead of the proposed 2018 start date. There should be no “dirty diesel” loophole left in EPA’s regulatory programs. [EPA-HQ-OAR-2014-0827-1210-A3 p.12] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.212.]]

MECA is concerned that the present proposed limited grandfathering of glider vehicle production for existing small businesses would still allow the continued production of up to 300 assembled gliders a year, per company. This exemption poses a significant threat to air quality as 300 trucks could emit the same amount of NOx as 7500 new heavy duty trucks. EPA should include a phase-out of this glider loophole completely that reduces the 300 glider kit limit per small existing business over a course of three years after which full compliance is required. This should provide sufficient time for small businesses to adapt their business models to produce and maintain clean diesels. Retaining a 300 per year limit indefinitely could result in a disproportionate number of dirty vehicles to continue to be produced and remain in the fleet for decades to come. To minimize the opportunity to abuse this exemption, EPA might consider limiting the conditions under which a glider vehicle may be purchased to legitimate situations such as when a vehicle is damaged in an accident and the engine can be salvaged. Requirements should include record keeping guidelines to support legitimate transactions to purchase glider vehicles. [EPA-HQ-OAR-2014-0827-1210-A3 p.12]

**Organization:** Mississippi Furniture Xpress (MFX)

MFX, LLC is one of the companies who would be negatively impacted by passage of this ruling due to our purchasing of glider trucks. This ruling would not only impact our company, but also our 150 employees as well as the numerous connected businesses with whom we contract and provide services throughout the country. [EPA-HQ-OAR-2014-0827-1338-A1 p.1]

In the past EPA regulations have been imposed with no opportunity for discourse and their impact on business and the livelihoods of those affected often not given consideration. This represents one of the
many reasons that the citizens of this country are dissatisfied with government. I have worked in the trucking industry for over 30 years and have seen the advancements related to safety and emissions by the industry as a whole. The changes have been significant and positive; however, our industry faces a constant barrage of costly and restrictive regulations that threaten our operations so greatly, that we as business owners are deeply concerned that tighter regulations will be too costly, time consuming and burdensome to overcome. Pending regulations by FMCSA regarding ELD's is enough to ruin many small companies, much less adding more restrictive and burdensome EPA rules. [EPA-HQ-OAR-2014-0827-1338-A1 p.1]

We purchased used trucks when we began our company and nearly went bankrupt trying to keep them running due to all of the problems caused by EPA regulations on engines after 2007. Those problems continue to be devastating to companies who operate trucks with certain engines; the cost of repairs often exceeds 50% of the cost of the truck itself. Buying glider trucks absolutely saved us from going out of business due to repair costs for the used trucks we had purchased. Further regulations to these trucks feels like overreach and we're unaware of studies which show that the small percentage of glider trucks being sold have any appreciable impact on the environment, whereas they are most certainly having a positive economic effect for the people and businesses that choose to purchase them. [EPA-HQ-OAR-2014-0827-1338-A1 p.2]

Our current understanding is that the EPA does not have legal authority for regulation of glider kits. EPA's Phase 2 Proposed Rule is being carried out under the authority of the Clean Air Act ('CAA'), which does not provide EPA authority to regulate the sale of motor vehicle components. Moreover, the CAA requires 4-years' lead-time for new or revised NOx, and PM requirements, which has not been met under the proposed regulations. EPA has been aware of the use of glider kits for over 35 years, and has not attempted to regulate them because they are not 'new motor vehicles' or 'new motor vehicle engines' under the CAA. As regulations by FMCSA have been repealed due to not having sufficient data to support their assertions, this proposed ruling by the EPA seems open to challenge on the same basis. [EPA-HQ-OAR-2014-0827-1338-A1 p.2]

Thank you for the opportunity to comment; however, we strongly oppose this proposed ruling and ask that it be abandoned due to the reasons cited. [EPA-HQ-OAR-2014-0827-1338-A1 p.2]

Organization: Mondial Automotive

EPA and NHTSA have specifically requested comment on their proposed regulation of 'gliders' as part of the Phase 2 Proposed Rule. Mondial Automotive, Inc. appreciates the opportunity to submit its comments on the Phase 2 Proposed Rule. As used in the industry, a 'glider kit' is a new cab, front axle, and frame rail/chassis that uses existing or rebuilt drivetrain components (engine, transmission, and rear axle) to repair or extend the life of a used truck. Mondial Automotive, Inc. is a downstream supplier of Original Equipment Parts and Components that are used in the production of 'glider kits'. The 'glider kit' industry drives a significant volume of business to local economies such as our community of College Point, NY. [EPA-HQ-OAR-2014-0827-1337-A1 p.1]

Glider History and its Economies - Glider kits have been around for almost 50 years and are used for a number of reasons. Gliders are less expensive than new trucks and offer a more economical option for smaller fleets and owner/operators to maintain the reliability of their commercial trucking operations. The reused drivetrain components constitute approximately 30-50% of the value of a new truck, which generates significant cost savings for small businesses and owner-operators. Rebuilding an engine and transmission uses 85% less energy than manufacturing them new, and results in engines and transmissions that are more reliable and efficient that pre-rebuild. With improved aerodynamics and low
rolling resistance tires on trucks assembled from glider kits, these rebuilt vehicles actually have better fuel efficiency than when they were new. The engines most commonly used in gliders actually have better fuel economy and greenhouse gas (GHG) emissions than today’s ultra-low NOx engines (pre-EGR EPA98 S60s). Wrecked or otherwise damaged trucks can be put back on the road economically by placing the undamaged powertrain components in a new cab/chassis. In addition to the use of glider kits for rebuilds, many CNG fleet operators prefer to buy glider kits and power them themselves, often recycling the fuel system or saving money on CNG system installation. Hundreds of small businesses have come to rely on gliders over the past 50 years as a cost-effective way of doing business. These businesses include glider distributors, glider assemblers, small fleets, owner/operators, and other small businesses in the commercial trucking industry. [EPA-HQ-OAR-2014-0827-1337-A1 p.1-2]

I. Additional Considerations with Glider Provisions

Although EPA states that it considered impacts on small businesses in drafting the Phase 2 Proposed Rule, the glider provisions particularly impact small businesses and it is not clear that EPA fully considered the consequences the proposed regulations will have or how they could be minimized. As EPA notes, the Small Business Advocacy Review Panel process—which EPA undertook to meet its legal requirements under the Regulatory Flexibility Act and Small Business Regulatory Enforcement Fairness Act—included only one glider assembler. As a result of this oversight, there are a number of additional ways that the proposal should be modified to mitigate the impacts of any glider regulation on small businesses, jobs, and the economy in general. [EPA-HQ-OAR-2014-0827-1337-A1 p.2]

A. Economic Impacts

- Gliders as a whole represent over 10,000 units annually. While this is insignificant as compared to new trucks sold it does support a very significant number of jobs both locally and nationwide. [EPA-HQ-OAR-2014-0827-1337-A1 p.2]
- Mondial Employs 47 employees locally, predominately in a minority populated urban area. [EPA-HQ-OAR-2014-0827-1337-A1 p.2]
- The end user of Gliders is the smaller business owner and employer who may not be economically competitive and is definitely at risk if such rulings were to attempt to force them to rely solely on new equipment. [EPA-HQ-OAR-2014-0827-1337-A1 p.2]
- The independent truckers buying one or a few gliders does not have the purchasing power to buy new trucks at the same acquisition costs as a large fleet placing them at a disadvantage. [EPA-HQ-OAR-2014-0827-1337-A1 p.2]
- OEM's like Daimler (DTNA) and Peterbilt and Kenworth (PACCAR), employ hundreds of men and women in the creation, support and manufacture of the base Glider chassis. [EPA-HQ-OAR-2014-0827-1337-A1 p.2]
- Detroit Diesel, is the largest supplier of rebuilt engines and engine parts in support of gliders and maintains an entire manufacturing facility in Ohio that would be devastated by the current proposal. [EPA-HQ-OAR-2014-0827-1337-A1 p.2]

B. ‘Glider Vehicle’ Exemption Cap

EPA has proposed that small manufacturers would be eligible for an exemption from EPA's proposed glider vehicle certification requirements under 40 C.F.R. § 1037.635 that would allow them to continue selling a limited number of glider vehicles. This cap would be based on the manufacturer's highest annual sales volume for calendar years 2010 through 2014 up to a maximum of 300 exempt glider vehicles. A cap of 300 vehicles is too low given the abrupt change this regulation brings to the 50-year-old glider industry and the disproportionate impact it will have on small businesses. A more reasonable
approach would be to begin with a higher initial cap and gradually reduce it over time to allow large and small businesses in the glider industry to adapt to EPA's new requirements. Specifically, if EPA decides to implement a certification requirement for glider vehicles, the small business exemption should start with a cap equal to the 2015 sales levels of vehicles in 2020 (complying with the statutory lead-time requirement) and then reduce the cap annually in levels that give business time to adjust. Such a phase-down would allow these small manufacturers to transition to other lines of business and to move their employees to other types of work without extensive layoffs. Many small manufacturers will already be limited by their highest annual sales volume and will not be affected by the cap. The adjustment of the cap applicable to glider assemblers, coupled with the additional lead-time required under the CAA, is also critical to saving literally thousands of jobs. [EPA-HQ-OAR-2014-0827-1337-A1 p.2-3]

In closing Gliders are a necessity to our national commerce. Catering to the smaller businesses and truckers who survive using gliders as a necessary tool to compete in their markets. Gliders are indeed 'Green' in respects to the re-use of components, and putting cleaner and safer vehicles than those replaced components and vehicles that would have been on the road otherwise. The EPA falls well short in any assumption that restricting gliders unreasonably will drive our customers to in essence 'NEW TRUCKS'. This is simply not the case. [EPA-HQ-OAR-2014-0827-1337-A1 p.3]

Organization: Motor & Equipment Manufacturers Association (MEMA)

In addition to representing original equipment suppliers, MEMA also represents remanufacturers and their suppliers. The proposed rule seeks to regulate non-new products under Phase 2, including gliders and remanufactured engines. There remains a legitimate need and purpose for glider kits and remanufactured engines and our members would like to support the reduction of potential objectionable uses of the standards. However, MEMA is concerned that the direction being proposed by the agency is swinging the pendulum too far in the other direction and has the potential to significantly impact this industry segment. [EPA-HQ-OAR-2014-0827-1274-A1 p.11]

Remanufactured parts are given an extended life, cost less to produce and purchase and minimize the impact on the environment by not ending up in the waste stream. The motor vehicle remanufacturing industry supports over 50,000 direct jobs in the U.S. and demonstrates a commitment to sustainability through product innovation and the incorporation of more environmentally-friendly manufacturing practices. The U.S. Congress has recognized the value of remanufactured parts and components as exemplified by the “Federal Vehicle Repair Cost Savings Act” (S. 565), which directs federal agencies to consider using remanufactured parts when maintaining federal vehicle fleets. This bill passed the Senate on June 15 and the House of Representatives on September 28. [EPA-HQ-OAR-2014-0827-1274-A1 p.11]

Remanufacturing is a standardized industrial process by which previously sold, worn or nonfunctional products are refurbished to a better condition and performance in order to reuse resources and reduce waste. The process incorporates technical specifications, including engineering, quality and testing standards to yield warranted products. In addition to remanufactured engines other examples of remanufactured components include: transmissions, alternators, starters, turbochargers, steering and suspension components and electronic control modules. Remanufacturing preserves some of the value of the original manufacturing – including energy costs, investment in capital and labor inputs – which recycling alone cannot do. This process saves about 85 percent of the energy and material used to manufacture similar new products. [EPA-HQ-OAR-2014-0827-1274-A1 p.11]
MEMA has concerns about the NPRM’s approach on gliders – particularly the agencies’ proposals: [EPA-HQ-OAR-2014-0827-1274-A1 p.12]

- to define used and remanufactured engines/equipment as “new” engines/equipment; [EPA-HQ-OAR-2014-0827-1274-A1 p.12]
- to impose on remanufactured engines the same compliance criteria as actual new engines for the year in which it was remanufactured (for all emissions); and, [EPA-HQ-OAR-2014-0827-1274-A1 p.12]

It is important to note that while a remanufactured component can be “manufactured again” to extend the service life, there are constraints as to how much and to what degree you can alter a component to meet newer design performance criteria beyond its original design. This task becomes increasingly more challenging the more complex the component/system. Furthermore, the proposed scope of the requirements for remanufactured engines would not only include GHG standards, but also all applicable criteria pollutant emissions standards; yet this Phase 2 rulemaking is a GHG rule, not for other pollutants. Also, the proposed timeline would kick in much sooner (by MY2018) than the other compliance requirements (MY2021). This timeline is impractical in terms of production planning and the remanufacturing process. Absent from the proposed rule are the data to demonstrate that the proposal will have a net positive impact on reducing CO2 emissions; nor is there a full evaluation of the cost-benefit impacts the proposal will have on rebuilt and remanufactured engines and components. As a result, while the NPRM assures that this is not a “ban” of glider kits – the proposed changes have the potential to significantly burden and overwhelm the remanufacturing sector. [EPA-HQ-OAR-2014-0827-1274-A1 p.12]

For all of these reasons, MEMA recommends that the agencies strike and remove the additional text from the definition of “new” in part 1068.30 that states: “Note that in certain cases, used and remanufactured engines/equipment may be ‘new’ engines/equipment.” The remanufacturer members of MEMA and MERA are prepared to work with the agencies on a practical approach to address the government’s concerns while still retaining this important industry sector for its intended and legitimate role and purpose. As we represent different manufacturers in this space, we anticipate that they will address these and related concerns in more detail in their company comments. [EPA-HQ-OAR-2014-0827-1274-A1 p.12]

Organization: National Association of Clean Air Agencies (NACAA)

We are also very much in favor of EPA’s proposal to close the existing loophole for glider kits and glider vehicles, under which used pre-2013 engines – with no limit on age – may be installed into new glider kits without meeting applicable standards. We agree with EPA that its regulations should be revised to require that only engines that have been certified to meet the prevailing standards be eligible for installation into new glider kits. The sale of glider kits has increased 10-fold since the implementation of federal 2007/2010 particulate matter (PM) and NOx emission standards. The proposed changes will stem the unrestricted sale of glider vehicles with older, higher-emitting engines. With respect to implementation of EPA’s proposed glider requirements, we believe this should occur as soon as possible but no later than January 2018. [EPA-HQ-OAR-2014-0827-1157-A1 p.2] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.52.]
Organization: National Automobile Dealers Association (NADA)

IV. GLIDER KITS

The Phase 2 proposal seeks to severely restrict the sale of glider kits by generally requiring that engines used in glider vehicles be certified to the standards applicable to the calendar year in which assembly of the glider vehicle is completed, and by requiring many rebuilders to obtain vehicle certificates. The Phase 2 proposal also contains new definitions of “glider vehicle” and “glider kit” ostensibly based on a common understanding of these terms. [EPA-HQ-OAR-2014-0827-1932-A1 p.3]

The Phase 2 proposal would continue to exempt small businesses using gliders to rebuild vehicles from the need to obtain vehicle certificates, but would limit the exemption to an annual production of 200 units (production in excess of the capped amount would be allowed, but subject to all otherwise applicable requirements including the Phase 2 standards). For example, a small business producing between 100 and 200 glider vehicles per year would be allowed to do so without having to certify them to current year GHG (and other emission) standards, so long as they meet applicable standards for the year of their manufacture. [EPA-HQ-OAR-2014-0827-1932-A1 p.3]

In its 2015 comments, NADA/ATD urged EPA and NHTSA to consider another alternative designed to harmonize with NHTSA’s long-standing “manufacture” exemption for vehicle rebuilding. That exemption keys on there being a single “donor” vehicle from which two of three used components (engine, transmission, and drive-axle) are incorporated into the rebuilt vehicle. This exemption from the definition of “manufacturing” allows the rebuilder to avoid having to meet NHTSA manufacturer registration and other requirements. NADA/ATD also suggested that when two of these three used components are incorporated into a rebuilt vehicle, using a glider kit, the used engine would only be required to meet emission standards applicable to its year of original manufacture and, if rebuilt, any subsequent running changes. Obviously, no emissions certification would be required. Under that alternative, it would matter not if the rebuilder was a small business or how many units were rebuilt in a year. [EPA-HQ-OAR-2014-0827-1932-A1 p.4]

With respect to the Memorandum referenced in the NODA, NADA/ATD is taking no position with respect to the legal opinions expressed therein. On the other hand, NADA/ATD has reviewed and does support certain additional glider engine considerations discussed in Section “I” of the Memorandum. These include no regulation of 2010 and later engines and engines less than three-years-old, the reuse of newer engines with remaining “useful life,” and the reuse of low mileage older engines. Lastly, NADA reiterates its support for the alternatives suggested in its 2015 comments. [EPA-HQ-OAR-2014-0827-1932-A1 p.4]

Glider Kits

The Phase 2 proposal seeks to severely restrict the sale of glider kits by generally requiring that engines used in glider vehicles be certified to the standards applicable to the calendar year in which assembly of the glider vehicle is completed, and by requiring many rebuilders to obtain vehicle certificates. The Phase 2 proposal also contains new definitions of ‘glider vehicle’ and ‘glider kit’ ostensibly based on a common understanding of these terms. [EPA-HQ-OAR-2014-0827-1309-A1 p.12]
The Phase 2 proposal also would continue to exempt small businesses using gliders to rebuild vehicles from the need to obtain vehicle certificates, but would limit the exemption to an annual production of 200 units (production in excess of the capped amount would be allowed, but subject to all otherwise applicable requirements including the Phase 2 standards). For example, a small business producing between 100 and 200 glider vehicles per year would be allowed to do so without having to certify them to current year GHG (and other emission) standards, so long as they meet applicable standards for the year of their manufacture. [EPA-HQ-OAR-2014-0827-1309-A1 p.12]

NADA/ATD urges EPA and NHTSA to consider another alternative designed to harmonize with NHTSA’s long-standing “manufacture” exemption for vehicle rebuilding. That exemption keys on there being a single “donor” vehicle from which two of three used components (engine, transmission, and drive-axle) are incorporated into the rebuilt vehicle. This exemption from the definition of “manufacturing” allows the rebuilder to avoid having to meet NHTSA manufacturer registration and other requirements. Likewise, NADA/ATD suggests that when two of these three used components are incorporated into a rebuilt vehicle, using a glider kit, the used engine would only be required to meet emission standards applicable to its year of original manufacture and, if rebuilt, any subsequent running changes. Obviously, no emissions certification would be required. Under this alternative, it would matter not if the rebuilder was a small business or how many units were rebuilt in a year. [EPA-HQ-OAR-2014-0827-1309-A1 p.12]

4 40 CFR 1037.801.

**Organization:** National Ready Mixed Concrete Association (NRMCA)

NRMCA supports maintaining the flexibility of ready mixed concrete producers to utilize their already purchased assets to their fullest capacity, such as with “glider kits.” To this end, NRMCA opposes the proposal’s suggestion to require glider kits contain Phase 2 compliant engines. Continuing to allow ready mixed concrete producers the opportunity to utilize refurbished trucks, truck parts and engines is an entrepreneurial inventiveness affording industry members economic and productivity advantages and competitiveness. Changing the current glider kit system will undoubtedly cause undue harm and hardship for many ready mixed concrete companies that base their business model on glider kits instead of purchasing brand new trucks. [EPA-HQ-OAR-2014-0827-1146-A1 p.3]

Upending the current glider kit system serves as an unnecessary coercion on market forces that alone will inevitably pressure the phase out of pre-Phase 2 engines. Requiring glider kits to be Phase 2 compliant would be redundant, unnecessary, and unfairly expeditious on the ready mixed concrete industry. [EPA-HQ-OAR-2014-0827-1146-A1 p.3]

NRMCA opposes any changes to the current glider kit schemes. NRMCA would like to highlight comments recently reported on that were made by Matthew Spears, executive director of EPA’s Heavy Duty Program at a recent session of the American Trucking Association’s Technology & Maintenance Council (September 22, 2015), in which he noted that the Phase 2 program changes to glider kits may be left alone when applied to concrete mixer truck chassis. NRMCA would very much support such a carve-out for ready mixed concrete trucks. As much, mixer trucks do fall in line with any criteria that would exclude their coverage based on low-mileage and/or vocational use. [EPA-HQ-OAR-2014-0827-1146-A1 p.3-4]
Glider Vehicles and Glider Kits

NRDC supports the EPA proposal to clarify requirements for glider vehicle and kit manufacturers and to require new gliders to use engines that meet the standards current to the year of the glider manufacturing. The EPA action will ensure that there is not a large and growing loophole allowing glider vehicles with high-emitting engines to displace new vehicles that meet current pollution standards. NRDC agrees that these requirements should apply equally for GHG and non-GHG pollutants. We also recommend that NHTSA move forward with implementing similar requirements for fuel consumption. [EPA-HQ-OAR-2014-0827-1220-A1 p.10]

Organization: Navistar, Inc.

Navistar supports the portion of the NPRM that addresses gliders. Further, Navistar suggests that the allowance is too high, and that gliders should either be limited to 200 per year or eliminated completely. [EPA-HQ-OAR-2014-0827-1199-A1 p.14]

Organization: Neapco

The proposed rule would have an unfavorable impact on Neapco Components. If we were unable to sell product to the glider kit industry, we would have to reduce our employment levels in Beatrice Nebraska and Pottstown Pennsylvania. [EPA-HQ-OAR-2014-0827-1134 p.1]

The proposed rule understates the benefits of a glider kit truck on the environment and also underestimates the benefits of improved highway safety by replacing an older truck with a glider kit truck with many improved components. The option of purchasing a glider kit truck also benefits small businesses who the government reports to be the primary source of new jobs in our country. [EPA-HQ-OAR-2014-0827-1134 p.1]

Organization: NGVAmerica

EPA has proposed for Phase 2 that no small business entity could produce more than 300 glider vehicles in any given model year without certifying (or recertifying) the vehicle and engine to the current EPA standards. This level of volume will limit the ability of OEM truck manufacturers to support their ongoing glider truck programs, which have proved beneficial to alternative fuel platforms and could be a solid foundation for the growth of alternative fuel usage. [EPA-HQ-OAR-2014-0827-1270-A1 p.8]

NGVAmerica, however, supports the proposal to provide a limited exemption for small manufacturers who produce completed glider trucks using pre-2007 engines. As described elsewhere in our comments, EPA should use the small business definitions currently set out in guidance provided for light duty aftermarket retrofit manufacturers. SBA regulations, 13 CFR 121.201, define a “small business” by the maximum number of employees; for example, this is currently 1,000 for heavy-duty vehicle
manufacturing and 750 for engine manufacturing. These levels also should be used for purposes of the Phase 2 rules. [EPA-HQ-OAR-2014-0827-1270-A1 p.8]

We understand the concerns raised by EPA regarding the continued use of older engines in essentially new vehicles and the propensity for this to greatly extend the life of some engines thereby delaying improvements in emission benefits. This concern is well founded in cases where pre-2007 engines are simply rebuilt and used with no improvements in emissions. However, modifying in-use engines to operate on natural gas does lead to improvements and reductions in criteria emissions. Based on this fact, we would urge EPA to expand the ability of glider manufacturers to continue to make use of pre-2007 natural gas (or other alternative fuels) retrofitfitted engines that are certified or approved, and that demonstrate significant emission reductions in criteria pollutants such as nitrogen oxides and particulate matter. One way to accomplish this would be to provide a separate allowance for gliders equipped with alternative fuel engines, or increase the total number of allowances for companies utilizing alternative fuel engines. [EPA-HQ-OAR-2014-0827-1270-A1 p.9]

We also urge EPA to expand the opportunities for glider manufacturers to make use of 2010 compliant engines that are retrofitted by small volume manufacturers to operate on alternative fuels. Post-2010 engines do not present the same issue with regard to potential in-use emissions and thus should not be limited. We believe that adopting this policy comports with EPA’s long standing policy of providing additional flexibility to small volume manufactures of alternative fuel systems and would help expand market opportunities for these companies and fleets interested in using alternative fuels. In some applications, such as larger engines, this may be the only way a fleet can expand its use of natural gas. [EPA-HQ-OAR-2014-0827-1270-A1 p.9]

Providing the flexibility described here will allow OEM Truck manufacturers to continue to produce a limited number of gliders each year, and will encourage greater use of alternative fuel trucks. [EPA-HQ-OAR-2014-0827-1270-A1 p.9]

Organization: North American Repower

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 309.]

You have asked specifically about the glider kits. In your Preamble, you say that people are going to glider kits to circumvent the Clean Air Act. That is not why they are doing it. Maybe you have more information than I do. Maybe there is somebody specifically trying to do that.

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

The agencies should close the “Glider Kit” loophole.

We strongly support the proposed measure to ensure that glider kits are subject to the same applicable regulations as other new trucks. This common sense measure will prevent gaming and will avoid significant amounts of unnecessary emissions of GHGs, NOx, and PM2.5. The agencies request comment on the appropriate magnitude of the exemption. While we agree that some minimal exemption opportunity is probably appropriate in limited cases, we urge the agencies to set this number as low as is practical without impeding small businesses with legitimate claims. [EPA-HQ-OAR-2014-0827-1221-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.139-140.]]
Organization: Nuss Truck & Equipment of Minnesota and Wisconsin

Nuss Truck & Equipment strongly supports the agencies' proposal to impose new requirements on companies assembling and offering for sale vehicles produced by installing used driveline components into new glider kits. EPA and NHTSA should require that manufacturers of these glider-based vehicles comply with all applicable and current greenhouse gas and criteria emissions standards. NHTSA should also enforce the existing regulations that require manufacturers of glider-based vehicles to comply with all applicable safety standards. Dealers such as ours have been subject to a growing unfair competition from this rapidly expanding market of non-compliant vehicles. [EPA-HQ-OAR-2014-0827-0918-A2 p.1]

Nuss Truck & Equipment sold glider kits in the past when our customers purchased to repair a wrecked truck, or worn out cab, hood and frame on a heavy duty truck, or because they owned a truck that recently had major investment in the powertrain, and it made sense to redeploy those components into a glider kit. Glider kit usage in the early 2000's dropped off significantly as our OEM manufacturers devoted time to building trucks to meet emission standards and not proposing a way around emissions (2002 - 2007). Now, truck purchasers have the ability to purchase a powertrain combination that they never owned in an existing truck, from assemblers who have chosen to exploit the law put in place that was intended to clean up air pollution. The original intent of selling glider kits has moved from a rebuilding mechanism to now mainly evading diesel emissions EPA mandates. We see many truck owners and small fleets from Minnesota and Wisconsin traveling long distances, passing by dozens of legitimate truck dealers, to purchase glider kits directly from a manufacturer in another state, just to avoid the current EPA emissions standards. That should not be a legally acceptable reason to purchase a glider kit, if we all want clean air. [EPA-HQ-OAR-2014-0827-0918-A2 p.1]

Nuss Truck & Equipment supports the application of glider kits as a means to repair badly damaged vehicles, while taking advantage of the remaining useful life in the damaged vehicle's driveline components. When conducted within the requirements of 49 CFR 571.(e), which sets forth NHTSA's rules for re-use of driveline components for installation into a glider kit, we have no specific concerns with such legitimate applications of glider kits. It's when these rules are violated, however, in an effort to offer for sale an essentially new vehicle whose production costs and total cost of ownership may be tens of thousands of dollars less than the fully compliant new products sold by our dealership that we strongly object to such an unfair disruption of market competition. Unfortunately, this practice has become widespread without consequence to the glider-based vehicle manufacturers, and it is unfairly and negatively impacting our business. In many cases, the manufacturers of glider-based vehicles are not collecting the 12% federal excise tax ('FET') that normally applies to new vehicle sales, giving customers even further financial incentive to purchase glider vehicles rather than fully compliant new vehicles. This abusive application of glider kits must be stopped; we strongly support the agencies' efforts to do so through appropriate new regulations and enforcement of existing regulations. EPA and NHTSA should seek to remedy this situation as soon as practicable, while protecting for the continued use of glider kits for legitimate purposes as we have described. [EPA-HQ-OAR-2014-0827-0918-A2 p.2]

We refer you to the comments of the Volvo Group North America for a more complete analysis and set of recommendations with respect to the regulation and enforcement of glider-based vehicles. Nuss Truck & Equipment supports the comments submitted by Volvo Group North America. [EPA-HQ-OAR-2014-0827-0918-A2 p.2]

The rapidly expanding glider-based vehicle market is seriously undermining the significant gains EPA, NHTSA, and the heavy-duty vehicle industry have made to reduce criteria and greenhouse gas
emissions, reduce fuel consumption, and improve roadway safety. The market availability of these non-compliant engines and vehicles poses an unfair competitive disadvantage to manufacturers that have undertaken the enormous effort and investment necessary to comply with all applicable emissions, fuel efficiency, and safety standards, and likewise an unfair competitive advantage to the dealer network representing those OEM's. It is therefore imperative that the agencies follow through by finalizing regulations that prohibit the production of glider-based vehicles for anything other than legitimate purposes, and that the agencies actively ensure compliance to those requirements. [EPA-HQ-OAR-2014-0827-0918-A2 p.2]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

To compound this problem, the new proposal would limit the number of glider kits that could be produced and sold — under the assumption that drivers who use them would have less incentive to purchase a new truck that would achieve even greater efficiency. The unavailability of gliders kits is not likely a sufficient factor to overcome the fact that new trucks may be prohibitively expensive for many truck owners. The agencies should not discourage the modification of older equipment at the expense of incremental environmental benefits. This is especially true considering that one of the major benefits of a glider kit is reduced fuel consumption. When a reliable engine is placed into a new aerodynamic tractor, this will clearly result in a reduction of GHG emissions, which should be applauded by the agencies. If the agencies wish to address glider kits in any way OOIDA believes this issue should be the subject of a separate rulemaking. [EPA-HQ-OAR-2014-0827-1244-A1 p.44-45]

Organization: PACCAR, Inc.

I. Glider Standards: EPA and NHTSA Should Adopt Glider Regulations that Reflect the Needs of Customers and Manufacturers.

Giders are and have been for many years a key tool for fleet and individual vehicle owners to cost effectively use all the vehicle major components, such as the engine, transmission, and rear axles, to transport goods to the American consumer and to do so at the lowest cost possible. PACCAR understands EPA’s concern regarding oxides of nitrogen (NOx) emissions that comes from earlier emission level engines that can be put into current model year gliders. Recognizing this concern as well as the needs of the market, PACCAR provides the following recommendation for glider provisions in the Phase 2 regulation. [NHTSA-2014-0132-0223-A1 p.2]

- GHG Vocational and Tractor vehicles should be allowed to have installed post-2010 emissions engines with no volume or no mileage limitations on the engine [NHTSA-2014-0132-0223-A1 p.2]

- Implementation of the requirement to install post-2010 emissions engines should be phase-in with full implementation tied to the start of the Phase 2 GHG regulation in 2021, except for Small Business as is noted below [NHTSA-2014-0132-0223-A1 p.2

- EPA-defined Small Manufacturers would be exempt from the requirements of the GHG regulation through 2021. The volume limit of gliders for 2018 through 2021 will be their highest build volume between 2012 and 2014, inclusive, or 300 units, whichever is smaller. There is no restriction prior to 2018. As of 2022, the exemption requires the installation of post-2010 engines, same as for non-exempt businesses. [NHTSA-2014-0132-0223-A1 p.2]

  a. Glider Manufacturers Do Not Have All the Details about the Final Glider Configuration.
In NODA document EPA-HQ-OAR-2014-0827-1627 titled “Legal Memorandum Discussing Issues Pertaining to Trailers, Glider Vehicles, and Glider Kits under the Clean Air Act” Section f. Controls on Manufacturers of Glider Kits, EPA states that “…glider kits include the entire tractor chassis, cab, tires, body, and brakes. Glider kit manufacturers thus control critical elements of the ultimate vehicle’s greenhouse gas emissions, in particular, all aerodynamic features and all emissions related to tire type.” EPA’s understanding of the content of a glider kit and the extent of the data knowledge of the glider manufacturer is incorrect. Gliders are built in a variety of configurations. Many do not have rear axles installed, thus no information is known by the manufacturer on the axle configuration, the rear axle ratio, or the rear tires. [NHTSA-2014-0132-0223-A1 p.2]

In some cases, the vehicle is modified during the assembly process to change the cab / sleeper configuration without the knowledge of the glider manufacturer. Other components that impact aerodynamics such as exhaust system configuration and roof fairing designs are not known by the manufacturer at the time of glider build. Thus the manufacturer does not always have the necessary data needed as input to GEM for that glider, which challenges the concept that the glider manufacturer is inherently the correct regulated entity for the glider as a finished vehicle. [NHTSA-2014-0132-0223-A1 p.2-3]

Additionally, in this same section, EPA states “Glider kit manufacturers also invariably know the final configuration of the glider vehicle, i.e. the type of engine and transmission which the final assembler will add to the glider kit. This is because the glider kit contains all necessary wiring, and it is necessary, in turn, for the glider kit manufacturer to know the end configuration in order to wire the kit properly.” Again, the reality is different from EPA’s understanding. The glider manufacturer does not always provide engine or transmission wiring for the major components that will be installed. Wiring harnesses can be ordered at the same time as the glider, but the reality is that the glider assembler often greatly modifies the harness so that it will work for a completely different and unintended engine. For example, wiring harnesses for a CAT engine are being reworked for a Detroit Diesel engine. It must be noted that even though these two engines are installed in significant numbers in gliders, neither of these engines are installed in PACCAR vehicles at the factory and have not been for nearly a decade. As a result, significant rework is required that is uncontrolled by PACCAR. Also, this means that the glider manufacturer does not necessarily know the engine or the transmission that will be installed. Transmission information is used only to determine the correct driveline length. Multiple transmissions that would have very different GEM inputs have the same effective lengths. Also, no information regarding manual versus automated manual configuration of a transmission are provided with the glider orders. [NHTSA-2014-0132-0223-A1 p.3]

b. Labeling of Gliders as “Not for Tractors” Adds No Value Under PACCAR’s Proposal.

In Section g. Alternative Provisions for Trailer and Glider Kit Manufacturers as Manufacturers of Motor Vehicle Parts, EPA proposes a unique label for gliders that will be used in Vocational applications. In the PACCAR proposal that is detailed at the start of this document, there is no difference between Tractor and Vocational vehicles, therefore there is no need for a unique labeling requirement. [NHTSA-2014-0132-0223-A1 p.3]

c. Requirements for Rebuilt / Remanufactured Engines to Meet Current Engine Standards are Not Needed.

The requirement outlined in Section h. Alternative Provisions for Engine Remanufacturers, that all engines that are rebuilt or remanufactured must meet the current model year engine standard if the engine is used in a glider is no longer required under the PACCAR proposal. Starting in 2021, all glider
engines must be post-2010 engines in compliant configurations with the appropriate aftertreatment system, thus eliminating this requirement and mitigating EPA’s concern regarding pre-2010 engines being rebuilt or remanufactured for installation into gliders. [NHTSA-2014-0132-0223-A1 p.3]

d. PACCAR Agrees with Provision for Installation of Post-2010 Engines Without Restriction

PACCAR urges EPA to finalize the provision in Section i. Glider Vehicles Using Newer Engines, to allow the installation of post-2010 engines, those meeting the 2010 NOx and PM emissions standards, to be installed in gliders starting in 2021 without limitation to mileage, age, or quantity per manufacturer or assembler. [NHTSA-2014-0132-0223-A1 p.4]

e. Delegated Assembly Provisions Should Reflect the Information Known by and Available to the Glider Manufacturer

PACCAR also urges EPA to revise 40 CFR 1037.130 Assembly instructions for secondary vehicle manufacturers, to include only Sections (a), (b)(1), (b)(2), (b)(4), and (c) as the provisions required when delegated assembly is used to support the assembly of gliders by secondary manufacturers. [NHTSA-2014-0132-0223-A1 p.4]

[Table can be found on p.4 of docket number NHTSA-2014-0132-0223-A1]

Supporting contracts, audits, affidavits, and documentation for each assembler and on-going support for each order of a glider are typically included with full delegated assembly provisions. EPA has not properly anticipated or included in the regulation development the associated burden for such a large number of assemblers if the Small Business exemption is removed. Limiting the delegated assembly requirements is the appropriate action, regardless of the decision on the Small Business exemption. [NHTSA-2014-0132-0223-A1 p.4]

PACCAR will work with the agencies on the appropriate content on gliders for end of year reporting. [NHTSA-2014-0132-0223-A1 p.4]

Gliders

The current proposal limiting the build of glider kits per year with non-current emissions engines is extremely stringent and overly burdensome to manufacturers, customers, and dealers. Also the requirement that each non-exempt glider have a current year emissions engine will render many powertrains as scrap parts even though they have recently been manufactured and are capable of powering a new vehicle body. [EPA-HQ-OAR-2014-0827-1204-A1 p.26]

Over the last three years, PACCAR has sold glider kits through the Kenworth and Peterbilt dealer network to over 1,200 unique individual customers who have assembled gliders or had gliders assembled for them. For model year 2014 alone, this number was more than 500 customers. In that three-year period, PACCAR sold glider kits to support those customer through 78 different dealer groups comprised of over 215 separate Kenworth and Peterbilt dealer locations across the United States. The vast majority of these dealer groups purchased fewer than 50 glider kits from PACCAR each of these years. Of these groups, 14 did not purchase any glider kits from PACCAR in 2014, the year on which EPA proposes to base the limit for glider exemptions, but did purchase fewer than 50 glider kits
in one or both of the preceding or trailing years. If EPA finalizes the rule as proposed, these dealers would be unable to purchase PACCAR glider kits and provide customers with an option to retain powertrains after January 1, 2018. [EPA-HQ-OAR-2014-0827-1204-A1 p.26]

PACCAR understands EPA’s concern about older, less efficient, higher-emission engines being installed into gliders when newer, more efficient, and cleaner powertrains are available. However, many glider purchasers have been involved in accidents, or have had other damage to the vehicle body, and are left with a fully functional powertrain. EPA’s proposal would unduly penalize those operators and others who are not attempting to avoid purchasing newer-model year engines but are simply trying to continue to use an existing, undamaged powertrain. [EPA-HQ-OAR-2014-0827-1204-A1 p.26]

PACCAR recommends that the agencies extend the effective date of any limitation to January 1, 2021 to align with the Phase 2 regulation implementation, which will provide more lead-time for the industry to understand and accommodate the change in regulation. PACCAR also strongly recommends that the agencies provide more flexibility for entities that did not assemble any gliders in 2014 but which have done so between 2014 and the effective date of the Phase 2 final rule. Specifically, if the implementation is set at the recommended January 1, 2021 date, EPA should allow the assembly of up to 300 gliders per year for any individual company as exempt from the Phase 2 regulation, provided that the engine/powertrain to be installed meets MY2010 or newer emission standards. EPA also should allow without limit the assembly of gliders where the engine meets the emissions standard for the year the glider was assembled. [EPA-HQ-OAR-2014-0827-1204-A1 p.26-27]

If the implementation is set at January 1, 2018 as proposed in the NPRM, then EPA should allow all small businesses, as defined by federal regulations, to assemble a minimum of 50 gliders per year as exempt from the engine / vehicle model year requirements, regardless of the emission standard of the engine, and up to their maximum sales in 2013 or 2014, or 300. The agencies also should allow the installation of engines that meet MY2010 or newer emission standards without a volume limit for any company. This will mitigate the EPA concern about non-DPF engines from being installed at current volumes and eliminates the issues of recently built powertrains not being allowed for installation in new gliders. [EPA-HQ-OAR-2014-0827-1204-A1 p.27]

Organization: Reeves Brothers Trucking, Inc.

**Organization:** Sierra Club

**Close the glider kit loophole**

We applaud the agencies for the proposed treatment of glider kits. In recent years, sales of glider kits have skyrocketed, accounting for roughly two percent of all Class 8 vehicles manufactured annually. Many of the engines used on these vehicles emit substantially greater amounts of NOX and particulate matter than current emissions standards allow. Under the proposal, glider kit manufacturers will no longer be able to exploit a loophole leading to more health-threatening pollution. We urge you to finalize the provisions that would close the glider kit loophole. [EPA-HQ-OAR-2014-0827-1277-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.190.]]

**Organization:** Terex Corporation

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 105-108.]

Comment number one, page 40529 of the proposal says that EPA requests comment on whether we should allow larger manufacturers to produce some limited number of glider kits.

Therefore, Terex proposes that if the EPA sets limits on the quantity of gliders produced, it should not be based solely on the number of employees the glider manufacturer has, but should also be based on the number of on highway vehicles it produces similar to the way the off highway transition program for equipment manufacturers is set up.

For example, Terex Corporation has approximately 20,000 employees globally, but only approximately 220 are involved in the manufacturer of gliders at one small facility located in Fort Wayne, Indiana. Should the proposed regulations continue unchanged, it would result in the redundancy of some 70 team members at the Fort Wayne facility. Therefore, Terex proposes if a company manufactured fewer than 1,000 on highway vehicles annually between calendar years 2010 and 2014, then it should be eligible for the same exemptions as a small manufacturer under the proposed 1037.635(b).

Comment number two, the proposed definition number three of ‘glider kit’ on page 40662 says that a ‘glider kit’ means ‘any other new equipment that is intended to become a motor vehicle with a previously used engine, include a rebuilt or remanufactured engine.’ Terex requests further clarification and/or a definition of ‘other new equipment.’ The intention of this request is to eliminate confusion over whether certain new parts or assemblies that would be used to repair an existing vehicle would be considered as ‘new equipment’ by the EPA.

Comment number three, page 40229 says that building a glider out of salvaged powertrain from vehicles destroyed in accidents is ‘an arguably legitimate purpose,’ and Terex agrees with the agencies on that.
The proposed limitation on gliders doesn't distinguish between repaired vehicles and glider kits. Terex suggests that language be added that allows for a used powertrain to be installed onto a new chassis for the case of repairing a damaged vehicle, and not be subject to regulations that are newer than the original bill date of the damaged vehicle.

And then my final comment number four is regarding page 40186. It says that six by six and eight by eight vehicle configurations are only manufactured for specialized vehicles that require extra traction for off road applications. They are very low volume sales, and their increased fuel consumption and CO2 emissions are not significant in comparison to the overall reductions of the Phase 2 program.

Therefore, Terex suggests that vehicles with six by six and eight by eight configurations must be added to the list of exemptions under the proposed 1037.635(b) concerning glider kits. Because these vehicles operate off road, they are far more susceptible to wear and tear type frame damage that is premature compared to the engines that were designed to operate for a million miles. For this reason, glidering six by six and eight by eight vehicles is and has always been common industry practice, even before the arrival of after treatment systems on diesel engines.

Organization: Truck & Engine Manufacturers Association (EMA)

Glider Kits

The same problems noted above also would flow from the agencies’ proposed treatment of glider kits. Glider-kit manufacturers should not be held responsible for the ultimate downstream configuration of the vehicle, so long as the glider-kit manufacturer has provided proper instructions to the vehicle finisher for the installation of emission-related components. Beyond that, and just as in the case of incomplete-vehicle manufacturers, the manufacturers of glider kits should not be transformed by regulation into the de facto guarantors of separate business entities that complete the manufacture of vehicles using glider kits. [EPA-HQ-OAR-2014-0827-1269-A1 p.36]

With respect to the agencies’ other proposals for regulating glider kits, EMA supports the agencies’ proposal to provide a small business exemption for any business entity that employs less than 1000 people and that falls under the production cap set forth in proposed section 1037.635(c). A small business exemption is necessary to avoid disproportionate impacts on a significant number of diverse business entities, including the small businesses that participate in the assembly of gliders. [EPA-HQ-OAR-2014-0827-1269-A1 p.36]

It should be noted that in their proposed regulation of glider kits, the agencies are, in effect, proposing to adopt regulatory requirements for vehicle parts, as opposed to motor vehicles. The CAA defines a “motor vehicle” as any “self-propelled vehicle designed for transporting persons or property on a street or highway.” (See 42 U.S.C. §7550(2)). A glider kit is not self-propelled and so, on its own, is not a “motor vehicle” within EPA’s regulatory jurisdiction. Thus, the glider kit manufacturer is not an entity over which EPA has regulatory authority. [EPA-HQ-OAR-2014-0827-1269-A1 p.36]

Organization: Truck Country of Wisconsin

As you know, there are differences between the two agency's in their respective views on regulatory frameworks for safety and air emissions and definitions of 'glider kits' [EPA-HQ-OAR-2014-0827-1468-A1, p.1]
NHTSA defines a 'glider kit' as motor vehicle equipment that primarily includes the chassis cab, but generally does not include the engine or rear axles. EPA defines 'glider kits' to both the complete and incomplete vehicles and applies its regulations to both. (See 40 CFR 1037.801 of EPA's proposed regulatory text). [EPA-HQ-OAR-2014-0827-1468-A1, p.1]

I support EPA's definition of 'glider kits' as an important step to ensure uniformity between EPA and NHTSA for the following reasons. [EPA-HQ-OAR-2014-0827-1468-A1, p.1]

Air pollution and emissions are a significant problem with 'Glider kits' support EPA's definition 'glider kits' as an important step to ensure uniformity between the EPA and NHTSA for the following reasons:

1. We agree with EPA's assessment that most gliders manufactured today use remanufactured model year 2001 or older engines. Typically these engines have and NOX and particulate matter (PM) emissions 20 to 40 times higher than today's clean engines. Since 2010 when EPA's current NOx and PM standards for heavy duty engines took effect, glider sales have increased nearly 10-fold as compared to the 2004-2006 time frame. [EPA-HQ-OAR-2014-0827-1468-A1, p.1]

2. We agree with EPA that this increase reflects an attempt to avoid using engines that comply with EPA's 2010 standards, and is an attempt to circumvent the Clean Air Act purpose to protect human health and the environment. [EPA-HQ-OAR-2014-0827-1468-A1, p.1]

3. The Trucking Industry has made enormous investments in new engines standards to comply with past and future EPA regulations. We believe this circumvents these standards and will make it harder to meet compliance. [EPA-HQ-OAR-2014-0827-1468-A1, p.1]

4. We agree with EPA's Clean Air Act definition of 'new motor vehicle' is not based on the condition of the parts assembled to create the vehicle but rather encompasses the entire vehicle, even if they incorporate some previously used components. [EPA-HQ-OAR-2014-0827-1468-A1, p.1]

In conclusion, Truck Country supports the new EPA requirements are being proposed in the HD Phase 2 Notice of Proposed Rulemaking. By proposing new requirements beginning January 1, 2018 that would generally require engines installed in new gliders to meet the same requirements as new emissions-compliant engines- both for GHGs and for other harmful pollutants such as NOx and PM. Beginning in model year 2021, Phase 2 standards for heavy duty vehicles would also apply to gliders. [EPA-HQ-OAR-2014-0827-1468-A1, p.2]

In addition, we oppose the HD Phase 1 exemption for small businesses that manufacture gliders for model years 2018 and beyond and we fully support EPA's proposal to end this blanket exemption on January 1, 2018. We agree with EPA to limit the grandfathering of existing small businesses that currently install the used engines and other used parts into gliders. These special provisions allow too much discrepancy to continue production of assembled gliders creating an already air quality problem for industries who have to meet the Clean Power Plan and Ozone regulations. [EPA-HQ-OAR-2014-0827-1468-A1, p.2]

Finally, we believe EPA's approach in resolving this issue in proposing these changes is in the best interest to improving air quality in this country and create consistency between the two agencies. Properly regulating the 'glider kit' issue will improve the health care of all citizens as we try to address greenhouse gas emissions for future generations. [EPA-HQ-OAR-2014-0827-1468-A1, p.2]

Organization: Union of Concerned Scientists (UCS)
GLIDER KITS

UCS supports the closing of a loophole that currently allows glider kits—chassis and powertrains assembled by a third party and sold as new trucks—to not comply with fuel economy, greenhouse gas, and other pollution control regulations. These vehicles have traditionally played an important role in maintaining investments when parts of trucks were rendered unusable due to accidents and until recently only a few hundred a year were sold. In recent years, however, thousands of glider kits have been sold annually to get around pollution control systems. This has led to extreme discrepancies in pollution from OEM-manufactured new vehicles and new glider kit vehicles. EPA analysis shows that while glider kits make up only 2 percent of Class 8 vehicle sales, they contribute nearly half of the total NOx and particulate emissions from all new Class 8 vehicles (EPA and NHTSA 2015). These glider kit vehicles should be regulated the same as any other new vehicle and this proposal will put them on equal footing with other new trucks. [EPA-HQ-OAR-2014-0827-1329-A2 p.13]

Organization:  Volvo Group

Glider Vehicles and Small Manufacturer Exemption

Volvo Group strongly supports the agencies’ proposal to take action within this proposed rulemaking to require that companies selling new vehicles produced by installing used driveline components into new glider kits certify the compliance of these vehicles and their engines to the prevailing greenhouse gas and criteria emissions standards. The glider-based market, which has exploded over the last several years, is built upon the allure of simpler, lower maintenance engine designs of the pre-2004 emissions era, wherein these vehicles can be produced at a much lower cost due to the use of used driveline components and exclusion of emission and safety related systems. In Volvo Group’s view, glider-kits can serve a legitimate purpose, that being a major repair to a vehicle that has been involved in an accident and is damaged to the point that only some driveline components are reasonably salvageable. Yet Volvo Group has deep concerns that the market which has emerged over recent years is one built upon circumvention of today’s stringent emissions standards rather than a legitimate use of glider kits, and agrees with the agencies that the practice must stop or be significantly limited. [EPA-HQ-OAR-2014-0827-1290-A1 p.60-61]

Volvo Group also supports the agencies’ proposal to eliminate the exemption to greenhouse gas and fuel efficiency requirements for small manufacturers, but proposes that the exemption sunset sooner than the agencies have proposed. [EPA-HQ-OAR-2014-0827-1290-A1 p.61]

Glider Kits can serve a Legitimate Purpose

The “glider kit” emerged some decades ago as an assemblage of new vehicle components absent the engine, transmission, and rear axles (the “driveline”). These kits were produced by vehicle OEMs, and made available for sale to dealers and other vehicle repair centers as a means to repair a vehicle that had been badly damaged in an accident or similar event. This permitted re-use of driveline components that had not yet accumulated end-of-life mileage by the time of the accident. Volvo Group believes this is a reasonable and practical application for a glider-kit; namely as a means for an individual truck owner to recover from such an unexpected event that would otherwise cut short the lifetime of a purchased capital good. [EPA-HQ-OAR-2014-0827-1290-A1 p.61]

For purposes of establishing acceptable practices concerning the application of glider kits in these instances, and to clarify what practices would constitute creation of a new vehicle obligating the
assembler to certain requirements under NHTSA safety regulations, NHTSA adopted language as follows: [EPA-HQ-OAR-2014-0827-1290-A1 p.61]

49 CFR §571.7 Applicability.

(a) General. Except as provided in paragraphs (c) and (d) of this section, each standard set forth in subpart B of this part applies according to its terms to all motor vehicles or items of motor vehicle equipment the manufacture of which is completed on or after the effective date of the standard. [EPA-HQ-OAR-2014-0827-1290-A1 p.61]

** * * * *

(e) Combining new and used components. When a new cab is used in the assembly of a truck, the truck will be considered newly manufactured for purposes of paragraph (a) of this section, the application of the requirements of this chapter, and the Act, unless the engine, transmission, and drive axle(s) (as a minimum) of the assembled vehicle are not new, and at least two of these components were taken from the same vehicle. [EPA-HQ-OAR-2014-0827-1290-A1 p.61]

Simply put, when assembling a motor vehicle using a new cab, as is the case with assemblies from glider kits, the final vehicle assembly is a new motor vehicle unless the engine, transmission and rear axle(s) are all used, and at least two of them come from the same donor vehicle. Said another way, if any of the three driveline components is new, the finished assembly is a new motor vehicle. Or, if all three are used components but were salvaged from more than two donor vehicles, the finished assembly is a new motor vehicle. The final assembler of any new motor vehicle is obligated, at minimum, to: (a) register with NHTSA as a vehicle manufacturer, (b) to create and register Vehicle Identification Numbers (VINs) with NHTSA, (c) certify compliance of the finished vehicle to all applicable NHTSA safety standards, (d) file reports regularly with NHTSA regarding safety defects, and (e) undertake recall obligations to correct certain safety defects. [EPA-HQ-OAR-2014-0827-1290-A1 p.61-62]

New Glider Kit Market is Based on Avoiding Emission Controls

A new market has emerged based on use of glider kits to create essentially new vehicles that do not comply with applicable safety, criteria emissions, or greenhouse gas standards.

While there is a limited, legitimate and practical application of glider kits in the heavy-duty truck market, a market has emerged whereby new vehicles are being assembled from glider kits -- not to repair a wrecked vehicle -- but rather to be offered for sale as new vehicles. These new vehicles are built with used or remanufactured engines that are not compliant with current criteria emissions standards at the time of vehicle manufacture. Similarly, neither these vehicles nor their installed engines are compliant to applicable greenhouse gas emissions and fuel consumption standards at the time of manufacture. Finally, these vehicles also do not comply with all applicable safety standards, and some glider vehicle manufacturers appear not to be complying with all obligations incumbent upon a new vehicle manufacturer per NHTSA regulations. [EPA-HQ-OAR-2014-0827-1290-A1 p.62]

Assemblers of glider vehicles (“glider vehicle,” as used herein, means a fully assembled vehicle, built from a glider kit, complete with used or remanufactured driveline components installed) have adopted a number of business practices for producing these vehicles. Often, the rear axles installed on glider vehicles are not, in fact, used components; they are actually new units as purchased from the glider-kit supplier. Some engines installed are rebuilt before installation, others are remanufactured engines purchased from a remanufacturing facility. The same holds true for transmission sourcing.
Remanufactured engines typically are produced from a process that renders it impossible to link a finished product to a source “donor vehicle.” None of these practices appear to be consistent with NHTSA regulations that allow the exception to the manufacturing of a new vehicle. [EPA-HQ-OAR-2014-0827-1290-A1 p.62]

Not only can these new glider-based vehicle assemblies be seen as a circumvention of regulatory obligations, they also set up an unfair competitive advantage to manufacturers of new motor vehicles who are complying with all applicable emissions, fuel consumption, and safety standards. Today’s cleanest, most fuel efficient and safest vehicles are necessarily tens of thousands of dollars more costly to produce, more expensive to maintain, and can cost more to operate, than glider-based vehicles. As such, heavy-duty truck OEMs and their dealers are unfairly forced to compete with these higher-emitting, less safe vehicles. Additionally, application of certain Internal Revenue Service rules can result in new vehicle sales where the purchaser is not obligated to pay the 12% Federal Excise Tax (FET) that normally applies to new vehicle sales, giving customers even further financial incentive to purchase glider vehicles rather than fully compliant new vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.62]

These unfair competitive advantages have led to a boom in glider vehicle sales in recent years. EPA and NHTSA state in the Preamble that total glider-based vehicle volumes were typically less than 1000 units prior to 2007. The Small Business Advocacy Review Panel for the Phase 2 proposal, however, notes that for 2011 and 2012, sales of glider vehicles “spiked to almost 4,000 per year.” Moreover, based on Polk registration data, Volvo Group estimates that 2014 glider-based sales were on the order of 6,000 units or more, about 3% of the total Class 8 market; and 6 times the pre-2007 estimates that EPA and NHTSA appear to rely on in the proposal. Some assemblers report that plans for major expansions of their assembly capacity are underway. Such a gross expansion will further frustrate the ability of OEM dealers to compete in the marketplace with fully compliant products. Without regulatory intervention, there’s little reason to expect this trend to be reversed, and therefore regulatory intervention is absolutely necessary. [EPA-HQ-OAR-2014-0827-1290-A1 p.62-63]

Glider-based Vehicles Have Huge Environmental Impact

Glider-based vehicle assemblies are having a huge impact on the environment, and introducing undue risk to American roadways.

In response to EPA’s Clean Diesel Program, manufacturers of heavy-duty engines introduced complex and expensive technologies including exhaust gas recirculation systems, diesel particulate filters, and selective catalytic reduction aftertreatment systems to achieve unprecedented reductions in NOx and particulate matter. Most glider vehicle manufacturers are installing pre-2004 engines, which lack all of the technologies mentioned above, and hence have substantially higher emissions. Even if these engines were fully compliant with all requirements in place prior to the advent of clean diesel technology requirements, the emissions from these engines compared to modern diesels are considerably higher. EPA’s own analysis as detailed in their recent glider Q&A document indicates that NOx and PM emissions from glider vehicles at current sales levels are equivalent to about 80 percent of the total NOx and PM emissions from the entire Class 8 sales fleet. Focusing on PM emissions, and applying the emissions levels indicated in Argonne National Lab’s recent update to the GREET Analysis13, at just 3% market penetration of the most egregious applications, the 2014 glider fleet emits twice the level of PM emissions that the 97% entire fleet of compliant vehicle sales emits that same year. [EPA-HQ-OAR-2014-0827-1290-A1 p.63]
These numbers are astounding; little more justification is needed to understand the importance of EPA taking action to address emissions from this market. [EPA-HQ-OAR-2014-0827-1290-A1 p.63]

While the impact of glider vehicles on heavy-duty greenhouse gas emissions and fuel consumption is not currently believed to be on the same scale as that of criteria emissions, the requirements promulgated in EPA’s current and proposed greenhouse gas regulations, and the growth being witnessed in the glider market, will certainly lead to a huge compliance gap between glider vehicles and fully compliant vehicles. At present, the majority of manufacturers of glider vehicles fall under the small manufacturer exemption to the GHG Phase 1 regulation, relieving them of any obligation to certify their products to demonstrate conformance to EPA and NHTSA greenhouse gas and fuel consumption standards. [EPA-HQ-OAR-2014-0827-1290-A1 p.63-64]

Finally, with respect to safety, heavy-duty OEMs are making huge investments to fully comply with Federal Motor Vehicle Safety Standards (“FMVSS”), so as to verify and deploy the best known technologies to ensure the safety of American roadways. According to the current NHTSA regulation and our understanding of the assembly practices and component sourcing applied by glider vehicle manufacturers today, these manufacturers should likewise be responsible for all current applicable FMVSS standards. It appears, however, that they are not meeting all of these requirements, including full vehicle certification, safety defect reporting obligations, and reporting of vehicle VINs for purposes of potential safety recall obligations. This practice is putting the safety of America’s roadways at risk and must be addressed. NHTSA must begin to take appropriate action to ensure these requirements are fulfilled by all manufacturers of heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.64]

Volvo Group Supports Action to Reform Glider Market

Based on all the foregoing arguments, Volvo Group supports the regulatory action that EPA and NHTSA are proposing to subject glider vehicles and their engines to the same criteria emissions and greenhouse gas emissions requirements as apply to other new vehicles manufactured for sale in the United States. Volvo Group believes that NHTSA also should take steps to fully enforce their existing vehicle safety requirements applicable to glider based vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.64]

With respect to EPA requirements, it is first important to recognize and clarify that vehicles produced from glider kits already are subject to GHG standards under 40 CFR Part 1037. This regulation applies to “all new heavy-duty vehicles, except as provided in § 1037.5” (40 CFR § 1037.1). With the exception of vehicles produced before 2014, none of the exclusions set forth under 1037.5 apply to vehicles produced from glider kits. Accordingly, these vehicles have been subject to EPA regulations since Jan. 1, 2014. EPA has recognized as much. In the proposal, the Agency states: “For EPA purposes, CO2 provisions of Phase 1 exempted gliders and glider kits produced by small businesses but did not include such a blanket exemption for other glider kits. Thus, some gliders and glider kits are already subject to the requirement to produce a vehicle certificate prior to introduction into commerce as a new vehicle. However, the agencies believe glider manufacturers may not understand how these regulations apply to them, resulting in a number of uncertified vehicles.” 80 Fed. Reg. 40138, 40215. Furthermore, EPA has identified at least one glider manufacturer that does not qualify as a small manufacturer, [RIA, Section 12.4], and it is unclear whether those that do have followed the requirements to notify EPA of their intent to produce excluded vehicles and label those vehicles as excluded pursuant to 40 CFR § 1037.150(c). [EPA-HQ-OAR-2014-0827-1290-A1 p.64]

While EPA believes some in the industry simply do not understand the Agency’s regulations, Volvo Group is concerned that EPA has underestimated the sophistication of many in this industry, for which
ignorance of the rules should not be an excuse for failure to comply. These include large glider vehicle manufacturers, which produce and sell complete glider vehicles that unquestionably are subject to GHG regulations. These are sophisticated operations that must be held accountable for complying with all EPA regulations to the same extent as other vehicle manufacturers. [EPA-HQ-OAR-2014-0827-1290-A1 p.64]

The small business exemption should be revoked sooner than EPA and NHTSA have proposed.

The sheer number of uncertified vehicles produced since 2014 also underscores a second significant shortcoming of EPA’s Phase 1 rule, which must be addressed in Phase 2; the small manufacturer exemption at 40 CFR § 1037.150(c). The exemption, as currently applied, exempts manufacturers that employ fewer than 1,000 employees. As explained in Volvo Group’s comments on the Phase 1 regulation, this exemption creates a sizable loophole for many manufacturers that produce substantial quantities of vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.65]

EPA has proposed phasing out the small manufacturer exemption by 2022, or one year after all other manufacturers are required to comply with the Phase 2 requirements. Volvo Group does not believe the small manufacturer exemption was justified in Phase 1, and opposes further extension of this loophole for another seven years. Volvo Group believes that the Small Manufacturer Exemption should be phased out by January 1, 2018. Such a schedule gives these manufacturers an additional four years of lead-time to meet Phase 1 GHG standards, above and beyond the lead-time afforded to their competitors. Failing this, the agencies should simply eliminate the one year delay and remove the exemption for the entirety of Phase 2, starting with the 2021 Model Year. [EPA-HQ-OAR-2014-0827-1290-A1 p.65]

Volvo Group is uncertain of the correct interpretation of the provisions of 40 CFR 1037.635. This section is entitled “Glider Kits”; however, the agencies lay out the necessary conditions to qualify for the limited production exemption described in that section as, „"..if you are a small manufacturer and you sold vehicles in 2014 under the provisions of § 1037.150(j).” The provisions at 1037.150(j) permit a manufacturer to install 2013 model year and earlier engines in vehicles (the provision has been revised in this proposal to sunset with vehicles having a date of manufacture January 1, 2018 or later). Many manufacturers, large and small, have installed 2013 model year engines in vehicles sold in 2014. This may have included vehicles having a 2013 date of manufacture, or having a 2014 date of manufacture, that were sold in 2014. There are no requirements to inform the agencies of the plan to sell vehicles under the provisions of 1037.150(j), nor to provide any reports to EPA. On its face, the limited volume exemption at 1037.635 effectively applies to all small manufacturers of vehicles. If this was the agencies’ intent, Volvo Group opposes the provisions, and considers that small business should not be afforded any exemptions. If this was not the agencies’ intent, then Volvo Group proposes that the agencies clarify the language to specify that the vehicles sold under the provisions of 1037.150(j) must have been vehicles produced by small manufacturers from glider kits, as the name of the section implies. [EPA-HQ-OAR-2014-0827-1290-A1 p.65]

EPA Should Review Glider Exemption and Stockpiling Potential

Since glider vehicle producers assemble vehicles from parts purchased from OEMs, engine remanufacturers and other suppliers, these companies do not require a substantial number of employees to be able to produce a substantial number of vehicles. In this regard, EPA’s small manufacturer exemption also creates a sizeable loophole for many glider vehicle producers, which in turn were able to produce (and continue to be able to produce) substantial numbers of uncertified glider vehicles. For this reason, Volvo Group supports EPA’s efforts to limit this loophole through the Phase 2 rulemaking, but
is concerned that the Agency’s efforts may be too little too late in terms of stemming the impact of
glider vehicles in undermining GHG and criteria emissions reductions achieved to date and in the future.
At a minimum, EPA should impose the proposed 300-vehicle annual limit on the production of glider
vehicles; although Volvo Group believes that even this limit likely far exceeds what is necessary to
allow for legitimate use of glider vehicles while preserving important emissions reductions. [EPA-HQ-OAR-2014-0827-1290-A1 p.65-66]

EPA is proposing to provide an exemption that would allow most glider-vehicle manufacturers (those
that qualify as small manufacturers) to avoid criteria emissions and greenhouse gas/fuel consumption
requirements for a limited number of glider vehicle sales each year. The proposal would limit the
number of exempt vehicles any manufacturer can sell in a given year, starting in 2018 with respect to
ingine compliance with criteria and CO2 emissions/fuel consumption requirements, and 2022 with
respect to vehicle compliance with CO2/fuel consumption requirements. The annual sales would be
limited to the manufacturer’s highest annual sales volume over the years 2010 through 2014, or 300
units, whichever is less. Volvo Group questions why such an annual exemption is deemed necessary or
appropriate, especially in light of the considerations set forth herein. [EPA-HQ-OAR-2014-0827-1290-A1 p.66]

In the Regulatory Impact Analysis, the agencies cite the recommendations of the Small Business
Advocacy Review (SBAR) Panel in support of the proposed glider provisions. In particular, the
agencies note “The Panel stated that it believes that the number of vehicles produced by small business
glider manufacturers is too small to have a substantial impact on the total heavy-duty inventory.” (RIA
at 12-6) Nowhere in either the RIA or the SBAR Panel report, however, do any of the agencies provide
a basis for this conclusion. Significantly, there is no discussion of the “spike” in production in 2011 and
2012 that the SBAR panel otherwise describes. There is no discussion or investigation of corresponding
and increasing spikes in 2013 and 2014; or any acknowledgment – never mind further investigation – of
this alarming trend. And there is no analysis of the impact of increased incentives to produce glider
vehicles that will be generated by the GHG Phase 2 proposal. In summary, the agencies rely on a
conclusory finding to dismiss what is likely to be a potentially significant undermining influence on the
effectiveness of the GHG and criteria emissions regulations. [EPA-HQ-OAR-2014-0827-1290-A1 p.66]

First, EPA fails to take into account the incentive it is creating for more companies to engage in the
manufacture of glider vehicles by codifying an exemption to the GHG Phase 2 regulations for these
vehicles. As discussed earlier, while the proposal would be limited to entities that both installed engines
pursuant to 40 CFR §1037.150(j) and qualify for the small manufacturer exemption, the universe of
entities that meet these criteria likely is larger than the universe of existing glider vehicle manufacturers.
Any entity that sold vehicles under the provisions of 40 CFR § 1037.150(j), regardless of its size at that
time, could enter the glider-vehicle business as long as it qualifies as a small manufacturer at the time it
elects to sell glider vehicles. If it elects to provide an exemption for glider vehicles, EPA should limit
the exemption to entities that both qualified as small manufacturers in 2014 and sold vehicles produced from glider kits under the provisions of 40 CFR § 1037.150(j). [EPA-HQ-OAR-2014-0827-1290-A1 p.66]

Second, it does not appear that EPA has adequately considered the impact of its decision to delay
imposition of any limits on these vehicles until 2018, when it proposes to require currently certified
ingines. The Agency, in doing so, is creating still further incentive for substantially increased
production in 2016 and 2017. While pre-buys are a known consequence of new regulatory requirements
(as occurred in 2007 and could again in 2016 prior to the reduced engine GHG standards effective with
the 2017 model year), EPA need not exacerbate them by providing a window for the unfettered
manufacture of non-compliant vehicles. At a minimum, EPA should adopt additional stringent measures
to prevent the stockpiling of glider vehicles after new standards take effect, and/or pull forward the 2018 sunset date. [EPA-HQ-OAR-2014-0827-1290-A1 p.66]

Moreover, even if the Panel’s conclusion were accurate when viewed on the basis of production inventory, this analysis makes no account of the impact these vehicles have on the emissions inventory. As illustrated earlier, we find the impact to be huge. Given the magnitude of the environmental impact these vehicles have compared to the fully compliant vehicles other manufacturers are obligated to sell, it would seem appropriate not to include any such exemption, or to limit the number to much less than 300. The Panel recommendations cited continue by saying, “The Panel also stated that there should be an allowance to produce some number of glider kits for legitimate purposes, such as for newer vehicles badly damaged in crashes.” If the agencies are seeking to provide adequate volume to cover what have been characterized as “legitimate” applications of glider kits (wrecked vehicles and similar), it may be more appropriate to promulgate regulations that define allowed practices (repair of badly damaged vehicles) and prohibited practices (manufacture of new vehicles from new and used components that do not comply with current criteria and GHG emission requirements). If the agencies are seeking to provide a reasonable exemption to support the viability of small businesses already in existence today, we believe the recommendation of the panel to limit the exemption to “allow sales levels as high as the peak levels in the 2010-2012 timeframe,” while retaining the condition that the annual volume never exceed 300 units per manufacturer, is the absolute maximum relief that should be granted. However, Volvo Group believes that the limit should be on the production of vehicles, rather than the sale. [EPA-HQ-OAR-2014-0827-1290-A1 p.67]

EPA has requested comment on whether the Agency should permit the sale of glider vehicles on the condition that they are equipped with 2010 or later model year engines, or somehow treat glider vehicles equipped with 2010 and later engines differently. It’s unclear from the request for comment whether this provision would pertain to the units that are built under the limited annual small business exemption or to those that are produced by companies that do not qualify for the small business exemption (and those quantities sold in a year above the exemption cap). Anticipating that the latter is the intention, Volvo Group does not support such a relaxation of the “full compliance” obligation that EPA and NHTSA have proposed. [EPA-HQ-OAR-2014-0827-1290-A1 p.67]

Definition of “New Motor Vehicle,” “Glider Kit” and “Glider Vehicle”

EPA has proposed adding new definitions of “glider kit” and “glider vehicle,” and amending the definition of “new motor vehicle” to highlight that vehicles produced from glider kits are subject to the Clean Air Act, including 40 CFR Part 1037. As noted above, Volvo Group agrees with EPA that Part 1037, as currently drafted, already plainly covers these vehicles. That said, Volvo Group supports efforts to clarify the applicability of Part 1037 in this regard, including clarification of relevant definitions as appropriate. Volvo Group is concerned, however, that the proposed definitions and/or amendments related to glider kits and vehicles may create additional confusion. [EPA-HQ-OAR-2014-0827-1290-A1 p.67]

First, EPA proposes to add, for purposes of clarification, the following to the definition of “new motor vehicle”: “For example, vehicles commonly known as ‘glider kits’ or ‘gliders’ are new motor vehicles.” Volvo Group strongly supports the inclusion of language specifically recognizing vehicles produced from glider kits in this definition. However, we are concerned with the inclusion of the term ‘glider kit’ in this definition in so far as it indicates that all types of glider kits – taken alone – are subject to Part 1037 and the Clean Air Act. Where such a kit is incapable of being “self-propelled,” it does not fall within the definition of “motor vehicle” under CAA § 216(2). We would recommend EPA revise the
language to state, “For example, vehicles produced from ‘glider kits’ are new motor vehicles.” [EPA-HQ-OAR-2014-0827-1290-A1 p.67]

Second, Volvo Group recommends that EPA amend the proposed definition of “glider kit” as follows: Glider kit means a new vehicle that is incomplete because it lacks an engine, transmission, or drive axle. A glider kit may include previously used parts. A glider kit becomes a new motor vehicle upon the installation of an engine, transmission, and axles, regardless of whether the ultimate purchaser has received title or placed it into service. [EPA-HQ-OAR-2014-0827-1290-A1 p.68]

Third, Volvo Group recommends that EPA amend the proposed definition of “glider vehicle” to state: Glider vehicle means a vehicle produced from a glider kit, or a new vehicle produced with a used engine. Volvo Group believes these definitions will more closely align EPA’s proposed regulations to current practices and ensure that vehicles produced from glider kits do not circumvent Clean Air Act requirements. [EPA-HQ-OAR-2014-0827-1290-A1 p.68]

EPA and NHTSA Actions addressing Glider Kits are Appropriate

The rapidly expanding glider-based vehicle market is seriously undermining the significant gains EPA, NHTSA, and the heavy-duty vehicle industry have made to reduce criteria and greenhouse gas emissions, reduce fuel consumption, and improve roadway safety. Even at just a few percent of total Class 8 market sales, the level of PM and NOx emissions from these vehicles is on par with or exceeds the emissions from the balance of sales fulfilled by fully compliant products. The market availability of these non-compliant engines and vehicles poses an unfair competitive disadvantage to manufacturers that have undertaken the enormous effort and investment necessary to comply with all applicable emissions, fuel efficiency, and safety standards. It is therefore imperative that the agencies follow through by finalizing regulation that prohibits the production of glider-based vehicles for anything other than legitimate purposes and that the agencies actively ensure compliance to those requirements. [EPA-HQ-OAR-2014-0827-1290-A1 p.68]

Also included in the NoDA were arguments related to the agencies’ authority to regulate glider vehicles and trailers. The Volvo Group fully supports EPA’s and NHTSA’s efforts to achieve efficiency gains and criteria emissions reductions as related to gliders and trailers, and offer our comments that follow accordingly. [EPA-HQ-OAR-2014-0827-1928-A1 p.3] [[This comment can also be found in section 1.3.1 of the Comment Summary.]]

Comments on Legal Memorandum Pertaining to Trailers, Glider Vehicles, and Glider Kits under the CAA - EPA-HQ-OAR-2014-0827-1627

Volvo agrees with EPA that the Agency has authority to establish emissions standards for complete new motor vehicles, and further that glider vehicles – or vehicles manufactured from glider kits – constitute complete new vehicles for purposes of the Agency’s authority to establish emissions standards.\(^5\) Volvo further agrees that the installation of non-new engines, such as rebuilt or remanufactured engines or used engines from “donor” vehicles, in a glider vehicle in and of itself is not determinative of whether that vehicle is new for purposes of compliance with Clean Air Act requirements. As we noted in our comments on the Proposed Rule, glider kits can serve a legitimate purpose, such as allowing individual truck owners to re-use driveline components that had not yet accumulated end-of-life mileage following an accident or other event that renders the rest of the vehicle unusable.\(^6\) Volvo agrees, however, that such legitimate uses should not become a loophole through which truck manufacturers are able to produce otherwise new vehicles not subject to current emissions requirements merely by installing a rebuilt, remanufactured, or otherwise non-new engine in the vehicle. For these same reasons, Volvo
agrees that the assignment of a vehicle identification number (VIN) from a pre-existing vehicle to a glider vehicle should not be determinative of whether the glider vehicle is new, as EPA notes. Rather, EPA should consider a limited exemption for production of glider kits that permits their legitimate use as replacement components, similar to what the Agency already provides for new replacement engines. [EPA-HQ-OAR-2014-0827-1928-A1 p.24-25]

Volvo generally supports EPA’s proposal to require that engines used in glider vehicles be certified to standards for the model year in which these vehicles are assembled. See 80 Fed. Reg. 40528. Volvo also agrees that this proposal is within EPA’s legal authority given, as discussed above, glider vehicles are essentially new motor vehicles. Moreover, the regulatory language proposed by EPA is appropriately confined to a section of the regulations specifically applicable to glider kits, proposed 40 CFR § 1037.635. This is important, as this requirement, if applied more broadly, could impinge on the legitimate and legal use by vehicle manufacturers of engines that have a model year different from the calendar year in which a vehicle is assembled. For instance, vehicle manufacturers are permitted to use previous model-year engines that remain in a vehicle manufacturer’s existing inventory, even if the engine model year differs from the calendar year in which the vehicle is manufactured. [EPA-HQ-OAR-2014-0827-1928-A1 p.25]

5 EPA’s position, as referenced here, is set forth in the document entitled Legal Memorandum Discussing Issues Pertaining to Trailers, Glider Vehicles, an Glider Kits under the Clean Air Act, USEPA February 2016 – Draft, at 2. (hereafter “Legal Memorandum”).

7 Legal Memorandum at 2.

Worldwide Equipment strongly supports the agencies’ proposal to impose new requirements on companies assembling and offering for sale vehicles produced by installing used driveline components into new glider kits. EPA and NHTSA should require that manufacturers of these glider-based vehicles to comply with all applicable and current greenhouse gas and criteria emissions standards. NHTSA should also enforce the existing regulations that require manufacturers of glider-based vehicles to comply with all applicable safety standards. [EPA-HQ-OAR-2014-0827-0948-A2 p.1]

Dealers such as ours have been subject to a growing unfair competition from this rapidly expanding market of non-compliant vehicles. Worldwide Equipment supports the application of glider kits as a means to repair badly damaged vehicles, while taking advantage of the remaining useful life in the damaged vehicle’s driveline components. When conducted within the requirements of 49 CFR 571.7(e), which sets forth NHTSA’s rules for re-use of driveline components for installation into a glider kit, we have no specific concerns with such legitimate applications of glider kits. It’s when these rules are violated, however, in an effort to offer for sale an essentially new vehicle whose production costs and total cost of ownership may be tens of thousands of dollars less than the fully compliant new products sold by our dealership that we strongly object to such an unfair disruption of market competition. It is important to understand that the small number of companies ignoring the purpose and intent of the
glider kit regulations are creating significant environmental issues as between 8,000 to 10,000 of these noncompliant engines were put in to service in glider kit rebuilds last year alone. Unfortunately, this practice has become widespread without consequence to the glider based vehicle manufacturers, and it is unfairly and negatively impacting our business. [EPA-HQ-OAR-2014-0827-0948-A2 p.2]

In addition to not having to follow the environmental regulations that legitimate dealers like Worldwide have to follow, the manufacturers of glider-based vehicles, in many cases, are not collecting the 12% federal excise tax (“FET”) that normally applies to new vehicle sales, giving customers even further financial incentive to purchase glider vehicles rather than fully compliant new vehicles. In addition to creating an unfair financial advantage over legitimate dealers like Worldwide Equipment, this failure to collect the appropriate taxes hurts local and state governments as well which has a direct impact on the maintenance of transportation infrastructure that is so vital to the entire trucking industry. And this abuse of the glider kit regulations, as noted, creates significant environmental damage through the use of non-compliant engines and other components. [EPA-HQ-OAR-2014-0827-0948-A2 p.2]

This abusive application of glider kits must be stopped and Worldwide Equipment, Incorporated strongly support the agencies’ efforts to do so through appropriate new regulations and enforcement of existing regulations. EPA and NHTSA should seek to remedy this situation as soon as practicable. [EPA-HQ-OAR-2014-0827-0948-A2 p.2]

In conclusion, the rapidly expanding glider-based vehicle market is seriously undermining the significant gains EPA, NHTSA, and the heavy-duty vehicle industry have made to reduce criteria and greenhouse gas emissions, reduce fuel consumption, and improve roadway safety. The market availability of these non-compliant engines and vehicles poses an unfair competitive disadvantage to manufacturers that have undertaken the enormous effort and investment necessary to comply with all applicable emissions, fuel efficiency, and safety standards, and likewise an unfair competitive advantage to the dealer network representing those OEM’s. It is therefore imperative that the agencies follow through by finalizing regulations that prohibit the production of glider-based vehicles for anything other than legitimate purposes, and that the agencies actively ensure compliance to those requirements. [EPA-HQ-OAR-2014-0827-0948-A2 p.3]

Response:

Environmental Impacts of Gliders

Current standards for NOx and PM are at least 90 percent lower than the most stringent previously applicable standards, so the NOx and PM emissions of any glider vehicles using pre-2007 engines are at least ten times higher than emissions from equivalent vehicles being produced with brand new engines. 80 FR 40528. However, most gliders being produced today use engines originally manufactured before 2002. Since these pre-2002 engines lack both EGR and exhaust aftertreatment, they would have NOx and PM 20-40 times current engines. If miscalibrated, emissions could be even higher. Thus, each glider vehicle using an older engine that is purchased instead of a new vehicle with a current MY engine results in significantly higher in-use emissions233.

233 Thus, Mondial’s statement that the 10,000 plus glider vehicles now produced annually is insignificant compared to the total number of tractors produced is seriously misplaced. The 10,000 gliders have the environmental impact of at least 200,000 fully compliant new tractors.
Clarke Power Services commented that the EPA has “not adequately defined the impact of the current number of Gliders which are assembled each year” and that “additional studies need to be made to adequately define the “right” number of Gliders allowed.” However, we do not see how the current rates of production would affect the “right number” to allow going forward. As described below, even a small number of glider vehicles using pre-2002 engines can have severe public health impacts. As described in Section XIII.B of the FRM Preamble, EPA’s final regulations focus more on the ensuring the right type of gliders are produced using the right type of engines, rather than the right number. In an effort to lessen economic impacts on small businesses, we are reluctantly allowing certain small businesses to produce a limited number of glider vehicles using the higher emitting engines. However, this allowance is not based on our estimate of current or future production rates.

While EPA does not have precise estimates of current glider production, it is clear that production of glider vehicles has increased by an order of magnitude from what it was in the 2004-2006 time frame – from a few hundred each year to thousands.\(^{234}\) EPA has previously estimated environmental impact of 5,000 glider vehicles per year, which would be roughly 2% of the Class 8 vehicles manufactured annually. We estimated that at that rate, these gliders could account for as much as one-half of total NOx and PM emissions from all new Class 8 vehicles.\(^{235}\) Several commenters supported EPA’s assessment of the environmental impacts of glider vehicles. Volvo suggested in its comments on the NPRM that the impacts were even greater, estimating that 2014 glider sales were “on the order of 6,000” and that they emit twice as many tons of PM as the rest of the 2014 vehicles. Similarly, as Volvo noted in its comments:

> EPA’s own analysis as detailed in their recent glider Q&A document indicates that NOx and PM emissions from glider vehicles at current sales levels are equivalent to about 80 percent of the total NOx and PM emissions from the entire Class 8 sales fleet. Focusing on PM emissions, and applying the emissions levels indicated in Argonne National Lab’s recent update to the GREET Analysis,\(^{236}\) at just 3% market penetration of the most egregious applications, the 2014 glider fleet emits twice the level of PM emissions that the 97% entire fleet of compliant vehicle sales emits that same year.

Even some commenters opposing EPA’s proposal acknowledged that glider sales are now over 10,000 units annually.\(^{237}\) No commenters disagreed with EPA’s assessment of NOx and PM impacts. Clarke Power Services suggested that the growing shortage of older engines will limit the impact of gliders. However, as shown in Appendix A to this section, even a single year at current production rates has serious public health consequences.

For the final rule, EPA has updated its analysis of environmental impacts of gliders, reflecting the comments received. See Appendix A to this Section 14. We project that without the new restrictions, glider vehicles on the road in 2025 would emit nearly 300,000 tons of NOx and nearly 8,000 tons of diesel PM annually. Although glider vehicles would make up only 5 percent of heavy-duty tractors on

---

\(^{236}\) The GREET Model Expansion for Well-to-Wheels Analysis of Heavy Duty Vehicles, ANL/ESD-15/9, Argonne National Laboratory, May 2015.

\(^{237}\) In its comments, Fitzgerald indicated that current sales of glider vehicles exceed 10,000 vehicles annually but termed these amounts “insignificant” compared with the total number of trucks. Unfortunately, as shown in the text above, this is not the case. Criteria pollutant emissions impacts of 10,000 glider vehicles is equivalent to at least 200,000 fully compliant new trucks.
the road, their emissions would represent about one-third of all NOx and PM emissions from heavy-duty tractors in 2025. Put into monetary terms using PM-related benefit-per-ton values described in Section IX.H, the removal of all unrestricted glider vehicle emissions from the atmosphere would yield between $6 to $14 billion in benefits annually (2013$). It is clear that removing even a fraction of these glider vehicles from the road will yield substantial health-related benefits. Moreover, the PM valuation is for particulate matter generally. Although there is evidence suggestive of a causal relationship between long-term PM_{2.5} exposures and carcinogenic effects (see 78 FR 3101/3 (Jan. 15, 2013), the causal connection with diesel PM (diesel exhaust) and carcinogenic effects is stronger. As described in Preamble Section VIII.A (6), exposure to diesel exhaust was classified as likely to be carcinogenic to humans by inhalation from environmental exposures, in accordance with the revised draft 1996/1999 EPA cancer guidelines.\textsuperscript{238,239} A number of other agencies (National Institute for Occupational Safety and Health, the International Agency for Research on Cancer, the World Health Organization, California EPA, and the U.S. Department of Health and Human Services) had made similar hazard classifications prior to 2002. EPA also concluded in the 2002 Diesel HAD that it was not possible to calculate a cancer unit risk for diesel exhaust due to limitations in the exposure data for the occupational groups or the absence of a dose-response relationship. In the absence of a cancer unit risk, the Diesel HAD sought to provide additional insight into the significance of the diesel exhaust cancer hazard by estimating possible ranges of risk that might be present in the population. An exploratory analysis was used to characterize a range of possible lung cancer risk. The outcome was that environmental risks of cancer from long-term diesel exhaust exposures could plausibly range from as low as $10^{-5}$ to as high as $10^{-3}$.

A quantified risk analysis is included in Appendix A to this Section 14. As discussed further below, this analysis indicates that for a single model year, assuming the use of 5,000-10,000 high polluting engines in glider vehicles, PM$_{2.5}$-related exposures are estimated to result in 350 to 1,600 premature mortalities. Several commenters argued that EPA is precluded from adopting any controls on installation of high polluting engines in glider vehicles until MY 2021. This could mean the production of 30,000 to 40,000 additional glider vehicles using the older high polluting engines. Using the same assumptions as above, these three additional model years of production are estimated to result in an additional 2,100 to 6,400 premature mortalities. Some commenters seemed to suggest that the trend of increasing production of glider vehicles with high polluting engines would eventually reverse itself, but this analysis shows that EPA cannot simply wait for this problem to go away on its own.

The EPA regards these estimates as significantly conservative. First, based on the public comments from both glider vehicle producers and producers of engines which comply with current standards, it likely underestimates the number of glider vehicles with high-polluting engines produced today. Second, the analysis considers only potential premature mortality attributable to exposure to PM$_{2.5}$. This is conservative for at least three reasons. First, it does not account for the carcinogenic potential of diesel exhaust PM, which is a subset of PM$_{2.5}$. Second, it does not consider other health and welfare benefits of reducing exposure to PM$_{2.5}$ (see Appendix Table A-5). Third, it does not quantify premature mortality and other health effects attributable to exposure to ozone. Although ozone is not emitted directly, the chief precursor is NOx (see Preamble section VII.A (3) and 80 FR 65299-300 (Oct. 26, 2015)), which glider vehicles emit in huge quantities, as noted above.

Some commenters argued that gliders offer an efficiency advantage compared to continuing to use older trucks, and that glider use also resulted in reduced HFC emissions from the A/C systems. However, this is a false comparison. While it may have been valid when glider vehicle sales were less than 1,000 per year, it is not valid for current sales. As supported by comments from truck manufacturers and dealerships, glider sales now come at the expense of sales of fully compliant new trucks. Nor is the commenters’ assertion regarding HFC emissions persuasive given the A/C leakage controls for tractors adopted in the Phase 1 rules. Some commenters stated that remanufacturing an engine and transmission uses 85% less energy than manufacturing them new, but did not provide an analysis for EPA to

---

240 See, e.g., Comment from Nuss Truck: “Dealers such as ours have been subject to a growing unfair competition from this rapidly expanding market of non-compliant vehicles. …[T]ruck purchasers have the ability to purchase a powertrain combination that they never owned in an existing truck, from assemblers who have chosen to exploit the law put in place that was intended to clean up air pollution. The original intent of selling glider kits has moved from a rebuilding mechanism to now mainly evading diesel emissions EPA mandates. We see many truck owners and small fleets from Minnesota and Wisconsin traveling long distances, passing by dozens of legitimate truck dealers, to purchase glider kits directly from a manufacturer in another state, just to avoid the current EPA emissions standards. That should not be a legally acceptable reason to purchase a glider kit, if we all want clean air.”

241 The comment of Truck Country of Wisconsin similarly describes the competitive conundrum facing dealers selling tractors with compliant engines: “1. We agree with EPA’s assessment that most gliders manufactured today use remanufactured model year 2001 or older engines. Typically these engines have and NOX and particulate matter (PM) emissions 20 to 40 times higher than today’s clean engines. Since 2010 when EPA’s current NOx and PM standards for heavy duty engines took effect, glider sales have increased nearly 10-fold as compared to the 2004-2006 time frame; 2. We agree with EPA that this increase reflects an attempt to avoid using engines that comply with EPA’s 2010 standards, and is an attempt to circumvent the Clean Air Act purpose to protect human health and the environment; 3. The Trucking Industry has made enormous investments in new engines standards to comply with past and future EPA regulations. We believe this circumvents these standards and will make it harder to meet compliance; and 4. We agree with EPA’s Clean Air Act definition of ‘new motor vehicle’ is not based on the condition of the parts assembled to create the vehicle but rather encompasses the entire vehicle, even if they incorporate some previously used components.”
evaluate. Clarke Power Services commented that newly rebuilt engines have lower criteria emissions than a “worn oil burning engine which is beyond its useful life.” However, that is not relevant to this discussion since engines can be rebuilt without replacing the chassis. The appropriate comparison is to new vehicles with fully compliant new engines. When compared to these engines, even the most carefully rebuilt and recalibrated 1998-vintage engine would have NOx and PM emissions at least 20 times as high as engines meeting current standards.

Finally, some commenters stated that glider engines actually have better fuel economy and greenhouse gas (“GHG”) emissions than today’s low NOx engines. However, this is not true. Even before Phase 1, engine manufacturers had improved fuel consumption significantly beyond 2009 levels. The 2014 Phase 1 standards required significant additional improvement and the Phase 1 2017 standards will result in even more improvement. Fleets purchasing gliders would thus see greater efficiency improvements by purchasing trucks meeting GHG standards for new vehicles and engines.

Potentially Legitimate Purpose of Gliders

Although EPA is addressing this issue because of the adverse public health and environmental impacts of glider vehicles, many commenters (including some who supported EPA’s proposed restrictions), commented that glider kits serve a legitimate purpose in some cases. Most identified cases in which relatively new vehicles suffer significant frame damage as the result of an accident or from a severe duty application, without significant damage to the driveline. Volvo stated:

> The “glider kit” emerged some decades ago as an assemblage of new vehicle components absent the engine, transmission, and rear axles (the “driveline”). These kits were produced by vehicle OEMs, and made available for sale to dealers and other vehicle repair centers as a means to repair a vehicle that had been badly damaged in an accident or similar event. This permitted re-use of driveline components that had not yet accumulated end-of-life mileage by the time of the accident.

Some commenters misinterpreted EPA statements about the “most legitimate” use of gliders in the NPRM and NODA to be a determination that some use of glider kits is legitimate. Although EPA has not taken a position on whether such use of glider kits is truly legitimate, we do agree that circumstances such as those addressed by Volvo represent their most legitimate use. Volvo commented that any allowances for glider kits should be limited to these legitimate purposes. While we are generally sympathetic to the goal of limiting the use of glider kits to the most legitimate circumstances, we do not think it would be possible to enforce restrictions based on the intent of the operator or assembler, so that such a regime would invite abuse (and thus serve to perpetuate environmentally unsound practices). We are also concerned that it would be difficult to enforce requirements based on the condition of the donor vehicle as a proxy for intent since the donor vehicle will typically be destroyed as part of the process. To the extent we reflect any of these factors in our regulations, we believe it will be more enforceable to base the requirements on the age and mileage of the engine, as explained in the following section of this response.

Some commenters suggested that another legitimate purpose of glider kits is to improve efficiency. For example, Clarke Power Services stated that trucking fleets purchasing glider vehicles “are not motivated by circumventing the EPA policies, but are most interested in being more efficient by removing old equipment from service and introducing a significantly improved heavy duty truck in its place.” We do not agree. First, the significant adverse public health and environmental consequences of order of magnitude and greater increases in NOx and diesel PM emissions would exist even if the commenter were correct. The commenter is in any case mistaken in suggesting that glider vehicles have a fuel efficiency advantage over new tractors. As explained above, with the advent of the Phase 1 GHG and
fuel consumption standards, fleets purchasing gliders would see greater efficiency improvements by purchasing trucks meeting GHG standards for new vehicles and engines. Although this would cost more upfront, these costs would be recouped via greater fuel savings within the first few years of ownership.

Treatment of Donor Engines within their Useful Life

In section (i) of the legal memorandum on issues pertaining to trailers, glider kits, and glider vehicles accompanying the Notice of Data Availability, EPA requested comment on finalizing special provisions for gliders using engines that are still within their original regulatory useful life (10 years and 435,000 miles for Class 8 vehicles) that would allow relatively new engines to be reused in gliders without recertification to standards corresponding to the year of assembly of the glider vehicle. Such engines would necessarily be cleaner than the pre-2002 engines being used in most gliders today, and by 2021, all would be compliant with the 2010 standards. This allowance would also be inherently consistent with the most legitimate use of glider kits because no one would scrap a chassis within the useful life unless it was severely damaged. Commenters generally supported this approach. Many also supported the additional approach EPA discussed in conjunction with the NODA that would ignore miles if the donor engine is less than three years old and ignore years if the engine had less than 100,000 miles. (These additional allowances would provide some additional flexibility for an engine not fully within its useful life). Some commenters argued that such a provision should only apply with respect to miles, and that EPA should not restrict this flexibility based on engine age so as not to disadvantage engines in very low usage applications. E-One’s comments suggested that EPA should adopt provisions to address emergency vehicles that last 10 to 20 years but may have traveled only 10-50,000 miles.

After considering these comments, EPA has decided to finalize the approach described in the NODA. (As described later, the proposed small business flexibility is also being adopted, but as an interim provision). We believe this addresses the most traditional, legitimate use of glider kits, which is for vehicles in severe duty applications (such as cement mixers and dump trucks) that incur substantial chassis damage before the engine reaches the 10-year end of its regulatory useful life. By 2020 nearly all glider vehicles would have to be produced using engines meeting the 2010 NOx and PM standards (since an older-than-10 year engine would be outside its regulatory useful life). Because the potential for adverse environmental effects from such vehicles is significantly reduced (compared to the more common current use of pre-2002 model year engines, with their much higher criteria pollutant emissions), EPA is allowing their continued use in glider vehicles without recertification to more stringent criteria pollutant standards, and without meeting GHG standards.

This approach provides this flexibility to very low use applications, such as those identified by E-One, where donor engines have less than 100,000 miles after 10 years. The final regulations will thus allow reuse of an engine more than 10 years old without recertification, as long as the engine can be shown to have fewer than 100,000 miles on it. The environmental impact of allowing this should be minimal because there should be very few engines that qualify and they will necessarily be in applications that operate infrequently. (Any vehicles that operate more than 10,000 miles per year would exceed 100,000 miles before 10 years).

At the other extreme, some Class 8 vehicles may reach 435,000 miles within a few years. Today’s Class 8 engines and vehicles are generally expected to last well beyond this point, so such engines would be installed in glider kits only if the chassis was defective or had been in a major accident. The NODA approach, which is being adopted, treats these engines as being within their useful life as long as they are less than 3 years old. This approach was supported by NADA. The environmental impact of allowing this should also be minimal because there should be very few engines that qualify and they will necessarily be engines certified to 2010 or later standards.
Treatment of MY 2010 and Later Donor Engines

Several commenters supported allowing unlimited production of glider vehicles if they use engines certified to 2010 or later NOx and PM standards, although Volvo opposed this concept. Daimler commented that “2010 and later engines are not currently being used in glider vehicles in large numbers,” but Clarke Power Services commented that the “industry is currently considering MY 2010 engines as the choice for Gliders moving forward.” EPA sees merit in this concept, but is concerned that it may not be appropriate in perpetuity. Obviously, reuse of engines originally certified to the 2010 standards for criteria pollutants would not have the same adverse environmental impacts as the current practice of reusing pre-2002 engines that have NOx and PM emissions 20-40 times higher than current engines. However, they would not necessarily be as clean for GHG or criteria pollutants as brand new engines with all new aftertreatment components. The Phase 1 and Phase 2 engine standards will result in brand new engines with lower GHG emissions (and better fuel efficiency) than pre-Phase 1 engines. And used 2010 aftertreatment components may be less effective at reducing NOx or PM than when new. Moreover, as described in Section I of the FRM Preamble, EPA may adopt more stringent NOx and/or PM standards for motor vehicles in the future. Thus, while using 2010 engines in glider vehicles would greatly reduce the concerns about NOx and PM emissions relative to current gliders, it would not eliminate all adverse public health and environmental impacts.

Sales patterns strongly support the idea that the surge in glider sales resulted from an attempt to avoid the 2010 criteria pollutant standards. Thus, it seems likely most purchasers of gliders today would not find gliders with 2010 engines nearly as attractive as they do current glider vehicles. Thus, we would not expect such an allowance to result in a continuation of the current surge in glider sales.

In an attempt to balance these factors, EPA is finalizing an interim provision – a provision which will sunset after EPA adopts new more stringent NOx and/or PM standards for motor vehicles in the future. Thus, while using 2010 engines in glider vehicles would greatly reduce the concerns about NOx and PM emissions relative to current gliders, it would not eliminate all adverse public health and environmental impacts.

Legal Authority to Regulate Complete Glider Vehicles and Incomplete Glider Kits

See Section 1.3.1 and preamble Section I.E.(1) for a discussion of EPA’s authority to regulate glider vehicles and glider kits. In addition, DTNA’s argument that this rulemaking should not address gliders because the primary focus of the rulemaking is control of GHGs rather than criteria pollutants, EPA notes that it gave ample notice of all issues relating to gliders, and provided multiple opportunities for public comment. The many comments on the issue from all types of stakeholders confirm the adequacy of notice here. The further comment that regulations on GHGs should not deal with other pollution has no legal basis. DTNA also commented that the engine rebuilding authority in section 202 (a)(3)(D) was not properly invoked because EPA had not proposed to amend the engine rebuilding regulations. EPA has included conforming amendments to 1037.150 (j), and 1068. 120 (f) in the final rules. DTNA’s argument that the rule addresses vehicle rebuilding, rather than engine rebuilding, is not correct. In addition to the reasons addressed in Preamble Section I.3, it is clear that the statutory authority over engine rebuilding authorizes EPA to determine what standards a rebuilt engine shall meet. See CAA section 202 (a)(3) (D) stating that “the Administrator may prescribe requirements to control rebuilding practices, including standards applicable to emissions from any rebuilt heavy-duty engines (whether or not the engine is past its statutory useful life).” Comments from, e.g. Mondial and MEMA made clear that all of the donor engines installed in glider vehicles are rebuilt. See also
1999 to 2002-model diesels were known for reliability, longevity and good fuel mileage. Fitzgerald favors Detroit's 12.7-liter Series 60 from that era, but also installs pre-EGR 14-liter Cummins and 15-liter Caterpillar diesels. All are rebuilt ....

Lead Time

See Section 1.3.1 of this RTC and preamble Section I.E.(1) for a discussion of EPA’s statutory obligation for lead time with respect to gliders and glider kits. From a more practical perspective, we note that little lead time is needed for the changes being adopted. Glider kit manufacturers already offer comparable vehicles that are fully compliant with current standards, and thus do not need extensive lead time. Such vehicles are often identical to the completed glider vehicles other than the powertrains.

Most small glider vehicle assemblers do not need additional lead time because they will be allowed to continue assembling gliders at pre-2015 rates. We are aware of one glider kit assembler that produces more than 300 vehicles from glider kits each year and it will need to reduce its production in 2017 and later. However, we do not believe that manufacturer truly needs additional lead time. This manufacturer indicates that it fills orders for glider vehicles within three to six weeks from placement of the order, which means the new restrictions should not impact any existing orders. 242 Any vehicles that are already on order should be completed before 2017. For 2017, the regulations will allow this manufacturer to produce at its 2014 production rate. This 2017 restriction applies with respect to the total annual production for 2017, so the manufacturer will be allowed to gradually reduce its production of high polluting glider vehicles. This provides sufficient lead time for it to find compliant engines before its production limit drops to 300 in 2018. It is unclear that additional lead time would change anything for this manufacturer other than allowing it to produce additional high polluting glider vehicles.

Finally, any consideration of lead time must necessarily be balanced against the potential environmental and public health impacts. As shown in Appendix A to this section, even a small number of additional glider vehicles would have severe impacts. For example, a one-year delay that allowed 10,000 additional glider vehicles to be produced with high polluting engines would result in the following impacts:

- 415,000 tons of addition NOx emissions
- 6,800 tons of additional PM emissions
- 700 to 1,600 premature deaths
- $3 to $11 billion in PM-related monetized disbenefits

Given the severity of these impacts, delaying these provisions cannot be justified by merely the potential for inconvenience to the industry. Rather commenters would needed to have demonstrated that it is not feasible to comply with these requirements within the lead time provided. They have not done so. Most commenters supporting additional lead time focused on statutory requirements that were addressed in Section 1.3.1. Commenters that did address economic impacts merely speculated about the impacts or made vague references to jobs or small business impacts. Of course, as many commenters pointed out, glider vehicle production with high polluting engines comes at the expense of domestic manufacturers producing engines complying with the latest criteria pollutant and GHG standards. See further discussion of Economic Impacts below. No commenters provided any specific basis that would justify

242 Advertisement for Fitzgerald Glider Kits in Overdrive magazine (December 2015).
delaying the prevention of premature mortalities and billions of dollars of benefits achievable by implementing these provisions according to the final regulations.

**Small Business Impacts**

Several commenters expressed concern about the impact of the proposed changes on small businesses that produce glider vehicles. However, commenters opposing the proposed requirements/clarifications did not address the very significant adverse public health and environmental impacts of the huge increase in glider vehicle production over the last several years. More importantly, EPA believes that with the changes being made in the final regulations, any small businesses that have been focused on producing gliders for traditional and legitimate purposes will not be significantly impacted by the new requirements, since they can use donor engines within their regulatory useful life for either age or mileage. Only those that have significantly increased production to create new trucks to circumvent the 2010 NOx and PM standards will have their sales significantly restricted. We are aware that Fitzgerald Gliders currently produces more than 300 vehicles from glider kits, and they appear to use all pre-2002 engines. It will need to cut back on its production of these vehicles (although it can continue unlimited production using low-polluting engines). Nevertheless, the company has previously acknowledged that they could “make a profit at 300 a year.” Now Fitzgerald Gliders comments that “300 vehicles is too low given the abrupt change this regulation brings to the 50-year-old glider industry and the disproportionate impact it will have on small businesses.” However, it failed to acknowledge in its comments that for most of the “50-year-old glider industry” total industry-wide production of glider vehicles was much closer to 300 per year than to current production rates. Fitzgerald Gliders also failed to note how rapidly they have increased production of glider vehicles over the last few years.

One commenter stated that EPA should also consider the impacts on small trucking companies. But here too, for the same reasons, trucking companies that seek gliders for traditional, legitimate purposes should be able to obtain them. Only those companies that seek to use older engines will be impacted, and these companies can produce glider vehicles using readily available compliant engines.

Some commenters argued that EPA did not include enough glider manufacturers in the SBREFA process. However, EPA met its obligations under SBREFA. See generally RTC section 15.4. One of the Small Entity Representatives was a manufacturer of glider vehicles. Small businesses also had two opportunities to provide comments on the requirements. It is unclear how having additional glider manufacturers involved in the process would have changed its result.

Volvo also commented that EPA should clarify that the exemption is limited to entities that both qualified as small manufacturers in 2014 and sold vehicles produced from glider kits under the provisions of 40 CFR § 1037.150(j). We believe that this is what the final regulations clearly state. However, DTNA commented that “EPA’s current proposal unfairly penalizes those small businesses that did not sell gliders in 2014, but might have sold them in 2013 or 2015.” However, the small business provisions are intended to prevent the regulations from having a significant impact on the businesses. It is unclear how any restrictions of gliders could have any impact on a business that sold none in 2014 that would meet the threshold for “significant.” Clearly, glider sales cannot be an important portion of a company’s revenues if they sold none in 2014.

---

PACCAR commented that EPA should eliminate the small business allowance altogether beginning in MY 2022 for gliders using pre-2010 engines. TCW opposed any relief for small businesses that assemble gliders, and Volvo commented that EPA should eliminate the small business exemption sooner than proposed. Consistent with Volvo’s comments on the risk of a pre-buy, we are finalizing an additional restriction for 2017. Nevertheless, while EPA may eliminate or reduce the small manufacture provisions in a future rulemaking, such an action at this time would be inconsistent with the SBREFA Panel’s recommendations, which EPA is choosing to largely follow to afford small businesses sufficient compliance flexibility, and to preserve opportunities for traditional uses of glider kits to provide a means of salvaging viable engines from non-viable powertrains. During the SBREFA process, EPA concurred with these recommendations, and without some more compelling reason, we believed it to be appropriate to allow this flexibility. Our recent reanalysis of the environmental impacts of even this small number of gliders suggests we may need to revisit it at some point within the Phase 2 time frame, especially if we find that this flexibility is being misused.

Terex Corporation comment that EPA should provide an exemption for any company manufactured fewer than 1,000 on highway vehicles annually between calendar years 2010 and 2014. However, we believe the other flexibilities allowing the use of newer engines will largely address Terex Corporation’s concerns.

Sales Caps

EPA received comments supporting higher caps and comments supporting lower caps. Commenters supporting higher caps did not argue that higher caps were necessary to allow for legitimate production at or below pre-2006 levels. Instead, these commenters seemed to be concerned solely about allowing continuation of very high sales. We see no basis for that. This would perpetuate the very conduct – continued use of high-pollution engines in contravention of standards for new vehicles and engines – which this action is intended to restrict. One commenter argued that the caps should be raised to account for the likelihood that the number of small businesses assembling glider vehicles would decrease as a result of the rule changes. However, we think the other revisions being made to allow additional glider vehicles to be produced without a sales cap (i.e. allowing continued use of donor engines within their useful life for either mileage or age) will offset any impacts on the availability of gliders that might result from a reduction in the number of businesses in this market.

Combined with the other flexibilities in the final rule, this small manufacturer allowance should allow the industry to produce glider vehicles near pre-2006 levels. While there may be disruptions for some companies, higher caps cannot be justified by merely the potential for inconvenience to the industry or even significant disruption for a few companies. Fitzgerald Gliders currently produces more than 300 vehicles from glider kits and is likely to be the small business that will be most impacted by this cap, but as noted above, they have acknowledged that they could “make a profit at 300 a year.”

EPA also received comments supporting potentially lower cap levels. ICCT agreed that glider sales should be restricted to a number that is consistent with pre-emission-regulation glider production, which they stated should be on the order of hundreds of units per year industry wide. Navistar suggested the cap be lowered to 200 units per year. Volvo commented that the cap is too high and that small manufacturers should not be allowed to exceed “the peak levels in the 2010-2012 timeframe” to be consistent with the SBREFA Panel Report. EPA is not reducing the maximum cap level or basing it on only 2010-2012 sales at this time. As just noted, it is clear that the cap of 300 glider vehicles will allow existing small businesses to remain profitable. Thus, as an interim policy, we believe this level

---

appropriately balances the environmental and economic impacts. See CAA section 202 (a)(3)(D) requiring consideration of “cost of compliance” as part of the standard setting process for rebuilt engines. Nevertheless, we recognize that this allowance will result in significant additional emissions of NOx and PM. We will continue to monitor this market and may lower these values in the future.

Consistent with Volvo’s comments, the final regulations apply the cap as a production cap rather than a sales cap.

Definitions

Terex asked for clarification of the proposed definition ‘glider kit’ to mean ‘any other new equipment that is intended to become a motor vehicle with a previously used engine, include a rebuilt or remanufactured engine.’ We have added the clarifying condition that this includes only assemblies that are “substantially similar to” complete vehicles. Volvo suggested the following definition of “glider kit”:

Glider kit means a new vehicle that is incomplete because it lacks an engine, transmission, or drive axle. A glider kit may include previously used parts. A glider kit becomes a new motor vehicle upon the installation of an engine, transmission, and axles, regardless of whether the ultimate purchaser has received title or placed it into service.

EPA explained in Section 1.3.1 why we believe glider kits are new motor vehicles, albeit incomplete motor vehicles. See also preamble section I.E.1 explaining further that in any case, manufacturers of entities assembling glider kits are “manufacturers” under the Act and can consequently can be required to test and certify. Volvo’s proposed definition would not be consistent with this. Nevertheless, we agree with Volvo that the glider vehicle provisions should not prevent vehicle manufacturers from using up their normal inventory of prior model year new engines when producing conventional new motor vehicles. The definitions being adopted will not interfere with this practice.

Identical Standards

Daimler commented that EPA should define “identical standards” to avoid uncertainty. As an example, they stated it is “unclear whether, under EPA’s proposed regulations, an earlier model year engine could be used in a glider vehicle assembled in a year when new OBD requirements are in effect.” In other contexts (such as export exemptions) EPA has previously interpreted this term strictly. This would clearly not allow differences in something as important as OBD requirements.

Economic Impacts

Commenters opposing the proposed changes argued that they would adversely impact hundreds of jobs. MEMA stated that the motor vehicle remanufacturing industry supports over 50,000 direct jobs in the U.S. Other commenters noted that allowing glider vehicle sales adversely impacts those producing and selling conventionally new vehicles, and penalizes those entities playing by the rules and producing new vehicles which pollute far, far less. In particular, several dealers that do not sell gliders commented that allowing gliders to circumvent newer emission controls creates an unfair competitive market. Volvo commented that gliders have an unfair competitive advantage because the “cleanest, most fuel efficient and safest vehicles are necessarily tens of thousands of dollars more costly to produce” than glider vehicles.

Considered together these comments suggest that jobs in the glider industry come at the expense of other jobs in the heavy-duty industry. Although EPA takes seriously any impacts on workers in the
glider industry, they do not justify allowing the continued avoidance of emission standards which results in millions of tons of additional pollution and substantial avoidable public health risks, especially considering the adverse impacts glider sales have on other workers in the U.S. Clarke Power Services commented that the “industry is currently considering MY 2010 engines as the choice for Gliders moving forward.” This suggests that any economic impacts compared to what would have happened without regulation are short-term rather than long-term.

Other commenters stated that gliders offer many advantages for operators over used trucks, including lower operating costs and improved safety. However, these operators could achieve these same or greater benefits by purchasing fully compliant new vehicles. MFX noted costs associated with the 2007-era vehicles, but they are no longer relevant. As noted above, with the advent of the Phase 1 standards, and even more so under the 2017 Phase 1 standards and, later, Phase 2 standards, operators will be able to purchase fully optimized Phase 1 or Phase 2 vehicles that will have much better fuel efficiency and reliability than the 2007 products.

Finally, some commenters argued that EPA should consider the economic impacts on small trucking companies that purchase glider vehicles or pay others to assemble glider vehicles from their donor vehicles. While we understand that small trucking companies may have less capital to purchase fully compliant new trucks than larger companies, we note that new glider vehicles are not inexpensive—generally costing at least two-thirds as much as a fully compliant new vehicles. Thus, any impact on these trucking companies would be marginal. Moreover, engines meeting the 2017 Phase 1 standards are likely to be more fuel efficient than the rebuilt pre-2002 engines, so these companies would likely recover the additional purchase costs from fuel savings.

Used Engines

One commenter suggested that EPA should prohibit the installation of used engines unless they have been rebuilt to the original certified configuration so as to (in the opinion of the commenter) reduce PM, NOx, and GHG emissions. However, as explained earlier, we believe the most legitimate use of glider kits is to salvage used components from newer vehicles that have been damaged in accidents. Thus, it would not be appropriate to ban used engines that have not been rebuilt to any particular configuration.

Labeling and Delegated Assembly

PACCAR commented that EPA should not require a unique label for glider vehicles that will be used in vocational applications. However, because glider vehicles are new vehicles they must comply with the same Phase 2 requirements as any other new motor vehicles. This includes proper labeling identifying the standards to which the vehicle is certified.

Similarly, for all glider vehicles produced by multiple manufacturers, the manufacturers must comply fully with the requirements of §§1037.620 through 1037.622. PACCAR’s comments urging less rigorous requirements for glider kits miss the point of these requirements, which is to ensure that the completed vehicles are in their proper certified configuration when placed into service. It is the manufacturer’s choice to produce vehicles in this way. If they find it too difficult to ensure the completed glider vehicles conform to the regulations, they can simply not offer glider kits similar to

Note again that removal of engines from donor vehicles, and installation of that engine into another vehicle continues to fall under the engine rebuilding provisions of part 86.004-40. See 86.004-40 second sentence (referred to “removal” which encompasses removal and installation into another vehicle).
current competitors. Nevertheless, as described in Section 1.4.4 of this RTC, we have revised the proposed delegated assembly requirements more generally, which may address some of PACCAR’s concerns.

**Natural Gas**

NGV America commented that the regulations should allow greater flexibility for natural gas fueled gliders because they are cleaner than diesel gliders. Diesel 2 Gas, Inc. commented that glider kits “are the only means by which hundreds of thousands of Class 8 Trucks can have access to natural gas as an engine fuel.” They stated that 2010 and newer engines “cannot be converted efficiently to dual fuel mode with any known technology” because of their electronics. However, we believe that the issue of circumvention is a concern for both natural gas and diesel gliders. We do not believe these comments justify special provisions for natural gas. Natural gas engines may be cleaner than diesel engines of the same vintage with respect to NOx and PM emissions, but natural gas conversions of older engines are not inherently cleaner than today’s SCR and DPF equipped diesel engines.

As noted earlier, glider vehicles are new motor vehicles, even if they reuse an engine from another vehicle. This is even more obviously true when the engine is converted from diesel fuel to natural gas as part of the process of producing the new glider. Such a vehicle retains even less of a connection to any existing vehicle. Moreover, the nature of the process addressed by NGV and Diesel 2 Gas suggests the purpose is to produce a new natural gas vehicle, rather than to salvage a newer powertrain from a damaged chassis. Thus, an argument could be made that they deserve less (not more) accommodation. EPA has no objection to conversion of existing vehicles to natural gas. However, natural gas gliders are more likely competing against other new vehicles that are fully compliant with current standards for criteria pollutants, as well as for GHGs. If Diesel 2 Gas is unable to convert newer engines, they are free to convert the older engines that remain in the older chassis. By retaining the old chassis, they would not be subject to the new glider kit requirements.

**Consideration of Existing NHTSA Regulations**

Some commenters suggested that EPA’s regulations should reflect principles laid out in existing NHTSA regulations. For example NADA/ATD urged EPA to harmonize with NHTSA’s regulations that require there to be a single “donor” vehicle from which two of three used components (engine, transmission, and drive-axle) are incorporated into the rebuilt vehicle. NADA/ATD further commented that “when two of these three used components are incorporated into a rebuilt vehicle, using a glider kit, the used engine would only be required to meet emission standards applicable to its year of original manufacture.” However, those regulations were promulgated pursuant to different statutory authority. They were also develop for different, albeit related purposes. Thus, EPA does not consider them to be necessarily relevant to this action. More importantly, such comments ignore the severe public health impacts of glider vehicles. These impacts are not lessened in anyway if the components come from a single donor vehicle.

**14.3 Technical Amendments - Heavy-Duty Vehicles Other than GHG**

Low Sulfur Labeling
regulation regarding Tier 3 fuels will remove this fuel from the marketplace. [EPA-HQ-OAR-2014-0827-1238-A1 p.36]

Response:
We amended 40 CFR 86.007-35(c) to discontinue vehicle labeling for ULSD, effective with model year 2014, on February 19, 2015 (80 FR 9101).

14.3.1 Alternate Emission Standards for Specialty Heavy-Duty Vehicles

Comment - Use of non-road engines in on-road vehicles

The NPRM requests comment on the “technical and regulatory issues surrounding the use of engines from chassis-certified vehicles in certain heavy-duty vehicles” and “on all aspects of this program to create alternate motor-vehicle emission standards that allow certified non-road engines to be used in the identified types of heavy-duty highway vehicles.” CARB generally supports U.S. EPA and NHTSA’s desire to facilitate the certification of innovative technologies that reduce GHG emissions, recognizes why U.S. EPA and NHTSA are considering allowing non-road engine use in hybrids, and lauds U.S. EPA and NHTSA’s seeking to encourage development of hybrid technology. In fact, CARB staff is considering provisions in its proposed Innovative Technology Regulation that would similarly allow limited use of non-road engines in on-road heavy-duty hybrids, but only in well-defined, limited situations (more detail on the Innovative Technology Regulation is at http://www.arb.ca.gov/msprog/itr/itr.htm ). As discussed further below, CARB staff believes that certain safeguards must be incorporated in 40 CFR 1037.605 to ensure that the provisions for innovation do not inadvertently allow abuse and unintended emission increases. [EPA-HQ-OAR-2014-0827-1265-A1 p.91-92]

From a technical perspective, the proposal to allow the use of downsized engines, including non-road engines, in on-road hybrid vehicles is justifiable. The combustion engine that is sized for use in a specific heavy-duty vehicle class is, in some cases, oversized, when installed in a hybrid vehicle in the same vehicle class. This is due to the sharing of the vehicle power load requirements by the electric motor in a hybrid system. The result is the combustion engine is occasionally being forced to operate in non-optimal regions of its torque map, which could lead to reduced engine efficiency and increased criteria pollutant emissions, as we have observed in a recent CARB-funded study conducted by NREL (available on our website at http://www.arb.ca.gov/msprog/aqip/hybrid test.htm). We also agree that, if properly structured, using non-road downsized engines has the potential to reduce both fuel consumption and emissions in hybrid vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.92]

Using non-road engines in a hybrid vehicle makes the most sense in series hybrid configurations where the primary purpose of the combustion engine is to provide power to charge the batteries that are used to propel the vehicle. The combustion engine in a series hybrid configuration can then be operated in a narrow region where it is most efficient and where its emissions can be more effectively controlled. CARB staff recommends against allowing the use of non-road engines in parallel hybrid applications due to the larger range of engine operating parameters that must be controlled in order to minimize criteria pollutant emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.92]

CARB staff recommends that U.S. EPA and NHTSA be cognizant of the fact that non-road engines are generally higher emitting than on-road engines, are certified to higher emission standards with less stringent useful life and durability requirements, and often, unlike on-road engines, are certified without a DPF. For example, the NOx and PM emission standards (40 CFR part 1039) for compression ignition non-road engines for 56 kW (75 hp) to 560 kW (750 hp) are 0.40 grams per kilowatt-hour (g/kW-hr)
(-0.3 grams per brake horsepower-hour (g/bhp-hr)) and 0.02 g/kW-hr (~0.015 g/bhp-hr), respectively. In comparison, the current NOx and PM emissions standards for on-road heavy-duty diesel engines are 0.20 g/bhp-hr and 0.01 g/bhp-hr, respectively. Contrasting the useful life requirements for on-road heavy-duty engines of 435,000 miles or 22,000 hours with the useful life for >=37kW non-road engines of 8,000 hours, or 5,000 hours for lower powered non-road engines (Table 4, 40 CFR 1039.101), the large differences in the required useful life for on-road and non-road engines, and the attendant effects on warranty provisions, could give rise to durability issues that we believe are significant. Hence, their use should only be allowed in the narrow circumstances where an appropriate on-road engine is not available to facilitate the use of an advanced technology. [EPA-HQ-OAR-2014-0827-1265-A1 p.93]

CARB staff is also cognizant of the potential for abuse when flexibility provisions are worded too broadly and hence suggests that some restrictions be added to the provision to prevent inappropriate use of non-road engines in on-road vehicles, such as use of a non-road engine to power an on-road truck that is also connected to a small electric assist battery. CARB staff recommends the Phase 2 regulations include several safeguards to prevent the unintended use of non-road engines in on-road vehicles more broadly than intended. [EPA-HQ-OAR-2014-0827-1265-A1 p.93]

We recommend the following safeguards:

- First, the scope of applicability should be clarified in 40 CFR 1037.605(a)(1) such that the provisions are restricted to engines in vehicles with hybrid powertrains used exclusively to charge batteries and, by extension, not to vehicles with engines that can also directly propel the drive train as in a parallel hybrid electric vehicle. In other words, the provisions should be restricted to series hybrids only. [EPA-HQ-OAR-2014-0827-1265-A1 p.93]
- Second, the provisions should be limited to vehicles with significant zero-emission range (for example, 35 miles zero-emission range). [EPA-HQ-OAR-2014-0827-1265-A1 p.93]
- Third, the non-road engine must meet a 0.01 g/bhp-hr PM standard and be equipped with a DPF. [EPA-HQ-OAR-2014-0827-1265-A1 p.93]
- Fourth, non-road compression ignition engines with maximum engine power less than 56 kW should not be allowed. We realize that such a prohibition has been proposed for incorporation in 40 CFR 86.007-11(g) of the criteria pollutant standard setting part for highway vehicles, but CARB staff recommends that similar language also be explicated in 40 CFR1037.605 of the GHG standard setting part itself, not just referenced as proposed, to avoid any confusion regarding the provisions applicability. Accordingly, CARB staff recommends that this concern be addressed via the inclusion of a qualifying phrase in the applicability portion of 40 CFR 1037.605, such as "... and the engines have maximum engine power ratings equal to or greater than 56 kW." (see underscored text in paragraph (a) of CARB staff’s revised regulatory text on page 118 below). [EPA-HQ-OAR-2014-0827-1265-A1 p.94]

With these safeguards incorporated, CARB staff would support the proposed Phase 2 provisions allowing use of non-road engines for on-road series hybrids. [EPA-HQ-OAR-2014-0827-1265-A1 p.94]

In addition, CARB strongly urges U.S. EPA and NHTSA to protect against possible criteria pollutant increases associated with allowing non-road engines to be used in on-road heavy-duty hybrid systems. [EPA-HQ-OAR-2014-0827-1265-A1 p.5]

Oppose/Requested Change Comment

Comment - OBD flexibility for specialty heavy-duty vehicles
CARB staff understands some manufacturers of hybrid engines and drivelines have had challenges meeting existing certification requirements, particularly for engine, driveline, and vehicle OBD. U.S. EPA and NHTSA’s proposal would allow up to 1,000 hybrid engines and vehicles per manufacturer per year to meet significantly reduced OBD requirements, in order to help enable these technologies to come to market sooner. While we agree with the intent of this proposal, we are concerned it would enable hybrid engine, driveline, and vehicle manufacturers to sell a potentially unlimited number of vehicles with almost no diagnostic capabilities over a period of years, as long as each manufacturer’s annual volume stays below 1,000. This approach could also provide an incentive for manufacturers to plan for low annual hybrid sales without ever having to invest in developing diagnostics capabilities. [EPA-HQ-OAR-2014-0827-1265-A1 p.94]

OBD is critical to not only ensure that vehicle after-treatment and other controls are working properly in-use, but also to address potential engine and driveline integration issues that can result in increased NOx emissions. While CARB staff concurs that integrating a fully functional diagnostic system into a vehicle utilizing an alternate standard engine may be challenging at first, the benefits of beginning the process early are worthwhile. Access to real-time/real-world data can only improve compatibility and accelerate refinements that will result in cleaner vehicles and more reliable diagnostic systems in the near term. [EPA-HQ-OAR-2014-0827-1265-A1 p.94-95]

CARB staff encourages U.S. EPA and NHTSA to set a sunset mechanism for the reduced OBD requirements that reflects the number of vehicles or amount of time needed for the hybrid truck market to launch. The NPRM suggests a few potential approaches to identifying an appropriate sunset mechanism. CARB staff suggests U.S. EPA and NHTSA explore a sunset for the proposed hybrid certification flexibility, potentially based on phasing in full OBD requirements once 5,000 to 10,000 unit volumes per manufacturer have been produced. U.S. EPA and NHTSA could initially require engine manufacturers diagnostics (EMDB) systems for manufacturers wishing to sell only a small number of engines annually and increase to full OBD requirements as a manufacturer applies to sell more engines. While such a sunset mechanism may or may not be triggered within the Phase 2 implementation timeframe, it would send an important signal to hybrid technology manufacturers that as the technology matures, they must plan for eventual OBD compliance. Without such a sunset mechanism, the 1,000 annual volume limit for reduced OBD may mean hybrid manufacturers never develop effective OBD systems. [EPA-HQ-OAR-2014-0827-1265-A1 p.95]

As mentioned previously, California is developing a proposed Innovative Technology Regulation intended to provide hybrid medium- and heavy-duty engines, drivelines and vehicles with more flexible diagnostics and other certification requirements at time of market launch, ramping up to full OBD over time. CARB staff looks forward to continued coordination with U.S. EPA and NHTSA in developing the proposed Innovative Technology Regulation and in aligning it with the proposed federal program to provide heavy-duty hybrids with OBD flexibility where appropriate. [EPA-HQ-OAR-2014-0827-1265-A1 p.95]

**Comment on Topic Where NPRM Requests Comment**

**Comment – Alternate emission standards for specialty heavy-duty vehicles**

The NRPM requests comments on the technical and regulatory issues of heavy-duty vehicles that use an engine from a smaller vehicle that is already covered by chassis-based certification under 40 CFR part 86, subpart S. For these vehicles, it is proposed that alternate standards would apply to the engine certification-based emission standards and certification requirements while all vehicle-based
requirements for evaporative and greenhouse gas emissions would continue to apply as specified in the regulation. [EPA-HQ-OAR-2014-0827-1265-A1 p.107-108]

While an engine from a chassis certified vehicle may fulfill the charging demands of a series heavy-duty hybrid, tailpipe emissions, evaporative emissions and OBD performance may be significantly compromised when the engine is used in heavy-duty hybrid applications. In the hybrid application, the engine would likely be commanded to operate at optimal efficiency speed-load points, which could be conditions that do not have optimized emissions control on the chassis cycles (e.g., sustained high load on a gasoline engine might result in enrichment for catalyst over temperature protection; it may also result in inadequate canister purging). Further, the OBD system would be calibrated to yield good OBD performance under duty cycles typically encountered by the chassis certified vehicles, which may be significantly different than the duty cycle experienced in the hybrid. A likely consequence is that diagnostics simply won’t experience the conditions necessary to execute (e.g., if the monitor in the chassis certified application is designed to detect malfunctions when the engine is idling and the engine is not idled in the hybrid application, the malfunction won’t be detected). A less likely yet plausible concern is that monitors will make non robust decisions (i.e., the diagnostic will indicate a malfunction is present when there isn’t one). Another consequence is that the correlation between emission levels and malfunction detection will be upset (e.g., malfunctions may likely be detected at much higher emission levels because the engine operates at higher duty cycles on average). These examples highlight the need to recalibrate the emission control system and OBD system to ensure good performance in the heavy-duty hybrid application. This can be difficult to achieve by the heavy-duty vehicle manufacturer wishing to design a heavy-duty hybrid if the vehicle manufacturer does not have the intimate knowledge of and ability to reprogram the original engine computer with a custom calibration. [EPA-HQ-OAR-2014-0827-1265-A1 p.108]

Oppose/Requested Change Comment

Comment - Exemption from on-road engine criteria pollutant standard for engines in vehicles with maximum speed at or below 45 mph

CARB staff recommends that the scope of the provisions be narrowed such that they do not apply universally to all vehicles with maximum speed at or below 45mph. The need to exempt engines solely on the basis of maximum speed is unclear and has not been thoroughly explained or justified in the Preamble. Furthermore, the use of an engine to directly propel a vehicle on the highway, even at less than 45mph, would necessitate the use of a highway certified engine per U.S. EPA and NHTSA’s own Preamble arguments regarding the representativeness of duty-cycle operation. CARB would not be opposed to relief for specific applications in this category should the need for relief be justifiably explained, but as the provision stands now it seems to have more potential to create new business opportunities that rely on the use of less stringent engines than it does to drive innovation to reduce emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.129]

Oppose/Requested Change Comment

Comment - Exemption of amphibious and speed-limited vehicles

The proposed classification of amphibious and speed-limited vehicles utilizing alternate emission standards as, “exempt from the requirements for greenhouse gases” would make it extremely difficult, if not impossible, to enforce violations of these provisions should they occur. This would be especially true for individual states, such as California, which would only have the emissions labels and nationwide end-of-year production reports as the sole means of differentiating compliant vs. non-
compliant vehicles within their borders. Although U.S. EPA and NHTSA propose to limit these exempted vehicles to no more than 200 federal units per manufacturer per MY, there are no guarantees that these engines will end up distributed evenly with respect to each of the 50 states. In fact, states with either coastal access or numerous accessible waterways, such as California, will probably receive disproportionately larger numbers of amphibious vehicles than will other states that lack such features. Furthermore, trying to hold manufacturers accountable to any standard is often untenable when vehicles and engines are considered exempt from regulation. CARB staff believes the potential for abusing this provision is significant and recommends that U.S. EPA and NHTSA address the issue by requiring manufacturers using these provisions to be granted an “abridged” form of a Certificate of Conformity prior to the introduction of their engines into commerce. This would greatly facilitate the in-use tracking and identifying of improper applications of the provision. As a template, U.S. EPA and NHTSA might consider adopting an abridged Certificate of Conformity similar to the abridged Executive Order that California grants for off-road compression-ignition engine families certified under the relief provisions in the Transition Program for Equipment Manufacturers in California (13 CCR 2423 (h)). [EPA-HQ-OAR-2014-0827-1265-A1 p.129-130]

CARB staff’s suggested revisions to 40 CFR1037.605 based on the comments above are indicated below in strikeout/underline format. [EPA-HQ-OAR-2014-0827-1265-A1 p.130]

§1037.605 Installing engines certified to alternate standards for specialty vehicles. (a) General provisions. This section allows vehicle manufacturers to introduce into U.S. commerce certain new motor vehicles if the installed engines are certified to alternate emission standards that are equivalent to standards that apply for non-road engines under 40 CFR part 1039 that have maximum engine power ratings equal to or greater than 56 kW or part 1048. See 40 CFR 86.007-11(g) and 40 CFR 86.008-10(g). The provisions of this section apply for the following types of vehicles: [EPA-HQ-OAR-2014-0827-1265-A1 p.130]

(2) Amphibious vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.130]

(3) Vehicles with maximum speed at or below 45 miles per hour. If your vehicle is speed limited to meet this specification by reducing maximum speed below what is otherwise possible, this speed limitation must be programmed into the engine or vehicle’s electronic control module in a way that is tamper proof. If your vehicles are not inherently limited to a maximum speed at or below 45 miles per hour, they may qualify under this paragraph (a)(3) only if we approve your design to limit maximum speed as being tamper proof in advance. [EPA-HQ-OAR-2014-0827-1265-A1 p.130]

(b) Notification and reporting requirements. Send the Designated Compliance Officer written notification describing your plans before using the provisions of this section. In addition, by February 28 of each calendar year (or less often if we tell you), send the Designated Compliance Officer a report with all the following information: [EPA-HQ-OAR-2014-0827-1265-A1 p.131]

(1) Identify your full corporate name, address, and telephone number. [EPA-HQ-OAR-2014-0827-1265-A1 p.131]
(2) List the vehicle and engine models for which you used this exemption in the previous year and identify the total number of vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.131]

(c) Production limits. You may produce up to 1,000 hybrid vehicles and up to 200 amphibious vehicles, under this section in a given MY. This includes vehicles produced by affiliated companies. If you exceed this limit, the exemption provision is void for the number of vehicles that exceed the limit for the MY. For the purpose of this paragraph (c), we will include all vehicles labeled or otherwise identified as exempt under this section. You must apply for and be granted an “abridged” Certificate of Conformity per the instructions in §1037.201(c)(to be determined) to use the provisions of this section. [EPA-HQ-OAR-2014-0827-1265-A1 p.131]

(d) Vehicle standards. Hybrid vehicles using the provisions of this section remain subject to all other requirements of this part 1037. For example, you must use GEM in conjunction with powertrain testing to demonstrate compliance with emission standards under subpart B of this part. Vehicles qualifying under paragraph (a)(2) or (a)(3) of this section are exempt from the requirements of this part, except as specified in this section; these vehicles must include a label as specified in §1037.135(a) with the information from §1037.135(c)(1) and (2) and the following statement: “THIS [amphibious vehicle or speed-limited vehicle] IS EXEMPT FROM GREENHOUSE GAS STANDARDS CERTIFIED UNDER THE SPECIAL ALLOWANCES OF 40 CFR 1037.605. [EPA-HQ-OAR-2014-0827-1265-A1 p.131]

Organization: Caterpillar Inc.

ALLOW FOR INNOVATION? PROVIDE GHG BENEFICIAL PROVISIONS

Caterpillar supports the EPA’s provision that allows nonroad CI and SI engines to be used in specialty vehicles as proposed in section 1037.605. Current new technology diesel engines for on-highway and nonroad are nearly identical in configuration and components, and thus, very similar in emissions. However, there are differences in the engine calibration and certification test cycles. Some of these differences potentially allow nonroad engines to be better suited in some on-highway applications. For example, nonroad constant-speed engines are better suited than on-highway engines in hybrid applications that rely on constant engine speed. The additional testing burden of the on-highway Federal Test Procedures adds certification burden and is not representative of in-use performance, thereby yielding zero environmental benefit in these applications. [EPA-HQ-OAR-2014-0827-1189-A1 p.4]

While we applaud the EPA for trying to address unnecessary burden and waste, we believe some of the parameters of the EPA’s proposed provisions may limit the benefit. First, a “hybrid powertrain” should not be limited to systems where the engine provides energy for a Rechargeable Energy Storage System (RESS). We recommend that, at the very least, it should apply to vehicles that have non-conventional powertrains, but have innovative, fuel-saving technologies. An example from Caterpillar’s nonroad experience would be the D7E track-type tractor. This product utilizes a compact electric drive train, centered on electric technology controlled by solid-state semiconductors, rather than the conventional mechanical drivetrain that is typically used in this size track-type tractor. Furthermore, we believe such provisions should not be limited to vehicles with a RESS, nor one where the engine must charge the RESS. The EPA should allow for all fuel-saving, innovative vehicle technologies to utilize the provisions of §1037.605. [EPA-HQ-OAR-2014-0827-1189-A1 p.4]

Finally, the volume limit of 1,000 units per year suggests that the EPA expects this to be a small manufacturer exemption rather than a viable industry solution. We recommend the EPA not have a volume limit to this provision; however, if the EPA feels that a limit is necessary to constrain the
quantity of such vehicles, then we recommend the volume be set at the “small manufacturer” definition in §86.016-1 (10,000 units per year). [EPA-HQ-OAR-2014-0827-1189-A1 p.4]

**Organization:** Cummins, Inc.

*Cummins opposes the use of non-road engines in hybrid powertrains* [EPA-HQ-OAR-2014-0827-1298-A1 p.29]

A flexibility provision is proposed that allows certain specialty vehicles to use non-road engines certified to either 40 CFR 1039 or 1048 in place of on-highway engine standards (40 CFR 86). Eligible vehicles are amphibious vehicles, vehicles with max speed <45 mph and hybrid vehicles. As written, the use of these non-road engines would also preclude the engine and hybrid systems from the HD on-highway OBD requirements. Cummins opposes the use of non-road engines in hybrid vehicles, specifically, for several reasons. [EPA-HQ-OAR-2014-0827-1298-A1 p.29]

First, the proposed non-road provisions (40 CFR 1039, 1048) do not currently certify engines for GHG emissions and have differing criteria emission certification requirements (e.g., test cycles, useful life, emission stringency). As stated in the Preamble, engine standards provide enforceable standards that require manufacturers to optimize CO2 and criteria emissions together. The lack of GHG standards for non-road engines eliminates this linkage between criteria and GHG pollutants no longer forcing consideration of all constituents during engine optimization, a key reason identified by the agencies for having separate engine standards (see 80 FR 40181). Furthermore, the on-highway in-use program would not apply to non-road engines, eliminating assurance and enforceability of NOx control in the real world. Finally, any potential CO2 environmental benefit coming from using a hybrid system may be offset by unregulated levels of N2O and CH4 that exceed the proposed emissions cap for on-highway engines. The ability to deliver regulatory integrity from the engine standards is called into question through use of non-road engines in the Phase 2 program. [EPA-HQ-OAR-2014-0827-1298-A1 p.29]

Second, the certification cycles differ between non-road and on-highway certification, so there is uncertainty in the impact on criteria emissions. The certification cycles were developed to specifically represent either non-road or on-highway application duty cycles. Therefore, it may not be appropriate to mix certification cycles. [EPA-HQ-OAR-2014-0827-1298-A1 p.29]

Finally, HD on-highway engines have been required to meet OBD requirements since MY10. By the start of the Phase 2 program, HD engines and hybrid systems would have contained OBD monitors for more than 10 and 8 model years, respectively. To meet these requirements, manufacturers have invested significant time and resources in developing and demonstrating OBD diagnostic capability. Since the proposed non-road engines do not contain such stringent diagnostics, the agencies lose the assurance of in-use compliance afforded by OBD, and an un-level playing field is created where manufacturers that have invested in OBD may be at a cost disadvantage compared to their non-road variants. [EPA-HQ-OAR-2014-0827-1298-A1 p.29]

*Cummins opposes use of chassis-certified engines in specialty vehicles* [EPA-HQ-OAR-2014-0827-1298-A1 p.33]

The agencies are requesting comment on the possibility of using engines from chassis-certified vehicles in certain heavy-duty vehicles, such as specialty vehicles (80 FR 40523). As stated previously, these engines are certified for specific vehicle attributes (e.g., weight, coastdown, etc.) which vary significantly from the wide array of available specialty vehicles. Furthermore, the agencies would need to fully study and understand if the chassis dynamometer test cycles can be appropriately applied for
medium- and heavy-duty specialty vehicles. Therefore, Cummins opposes the use of chassis-certified engines in specialty vehicles. [EPA-HQ-OAR-2014-0827-1298-A1 p.33-34]

**Organization:** Innovus Enterprise LLC

**Suggested Alternatives and Comments.**

**Item 1: Alternate Emission Standards for Specialty Heavy-Duty Vehicles**

On page 40522 of the proposed rules, under XIV A(1), it states; “Development of EPA’s emission control programs is generally focused on a consideration for the technology, characteristics and operating parameters of conventional vehicles, and typically includes efforts to address concerns for special cases.” EPA requests comment on all aspects of this program to create alternate motor-vehicle emission standards that allow certified non-road engines to be used in identified types of heavy-duty highway vehicles. The EPA recognizes that the costs of regulatory compliance and the mismatch to the specified duty cycle of some specialized vehicles can make it cost-prohibitive for engine manufacturers to certify such an engine under the heavy-duty highway engine program. Since the non-road duty cycles would generally better represent the in-use operating characteristics of these vehicles, the EPA expects the non-road test procedures to be at least as effective in achieving in-use emission control. EPA’s non-road emission standards have reached a point that involves near parity with the level of emission control represented by the emission standards for heavy-duty highway engines. [EPA-HQ-OAR-2014-0827-1116-A1 p.4]

**Innovus Enterprise LLC Suggestion:** §1037.605; In addition to the hybrid, amphibious and speed limited vehicle, add a fourth category as follows: [EPA-HQ-OAR-2014-0827-1116-A1 p.4]

1. §1037.605 (a)(4). Specialty vehicles that are designed primarily for high mobility or off-road use as well as to perform multi-role vocational work functions. These vehicles have specifically engineered drive trains and chassis for austere terrain conditions and work routines which are not typical in conventional highway vehicles. The vehicles accommodate various implements and attachments to perform these work functions. In addition to vehicle propulsion, the vehicle engine is used to power these implements and attachments while the vehicle is either standing still or in motion. The typical engine-driven power systems include power takeoffs, heavy-duty hydraulic systems and high-power electric control systems. [EPA-HQ-OAR-2014-0827-1116-A1 p.4]

2. §1037.605 (c) Add provision limiting this high mobility off-road category to 200 vehicles in a given model year. [EPA-HQ-OAR-2014-0827-1116-A1 p.4]

3. §1037.605 (d) In the third sentence, add the words “or (a)(4)” after the words “..under paragraph (a)(2) or (a)(3).” Also add the words “or high mobility off-road” to the last sentence within the brackets. [EPA-HQ-OAR-2014-0827-1116-A1 p.4]

**Rational:** Our innovative technology is capability technology as described in paragraphs 8, 9 and 10 above. The vehicles we manufacture employ innovative technology not available from any other manufacturer in America. Our environmental technology is cutting edge - already in sister configurations meeting Euro 6 and Tier 4 standards. Our vehicle/engine technology coupled with the unique characteristics and dynamic operating parameters mentioned above validate a special case for special provisions. The cost of regulatory compliance and the mismatch to the specified duty cycle indeed make it cost-prohibitive for us to certify such an engine for such a vehicle under the heavy-duty highway engine program. Of course EPA’s non-road emission standards have reached a point that is near parity with the level of emission control represented by the emission standards for heavy-duty highway engines. For this, we feel our situation fits very nicely into the spirit and intent of this new provision. Additionally, since these vehicles are for a niche market, the low volume of 200
vehicles/engines per year is reasonable and consistent with the amphibious and limited speed vehicle provisions. We also concur with the EPA’s suggestion for simplified diagnostic controls for 40 CFR Part 1039. [EPA-HQ-OAR-2014-0827-1116-A1 p.4-5]

**Organization:** Daimler Trucks North America LLC

**Alternate Emission Standards for Specialty Heavy-Duty Vehicles** - The agencies requested comment on aspects of the program to create alternate motor-vehicle emission standards that allow certified nonroad engines to be used in the identified types of heavy-duty highway vehicles. 80 FR 40523. We are not certain that this alternative benefits any manufacturer, so we agree with the agencies’ decision to exclude such a provision from the vehicle-side of the regulations. That is, we agree that all vehicle-based requirements should continue, regardless of the use of this alternative certification option. [EPA-HQ-OAR-2014-0827-1164-A1 p.102]

**Organization:** Allison Transmission, Inc.

**Alternative Standards for Hybrid Systems Should Be Adopted With Changes To Account for Hybrid Manufacturing Process**

EPA has requested comment concerning a program for alternate motor vehicle standards for hybrid vehicles, specifically to allow the use of certified non-road engines in heavy-duty hybrid vehicles. Compression-ignition engines could be certified to alternative standards equivalent to those in 40 C.F.R. Part 1039; spark ignition engines could be certified to Blue Sky standards in 40 C.F.R. Part 1048. EPA proposes a limit of no more than 1,000 hybrid vehicles and no more than 200 amphibious or speed limited vehicles per manufacturer would be allowed to be certified to these alternative limits in any MY. [EPA-HQ-OAR-2014-0827-1284-A1 p.59]

Allison Transmission believes that adopting this program could provide a large benefit to the HD hybrid landscape. Allison believes the current HD hybrid industry is fragile. At the current sales volume, forcing additional complexity on the industry may result in engine manufacturers abandoning the market and in innovative hybrid manufacturers avoiding the market altogether. By maintaining a reasonable engine emissions requirement and the same vehicle level GHG requirement, EPA will ensure environmental targets are achieved by these specialty vehicles. And by lessening the OBD requirement of the components, EPA is allowing the technical challenge of a HD hybrid to become manageable. Allison believes the ARB innovative technology program would benefit from this same approach, and we are hopeful that ARB can adopt this same strategy for their program. [EPA-HQ-OAR-2014-0827-1284-A1 p.59]

Allison has reviewed the language on this matter in the Preamble of the proposed rule and the proposed regulatory text at 40 C.F.R. 1037.605 and submits the following comments/clarifications thereto: [EPA-HQ-OAR-2014-0827-1284-A1 p.59]

1. 40 C.F.R. 1037.605 as proposed allows vehicle manufacturers to introduce alternative standard vehicles into commerce. From the construction of this provision, i.e., the reference to “vehicles with a hybrid powertrain,” it is assumed that all hybrid products would qualify for alternative standards, subject to limits on the volume of such vehicles in a MY. [EPA-HQ-OAR-2014-0827-1284-A1 p.59]

2. 40 C.F.R. 1037.605 also indicates that it allows a “vehicle manufacturer” to introduce vehicles into commerce that are certified to alternative emission limits. Given the structure of the hybrid market, however, Allison recommends that EPA consider whether it has authority to allow annual volume limits
to apply with respect to the hybrid manufacturer in addition to the vehicle manufacturer. [EPA-HQ-OAR-2014-0827-1284-A1 p.59]

Although the vehicle manufacturer would still remain responsible for the certification of the vehicle, such a step would recognize the horizontal nature of the HD industry. [EPA-HQ-OAR-2014-0827-1284-A1 p.60]

The bulk of the investment into hybrid technology development has been done and is being done at the component supplier level, by hybrid system manufacturers, not by vehicle manufacturers. Thus, EPA should account for the fact that a vehicle manufacturer may acquire hybrid systems from several hybrid manufacturers and that a volume limit -- if applied solely to the vehicle manufacturer -- may not allow smaller hybrid manufacturers to benefit (e.g., if their systems were purchased after a vehicle manufacturer had reach the annual volume limit, they may not qualify for the alternative standards even if other hybrid manufacturers did qualify by being purchased earlier in the year). EPA could implement this recommendation through the clarification of the proposed regulatory language. Specifically, 40 C.F.R. 1037.605(c) as proposed should be revised as follows: [EPA-HQ-OAR-2014-0827-1284-A1 p.60]

“(c) Production limits.

(1) You may produce up to 1,000 hybrid vehicles under this section in a given model year. This limit applies both to the vehicle manufacturer and its affiliated companies and separately to other manufacturers who produce hybrid systems (i.e., hybrid system manufacturers). Hybrid system manufacturers may produce up to 1,000 hybrid vehicles under alternative emission standards that are equivalent to standards that apply for nonroad engines as referenced in subsection (a). A vehicle manufacturer must verify that any hybrid system manufacturer will not produce more than 1,000 hybrid systems in a year, including those incorporated into a vehicle receiving an alternative standard under this section. [EPA-HQ-OAR-2014-0827-1284-A1 p.60]

(2) A vehicle manufacturer may additionally produce up to 200 amphibious vehicles and up to 200 speed-limited vehicles under this section in a model year. For these vehicles, the production limits apply to vehicles produced by affiliated companies. [EPA-HQ-OAR-2014-0827-1284-A1 p.60]

(3) If a manufacturer exceeds any limit contained in this paragraph (c), the exemption is void for the number of vehicles that exceed the limit for the model year. For the purpose of this paragraph (c), we will include all vehicles labeled or otherwise identified as exempt under this section. [EPA-HQ-OAR-2014-0827-1284-A1 p.60]

(4) For purposes of this paragraph (c), a hybrid system manufacturer is defined as any person who manufactures or assembles the hybrid propulsion system of a vehicle, including the drive unit, power inverter, system controller and energy storage features other than a conventional battery system or conventional flywheel. Nothing in this paragraph shall be construed to require a hybrid manufacturer to obtain a certificate of conformity.” [EPA-HQ-OAR-2014-0827-1284-A1 p.60-61]

Organization: Navistar, Inc.

In addition, the hybrid OBD flexibility proposed under Section XIV.A.1 of the NPRM Preamble presupposes that manufacturers will be capable of cost-effectively complying with an as-yet-to-be-defined CARB certification flexibility with unknown stringency. The impact of OBD can easily be extended to include mild hybrids or those that rely on engine--off at idle systems to reduce GHG
emissions. In this example, OBD requirements which rely on threshold and in use performance monitoring, as well as readiness can be affected by changes in operational mode during key on, engine on/off operation. In addition prolonged engine off at idle strategies can impact the rate of heat loss from aftertreatment which may increase fuel consumption triggered by warm up strategies once the engine resumes operation. The trade off in engine durability also extends to turbocharger systems which rely upon a forced lubrication system to prevent coking and premature wear due to hot engine shutdown. The accelerated deterioration of either the aftertreatment or turbocharger system can have a significant impact on engine efficiency, as well as fuel economy and warranty cost. [EPA-HQ-OAR-2014-0827-1199-A1 p.39-40]

**Organization:** Union of Concerned Scientists (UCS)

**LOW VOLUME EXEMPTION FOR HYBRID MANUFACTURERS**

Hybrid vehicles augment an engine with an electric motor and often utilize an engine outside of its typical operating regime. In some cases, this may also allow for a downsized engine, with the motor capable of providing sufficient additional power for the vehicle. Because of these operational characteristics, hybrids may therefore provide a unique challenge for criteria emissions (NREL 2015). [EPA-HQ-OAR-2014-0827-1329-A2 p.24]

Because the engine is being run under atypical conditions, significant additional calibration and testing may be required in order to certify the powertrain. This testing can be expensive and time-consuming, particularly for small-volume manufacturers. For this reason, the agencies have proposed a 1,000 engine low-volume exemption for hybrid manufacturers, wherein they can certify up to 1,000 vehicles with engines certified only to non-road engine standards. [EPA-HQ-OAR-2014-0827-1329-A2 p.24]

This is a significant reduction in the test burden for small manufacturers and will help lower the barrier for innovative manufacturers. However, based on the results of the NREL study, which show substantially higher criteria emissions for certain hybrids, we find reasons for concern if there is not some reasonable limit to the longevity of this credit. The agencies should institute either a cumulative volume-limit or sunset date for this provision to ensure that it does not result in undue environmental damages. [EPA-HQ-OAR-2014-0827-1329-A2 p.24]

**Response:**

California ARB made several suggestions to revise the proposed approach of setting alternative emission standards for specialty vehicles. We agree with some of these and have made appropriate revisions to the provisions. However, we disagree with others. Specifically:

- We do believe it is not appropriate to limit the alternative standards to certain kinds of hybrid vehicles, or to set minimum performance specifications as qualifying criteria for the alternative standards. This is largely because there are nearly infinite possible ways for manufacturers to configure their systems, which would make such a system review especially difficult. More importantly, our interest is driven primarily by the desire to ensure that vehicle manufacturers are able to get the engines they need to produce their vehicles. If a manufacturer needs a 70 kW engine for any kind of hybrid vehicle, and there is no such engine certified to the regular heavy-duty highway standards, we believe it is appropriate to allow for accessing the wider range of nonroad engines that is available through these alternative standards.
- We have revised the regulation to require manufacturers to meet a PM standard for compression-ignition engines that is equivalent to the highway standard (0.020 g/kW-hr
equates to 0.01 g/hp-hr standard when rounding is taken into account). As with the regular PM standard, it would not be appropriate for us to require that manufacturers use any particular type of technology.

- We are leaving other emission standards unchanged from those that apply under the respective nonroad programs. Any small loss in stringency or durability associated with the nonroad standards is mitigated by the low production volumes in question, and the fact that qualifying specialty vehicles will often be used far less than conventional vehicles. We do not expect hybrid vehicles in particular to cause a problem with increased emissions of criteria pollutants.

- We have revised the regulation to more directly state that the alternative standards do not apply for engines below 56 kW.

- We have revised the regulation to state that vehicle manufacturers can use an engine meeting the alternate emission standards only if there is no suitable engine already certified to the regular heavy-duty highway standards.

- We have revised the regulation to discontinue the provision for alternate standards for hybrid vehicles after model year 2027. This will allow a substantial period to develop and build the technology and market for hybrid technology. If hybrid technology reaches widespread use before that time, the production limits associated with the alternate standards will lead manufacturers to certify engines to the regular heavy-duty highway standards, including OBD, before 2027. On the other hand, if we see a need to extend the program beyond 2027, we may consider revising this sunset in a future rulemaking.

- California ARB properly recognizes We acknowledge that our proposal to apply the alternate standards to speed-limited vehicles may create new business opportunities. However, we do not want vehicles to be locked out of the marketplace because they have specific engine needs that cannot be met with available highway-certified engines. Vehicles may be speed-limited for any number of reasons, but the unifying feature is that these vehicles will not (may not) operate on interstate highways, which means their purposes and operating characteristics will inherently different than conventional cars, trucks, and buses. For example, large truck-mounted cranes, aircraft de-icing vehicles, and integrated wood-chipping trucks may qualify as motor vehicles, but they are much more likely to have operating characteristics of nonroad equipment. In fact, some of these vehicles are mistakenly using nonroad engines today. This rule will allow us to constructively engage with these vehicle manufacturers to ensure that their vehicles can get the power they need with engines that are properly certified to EPA emission standards.

- The recommendation to require an abridged certificate of conformity to ensure compliance for amphibious and speed-limited vehicles is odd, given that we proposed a requirement for these engines to receive a full certificate of conformity demonstrating compliance with the alternate heavy-duty highway emission standards, with annual reporting of production volumes. We are also adding a requirement for engine manufacturers to have a request for these engines from the vehicle manufacturer before shipping engines certified to the alternate emission standards. It is true that amphibious vehicles are more likely to be used in areas with coastal access and accessible waterways; however, it is not clear that evenly distributing such vehicles across accessible waterways would lead to any greater proportion of vehicles being used in California.

Cummins also raised several points:

- We have revised the regulation to require that compression-ignition engines meet the same N2O standard that applies for other heavy-duty highway engines. Also, as noted above, we are adopting a more stringent PM emission standard for compression-ignition engines.
Other differences that might lead to a reduced level of control are mitigated by the low production volumes in question, and the fact that many qualifying specialty vehicles will often be used far less than conventional vehicles.

- We recognize that the nonroad duty cycles are different than those that apply for conventional heavy-duty highway engines. However, this is part of the rationale for adopting alternative standards. Specialty vehicles are unlikely to be used in ways that are well represented by the heavy-duty highway duty cycles, with respect to vehicle speed or acceleration, or with respect to engine speeds and loads. The nonroad cycles will likely provide a more appropriate means of measuring emissions from these engines.
- We agree that a manufacturer with an engine certified to the regular heavy-duty highway engine standards should not be overlooked by specialty vehicle manufacturers in the search for appropriate power selection. We have therefore revised the regulation to disallow the use of engines certified to the alternate standards if a suitable engine has been certified to the regular heavy-duty highway standards.
- We agree that it would not be appropriate to rely on an engine from a vehicle that had been certified to the chassis-based program as part of this program of alternate standards for specialty vehicles. We are therefore not allowing such certificates to serve as the basis for meeting alternate highway engine standards as described in this section.
- We agree that a manufacturer-run in-use testing program is a valuable tool for evaluating compliance with emission standards and are accordingly considering whether to pursue such a program for nonroad compression-ignition engines.

The provisions related to alternate standards for specialty vehicles represent a significant deviation from the standards and program requirements that apply to other highway engines and vehicles. As such, it is important to have clear, well-defined qualifying criteria. Hybrid engines and vehicles by their nature involve storing energy produced by the engine for later use to propel the vehicles (or perform some other function). We disagree with Caterpillar’s assertion that some variety of innovative powertrains should qualify for the alternate standards. This would require that we draw clear lines where the technology does not support such a clear demarcation. Manufacturers may generate off-cycle credits for non-hybrid powertrain innovations to reduce fuel consumption.

We set the annual cap of 1000 hybrid vehicles based on the expectation that higher production volumes would allow engine and/or vehicle manufacturers to invest as needed to meet the OBD requirements, emission standards, and other provisions that apply for engines and vehicles not covered by these alternate standards. We are aware that nonroad duty cycles may be more appropriate than the highway duty cycles for engines installed in hybrid vehicles. If production volumes for any specialty vehicles exceed the limits imposed under § 1037.605, vehicle manufacturers would need to install engines certified to the regular highway standards, which might include different emission measurement protocol under 40 CFR 1065.10(c)(1) or (2). Depending on the specific circumstances, this may allow for certifying based on a different duty cycle if that better represents in-use operation, or if the engine cannot operate over the specified procedure.

The proposal by Innovus to include certain rough-terrain vehicles fits with the intent of the proposed alternative standards for specialty vehicles. The challenge is to describe these vehicles in a way that focuses vehicle characteristics that properly separate qualifying vehicles from other heavy-duty highway vehicles that may be designed for more severe duty, but that do not deserve special treatment for engine selection. We chose to focus on axle configurations that involve a substantial additional engineering and cost to manage rough terrain. Specifically, the final regulation defines qualifying vehicles as:

All-terrain motor vehicles with portal axles (i.e., axles that are offset from the corresponding wheel centerline by a gear assembly) or any axle configuration involving gear reduction such that the wheels rotate more slowly than the axle.
As suggested by Innovus, these vehicles would be subject to the same production limits and other provisions that apply for amphibious vehicles and speed-limited vehicles.

Hybrid vehicles using engines certified to alternate highway standards under 40 CFR 1037.605 must meet all the greenhouse gas standards that apply to the vehicle, in line with Daimler’s recommendation. However, we specify that qualifying speed-limited vehicles, amphibious vehicles, and all-terrain vehicles are exempt from the vehicle-based greenhouse gas standards. This is very similar to the provisions adopted at 40 CFR 1037.631, except for the specified production limits. A significant reason for the differing treatment of these vehicle types is that manufacturers would be allowed to produce many more hybrid vehicles than the other vehicle types.

We affirm Allison’s understanding that all hybrid powertrains would qualify as specialty vehicles under 40 CFR 1037.605. However, we believe it is necessary and appropriate to identify the vehicle manufacturers’ production volumes as the basis for setting production limits, largely because they are the ones making the product that is subject to standards under 40 CFR part 1037. Any other approach would involve requirements for manufacturers that are not subject to certification requirements, and would inevitably involve disputes about who is responsible, or even how to count companies, in business arrangements involving multiple manufacturers. Allowing 1000 hybrid units to use engines meeting alternate standards under 40 CFR 1037.605 may allow for a greater number of systems than if we would limit the number of hybrid systems from hybrid manufacturers, but we expect vehicle manufacturers to have challenges meeting their own responsibilities with respect to sourcing engines and integrating hybrid powertrains with their overall vehicle designs.

Cummins appropriately raises a concern about companies gaining a competitive advantage by meeting the alternate standards, compared to other companies that have already put in the design work to meet the full standards. This highlights the competing concerns—wanting to provide relief to expand the availability of engines for specialty vehicles without harming those companies already offering compliant products. We continue to believe that alternate standards are needed in many cases to allow manufacturers of specialty vehicles to meet their unique demands for power in their unconventional vehicles. We have adopted three provisions to address the competitiveness concern. First, the sales limit ensures that the alternate standards are geared toward production of niche or pilot vehicle designs. If manufacturers need more than 1000 engines annually for hybrid vehicles, for example, we expect that there should be sufficient funds available for meeting the full set of highway standards for those engines. Second, the alternate standards for engines installed in hybrid vehicles expire after 2027. That transition period allows time for the incentive of increasing sales of hybrid vehicles, with the expectation that these designs will eventually no longer need to be treated as a niche product with relief from certification requirements. If we need to revise the regulations to accommodate unique designs or in-use engine operating schedules, we can pursue that in a later rulemaking. Third, we have added a provision to disallow using the alternate standards if there is an engine certified to the full set of requirements of 40 CFR part 86 that has the appropriate physical and performance characteristics to power the vehicle in question. This should limit the use of alternate standards to those cases, as intended, where vehicle manufacturers are unable to get the appropriate engine for their vehicle design without the alternate standards.

We disagree that the proposed alternate standards presupposes anything about California’s policy on hybrid vehicles. We are adopting these provisions on their own merits and expect vehicle and engine manufacturers to pursue them as appropriate for their business and engineering interests. We expect manufacturers to account for the real-world impacts of hybrid powertrains on engine durability.

**14.3.2 Chassis Certification of Class 4 Heavy-Duty Vehicles**

**Organization:** Alliance of Automobile Manufacturers and Association of Global Automakers
6. EPA should allow the optional use of chassis based dynamometer certification for over 14,000 lbs GVWR

In the NPRM, at 80 FR 40523, EPA requests comments on the applicability of chassis-based certification and whether it should be available for vehicles over 14,000 lbs GVWR. Automakers support a change to the requirements that would make the choice of dyno for vehicles over 14,000 GVWR be optional according to the manufacturer, and that EPA perform confirmatory tests according to the dyno selected by the manufacturer (engine dyno confirmed on engine dyno; chassis dyno confirmed on chassis dyno). [EPA-HQ-OAR-2014-0827-1271-A1 p.11]

Organization: Cummins, Inc.

Cummins opposes chassis-certification of GHG emissions for Class 4-6 complete and cab-complete vehicles [EPA-HQ-OAR-2014-0827-1298-A1 p.32]

Under the current Phase 1 rule (40 CFR 1037.150(l)), HD spark-ignited vehicles above 14,000 lbs Gross Vehicle Weight Rating (GVWR) can certify to chassis standards based on a ‘complete sister vehicle’ concept for GHG emissions. However, such vehicles must be certified to engine dynamometer standards for all other emissions standards. Cummins opposes any regulation that allows for a mixed (engine and chassis dynamometer) certification of criteria and GHG emissions. The difference in chassis and engine dynamometer procedures (e.g., operating speeds and loads) provides a potential inconsistency between the control of GHG and criteria emissions under typical operation and undermines regulatory integrity. [EPA-HQ-OAR-2014-0827-1298-A1 p.32]

Vehicles above 14,000 lbs (e.g. class 4-6 vehicles) are typically engineered and marketed to meet vocational requirements. Many of the vehicles in this class are not sold as complete, ready to be placed into service, vehicles. The typical sales path to the end-user is through a specialty body or utility function builder. While the vehicle OEM can communicate parameters such as aerodynamic design standards to which the finish builders must comply, the finished body may exceed the frontal projection and/or may affect air flow quite differently than on a complete pickup truck or even on the bare “cab-complete” vehicle. Hence it is not appropriate to use coastdown and test weight information of a complete sister vehicle (in Class 2b/3) for chassis certification of vehicles above 14,000 lbs GVWR. [EPA-HQ-OAR-2014-0827-1298-A1 p.33]

For these reasons, we believe engine dynamometer certification for GHG, consistent with certification for criteria emissions, should be applied to this category of vehicles. [EPA-HQ-OAR-2014-0827-1298-A1 p.33]

Cummins opposes chassis-certification of criteria and GHG emissions for HD vehicles above 14,000 lbs GVWR [EPA-HQ-OAR-2014-0827-1298-A1 p.33]

The agencies are requesting comment (80 FR 40523) on allowing vehicles above 14,000 lbs GVWR to be certified on chassis dynamosimeters to demonstrate compliance to criteria and GHG emissions standards. The metrics used for chassis certification were developed and validated for vehicles with GVWR less than 14,000 lbs, without consideration of the heavier vehicles being regulated in this rulemaking. At a minimum, the agencies would need a detailed study to fully understand the applicability of the chassis certification protocols and standards to HD vehicles above 14,000 lbs. Also, as stated above, vocational vehicles are not typically sold as complete, so the final aerodynamic characteristics of the certified vehicle are not known at the time of certification. The agencies recognize this dynamic of the Class 4 and above market and determined the robust regulatory framework of
certifying criteria and GHG emissions on engine dynamometer test cycles as appropriate for these class of vehicles (for example, see 80 FR 40331). For these reasons, Cummins does not support chassis-certification of HD vehicles above 14,000 lbs GVWR. [EPA-HQ-OAR-2014-0827-1298-A1 p.33]

**Organization:** American Automotive Policy Council

**Chassis certification option**

AAPC concurs that vehicles up to 16,000 lbs GWVR can be combined with Class 2b/3 heavy-duty chassis certified products and they would follow the applicable heavy-duty chassis certified emission regulations without seeking additional Agency approval. [EPA-HQ-OAR-2014-0827-1238-A1 p.28]

**Organization:** Allison Transmission, Inc.

**Optional Chassis Certification Should Not Utilize Bright-Line Test Based on Weight**

EPA and NHTSA are proposing to continue Phase 1 provisions that allow optional chassis certification for vehicles over 14,000 lb GVWR. The agencies have posed several questions with regard to how such provisions might be retained or changed for Phase 2. [EPA-HQ-OAR-2014-0827-1284-A1 p.44]

Allison believes that EPA should not treat 14,000 lb GVWR as a bright line test, but instead allow for chassis certification above that weight in order to reduce the regulatory burdens associated with certification of such vehicles. Allison, however, favors a provision that would limit such a certification option to vehicles that share design characteristics with certified vehicles below 14,000 lb GVWR. As noted in EPA’s discussion of this option, this approach would be similar to that taken by the State of California. Adopting this approach would alleviate some of the regulatory burden that might occur with differing treatment of this compliance option. If this approach is not allowed, then vehicles that straddle the 14,000 lb limit and share significant design characteristics would be subject to different certification rules that would force unnecessary complication and cost for manufacturers in that weight range. [EPA-HQ-OAR-2014-0827-1284-A1 p.44]

**Response:**

We have revised the regulation to include a limited allowance for vehicles above 14,000 lbs GVWR to be certified to the chassis-based program in 40 CFR part 86, subpart S. This applies equally to criteria and greenhouse gas standards.

We agree with Cummins that the chassis-based program was developed for vehicles designed and manufactured as complete vehicles. We are accordingly specifying that vehicles above 14,000 lbs GVWR may be certified under the chassis-based program only if the vehicles are otherwise properly characterized as being part of a test group for certification under 40 CFR part 86, subpart S. This allows for a family of Class 2b and Class 3 vehicles to include some number of vehicle configurations that have features involving more robust frames and other systems to qualify for GVWR values above 14,000 lbs. This is very similar to the approach suggested by Allison and adopted by California ARB.

**14.3.3 On-Board Diagnostics for Heavy-Duty Vehicles**

**Organization:** Truck & Engine Manufacturers Association (EMA)

EPA Alignment With CARB OBD Requirements
EPA seeks comment on whether the Agency should change its OBD requirements to simply require that manufacturers meet CARB’s OBD requirements. EMA opposes any such change to EPA’s OBD program. [EPA-HQ-OAR-2014-0827-1269-A1 p.64]

EPA’s separate OBD requirements have proved beneficial and will continue to do so. For example, EPA used its OBD flexibility provisions to delay the OBD requirements for hybrid vehicles until the 2017 model year, which prevented significant market disruptions and allowed for the continued availability of 49-state certified hybrid vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.64]

Moreover, CARB has created a regulatory paradigm where it preserves the ability to change the technical requirements of its OBD program every two years, which, in essence, creates an improper BACT-based approach for mobile source regulation. Because of the increasingly burdensome nature of CARB’s OBD program, manufacturers need to preserve the option of certifying a 49-state engine for OBD purposes. Consequently, EPA should not opt-in to CARB’s OBD program. [EPA-HQ-OAR-2014-0827-1269-A1 p.64]

**Organization:** Volvo Group

**EPA Should Not Delegate Authority to Regulate OBD Systems to California**

In the proposed rule, EPA requests comment on: (1) whether EPA should amend its OBD regulations to require that manufacturers comply with California OBD requirements, (2) whether EPA should preserve its own specifications for on-board diagnostics for “any special situations,” and (3) “the need to make any adjustments or allowances from the California ARB regulations to work for EPA implementation.” [EPA-HQ-OAR-2014-0827-1290-A1 p.70]

Volvo Group does not oppose providing manufacturers with an option for complying with federal OBD requirements by demonstrating compliance with California OBD requirements. As EPA notes, this approach already is in place for light-duty vehicles and heavy-duty vehicles below 14,000 lbs. GVWR. See 40 CFR § 86.1806-17(j). For manufacturers that elect to certify products in both California and the 49 states, this flexibility can be beneficial in allowing them to adopt harmonized strategies for compliance. The existing regulation, however, *does not require* manufacturers to comply with California Air Resources Board (CARB); it merely provides that compliance with such is sufficient for meeting EPA OBD requirements. [EPA-HQ-OAR-2014-0827-1290-A1 p.70]

Volvo Group strongly opposes, however, any proposal that would *require* manufacturers to comply with CARB OBD (or other) requirements for purposes of 49-state certification. [EPA-HQ-OAR-2014-0827-1290-A1 p.70]

At the outset, Volvo Group believes EPA’s proposal would amount to an unauthorized and inappropriate delegation of its authority and responsibility to promulgate mobile source regulations to the state of California. No provision of the Clean Air Act authorizes EPA to delegate its authority to promulgate mobile source regulations to states. Indeed, the statute expressly prohibits states from adopting their own mobile source regulations absent a specific waiver of federal preemption by the EPA Administrator. CAA § 209, 42 U.S.C. § 7543. Moreover, where Congress intended to allow EPA to delegate its CAA authority to states, it expressly provided for such. See, e.g., CAA §112(l), 42 U.S.C. § 7412(l) (Providing EPA authority to delegate authority to states for implementation of stationary-source air toxics programs). Again, Congress did not provide for this with respect to mobile source regulations under Title II of the Clean Air Act. Accordingly, Volvo Group does believe EPA has the authority to pass this responsibility on to the state of California. [EPA-HQ-OAR-2014-0827-1290-A1 p.70-71]
EPA’s adoption of CARB OBD regulations, meanwhile, is inappropriate for a number of other reasons. First, as EPA presumably would not have any process in place for certification of OBD systems, this approach would force manufacturers to participate in the California certification process, regardless of whether they intend to sell vehicles in the state of California. Subjecting manufacturers to the jurisdiction of any particular state, even if they do not intend to transact any business in that state, for purposes of gaining approval to sell vehicles in other states represents an improper use of EPA’s regulatory authority. If EPA intends to enforce standards applicable to vehicles, the Agency must adopt such standards itself through a formal rulemaking process, and must have its own process in place for granting related certificates. [EPA-HQ-OAR-2014-0827-1290-A1 p.71]

Second, by deferring to California OBD regulations, EPA would effectively be denying manufacturers and other parties the ability to participate in the rulemaking process envisioned by the Clean Air Act and the Administrative Procedure Act. Manufacturers and other parties would be required to participate in the California rulemaking process, pursuant to California law, for purposes of challenging a federally-imposed requirement. Likewise, they would be required to challenge federally applicable OBD regulations in California courts under California law, and would be stripped of their ability to challenge regulations under the Administrative Procedure Act and the Clean Air Act. [EPA-HQ-OAR-2014-0827-1290-A1 p.71]

Volvo Group also has concerns with regard to the practical implications of mandating that manufacturers comply with California OBD regulations for purposes of meeting federal requirements. Volvo Group supports and echoes the concerns raised by EMA in this regard. Specifically, Volvo Group is concerned EPA will eliminate important opportunities to ensure much needed flexibility is provided for under new OBD regulations. By deferring to California’s requirements, EPA will not be in a position to provide flexibility and regulatory relief for vehicles sold in other markets. [EPA-HQ-OAR-2014-0827-1290-A1 p.71]

Volvo Group also agrees with EMA that the increasingly burdensome nature of CARB’s OBD program necessitates that manufacturers have the option of certifying to a 49-state program if necessary. The need for such flexibility is demonstrated by the OBD experience to date. In its response to comments on the final rule establishing OBD requirements for 2010 and later heavy-duty engines, for instance, EPA acknowledged that it did not share CARB’s position with respect to a “step-down” in increased stringency of OBD systems for malfunctions of aftertreatment devices in the 2013 and 2016 model years. EPA noted: “The California Air Resources Board is willing to go forward with some uncertainty as regards the ability of manufacturers to meet the complete set of ‘stepped down’ thresholds in 2013 and 2016. EPA is not so comfortable moving forward with that level of uncertainty.”[EPA-HQ-OAR-2014-0827-1290-A1 p.71-72]

Similarly, there are a number of OBD monitors that EPA has acknowledged are technically infeasible, but CARB has required nonetheless. EPA, for instance, eliminated the OBD thresholds associated with monitoring of NMHC converting catalysts and feed gas in the final OBD rule. See 74 Fed. Reg. 8310, 8323 (Feb. 24, 2009). As EPA noted, the Agency “made these changes for the final rule because we have been convinced by manufacturers that there exists no robust method of detecting loss of NMHC conversion at the levels required for threshold monitoring.” Id. CARB, however, elected to adopt OBD monitoring requirements for these functionalities, notwithstanding. Another example is CARB’s requirement to reduce the DPF OBD monitor threshold in 2016, which will force manufacturer’s to require a PM sensor for the first time. This is not yet a requirement for EPA certification. In addition, there are notable differences between monitors required by CARB and EPA for DOC NMHC conversion, DPF NMHC conversion, DOC feed gas, DPF feed gas, DPF filtration efficiency, and miss-fire. [EPA-HQ-OAR-2014-0827-1290-A1 p.72]
Finally, it also bears noting that CARB has adopted questionable testing requirements related to OBD systems that impose extremely burdensome, costly and unjustified requirements on engine and vehicle manufacturers with little to no corresponding benefit. See 13 CCR § 1971.5 Manufacturers who do not elect to sell vehicles in California should not be subject to these requirements, but could be if EPA elects to adopt CARB requirements. In fact, these regulations underscore the inherent problem with EPA’s proposed approach insofar as they were challenged, and ultimately upheld by a California court based on California law, Engine Manufacturers Ass’n v. California Air Resources Board, 180 Cal.Rptr.3d 667 (Calif. Crt. Ap. 2014). There has never been a determination as to whether EPA would have authority to enforce the same requirements under federal law. EPA’s adoption of California OBD requirements could raise multiple questions along these lines, prompting potentially costly litigation over EPA’s authority to impose CARB regulations with each new iteration of such regulations. [EPA-HQ-OAR-2014-0827-1290-A1 p.72]

Organization: Cummins, Inc.

*Cummins opposes changes to EPA OBD regulations to require manufacturers meet ARB OBD requirements* [EPA-HQ-OAR-2014-0827-1298-A1 p.28]

EPA is requesting comment on changing their OBD regulation to require manufacturers to meet ARB OBD requirements. For reasons outlined in EMA’s comments, Cummins opposes this approach. [EPA-HQ-OAR-2014-0827-1298-A1 p.28]

Organization: Daimler Trucks North America LLC

9. OBD

**GHG Phase 2 OBD** – The agencies requested comments regarding OBD certification provisions in the Phase 2 proposal. 80 FR 40524. In particular, the agencies asked about the need to preserve EPA specifications for on-board diagnostics for any special situations and the need to make any adjustments or allowances from the California ARB regulations to work for EPA implementation. DTNA recommends that EPA maintain its current practice of approving OBD systems that have been approved by ARB. However, DTNA also recommends that that EPA preserve its own OBD specifications so as to provide flexibility that may arise in the future as ARB promulgates new requirements that may, as has been the case for hybrid technology, become a barrier to implementation of new technologies. [EPA-HQ-OAR-2014-0827-1164-A1 p.29-30]

DTNA also requests the agency look at the history of work required to meet OBD requirements and, when setting the timing of emission change overs, consider the future work that will be required. The efforts spent on OBD development essentially are equal to those spent on emissions development, but on top of this the ARB layers the additional burden of improving OBD systems every year. OBD development becomes a particular timing challenge because time consuming final development and validation testing of OBD calibrations can only begin after near production calibrations are finalized. Because of OBD demands it is no longer possible to finalize production calibrations close to start of production as had been the case prior to inception of OBD. The agencies should recognize the new realities of development needs and provide at least 5 years between each emission change. [EPA-HQ-OAR-2014-0827-1164-A1 p.30]

Organization: Innovus Enterprise LLC

*Item 3: 40CFR 86.010-18 On-Board Diagnostics for Heavy-Duty Vehicles.*
On page 40523 of the proposed rule, EPA requests comments on the need to preserve EPA specifications for OBD and on the need to make adjustments or allowances from the CARB regulations to work for EPA implementation. It is our position the EPA should not default to CARB for setting what would in effect be national standards. On the contrary, we should be working towards harmonization back to the EPA national standards. We should have standards which cross all 50 States and standards where authentic promulgation of regulation is conducted. We will stop and leave the political discussion as to whether there truly is efficiency and effectiveness in the CARB mobile source program for another forum. However, the fact many large manufactures certify now to CARB standards for a 50 state solution should not be misconstrued as being a favored option but one out of necessity.

Our suggestion: Yes, keep the EPA specifications, especially for small business such as ourselves who are trying to work through an EPA certification plan for HDDE and OBD. [EPA-HQ-OAR-2014-0827-1116-A1 p.8]

Comment on Topic Where NPRM Requests Comment

Comment – OBD for heavy-duty vehicles

The NRPM requests comment on the proposal to change U.S. EPA and NHTSA regulation to simply require manufacturers to meet the California OBD requirements. Given that, as U.S. EPA and NHTSA state, manufacturers in almost all cases certify based on the California regulations and procedures today, CARB staff generally supports this proposal. However, because California OBD requirements are in some cases more stringent than federal OBD requirements, it is important to note that some vehicles and engines currently certified through U.S. EPA and NHTSA alone as federal certifications may not be able to comply with California requirements without significant improvements to their OBD systems. If a manufacturer seeks certification of previous federal only system in California, CARB staff will require necessary improvements, which could be a significant increase in workload for the applicant and staff and could consequently increase certification timing for all applicants, depending on the additional volume of certifications. Additionally, staff has some questions regarding those situations in which U.S. EPA and NHTSA would continue to reserve the right to certify vehicles or engines as “Federal Only” certifications. Specifically, if U.S. EPA and NHTSA desire to maintain special situations it must be made clear that the vehicle is not certified to the California OBD regulation by CARB and the OBD compliance parameter identification (PID) from the scan tool (PID $1C in SAE Standard J1979) would need to report that it is a federal vehicle, even if U.S. EPA and NHTSA used the California requirements as the basis for their certification. Also, it is not clear whether U.S. EPA and NHTSA would select separate engine families for demonstration under 40 CFR 1971.1 (i) that are independent and addition to the families selected by CARB. [EPA-HQ-OAR-2014-0827-1265-A1 p.109]

Organization: Odyne Systems LLC

There are still open questions around the central operator of the Malfunction Indicator Light (MIL) for Heavy-Duty Onboard Diagnostics (HD OBD) systems. As Odyne is a systems provider and not an OEM, we manage the diagnostics of our system and not the vehicle. Since OBD can be handled differently by each OEM and is not standardized, it is difficult for Odyne to understand how we fit into the process. EPA may seek to have every vehicle fully OBD compliant, though it will be critical to differentiate between the conversion technology and its basic diagnostics limitations. There must be a clear definition and understanding of the difference between full OBD and basic diagnostics. For example, we have basic diagnostics incorporated into our system, though we are not certain if this meets base requirements. In this case, we do not trigger the MIL since we use our own operator display. We
have also run into issues relative to vehicle emissions readiness during testing. Again, since we do not have control over the vehicle, and do not have OEM support; it is very difficult to figure out how to precondition the vehicle to get the monitors ready and working. Also each OEM / vehicle may have different strategies for operating their monitors. We can demonstrate that we do no harm and do not create any MIL/DTC, but it is very difficult to address the monitors without support. Another issue we experienced is that there are not common or standardized scan tools to use, so we have had to work with several tools to cover all the vehicles we manage. Overall, we would like to urge EPA to allow for flexibility in allowing innovative and smaller manufacturers to navigate OBD issues. [EPA-HQ-OAR-2014-0827-1239-A1 p.24-25]

EPA Must Ensure Flexibility in Implementing California OBD Requirements

Under 40 C.F.R. 1806-17, specified LDVs, medium-duty passenger vehicles and certain HD vehicles must comply with the 2013 OBD requirements adopted for California (with certain enumerated exceptions). EPA has requested comment on whether the agency should require that manufacturers meet California OBD requirements in a manner similar to that contained in this provision. [EPA-HQ-OAR-2014-0827-1284-A1 p.58]

While Allison believes that there is a benefit from aligning EPA and California OBD requirements, we have concerns that adopting California OBD standards could limit the ability to utilize alternative approaches, such as those outlined in the Proposed Rule at Section XIV(A)(1) with respect to the certification of hybrid vehicles. Within the final rule, EPA must maintain the ability to address the sometimes difficult problems that arise with regard to certification; any provision to implement this concept should allow for the development of a common set of requirements that may be applied nationally and contain needed flexibilities. [EPA-HQ-OAR-2014-0827-1284-A1 p.58]

While EPA has not put forward proposed regulatory language for such a provision, Preferences 40 C.F.R. 1806-17. This specifies a particular California OBD-II requirement (California 2013 OB-II requirements contained in 13 C.C.R. 1968.2, as enacted on July 31,2013). Any reference to California regulations with regard to future HD OBD standards must follow a similar course. That is, EPA should reference an existing California provision with specificity so as to remove any suggestion that updates or revisions to the current regulation are allowable solely at the behest of the state. In addition, as provided within 40 C.F.R. 1806-17, EPA should also allow for certain exceptions to apply and not merely incorporate the California regulation by reference. That is, EPA should retain within the regulation the ability to revise requirements or grant exceptions. [EPA-HQ-OAR-2014-0827-1284-A1 p.58]

Alternately, California is working on “Proposed Regulation to Provide Certification and Aftermarket Conversion Flexibility for Innovative Medium- and Heavy-Duty Engine and Vehicle Emission Reduction Technologies (Innovative Technology Regulation),” EPA should evaluate this approach in order to develop common approach to standards in this area. Volume thresholds contained in the California initiative, however, would need to be adjusted upwards to reflect the national scope of the program. [EPA-HQ-OAR-2014-0827-1284-A1 p.59]

Response:

We have decided not to act on the request for comment related to heavy-duty OBD certification. This preserves the existing policy of allowing manufacturers to meet federal requirements by demonstrating compliance with California ARB’s OBD standards, while keeping the analogous OBD standards in EPA’s regulations. See Section 14.3.1 for responses to comments related to alternate engine standards (including alternate diagnostic requirements) for some specialty vehicles including hybrids.
14.3.4 Nonconformance Penalties (NCPs) for Heavy-Duty Vehicles 1908

Organization:  Volvo Group

Revisions to Non-Conformance Penalty Provisions

EPA regulations currently establish three criteria for determining whether, as a result of adopting a new or revised emission standard, non-conformance penalties (NCPs) allowing manufacturers to circumvent the standards are necessary and justified. These criteria are: (1) that the emission standard in question must become more difficult to meet; (2) that substantial work must be required to meet the standard; and (3) that there is likely to be a manufacturer that cannot meet the standard for technical reasons (a “technological laggard”). These criteria have served as the backbone for previous NCP rulemakings, and further serve as important markers for manufacturers and other parties to gauge whether an NCP is justified. [EPA-HQ-OAR-2014-0827-1290-A1 p.79]

In the NPRM, EPA now states in response to comments raised in the 2012 NCP rulemaking process that the existing NCP regulations do not require the Agency to find these criteria are met for purposes of setting an NCP. Specifically, EPA states “the actual regulatory text has never stated that EPA may establish NCPs only if all criteria are met, but rather that EPA shall establish NCPs ‘provided that EPA finds’ the criteria are met.” 80 Fed. Reg. at 40525. Volvo Group disagrees with this assessment, which appears to make a distinction without a meaningful difference. EPA must make a finding on each of the criteria, and that finding must be subject to public review and scrutiny. This is imperative to a robust NCP-setting process that adequately protects complying manufacturers’ competitive interests. [EPA-HQ-OAR-2014-0827-1290-A1 p.79-80]

The Agency then proposes language that “would explicitly state where EPA cannot determine if all of the criteria have been met, we may presume that they have.” Id. In other words, EPA wants to change the language to allow it to set NCPs without having to prove that the criteria are met, and thus eliminate any challenge to an NCP rule based on the criteria. [EPA-HQ-OAR-2014-0827-1290-A1 p.80]

To achieve this goal, EPA proposes that it be allowed to simply presume, without more evidence and analysis, the first two criteria have been met, and base the NCP decision solely on whether there is a technological laggard. 80 Fed. Reg. 40556. Proposed 86.1103-2016(c)(4) states: “Where we are uncertain whether the first and/or second criteria have been met, we may presume that they have been met and make our decision based solely on whether or not the third criterion has been met.” There is no valid reason for the regulations to allow such broad discretion without any required standard or review to be met or any real opportunity for review. Under the proposal, EPA would effectively be able to issue NCPs without giving the public any meaningful opportunity for reviewing and – where necessary – contesting the decision. [EPA-HQ-OAR-2014-0827-1290-A1 p.80]

As if such deference is not enough, EPA further proposes that the Agency may presume that a manufacturer is a technological laggard: (c)(4) as proposed states: “Where we find that a manufacturer will fail to meet a standard but are uncertain whether the failure is a technological failure, we may presume that the manufacturer is a technological laggard.” Id. [EPA-HQ-OAR-2014-0827-1290-A1 p.80]

Thus, EPA proposes that it may assume criteria one and two have been met, and then may presume, without more evidence and analysis, that a manufacturer is a technological laggard. Together, these two proposed changes vitiate the criteria. If this language becomes the rule, EPA will in effect delete the three criteria from the rule, and could simply flip a coin when it comes to deciding whether to
promulgate an NCP rule. It does not provide a process under which EPA would be accountable to the public, and would allow the Agency to establish NCPs for any reason – without any real possibility of public review. The proposed language indicates that EPA believes it should be allowed to avoid examining the facts against the criteria, and make a decision regarding NCPs without any public accountability. As proposed, this language represents a significant change in how EPA would evaluate and promulgate NCPs. Accordingly, Volvo Group opposes the proposed amendments to the NCP provisions related to the criteria for determining whether an NCP rule is justified. [EPA-HQ-OAR-2014-0827-1290-A1 p.80]

Instead, we call on EPA to strengthen the regulatory requirements to ensure that the Agency appropriately reviews the existing criteria. Further, EPA should be held accountable to the statutory requirement to only promulgate NCPs if needed, and ensure that the penalty be set to “remove any competitive disadvantage to manufacturers whose engines or vehicles achieve the required degree of emission reduction ....” This process must be conducted in full view of the public; with the Agency’s cost basis and calculations an open book for public input and comments. [EPA-HQ-OAR-2014-0827-1290-A1 p.80]

Response:

EPA agrees with Volvo statement that the “criteria . . . serve as important markers for manufacturers and other parties to gauge whether an NCP is justified.” However, we disagree with Volvo that these criteria were originally intended to create a burden of proof for EPA or to limit EPA’s ability to establish NCPs. As explained in the NPRM we believe they were established merely “to clarify that manufacturers should not expect EPA to initiate a rulemaking to establish NCPs where these criteria were not met.”

More importantly, we believe Volvo ignores the actual language of the statute, which makes no mention of these criteria. In §206(g)(1), the Act states:

In the case of any class or category of heavy-duty vehicles or engines to which a standard promulgated under section 7521(a) of this title applies, except as provided in paragraph (2), a certificate of conformity shall be issued under subsection (a) of this section and shall not be suspended or revoked under subsection (b) of this section for such vehicles or engines manufactured by a manufacturer notwithstanding the failure of such vehicles or engines to meet such standard if such manufacturer pays a nonconformance penalty as provided under regulations promulgated by the Administrator after notice and opportunity for public hearing. In the case of motorcycles to which such a standard applies, such a certificate may be issued notwithstanding such failure if the manufacturer pays such a penalty.

Thus, the Act seems to presume that NCPs will be available and requires EPA to allow certification in most cases. To the extent there is a burden of proof on EPA, it would seem to be a burden to prove that NCPs are not appropriate rather than a burden to prove that they are. The criteria were created to help EPA show when NCPs are not appropriate. Volvo imagines a “statutory requirement to only promulgate NCPs if needed” but offers no basis for this belief.

Volvo also overstates the discretion EPA could exercise under the proposed regulations. The text to which Volvo objects merely explains how EPA would make its decisions when it is unclear whether the criteria are fully met. It does not envision that EPA would make a decision contrary to the facts, but rather that EPA may sometimes be forced to evaluate the criteria with limited information. Since the Act seems to presume that NCPs will be available, we believe that EPA should be allowed to establish NCPs when the extent to which the criteria have been met is unclear. Moreover, EPA would continue to
solicit public comments on its assessment of the criteria, allowing the public to provide any additional information that could change EPA’s assessment.

Finally, we note that as long as any NCPs are high enough to remove any competitive disadvantage to complying manufacturers, there is no harm to the complying manufacturers.

14.3.5 Modifying Certified Vehicles for Competition

Organization: Specialty Equipment Market Association (SEMA)

The EPA included a proposal hidden within the rulemaking to make it illegal for certified motor vehicles to be converted into vehicles used solely for competition. Specifically, the proposed rule (“Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles--Phase 2”) would add the following language to 40 C.F.R. Part 86(40 C.F.R. § 86.1854), a section of the regulations applicable to new and in-use vehicles, including light duty vehicles:

“Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines.” 80 Fed. Reg. 40138, 40565 (July 13, 2015). [EPA-HQ-OAR-2014-0827-1469-A1, p.1]

These comments are limited to that topic. Although the comments are filed after the October 1, 2015 deadline, SEMA contends the change regarding competition use only vehicles is not within the scope of the GHG rulemaking for medium- and heavy-duty vehicles and that the public was not adequately put on notice of its inclusion. The comments will also address the merits of the issue. [EPA-HQ-OAR-2014-0827-1469-A1,p.1]

EPA Policy on Motor Vehicles Used for Competition

The proposed rule is attempting to bring vehicles used solely for competition within the purview of the Clean Air Act’s definition of “motor vehicles” required to be certified to relevant mobile source emissions standards and remain in their certified configuration. This interpretation of the Clean Air Act’s definition of “motor vehicle” is not in line with the statutory language or legislative history. [EPA-HQ-OAR-2014-0827-1469-A1, p.5]

In the Motor Vehicle Air Pollution Control Act of 1965, Congress first defined the term “motor vehicle” for the purpose of regulating air pollution as “any self-propelled vehicle designed for transporting persons or property on a street or highway.” See Motor Vehicle Air Pollution Control Act, Pub. L. No. 89-272, 79 Stat. 992 (1965) at § 208(2). The 1965 Act sought to regulate emissions from new motor vehicles by making it illegal for “any person to remove or render inoperative any device or element of design installed on or in a motor vehicle or motor vehicle engine in compliance with regulations under this title prior to its sale and delivery to the ultimate purchaser.” Id. at § 203(a)(3) (hereinafter, the “anti-tampering provision”). [EPA-HQ-OAR-2014-0827-1469-A1, p.6]

In 1970, Congress passed the Clean Air Amendments of 1970 (hereinafter, the “1970 Clean Air Act”). Clean Air Act, Pub. L. No. 91-604, 84 Stat. 1676 (1970). The 1970 Clean Air Act created an unprecedented scheme for regulating both stationary and mobile sources of air pollution. The 1970 Clean Air Act did not disturb the definition of “motor vehicle” put in place in 1965 (nor did any other subsequent amendments to the law), but lawmakers did add language to regulate vehicles after first retail sale. The lawmakers expanded the anti-tampering provision to add that no person could render the
emissions controls inoperative “after such sale and delivery to the ultimate purchaser.”” Id. at §7(a)(3). Despite this intent to regulate some vehicles after first retail sale, Congress did not intend the 1970 Clean Air Act to extend the purview of the law to cover vehicles manufactured or modified for racing. The following clarification on this point was made during the House consideration of the congressional conference committee report on the Clean Air Act as signed into law by President Nixon (H.R. 17255):

MR. NICHOLS. I would like to ask a question of the chairman, if I may. I am sure the distinguished chairman would recognize and agree with me, I hope, that many automobile improvements in the efficiency and safety of motor vehicles have resulted from experience gained in operating motor vehicles under demanding circumstances such as those circumstances encountered in motor racing. I refer to the tracks at Talladega in my own State, to Daytona and Indianapolis, competition.

I would ask the distinguished chairman if I am correct in stating that the terms “vehicle’ and “vehicle engine” as used in the act do not include vehicles or vehicle engines manufactured for, modified for or utilized in organized motorized racing events which, of course, are held very infrequently but which utilize all types of vehicles and vehicle engines?

MR. STAGGERS. In response to the gentleman from Alabama, I would say to the gentleman they would not come under the provisions of this act, because the act deals only with automobiles used on our roads in everyday use. The act would not cover the types of racing vehicles to which the gentleman referred, and present law does not cover them either. [EPA-HQ-OAR-2014-0827-1469-A1, p.6]

While it is clear from the legislative history that the Clean Air Act was not intended to regulate race vehicles, that fact should have become even clearer as a result of the 1990 Amendments to the Act. The amendments were made to provide EPA with authority to regulate non-road vehicles and the engines used therein. See 42 U.S.C. § 7550(10)-(11) (2015). Since the term “nonroad vehicle” could easily have been interpreted to include race vehicles, Congress used language to unequivocally exclude vehicles used solely for competition from the definition of “nonroad vehicle.” See id. (“The term ‘nonroad vehicle’ means a vehicle that is powered by a nonroad engine and that is not a motor vehicle or a vehicle used solely for competition.”). [EPA-HQ-OAR-2014-0827-1469-A1, p.7]

The fact that Congress separated out “vehicles used solely for competition” from “motor vehicles” in the definition of “nonroad vehicle” is also instructive, as it indicates the term “motor vehicle” was not understood as covering a “vehicle used solely for competition.” See 42 U.S.C. § 7550(10) (2015) (defining a nonroad motor vehicle as “not a motor vehicle or a vehicle used solely for competition”) (emphasis added). It is also noteworthy that Congress referenced racecars as vehicles used solely for competition – not vehicles built solely for competition. [EPA-HQ-OAR-2014-0827-1469-A1, p.7]

Based on the statutory text and the legislative history, it is clear that vehicles used solely for competition, including a race vehicle that has been created by converting a certified vehicle to a racecar,
are not within the purview of the Clean Air Act. Administrative rulemaking is not a process by which an agency is permitted to circumvent Congress, however, it appears that the EPA is attempting to alter current law as it relates to vehicles used solely for competition. The EPA’s proposal would alter current law by adding the following provision to the regulations: “Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines.” See Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles--Phase 2, 80 Fed. Reg. 40138, 40565 (July 13, 2015). This new language is in conflict with the statutory text and legislative history and should not be inserted into the regulations unless Congress indicates an intent for such a rule to be put in place. [EPA-HQ-OAR-2014-0827-1469-A1, p.7]

Conclusion

Based on the foregoing, SEMA objects to the inclusion of language relating to vehicles used solely for competition in this greenhouse gas rulemaking and requests that it be removed. Among other problematic rhetoric unnecessarily included in the proposal, the following new language regulating all vehicles, including light-duty vehicles, is especially out of place in a rulemaking for greenhouse gas standards covering medium-and heavy-duty vehicles. The language is also out of sync with governing law. [EPA-HQ-OAR-2014-0827-1469-A1, pp.8-9]

Therefore, we specifically request the EPA remove the following proposed language:

§ 86.1854-12 Prohibited acts.
   * * * * *
   (b) * * *
   (5) Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of paragraph (a)(3) of this section and 42 U.S.C. 7522(a)(3). [EPA-HQ-OAR-2014-0827-1469-A1, p.9]

Administrative Procedure Act

Overview: The Administrative Procedure Act (hereinafter, the “APA”) establishes the process by which federal agencies develop and issue regulations. See Administrative Procedure Act, 5 U.S.C. § 553 (2015). Among other considerations, the law is intended to provide adequate opportunity for the public, and interested parties in particular, to comment on proposed rules. SEMA contends that the EPA failed to comply with the APA when it proposed changes to the regulations to prohibit conversion of certified motor vehicles to competition use only vehicles. SEMA’s analysis below includes factors that courts have considered when evaluating agency compliance with the APA. [EPA-HQ-OAR-2014-0827-1469-A1, p.2]

Failure to Alert Public of Rulemaking: The table of contents for the 629-page rulemaking does not alert the public that the EPA is proposing a significant policy change on how competition use engines/vehicles are regulated. The table of contents does not include reference to “Competition Use Engines/Vehicles.” The topic is covered along with other seemingly minor issues under the heading “XIV. Other Proposed Regulatory Provisions.” [EPA-HQ-OAR-2014-0827-1469-A1, p.2]

Non-Germane: The subject rulemaking will establish the next generation GHG emissions and fuel economy standards for medium- and heavy-duty engines and vehicles. The subject matter referenced in the rulemaking’s title and considered within the broader scope of the rulemaking does not logically
encompass the modification of a certified vehicle for competition use. Further, this is not the first time the EPA has issued GHG emission standards for medium- and heavy-duty engines/vehicles. Therefore, inclusion of an unrelated topic within a continuing series of rulemakings is unexpected, if not unprecedented. [EPA-HQ-OAR-2014-0827-1469-A1, p.2]

Rulemaking Does Not Cover Light-Duty Vehicles: By its terms, the rulemaking covers medium- and heavy-duty engines and vehicles. It does not apply to light-duty engines and vehicles, which are regulated under separate EPA rulemakings. Nevertheless, many certified light-duty vehicles may be modified for competition use, and the section of the rules into which the EPA seeks to insert a prohibition against street-to-race vehicle conversions is applicable to light-duty vehicles. The public has not been put on notice that the rule governing medium- and heavy-duty engines/vehicles potentially applies to certified light-duty engines/vehicles. [EPA-HQ-OAR-2014-0827-1469-A1, p.2]

Change of Policy: Before the Clean Air Act was enacted and since that date, thousands if not millions of certified vehicles have been modified to become vehicles used solely for competition. Products have been manufactured, sold and installed on these competition vehicles throughout this time. SEMA has been working with the EPA on ways to regulate potential dual-use products, defined as products that could be used on both competition-use only and certified motor vehicles. However, the EPA has never implemented a policy making it illegal for certified vehicles to become competition-use only vehicles. Such a policy would overturn decades of understanding within the regulated community and expose that community to unfair findings of noncompliance and civil penalties. [EPA-HQ-OAR-2014-0827-1469-A1, pp.2-3]

Arbitrary, Capricious and an Abuse of Discretion: The EPA is seeking to change policy that has been in place for decades and it does not adequately address this change in the summary or explanatory text published in the Federal Register. The only text that could be read as explaining the proposed addition of the language to prohibit street-to-race vehicle conversions are the following paragraphs within the 629-page proposed rule, which do not even reference the part being changed – part 86:

The existing prohibitions and exemptions in 40 CFR part 1068 related to competition engines and vehicles need to be amended to account for differing policies for nonroad and motor vehicle applications. In particular, we generally consider nonroad engines and vehicles to be “used solely for competition” based on usage characteristics. This allows EPA to set up an administrative process to approve competition exemptions, and to create an exemption from the tampering prohibition for products that are modified for competition purposes. There is no comparable allowance for motor vehicles. A motor vehicle qualifies for a competition exclusion based on the physical characteristics of the vehicle, not on its use. Also, if a motor vehicle is covered by a certificate of conformity at any point, there is no exemption from the tampering and defeat-device prohibitions that would allow for converting the engine or vehicle for competition use. There is no prohibition against actual use of certified motor vehicles or motor vehicle engines for competition purposes; however, it is not permissible to remove a motor vehicle or motor vehicle engine from its certified configuration regardless of the purpose for doing so. [EPA-HQ-OAR-2014-0827-1469-A1, p.3]

EPA is proposing in 40 CFR 1037.601(a)(3) to clarify that the Clean Air Act does not allow any person to disable, remove, or render inoperative (i.e., tamper with) emission controls on a certified motor vehicle for purposes of competition. An existing provision in 40 CFR 1068.235 provides an exemption for nonroad engines converted for competition use. This provision reflects the explicit exclusion of engines used solely for competition from the CAA definition of “nonroad engine.” The proposed amendment clarifies that this part 1068 exemption does not apply for motor vehicles. [EPA-HQ-OAR-2014-0827-1469-A1, p.3]

SEMA contends that to change the policy now, without proper public notice, would be considered arbitrary, capricious and an abuse of discretion under the APA. If the EPA intends to change decades of previously applied policy, SEMA contends such a change must take place within a separate rulemaking. Further, as will be explained below, SEMA contends that existing law establishes a clear policy for vehicles used solely for competition and that only Congress has the authority to make the proposed policy change, not the EPA through a rulemaking. [EPA-HQ-OAR-2014-0827-1469-A1, p.4]

The EPA’s proposed policy change has no basis in the evidence or analysis presented. Under the APA, an agency has an obligation to publish a statement of reasons that will be sufficiently detailed to permit potential judicial review. In this instance, the EPA has placed the burden on the public to provide justification for maintaining decades of previous interpretation of marketplace activities affirming that street vehicles can be modified to create vehicles to be used solely for competition. The EPA notes expanded powers when it states: “This allows EPA to set up an administrative process to approve competition exemptions, and to create an exemption from the tampering prohibition for products that are modified for competition purposes.” While threatening in potential scope, this statement is unexplained and fails to meet a conclusion of reasonableness and rationality. For example, the term “administrative process” could be interpreted as authorizing the EPA to establish a database of motor vehicle registrations to confirm that none of the millions of vehicles in the national vehicle fleet have been converted to competition use. [EPA-HQ-OAR-2014-0827-1469-A1, p.4]

Due Process Considerations

Constitutional due process demands agencies provide adequate notice to regulated individuals. This notice can be made through the informal notice and comment rulemaking process using the Federal Register, or actual notice may be provided directly to interested members of the public. As settled Supreme Court precedent instructs: “An elementary and fundamental requirement of due process in any proceeding which is to be accorded finality is notice reasonably calculated, under all the circumstances, to apprise interested parties of the pendency of the action and afford them an opportunity to present their objections.” See Mullane v. Cent. Hanover Bank & Trust Co., 339 U.S. 306, 314 (1950). [EPA-HQ-OAR-2014-0827-1469-A1, p.5]

The EPA has failed to provide actual notice of their proposed changes to the regulated industry despite ample opportunity to do so. SEMA has been in discussions with the EPA for years on the issue of street-to-race vehicle conversions. The discussions have focused on helping the EPA find ways to prevent racing products from finding their way onto street vehicles. In fact, EPA personnel participated in a presentation at an industry trade show sponsored by SEMA on November 5, 2015 to speak to this very issue and made no mention of the pending rulemaking proceeding. It does not seem unreasonable that the EPA should make some effort to communicate to the industry a rulemaking that seeks to regulate street-to-race vehicle conversions in light of this extensive history between the Agency and the regulated entities. [EPA-HQ-OAR-2014-0827-1469-A1, p.5]

Where the Federal Register is used to provide constructive notice to interested parties, the entry should at least be drafted in a manner reasonably calculated to inform the reader that the agency is attempting to regulate in a particular area. In this instance, the EPA has titled its rulemaking “Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles--Phase 2,” and its summary provides insufficient notice that light-duty engines and vehicles, specifically those
used solely for competition, are affected by the proposed rule. [EPA-HQ-OAR-2014-0827-1469-A1, p.5]

Other Implications and Considerations

The proposed rule would create new law without adequate notice to the regulated parties, most importantly the motorsports industry, and upset decades of industry practice. The National Association for Stock Car Auto Racing (NASCAR) was founded in 1948 on the premise that ordinary street cars could be converted into racing machines. Conversely, participants in demolition derbies seek to destroy other former street vehicles that have been modified for potential destruction. In between these two extremes are a myriad of other types of racing events, with participants that range from professionals to novices using vehicles that have been modified for racing use. If the EPA intends to continue its push for a policy prohibiting conversion of street vehicles to vehicles to be used solely for competition, it must put the motorsports industry on proper notice and explain its rationale, including the statutory authority for such a prohibition. [EPA-HQ-OAR-2014-0827-1469-A1, p.8]

Response:

The proposal included a clarification related to vehicles used for competition to ensure that the Clean Air Act requirements are followed for vehicles used on public roads. This clarification is not being finalized. EPA supports motorsports and its contributions to the American economy and communities all across the country. EPA’s focus is not (nor has it ever been) on vehicles built or used exclusively for racing, but on companies that violate the rules by making and selling products that disable pollution controls on motor vehicles used on public roads. These unlawful defeat devices lead to harmful pollution and adverse health effects. The proposed language was not intended to represent a change in the law or in EPA’s policies or practices towards dedicated competition vehicles. Since our attempt to clarify led to confusion, we have decided to eliminate the proposed language from the final rule.

We will continue to engage with the racing industry and others in its support for racing, while maintaining our focus where it has always been: reducing pollution from the cars and trucks that travel along America’s roadways and through our neighborhoods.

14.4 Additional Technical Amendments

14.4.1 Miscellaneous Amendments to 40 CFR Parts 85, 86 and 6001915

Organization: Daimler Trucks North America LLC

Part 85 Changes - We agree with all the changes or modifications done to Part 85. Daimler also described several provisions requiring further discussion. [EPA-HQ-OAR-2014-0827-1164-A1 p.121]

Organization: California Air Resources Board (CARB)

Support Comment

Comment – CARB Staff Supports Improved Definitions

The CARB staff supports U.S. EPA and NHTSA’s proposed addition of, and clarification to, definitions throughout the proposed language, specifically in 40 CFR 86.1803-01, the addition of definitions for a cab-complete vehicle, an incomplete vehicle, transmission type, the addition of automated manual and continuously variable transmissions to the list of basic transmission types (page 40573 of the NPRM). [EPA-HQ-OAR-2014-0827-1265-A1 p.188]
Support Comment

Comment – Miscellaneous support

The CARB staff supports the addition of DPF filters to the list of items that require a regular maintenance interval of 50,000 miles/1500 hours (40 CFR 86.004-25 (b)(4)(i)). [EPA-HQ-OAR-2014-0827-1265-A1 p.189]

Response:

We are adopting the provisions as proposed and as supported by the commenters.

14.4.2 Applying 40 CFR part 1068 to Heavy-Duty Highway Engines and Vehicles

Organization: American Automotive Policy Council

Emissions Defect Reporting Provisions

The Heavy-Duty GHG Proposal includes changes to the Emissions Defect Reporting for heavy-duty vehicles and engines. Full-line manufacturers have been reporting emission defects for many years. These manufacturers have consistent tools and processes for both light-duty and heavy-duty vehicles and engines. The proposed regulatory changes to § 85.1901 would force full-line light- and heavy-duty vehicle manufacturers to use two separate defect reporting processes, adding little value at the cost of unwarranted complexity and opportunity for error. EPA should allow full-line manufacturers that have robust emissions defect reporting processes to continue to use the existing emissions defect reporting regulations for all vehicles. [EPA-HQ-OAR-2014-0827-1238-A1 p.35]

Organization: Volvo Group

Defect Reporting and Recall Procedures

Manufacturers should retain the option to submit defect reports and manage recalls under the provisions of Part 1068 or Part 85 [EPA-HQ-OAR-2014-0827-1290-A1 p.68]

EPA proposes that heavy-duty engine and vehicle manufacturers submit emissions related defect reports according to the provisions of 1068.501, effective in 2018. Currently, heavy-duty manufacturers have the option of submitting defect reports according to the procedures detailed in §85.1901, or using the procedures in §1068.501. [EPA-HQ-OAR-2014-0827-1290-A1 p.68]

Volvo Group has invested considerable time and resources to improve the processes and systems used to identify, track, quantify, and characterize defects so as to reliably and accurately keep EPA informed according to the requirements of §85.1901. These improved processes and systems are now, and have been for some years, quite robust. A number of the tracking mechanisms and information sources contained in §1068.501 that are used to identify emissions-related defects are already integrated into systems being used today to identify and track emissions related defects according to §85.1901. The one that is not, in-use testing, is not believed to be a viable means for discovering systemic failures of emissions related defects. As an integrated manufacturer, we have no external vehicle manufacturers that could be a source for defect information. [EPA-HQ-OAR-2014-0827-1290-A1 p.68]
Volvo Group does, in fact, have a system for reporting defects according to California warranty reporting requirements. This system is currently adapted to the volume of engines sold in California. To adapt that system to support nation-wide sales would potentially affect the accuracy of the report and would be cost prohibitive with little gain because, as mentioned earlier, most of the information sources required per Part 1068 are already integrated into existing systems used for defect reporting under Part 85. Furthermore, the thresholds defined in Part 1068 are more forgiving than those currently defined in Part 85 as followed by Volvo Group, and therefore may be less, rather than more informative to the Agency for purposes of controlling and addressing emissions related defects. [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

Considering the foregoing, and considering the investment made to build a robust system for reporting defects under the provisions of Part 85, Volvo Group proposes that EPA maintain the option to heavy-duty highway engine and vehicle manufacturers to report under the provisions of Part 85 or Part 1068. While 1068.501 (a)(6) already provides that “You may ask us to allow you to use alternate methods for tracking, investigating, reporting, and correcting emission-related defects...,” Volvo Group proposes that you explicitly state the manufacturer’s option to report defects and manage recalls under Part 85. [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

Response:

EPA is concerned that the defect-reporting provisions of 40 CFR part 85 are outdated. They rely on manufacturers to set up their own reporting protocol, with the expected result that compliance practices will vary widely from one manufacturer to another. It is also the case that the reporting threshold of 25 vehicles is far too low in the context of engine and vehicle models that with annual production volumes of 50,000 units, or much more. We adopted defect-reporting provisions in 40 CFR part 1068 that address these concerns in a way that provides realistic thresholds that are dependent on production volumes, with an additional feature to provide an initial, higher threshold to allow for filtering out defects that turn out to be unrelated to emissions. We intend to pursue similar changes for light-duty vehicles in a future rulemaking, as noted in the next section. The question for this rulemaking is whether to make changes to all light-duty vehicles and heavy-duty engines in one later rule, or to make progress in this rule by migrating the defect-reporting requirements for heavy-duty engines now.

AAPC states a preference to change nothing. We believe, rather, that it is in the interest of both EPA and manufacturers to migrate to updated defect-reporting requirements in stages, gaining experience that will further inform later stages of rulemaking changes.

It is not clear how Volvo can have a system that already aligns closely with the new requirements, yet claims that it would be cost-prohibitive to make the change. It is also unclear why information from in-use testing is considered non-viable for purposes of identifying emission-related defects. The new defect-reporting program simply requires the manufacturer to make note of information revealing that engines have emission-related defects. If in-use testing does not reveal engine defects, it is not factored into the assessment; conversely, if in-use testing reveals engine defects, those should be counted along with defect information from other sources. We are aware that the new thresholds allow for a greater number of defects that go unreported; we count that as a positive feature of the new program because, as noted above, a defect-reporting threshold of 25 units is badly matched to production volumes of heavy-duty highway engines.

The provision in §1068.501 allowing for an alternate defect-reporting plan says that we may approve plans that are at least as effective as the new program. We will not approve methods based on 40 CFR part 85 as an alternate method.
14.4.3 Applying 40 CFR part 1068 to Light-Duty Vehicles, Light-Duty Trucks, Chassis-certified Class 2B and 3 Heavy-Duty Vehicles and Highway Motorcycles

Organization: Alliance of Automobile Manufacturers and Association of Global Automakers

1. Emission defect reporting, recall and hearing provisions should be proposed in a separate rulemaking

We do not support the proposal to amend the emission defect, recall and hearing provisions for any on-highway vehicles in this rulemaking. The emission defect and recall provisions are well established regulatory processes with well understood inputs and outputs. Any proposal to amend them warrants consideration via a rulemaking process that evaluates the opportunities, benefits, burdens, and costs of any changes. Although we would be prepared to offer comment and input to such a rulemaking in the future, we do not at this time support further action on it in this proposal. [EPA-HQ-OAR-2014-0827-1271-A1 p.3-4]

While the Preamble does contain some discussion with respect to the movement of recall- and hearings-related general compliance provision for the LD sector into Part 1068 (see 80 FR 40530), the NPRM contains virtually no discussion of the LD proposal to require a transition to the emission defect reporting provisions in Part 1068. There is only a cursory, one-paragraph mention of the issue (80 FR 40526), as if to suggest that changes in defect reporting requirements are a matter of little consequence. In the context of this 629-page rulemaking, Alliance and Global Automakers members nearly missed the issue. Given the minor mention and lack of substantive discussion, it is not clear to the industry whether EPA’s intention was simply to get an initial industry reaction to the proposal, or whether the Agency is really intending to finalize defect reporting changes as part of this HD rulemaking. [EPA-HQ-OAR-2014-0827-1271-A1 p.4]

Current regulations allow manufacturers of heavy duty on-highway engines to optionally use the defect reporting provisions of 1068.501. This allows for manufacturers who only produce heavy duty on-highway engines and other off-highway engines already subject to 1068.501 to use a single defect reporting process. This also allows for manufacturers who produce both light duty and heavy duty on-highway products to use a single harmonized defect reporting process. The proposed regulatory changes to section 85.1901 would force full-line light and heavy duty vehicle manufacturers to use two separate defect reporting processes, adding little value at the cost of unwarranted complexity and opportunity for error. [EPA-HQ-OAR-2014-0827-1271-A1 p.4]

If the Agency wishes to eliminate the flexibility described above, we think it should explain its reasons for doing so. However, the NPRM offers no insight into EPA’s thought process, options it considered, projected impacts on manufacturers, or overall benefits and costs of the proposal. In the absence of this kind of substantive analysis, we do not think the issue is adequately teed up for rulemaking. In discussions with EPA Staff, EPA indicated that it is only seeking comments on light-duty defect reporting issue at this time and that EPA will conduct a separate rulemaking on this issue at some future date. [EPA-HQ-OAR-2014-0827-1271-A1 p.4]

In light of the above, we do not support EPA’s proposal to change the defect reporting requirements at this time. We recommend that EPA’s final rule not include any provisions for changing emission defect, recall and hearing procedures as proposed. However, the Automakers are committed to working with EPA on issues of this kind, through meetings, workshops and other opportunities for dialogue. If EPA continues to believe that changes to the defect reporting provisions are desirable, we would be happy to engage in further discussions with EPA Staff. We think that further dialogue of this nature would
benefit both the Agency and the industry ahead of any proposal to alter the defect reporting requirements as part of a future rulemaking on this issue. [EPA-HQ-OAR-2014-0827-1271-A1 p.4-5]

Finally, we note there is a typographical error in 1037.250(b)(5): “Also identify the technologies that make up the certified configuration for each vehicle your produce.” [EPA-HQ-OAR-2014-0827-1271-A1 p.15]

**Organization:** Daimler Trucks North America LLC

**Defect reporting provisions for LDVs** – The EPA proposes to revise defect reporting provisions covering, among other things, light-duty vehicles. 80 Fed. Reg. 40530 and 40 CFR § 1068.501 (July 13, 2015). DTNA agrees with the position conveyed by the Alliance of Automobile Manufacturers: while adjusting the defect reporting provisions looks like a good idea, the information presented by EPA is too general and imprecise for us to truly understand how the rules would impact manufacturers. The proposal needs to be elaborated in much more detail before we can comment adequately. That said, we are generally interested in replacing a fixed threshold of 25 defects as the basis for defect reporting with a scaled approach that would require defect reporting only after the manufacturer finds some larger number of actual emission-related defects. For example, investigating once possible defects exceed 5 to 10% of production, with a requirement to report defects if confirmed defects exceed a rate of 1 to 2% of production or 25 defects, whichever is greater, may be a workable approach. Note that we think it still important to include the 25 defect threshold so that small production runs are not inadvertently drawn into excessive amounts of reporting. We wish to add that we recommend that California adopt a similar system to the EPA, so that we can have one system nationwide. [EPA-HQ-OAR-2014-0827-1164-A1 p.136]

**Applying the General Compliance Provisions of 40 CFR Part 1068** – The agencies request comment on requiring manufacturers to follow the California defect-reporting scheme for their EPA-certified vehicles. We have one concern with the California reporting requirements, which require reports at numerical thresholds based on one state’s worth of defects, being used for reporting on 50 states’ vehicles or engines; the impact would be to require many reports in cases where there are no significantly repeated problems. However, there may be some benefits to a change, in particular because we think that Part 1068 requires reporting too early in a process, when a manufacturer is not sufficiently certain there is even a problem to report—potentially resulting in the agency getting too many unnecessary reports. Additionally reporting per failure mode would be preferred over providing unfiltered warranty claims, as this would allow manufactures to do deep analysis of potential defects and report defects that are known to potentially affect emissions. Reporting of unfiltered warranty claims would require significant resource of EPA to analyze data, and duplicate the same work done by a manufacturer, as any one component may have several potential different failure modes, and some may have no effect on emissions. [EPA-HQ-OAR-2014-0827-1164-A1 p.117]

**Organization:** Motorcycle Industry Council, Inc. (MIC)

1. Proposal to **Apply Part 1068 General Compliance Provisions to Highway Motorcycles.**

MIC supports this proposal as a general proposition. It should provide needed harmonization with other products, such as off-highway motorcycles and ATVs, which are also manufactured by a number of our members and which are already subject to Part 1068. Harmonization will promote better understanding of EPA requirements by all our members, and help promote compliance. [EPA-HQ-OAR-2014-0827-1158-A1 p.1]
2. Proposal to Apply Subpart F (Reporting Defects and Recall) of Part 1068 to Highway Motorcycles.

EPA is asking for comments in particular on its proposal to include the reporting and recall provisions in Subpart F of Part 1068 to highway motorcycles. MIC agrees that Subpart F, including the proposed amendments to Secs. 1068.501, 1068.505 and 1068.515, should be included and made applicable to highway motorcycles, as part of the overall movement toward harmonization. However, MIC is strongly opposed to the suggestion (at 80 FR 40530) of adopting the California regulations governing reporting of defects and recall on a national basis. While the concept of uniform national provisions for reporting and recall is an appealing one, we believe that objective should be achieved by extending EPA regulations to California, rather than by applying California's regulations nationally. California's reporting and recall regulations (13 CCR 2111-2121 and 2122-2135) are unnecessarily burdensome and complex (with no less than three overlapping types of reports) and have a history of causing disputes and even litigation. The EPA regulations appear to be much clearer and less complex, and would be the preferred model for nationalization. We encourage EPA to work with the California Air Resources Board on extending the EPA regulations to California. [EPA-HQ-OAR-2014-0827-1158-A1 p.1-2]

Response:

In the final rule we are adopting the proposed migration of hearing procedures to 40 CFR part 1068. As described in the Preamble, this change aligns with regulations adopted by EPA’s Office of Administrative Law, and provides a unified set of hearing provisions for all sectors covered by emission standards under Title II of the Clean Air Act. The old and new hearing procedures are nearly identical, so we expect no adverse circumstance to result from the migration.

We are retracting the proposed change to migrate recall provisions for vehicles certified to standards under 40 CFR part 86, subpart S. We believe this would involve only very minor changes, but we agree with the industry that this is better accomplished in a later rulemaking with greater opportunity for deliberation. In particular, we are currently in the process of exploring implementation of recall provisions in a way that will likely lead to a better understanding of the practical opportunities and limitations under the current recall regulations. We will likely be ready to propose regulatory changes in the near future that streamline requirements, reduce unnecessarily restrictive specifications, and improve our ability to effectively manage the overall recall experience.

We did not propose to migrate defect-reporting requirements for vehicles certified under 40 CFR part 86, subpart S, but rather requested comment on the idea in an effort to explore interest. We are aware that the current defect-reporting protocol in 40 CFR part 85 has led to widely varying implementation practices by different manufacturers. This may lead to a competitive advantage for companies that take a more lenient approach. We expect to pursue this migration to 40 CFR part 1068 in a later rulemaking. We will at that point be ready to work with manufacturers, individually and collectively, to design an updated defect-reporting program that is streamlined and effective, and provides a level playing field for all manufacturers.

We look forward to updating the certification and compliance regulations for highway motorcycles similar to what has been done for recreational vehicles and other sectors. While we contemplated a head start on this migration for recall and defect-reporting, we are not finalizing those changes in this rule. We believe it is most important to adopt updated recall and defect-reporting procedures for highway motorcycles and light-duty vehicles at the same time. This will allow us to consider these sectors together in determining any appropriate provisions that should apply differently than what we have already adopted in 40 CFR part 1068. It will also allow us to update reporting software for both as part of a single effort.

14.4.4 Amendments to General Compliance Provisions in 40 CFR part 1068
**Organization:** Daimler Trucks North America LLC

We agree with the changes done on Part 1068. [EPA-HQ-OAR-2014-0827-1164-A1 p.121]

**Organization:** Truck & Engine Manufacturers Association (EMA)

The Preamble description of the proposed change to §1068.201 references the ability to change an engine from one exemption to another. This clarification is welcome, but the proposed regulatory language change in §1068.201(c) falls short of clarifying the ability to change labels when making such an exemption change. EMA requests that the regulatory requirements as described in §1068.201(c) be revised to clarify that labels can be changed for exemptions that are allowed, without approval by the Agency. [EPA-HQ-OAR-2014-0827-1269-A1 p.85]

**Response:** We have removed the proposed changes to §1068.201 from this rulemaking, which will allow us to address issues related to redesignating exempt engines in a future rulemaking. We note that current regulations at §1068.101(b)(7) describe provisions related to removing and replacing incorrect emission labels.

The Preamble discussion of §1068.240 describes a requirement to identify the disposition of the engine being replaced in addition to a revision to the reporting requirements. The proposed regulatory language includes the welcome change to the reporting requirements, but does not include any requirements associated with the disposition of the replaced engine. EMA supports the lack of regulatory requirements associated with the disposition of the replaced engine, and therefore requests that EPA not implement any requirements associated with engine disposition without a subsequent notice and comment rulemaking process. [EPA-HQ-OAR-2014-0827-1269-A1 p.85]

**Response:** The revised regulation clarifies that an engine may count as a tracked replacement engine under §1068.240(b) only if the manufacturer meets all applicable requirements by the (revised) due date for the required report. It is clear that the disposition of the engine is one of the conditions for tracking under paragraph (b), so this particular point does not need to be called out separately. We will consider adding this to the regulation if there is any uncertainty on that point for implementation.

EMA also supports the proposed amendment to §1068.240(c)(3), which would change the reporting requirement for replacement engines from March 31st to September 30th. However, EMA requests clarification regarding the proposed regulatory language stating that “you must also include the total number of replacement engines you produced under paragraph (b), (d), and (e) of this section.”

Currently 40 CFR 1042.615(a) specifies that it applies in lieu of §1068.240(b), and includes the reporting requirements as specified in §1042.615(a)(3). To avoid confusion and the potential for duplicate reporting, EMA requests that §1068.240(c)(3) be revised to state: “you must also include the total number of replacement engines you produced under paragraph (b), (d), and (e) of this section, including engines previously reported per 40 CFR 1042.615(a)(3).” [EPA-HQ-OAR-2014-0827-1269-A1 p.85-86]

**Response:** We have revised §1068.240 to reference the marine engines as suggested by EMA.

The substantial revision to Subpart G providing clarification regarding the available hearing procedures may be both necessary and desirable to address the wide diversity of products regulated per Part 1068. However, EMA objects to the proposed regulatory provisions to the extent that they are inconsistent with any provisions of the federal Administrative Procedures Act (including section 553 through 557 of
Title 5), section 307 of the CAA, or subpart 22 of Title 40 of the Code of Federal Regulations. [EPA-HQ-OAR-2014-0827-1269-A1 p.86]

**Response:** We believe the hearing procedures as adopted in 40 CFR part 1068, subpart G, are wholly consistent with the Administrative Procedures Act. We will be ready to adopt any amendment that may be needed to achieve this objective.

The changes proposed to section 1068.505, which relate to remedial requirements regardless of age or extent of service, require clarification. The qualifying requirement that “a determination is made that a substantial number of properly maintained and used engines/equipment do not conform” assumes that the vast majority of the affected engines/equipment are still within their regulatory useful life as prescribed by the applicable regulatory sub-part. However, the related provisions regarding the need to contact the current owners of engines/equipment, regardless of age, are not feasible for nonregistered engines/equipment. Accordingly, EMA recommends that the regulatory language be modified to clarify that while engines/equipment cannot be excluded, the Agency’s determination will include an assessment of the ability of the recall to be effective given the manufacturer’s ability to identify engines/equipment that are subject to the recall. [EPA-HQ-OAR-2014-0827-1269-A1 p.86]

**Response:** We disagree that the qualifying requirement involves any assumption about the status of in-use vehicles. This is merely establishing a principle that manufacturers may not exclude older vehicles from a recall action on the basis of age, once a recall order is issued. It is always understood that manufacturers will be able to perform recall repairs only to the extent that the vehicles are available.

The proposed change to section 1068.505(c) revising the response time for manufacturers required to submit a remedial plan from 60 days, to a designated date but no less than 45 days, provides needed flexibility for circumstances where the 60-day mandate is not feasible. However, the “no less than 45 days” requirement results in significant concern that the 45-day minimum will become the Agency default, regardless of the complexity of the required remedial plan. Accordingly, EMA recommends that the language be revised to require the submission of a preliminary remedial plan allowing the Agency and the manufacturer to determine the appropriate additional required information in accordance with the provisions in 40 CFR 1068.510. [EPA-HQ-OAR-2014-0827-1269-A1 p.86]

**Response:** The manufacturer’s submitted plan is understood to be subject to EPA review for completeness. If there are some things that cannot be addressed or resolved in this timely submission, EPA will work with the manufacturer to supplement that initial submission as needed for an effective recall. It is also understood that manufacturers will respond to EPA input on revisions to the draft remedial plan in a timely manner. We believe the regulatory language as proposed aligns with the suggested approach.

The proposal to change the language in section 1068.515(c) from stating “where” the repair or inspection was completed to “the facility” is acceptable, but EMA requests that the Agency recognize that an electronic tracking system may be a viable option for providing the detailed information, thereby allowing the required label to be significantly less space-consuming. [EPA-HQ-OAR-2014-0827-1269-A1 p.86]

**Response:** We agree with the comment and have revised the regulation accordingly.

**Organization:** Volvo Group
Part 1068 scope of recall and labeling provisions are unduly burdensome with little gain [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

Addressing specifically the provisions of Part 1068, we have concern about the requirements in 1068.505(a) which states “You must remedy at your expense noncompliant engines/equipment that have been properly maintained and used, as described in § 1068.510(a)(7), regardless of their age or extent of service accumulation at the time of repair.” [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

While we agree that it is correct to focus the consideration for a recall on products that are within their useful life, we have concern that the language EPA proposes to add could be interpreted to require the recall of all vehicles and engines still in operation, regardless of whether they have exceeded their useful life. This is beyond the requirements of the regulation and the Clean Air Act. Specifically, the Clean Air Act provides: [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

...the manufacturer of each new motor vehicle and new motor vehicle engine shall warrant to the ultimate purchaser and each subsequent purchaser that such vehicle or engine is (A) designed, built, and equipped so as to conform at the time of sale with applicable regulations under section 7521 of this title, and (B) free from defects in materials and workmanship which cause such vehicle or engine to fail to conform with applicable regulations for its useful life (as determined under section 7521(d) of this title). 42 U.S.C. 7541(A) (Emph. added) [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

EPA, therefore, should either eliminate the proposed language, or clarify it to state: [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

You must remedy at your expense noncompliant engines/equipment that have been properly maintained and used and are still within their useful life, as described in § 1068.510(a)(7). [EPA-HQ-OAR-2014-0827-1290-A1 p.69]

This is important for practical as well as legal reasons. Engines and vehicles that exceed their useful life are typically under a second or even third owner, so the opportunity to locate the owners is limited. Further, compared to the cost, there is little value to performing repairs on engines or vehicles that are approaching the end of their productive life. Most older vehicles are in less intensive operations, and so their emissions contribution is limited. The scope of the recall should therefore be limited to those units that are within their useful life. This makes the requirement similar to the NHTSA practice of limiting the scope of the recall to engines/vehicles no more than 10 years old. [EPA-HQ-OAR-2014-0827-1290-A1 p.70]

Another point we’d like to address are the provisions set forth in 1068.510 and 1068.515 requiring that a label be installed on each engine or vehicle that has been repaired in a recall. This requirement would be new for the industry, and is unduly burdensome because it would add unnecessary expense and complication to the recall process without significant benefit. Achieving good adhesion of a label to a vehicle and especially an engine surface is an engineering challenge, even in the controlled and clean conditions of the new product manufacturing facilities. It’s all the more difficult in the service bay with engine installed in a vehicle. Finding a visible, flat, cleanable surface to apply a label that will remain free from damage and debris is a surprisingly difficult challenge under the hood of a heavy duty vehicle. Such a surface would also have to be clear from sources of excessive heat or engine fluids. In lieu of such a label, a more reliable and simpler access to any recall status for an engine or vehicle is available from dealer and manufacturer electronic records. We would propose that the labeling requirement be removed. [EPA-HQ-OAR-2014-0827-1290-A1 p.70]
Response:

While the regulatory useful life defines a parameter to characterize a manufacturer’s obligation to design and produce engines, the statutory direction to execute a recall describes an obligation to remedy nonconformities on all properly maintained and used vehicles. CAA section 207(c)(1) follows:

If the Administrator determines that a substantial number of any class or category of vehicles or engines, although properly maintained and used, do not conform to the regulations prescribed under section 202, when in actual use throughout their useful life (as determined under section 202(d)), he shall immediately notify the manufacturer thereof of such nonconformity, and he shall require the manufacturer to submit a plan for remedying the nonconformity of the vehicles or engines with respect to which such notification is given. The plan shall provide that the nonconformity of any such vehicles or engines which are properly used and maintained will be remedied at the expense of the manufacturer.

As noted above recall effectiveness always depends on an imperfect ability to identify and procure subject vehicles. However, we believe the statute and therefore the regulations should not allow manufacturers to elect not to remedy a nonconformity under a recall simply because a vehicle is no longer within the useful life period specified it the regulation.

Recall labels are already required for motor vehicles and motor vehicle engines under 40 CFR 85.1803(c). We believe manufacturers can accomplish the engineering necessary to find a location and apply a label with good adhesion to recalled vehicles.

AAPC has the following concerns: [EPA-HQ-OAR-2014-0827-1238-A1 p.35]

- The proposal would require defect reports to be submitted as soon as an investigation is initiated and investigation progress reports must be submitted twice a year until the investigation closes, which could be the full useful life of the vehicle. Thus, manufacturers could be required to file numerous “defect reports” even if the ultimate outcome of the investigation is that there is no defect. This increases both manufacturer and EPA workload for no apparent benefit. EPA should only require reports when defects have been identified, per 40 CFR 1068.501(c). [EPA-HQ-OAR-2014-0827-1238-A1 p.35]
- Current Emissions Defect Reporting requirements apply for five years from the end of the model year in which such vehicles or engines were manufactured. The proposed provisions require emissions defect reporting for the full useful life of the engine/vehicle. This will require substantially more resources for manufacturers and Agencies to monitor and track. This is not value added; it is highly unlikely that defects in design, materials, or workmanship will only become evident more than five years after the end of the model year in which the vehicle was produced. In addition, as time passes the investigation will be confounded by whether the issue identified is normal wear and tear or a defect. [EPA-HQ-OAR-2014-0827-1238-A1 p.35]
- The proposal requires manufacturers to monitor warranty claims and conduct an investigation when the warranty claims and/or other indicators exceed a specified threshold. This may discourage manufacturers from offering any additional warranty, including extended service plans, beyond five years or the regulated warranty. [EPA-HQ-OAR-2014-0827-1238-A1 p.35]
For these reasons, we recommend that the Emissions Defect Reporting requirements continue to apply for five years from the end of the model year in which such vehicles or engines were manufactured. [EPA-HQ-OAR-2014-0827-1238-A1 p.36]

AAPC makes the following recommendations: [EPA-HQ-OAR-2014-0827-1238-A1 p.36]

- EPA should only require reports when defects have been identified, per 40 CFR 1068.501(c). [EPA-HQ-OAR-2014-0827-1238-A1 p.36]

Emissions defect reporting requirements continue to apply for five years from the end of the model year in which such vehicles or engines were manufactured. [EPA-HQ-OAR-2014-0827-1238-A1 p.36]

Response:

The innovation of the defect-reporting methodology for §1068.501 is to set a relatively high threshold for unscreened defects, which triggers the need for an “investigation.” This prospective investigation involves a greater effort to evaluate future defects to confirm whether or not they are emission-related defects. This allows the manufacturer to apply a more focused attention after processing a relatively large number of defects where it is not clear that the defect is emission-related. The lower threshold for confirmed emission-related defects benefits from this screening approach, with the result that defect reports are more likely to involve substantial nonconformity.

It is true that investigation reports are ongoing, but we note that these reports (and the corresponding investigation) are triggered by a high enough level of observed defects that the manufacturer should be paying more attention to determine the cause of the problem. This should align well with the manufacturer’s own interest to address defects, whether or not they are emission-related. Investigation reports may ultimately lead to a defect report, but we find investigation reports to be of significant value in either case.

Manufacturers are expected to monitor warranty claims and other indicators of defects. We would expect manufacturers to never see warranty claims beyond the first five years of a vehicle’s life. Other indicators, such as orders for replacement parts do not involve greater effort to include older vehicles. There may be more incidences of normal wear, but that can be accounted for in considering whether there are emission-related defects. We believe it is appropriate to keep the requirement to monitor for defects throughout the useful life.

The manufacturers’ option to offer extended warranty provisions to their customers is a business and marketing decision for the companies. This may be affected by statutory and regulatory requirements related to emission standards, but this should not cause us to change the way we implement emission standards and related requirements.

Organization: Motorcycle Industry Council, Inc. (MIC)

As an additional amendment to Subpart F, we recommend that EPA add provisions to Sec. 1068.505 making it clear that recalls may be made applicable to engine/equipment family subgroups, and not necessarily to full engine families, so that, where a subgroup is the principal or only source of a defect, a targeted recall of smaller scope can be implemented. This would avoid the problem of over-broad recalls that has been a matter of contention in the past under the California program. [EPA-HQ-OAR-2014-0827-1158-A1 p.2]

MIC is not opposed to this amendment [to 40 CFR 1068.27], but because confirmatory testing has the potential for causing a manufacturer undue hardship by delaying production for weeks and even months,
we request that language be added to specify, where EPA performs confirmatory testing for statistical or market coverage reasons, and not based on evidence suggesting that a vehicle or engine will likely be in noncompliance, that EPA will in such cases issue a conditional certificate of compliance. The conditional certificate would provide that the manufacturer must effect repairs, including recall if necessary, to correct vehicles or engines shown by testing not be in compliance. We suggest adding a new subsection (d) to sec. 1068.27, to read as follows: [EPA-HQ-OAR-2014-0827-1158-A1 p.2]

(d) When we perform confirmatory testing and do not have any prior evidence or cause to believe that the engines/equipment cannot comply with applicable regulations, we will issue, at the manufacturer's request, a certificate of conformity that is conditional on test results demonstrating compliance with all the regulations of this chapter. If our testing demonstrates noncompliance, the manufacturer must make all repairs required to bring the engines/equipment into compliance, including, where we order it, non-voluntary recall as specified in Subpart F of this Part. [EPA-HQ-OAR-2014-0827-1158-A1 p.2]

Response:
We believe the recall provisions already allow EPA to order a recall for a subset of engines or vehicles from a family.

Manufacturers should plan their timelines for submitting applications for certification to allow for confirmatory testing by the Agency. Note that the regulation at 40 CFR 1068.103(c) allows manufacturers to start production once they submit an application; however, those products may not be shipped before the certificate is issued.

Organization: Navy

Navy requested that we expand the automatic exemption for national security to address concerns about access to low-sulfur diesel fuel outside the United States. See Section 14.4.9.

14.4.5 Amendments to Light-Duty Greenhouse Gas Program Requirements 1926

Organization: Alliance of Automobile Manufacturers and Association of Global Automakers

2. Changes to Global Warming Potentials must be accompanied with evaluation and adjustment of GHG standards to maintain existing stringency of the GHG standards

In the NPRM, at 80 FR 40206, EPA proposes to adopt an updated value from the IPCC Fifth Assessment Report for the global warming potential (GWP) of methane (CH4), which would increase the value for CH4 from 25 to a range 28-36. However, neither in the NPRM nor in the RIA is there any discussion about the effects on the stringency of meeting existing LD GHG standards. Automakers do not support the change to GWP of CH4 without a change to the stringency of the GHG rules. We note that EPA, in promulgating the LD GHG rules, stated that it was committed to maintain the stringency of GHG standards [See 77 FR 62777 (October 15, 2012); CH4 emissions make up a component of CREE calculations used to determine compliance with the GHG standards. [EPA-HQ-OAR-2014-0827-1271-A1 p.5]

Response: We are changing the methane GWP, but we are not applying this change to light-duty vehicles in this rulemaking.
3. Regulatory flexibilities being proposed for HD should be extended to LD as well

a. The ability for chassis certified HD vehicles to attest to N2O compliance using an engineering statement (in Part 86 Subpart S 86.1819-14(e)(6)) should also be allowed for LD

In the NPRM at 80 FR 40342, EPA proposes to maintain in the HD GHG Phase 2 program the N2O compliance provisions from the Phase 1 program, and to allow attestation to the N2O standards. We recommend that the ability for chassis-certified HD vehicles to attest to N2O compliance using an engineering statement (in Part 86 Subpart S 86.1819-14(e)(6)) should also be allowed for LD. EPA should allow the continued use of attestation to N2O standards, including the attestation to higher N2O caps (i.e., alternate N2O standard), for all gasoline powered EDVs and FEDVs. [EPA-HQ-OAR-2014-0827-1271-A1 p.5]

The measurement of N2O is still evolving, and since it currently requires many non-automated operations, it greatly increases resource burdens in high-volume production testing LD laboratories. Since most vehicles will meet the N2O cap standards while still meeting the NOX or NMOG+NOX standards, allowing attestation to the standard would still allow the agencies to test for N2O and maintain applicability of N2O standards while reducing costs and testing burden. [EPA-HQ-OAR-2014-0827-1271-A1 p.5]

Response: Revisiting issues related to N2O measurement for the light-duty program are outside the scope of this rulemaking. See the earlier rule for a discussion of N2O measurement.

b. Any option for smaller ETW increments/classes or to analytically adjust FE/GHG test results for HD vehicles should also be made available for LD vehicles

In the NPRM, at 80 FR 40531, the EPA proposes to allow the use of smaller equivalent test weight (ETW) classes for HD vehicles. We support the availability of an option for manufacturers to use smaller ETW increments/classes or to analytically adjust FE/GHG test results for HD vehicles and recommend that these same options be made available for LD vehicles, provided that the option is allowed at the Test Group or Engine Family Level. [EPA-HQ-OAR-2014-0827-1271-A1 p.6]

At this time, the ability of manufacturers to perpetuate an ETW increment change through their respective fleets is unknown. The Automakers are currently investigating the added test burden and workload of developing data at more discrete ETW intervals and anticipate submitting supplemental comments providing this information to the HD GHG NPRM docket. [EPA-HQ-OAR-2014-0827-1271-A1 p.6]

The smaller ETW bins should be allowed at the test group level. Besides test burden and related workload, allowing smaller ETW bins at the test group level will lead to more manufacturers using said bins. This is primarily due to how vehicle programs are managed. Using smaller ETWs would be difficult to implement across an entire manufacturer because program planners are often only responsible for mass within a given platform, model, or even test group. Typically, mass reductions must be justified as narrowly as the test group. Forcing mass reduction justifications beyond the test group level will likely lead to manufacturers maintaining the status quo with respect to ETW. By restricting ETW options to the test group level, manufacturers will not be able to “pick and choose” on a sub configuration level. Test group implementation will allow manufacturers to move vehicles to the smaller ETW bins in a stepwise manner. [EPA-HQ-OAR-2014-0827-1271-A1 p.6]
Also, expanded use of either Analytically Derived Fuel Economy (ADFE) or Analytically Derived CO2 (ADCO2) due to smaller ETW bins should not infringe upon the maximum allowed. This can be justified in that new use of ADFE or ADCO2 would likely only adjust data within a test group, platform, or model. [EPA-HQ-OAR-2014-0827-1271-A1 p.6]

ADFE and ADCO2 as a result of ETW changes should also not be subject to the same confidence level adjustments, or penalties, as traditional analytical adjustments because adjustments due to ETW are between vehicles that are very similar and any confidence penalties, although small, could have a significant impact on small GHG gains due to smaller ETW bins. [EPA-HQ-OAR-2014-0827-1271-A1 p.6]

Response: The suggested changes for the light-duty program are outside the scope of this rulemaking.

4. Comments on EPA’s proposed changes to 40 CFR 600.116-12 (80 FR 40533, 80 FR 40574) and proposals to make minor changes to correct errors and clarify regulations; Comments to NHTSA regarding related provisions of 49 CFR 538.5 and 538.6 [EPA-HQ-OAR-2014-0827-1271-A1 p.7]

In the NPRM, at 80 FR 40574, EPA proposes to add a new paragraph (c)(2) to 40 CFR 600.116-12, pertaining to the treatment of plug-in hybrid electric vehicles for the purposes of Corporate Average Fuel Economy (CAFE). Although further explanation of the intent and reasoning of the changes is limited in the Preamble [80 FR 40533], we make the following comments based on the apparent intent of the proposed regulatory text as currently drafted. [EPA-HQ-OAR-2014-0827-1271-A1 p.7]

In the proposed paragraph (c)(2), the agency sets forth methods to calculate the fuel economy performance for hybrid electric vehicles which have plug-in capability, distinguishing between those which do, and those which do not, qualify as dual fueled automobiles under 49 CFR 538.5. The Automakers note that 49 CFR 538.5 pertains only to passenger automobiles, not to non-passenger automobiles such as light trucks or medium-duty passenger vehicles. For example, 49 CFR 538.5(b) reads, “The minimum driving range that a passenger automobile using electricity as an alternative fuel must have in order to be treated as a dual fueled automobile pursuant to 49 U.S.C. 32901(c) is . . .” [emphasis added] Therefore, the agency proposed language is not clear as to how non-passenger automobiles are to be treated. The Automakers recommend that EPA draw a distinction in calculation method based only on the existing definition of “dual fueled automobile” found at 40 CFR 600.002, which appropriately notes the limitation of the minimum driving range requirements to only passenger automobiles. [EPA-HQ-OAR-2014-0827-1271-A1 p.7]

At the proposed paragraph (c)(2)(ii) (80 FR 40574), for vehicles that qualify as dual fueled automobiles, there are two options for manufacturers: (1) determine fuel economy using utility factors, but without the petroleum equivalence factor as described in the proposed (c)(2)(i); or (2) determine fuel economy using the harmonic average of the fuel economy in charge sustaining mode and the miles per gallon equivalent measured while operating on electricity, adjusted using the petroleum equivalence factor. In the first option, the manufacturer receives potentially greater weighting of electric operation, but is
prevented from applying the petroleum equivalence factor. In the second option, the petroleum equivalence factor is permitted, but the weighting of the two values is defined as equal (50% charge-sustaining miles per gallon, and 50% electric operation). [EPA-HQ-OAR-2014-0827-1271-A1 p.7]

The proposed approach is inconsistent with 49 U.S.C. 32905(e), as amended by the Carl Levin and Howard P. “Buck” McKeon National Defense Authorization Act for Fiscal Year 2015. The amended statute permits a manufacturer to apply a utility factor-based approach and the petroleum equivalence factor in combination for 2016 and subsequent model year vehicles or, at the manufacturer’s option, an equal weighting with the petroleum equivalence factor. The Automakers recommend redrafting the text to permit a manufacturer to choose a utility factor based approach in combination with the petroleum equivalence factor for model years after 2015. [EPA-HQ-OAR-2014-0827-1271-A1 p.8]

Specifically, we recommend the following changes to the proposed text for the added paragraph 40 CFR 600.116-12(c)(2) (redline relative to proposed text in the NPRM): [EPA-HQ-OAR-2014-0827-1271-A1 p.8]

(2) Determine fuel economy values to demonstrate compliance with CAFE standards as follows: [EPA-HQ-OAR-2014-0827-1271-A1 p.8]

(i) For vehicles that do not qualify as dual fueled automobiles under 49 CFR 538.5, determine fuel economy using the utility factors described in paragraph (c)(1) of this section. Do not use the petroleum-equivalence factors described in 10 CFR 474.3. [EPA-HQ-OAR-2014-0827-1271-A1 p.8]

(ii) For vehicles that qualify as dual fueled automobiles under 49 CFR 538.5, determine fuel economy based on the procedure described in paragraph (c)(2)(i) of this section, or based on the following equation, separately for city and highway driving: [EPA-HQ-OAR-2014-0827-1271-A1 p.8]

\[
MPGeCAFE = \frac{1}{0.5/\text{MPGgas} + 0.5/\text{MPGelec}}
\]

Where:

\[\text{MPGgas} = \text{The miles per gallon measured while operating on gasoline during charge sustaining operation as determined using the procedures of SAE J1711 (incorporated by reference in § 600.011).}\]

\[\text{MPGelec} = \text{The miles per gallon equivalent measured while operating on electricity. Calculate this value by dividing the equivalent all-electric range determined from the equation in § 86.1866-12(b)(2)(i) by the corresponding measured Watt-hours of energy consumed; apply the appropriate petroleum-equivalence factor from 10 CFR 474.3 to convert Watt-hours to gallons equivalent. Note that if vehicles use no gasoline during charge-depleting operation, MPGelec is the same as the charge-depleting fuel economy specified in SAE J1711.} [EPA-HQ-OAR-2014-0827-1271-A1 p.8]

(iii) Optionally, for 2016 and subsequent model year vehicles that qualify as dual fueled automobiles, determine fuel economy based on the following equation, separately for city and highway driving: [EPA-HQ-OAR-2014-0827-1271-A1 p.9]

\[
MPGeCAFE = \frac{1}{\text{UF}/\text{MPGelec} + (1-\text{UF})/\text{MPGgas}}
\]

Where:
UF = The appropriate utility factor for city or highway driving as described in paragraph (c)(1) of this section. [EPA-HQ-OAR-2014-0827-1271-A1 p.9]

Response: EPA agrees that the proposed regulatory text lacked clarity regarding the appropriate calculation method for non-passenger automobiles. EPA also agrees with the commenter regarding utility factors for dual-fueled automobiles. The final rule includes the appropriate changes to the regulatory text.

c. Interpretation of driving range in the context of 49 CFR 538.5 and 538.6

NHTSA proposes to update the authority citation for 49 CFR 538.5. [80 FR 40765] While NHTSA considers changes to 538.5, the Automakers urge NHTSA to consult with EPA on relatively recent developments in test procedures to measure the emissions and fuel economy of alternative fueled vehicles which use electricity. When sections 538.5 and 538.6 were last amended, NHTSA interpreted that the minimum driving range was to be measured operating on electricity alone, generally citing the need for off-board electricity use to meet Congressional intent and the lack of a fuel economy test able to measure a hybrid electric vehicle operating on a combination of electricity and petroleum fuel. [63 Fed. Reg. 66064, December 1, 1998] In the time subsequent to this rulemaking, manufacturers have introduced plug-in hybrid models which make use of stored off-vehicle electricity and petroleum fuel in combination (a.k.a. blended operation). To evaluate vehicles with this type of operation, the California Air Resources Board developed test and calculation methods to determine an “equivalent all electric range,” effectively measuring how far a plug-in hybrid electric vehicle could travel on the stored off-board electricity if only the electric portion of blended operation is considered. [E.g. see California Exhaust Emission Standards and Test Procedures for 2009 through 2017 Model Zero-Emission Vehicles, and Hybrid-Electric Vehicles, in the Passenger Car, Light-Duty Truck and Medium-Duty Vehicle Classes] Given the wide variety of plug-in hybrid technology applications possible and the availability of test procedure and calculation methods capable of determining the off-board electric portion of blended operation, the Automakers recommend that NHTSA clarify its interpretation of the minimum driving range to be based on equivalent all electric range. This could be accomplished within the Preamble of the Final Rule which will be associated with this rulemaking and/or with minor modifications to 49 CFR 438.6. [EPA-HQ-OAR-2014-0827-1271-A1 p.9]

Response: EPA agrees with the manufacturers that the equivalent all-electric range is often the most appropriate metric for comparing the electric driving capability – and the commensurate reduction in petroleum fuel use – of plug-in hybrid electric vehicles. In fact, EPA has already set a precedent by using the equivalent all-electric range as qualification criteria for use of the production multipliers applicable to plug-in hybrid electric vehicles in the 2017-2021 model years (see 40 CFR 86.1866-12). We chose to use the equivalent all-electric range in this case to avoid discriminating against vehicles that “blend” use of electricity with gasoline but that still displace petroleum as much as vehicles that have a pure all-electric driving range. However, NHTSA will evaluate the underlying statute and determine whether or not the law will allow the interpretation requested by auto manufacturers.

8. Comments on additional issues

a. EPA should include an amendment to allow additional flexibility for the certification fuel used for fuel economy, CAFE and greenhouse gas emissions testing [EPA-HQ-OAR-2014-0827-1271-A1 p.13]

The Tier 3 Final Rule [79 FR 23414, April 28, 2014] resulted in a change in the certification fuel used for emissions testing but did not provide test procedure adjustments to allow the new certification fuel to
be used for fuel economy-related testing, including the LD CAFE and GHG emission programs. As a result, industry must currently conduct duplicative testing on two separate fuels, which adds additional test burden and unnecessary, additional compliance costs. The Agency included a threshold date of model year (MY) 2019 in part 600.117 when dual testing must cease and which might indirectly result in the elimination of E0 test fuel for CAFE and GHG compliance testing after MY2019. [EPA-HQ-OAR-2014-0827-1271-A1 p.13]

While the Tier 3 rulemaking promised an expeditious follow-up rulemaking to address test procedure adjustment factors and allow the new certification fuel for CAFE and GHG testing, efforts are slow to start, and it is not clear if they will be completed prior to MY 2019. Automakers greatly support EPA efforts to perform the evaluations necessary to arrive at proper corrections to test with the changed fuels. In the undesired scenario of these evaluations not being completed in time, or of the correction being insufficient, it would be prudent for the Agency to consider extending the MY2019 threshold date. Therefore, we recommend that EPA amend section 600.117 to extend the end date and clarify that E0 test fuel will remain the official compliance test fuel for CAFE and GHG testing until changed by a subsequent rulemaking. We do not wish for any extension of the date past the MY 2019 end date to reduce the urgency to complete the necessary test procedure adjustments, but such flexibility is necessary to ensure industry planners that they will not be subject to both a change in CAFE/GHG stringency and/or loss of the double testing flexibilities after MY2019. Automakers look forward to continuing to work with the Agency to speedily evaluate and determine correct adjustment factors for the changes to test fuels. [EPA-HQ-OAR-2014-0827-1271-A1 p.13]

Response: Testing in support of amendments to address these fuel effects is ongoing. We intend to continue with the approach described in 40 CFR 600.117, including the specified timeline. We will continue to interact with manufacturers in the effort to resolve these issues.

14.4.6 Testing with Aftertreatment Devices Involving Infrequent Regeneration

Organization: Alliance of Automobile Manufacturers and Association of Global Automakers

5. Comments to proposed changes to Part 1065

a. Infrequent regeneration procedures should be harmonized

In the NPRM at 80 FR 40533, the EPA proposes to harmonize the common elements of infrequent regeneration factor (IRAF) procedures in 40 CFR Part 1065 for highway, locomotive, marine and land-based non-road compression ignition engines. Automakers support this change to implement consistent procedures to incorporate the emissions effects of infrequent regeneration for HD vehicles. This would extend the current procedures and requirements used for LD and make them applicable for HD. [EPA-HQ-OAR-2014-0827-1271-A1 p.9-10]

Organization: Truck & Engine Manufacturers Association (EMA)

Comments on the Proposed Technical Amendments to Part 86

The proposed revisions to section 86.004-28(i) and (j) (and to section 1065.680) would modify the handling of infrequent regeneration adjustment factors (IRAFs). Subparagraph (i) permits the continued use of the current methodology through the end of model year 2020. Subparagraph (j) specifies the new
methodology for handling IRAFs and points to 1065.680, a common procedural section referenced by several standard-setting Parts. The new methodology would be used beginning in model year 2021. [EPA-HQ-OAR-2014-0827-1269-A1 p.73]

The ability to continue to use the current IRAF calculation process through the end of model year 2020 is critical for lead time and product stability. Having the new requirements become effective in model year 2021 is appropriate, as several other product changes become effective with that model year, and the product changes needed to accommodate the revisions to the IRAF calculation procedures can be made at the same time. [EPA-HQ-OAR-2014-0827-1269-A1 p.73]

Accordingly, EMA supports the proposed changes and recommends that they be finalized as proposed. [EPA-HQ-OAR-2014-0827-1269-A1 p.73]

Comments on the Proposed Technical Amendments to Part 1065

The standards for several regulatory categories (on-highway, locomotive, marine, and land-based nonroad engines, etc.) have become more and more stringent, requiring the use of emission control devices that often require infrequent regeneration to maintain their effectiveness and/or prolong their life. As a result, the provisions describing the process to account for the potential emissions from these infrequent regenerations, commonly referred to as infrequent regeneration adjustments factors or “IRAFs” are needed in numerous CFR Parts. [EPA-HQ-OAR-2014-0827-1269-A1 p.85]

EPA’s proposal to put the common elements relating to IRAFs in Part 1065 is a good idea and is supported by EMA. Likewise, putting sector or category-specific elements in the sector-specific Parts is appropriate and also supported by EMA. [EPA-HQ-OAR-2014-0827-1269-A1 p.85]

EMA has reviewed the proposed language of new section 1065.680 - “Adjusting emission levels to account for infrequently regenerating Aftertreatment devices” - and generally agrees with the proposal. EMA also agrees that it is helpful to have the cited examples in section 1065.680, which illustrate and clarify the various embedded calculations. [EPA-HQ-OAR-2014-0827-1269-A1 p.85]

**Organization:** Daimler Trucks North America LLC

**Part 1065** - We agree with all the proposed changes done to Part 1065 except for section 1065.680 - adjusting emission levels to account for infrequently generating aftertreatment devices. On this section we recommend not removing the weighting factor that EPA first published on a 2006 guidance comment. [EPA-HQ-OAR-2014-0827-1164-A1 p.121]

**Organization:** California Air Resources Board (CARB)

**Support Comment**

**Comment – Adjustment factors for infrequent regeneration events**

CARB staff supports the proposed use of adjustment factors for correction of CO2 emission results and fuel consumption from infrequent regeneration events from heavy-duty engines equipped with exhaust aftertreatment. However, CARB staff has concerns regarding the continued use of the methodology for calculation of infrequent regeneration adjustment factors (IRAFs) as specified in 40 CFR 1065.680. [EPA-HQ-OAR-2014-0827-1265-A1 p.103]
The primary concern stems from the application of the adjustment factors to discount both FTP and heavy-duty SET emissions. Instead, the adjustment factors should be applied in such a way as to apply the discounted FTP regeneration emissions to the SET regeneration emissions. In addition, staff believes that adjustment factors should be developed separately for each engine family. Due to the concerns with manufacturers inappropriately calculating adjustment factors, staff does not recommend allowing carry-across of adjustment factors from one engine family to another. [EPA-HQ-OAR-2014-0827-1265-A1 p.103]

Specifically regarding the application of IRAFs to FTP and SET emissions, staff understands that heavy-duty manufacturers have been calculating adjustment factors based on a U.S. EPA guidance document (REF CISD-06-22 HD-HWY). The concept in this document is to allow an offset in regeneration emissions from city-type driving to highway-type driving. CARB staff believes the example provided in this guidance document is flawed in that it applies discounted adjustment factors for both the FTP and SET cycles. In this example, the regeneration emissions were not applied to the SET. A true offset would seek to balance the emissions between city and highway driving. That is, if the regeneration emissions were offset from the FTP then the balance would be added to the SET; not subtracted, as done in the guidance document. This becomes more evident in the calculation of the new frequency factors, \( F \), in the RIA’s example. [EPA-HQ-OAR-2014-0827-1265-A1 p.103]

The FTP regeneration frequency is decreased from 0.2 to 0.06; however, the SET frequency is also decreased from 0.05 to 0.035. This double discounting in frequency is not reasonable and does not follow our understanding of in-use regeneration frequency. Instead, there should be a composite frequency, \( F' \), that resides between the individual cycle frequencies (i.e., 0.05 < \( F' \) < 0.2). [EPA-HQ-OAR-2014-0827-1265-A1 p.104]

CARB staff suggests that U.S. EPA and NHTSA develop a representative composite frequency that takes into account the SET and FTP frequencies similar to the example equation below. Using the data provided in U.S. EPA guidance document, an equation to offset emissions with in-use driving averaged at 30 percent city (FTP-like driving) and 70 percent highway (SET-like driving) would be as follows: [EPA-HQ-OAR-2014-0827-1265-A1 p.104]

\[
F' = F_{ftp} \times \text{offset} + F_{set} \times (1 - \text{offset})
\]

\[
F' = 0.20 \times 0.3 + 0.05 \times (1 - 0.3) = 0.095 \text{ Where offset = percent city driving}
\]

The new frequency, \( F' \), would be used for both FTP and SET calculations of upward adjustment factors. [EPA-HQ-OAR-2014-0827-1265-A1 p.104]

[Table 16 can be found on p.104 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

Further, CARB staff recommends utilizing existing standardized data stream parameters or developing new ones that characterize regeneration frequency on in-use engines (e.g., average regeneration frequency as a function of integrated fuel consumed, integrated work, positive kinetic energy) to complement analysis and conclusions made at the time of certification. For example, 2013 and newer MY diesel vehicles support in-use regeneration information through scan tool output. Vehicles using the SAE Standard J1939 protocol must support either SPN 5827 – ‘Aftertreatment 1 Average Distance Between Active DPF Regenerations’, or SPN 5454 – ‘Aftertreatment 1 Diesel Particulate Filter Average Time Between Active Regenerations.’ Vehicles using the SAE Standard J1979 protocol must support PID $8B which includes both ‘average time between regens’ and ‘average distance between regens.’ [EPA-HQ-OAR-2014-0827-1265-A1 p.105]
Using these in-use data, a manufacturer can calculate an in-use regeneration frequency. Also, U.S. EPA and NHTSA can use these data for verification and compliance of the manufacturer’s reported regeneration adjustment factors. The example below shows how the in-use data might be used to confirm reported adjustment factors: [EPA-HQ-OAR-2014-0827-1265-A1 p.105]

\[ F = \frac{\text{distance to complete Regen}}{\text{distance to complete Regen} + \text{avg. dist. between Regens}} \]

A similar equation can be developed using a time basis:

\[ F = \frac{\text{time to complete Regen}}{\text{time to complete Regen} + \text{avg. time between Regens}} \]

In closing, CARB staff strongly suggests that U.S. EPA and NHTSA revise the IRAF calculation methodology to accurately account for infrequent regeneration emissions on both FTP and SET test cycles. [EPA-HQ-OAR-2014-0827-1265-A1 p.105]

**Response:**

EPA recognizes the engine and vehicle industry associations’ affirmation of the proposed regulatory changes. We are finalizing these provisions as proposed.

We specifically amended the regulation to move away from the weighting factors from the 2006 guidance documents. The unified approach to infrequent regeneration adopted in this rule allows for a technically robust method of accounting for upward and downward adjustment factors that applies broadly to the various engine sectors.

The IRAF procedure as outlined in §1065.680, does not contain any discounting as described by ARB in their comments. Specifically ARB references specific discounting of the regeneration frequency, or \( F \), for both the FTP and SET. §1065.680 does not discount \( F \), nor does it give any specific information for the FTP. All examples given are for the RMC (or SET). It is possible that ARB has confused their comments on §1065.680 with concerns over what is contained in the EPA IRAF guidance document CISD-06-22 HD-HWY. §1065.680 is an attempt to move away from CISD-06-22 HD-HWY and make improvements where applicable. Further, EPA does not believe that it is appropriate to develop a composite regeneration frequency, \( F \), because emissions from IRAF are accounted for on a duty-cycle specific basis and as such, it is appropriate to utilize an \( F \) developed for each specific duty-cycle.

Use of actual in-use data is allowed, but not required for generating \( F \). \( F \) can be generated based solely on laboratory data. It is not clear to EPA how the use of OBD monitoring would make \( F \) any more accurate. If you have OBD data for a given engine family from 10 different vehicles and \( F \) is not timer-based, that does not make \( F \) more accurate. After all, the duty cycle of the 10 vehicles from which the data was acquired is not guaranteed to represent the entire fleet of vehicles that the engine family is installed in. Therefore, EPA will continue to allow laboratory-generated values for \( F \).

### 14.4.7 Additional Test Procedure Amendments

**Organization:** Alliance of Automobile Manufacturers and Association of Global Automakers

**b. Comments on additional test procedure amendments to Part 1065 and Part 1066**

The Automakers do not support the proposed change to 1065.15(a)(2)(ii) – Allowance to report NMOG instead of NMHC -- as written. Rather than making this change for all fuels, we recommend that it not
be applicable to diesel fuels. Applying this change to diesel fuels would necessitate significant and costly changes to test equipment and procedures to test diesel vehicles by requiring off-line chemical lab speciation of exhaust. Such a change is not needed. [EPA-HQ-OAR-2014-0827-1271-A1 p.10]

**Response:** EPA will remove the changes proposed in the NPRM. We have replaced this with an allowance for engine manufacturers to subtract ethane from measured hydrocarbon to demonstrate compliance with standards, as described below.

In the NPRM, at 80 FR 40534, the EPA proposes changes to Part 1065 and Part 1066. Specifically, EPA proposes the following changes:

• § 1066.210: Revise the dynamometer force equation to incorporate grade, consistent with the coastdown procedures being proposed for heavy-duty vehicles. For operation at a level grade, the additional parameters cancel out of the calculation. [EPA-HQ-OAR-2014-0827-1271-A1 p.10]

**Response:** See detailed response below.

• § 1066.605: Adding an equation to the regulations to spell out how to calculate emission rates in grams per mile. This calculation is generally assumed, but we want to include the equation to remove any uncertainty about calculating emission rates from mass emission measurements and driving distance. [EPA-HQ-OAR-2014-0827-1271-A1 p.10]

**Response:** We have added this equation to 40 CFR 1066.605.

• § 1066.815: Create an exception to the maximum value for overall residence time for PM sampling methods that involve PM samples collected for combined bags over a duty cycle. This is needed to accommodate the reduced sample flow rates associated with these procedures. [EPA-HQ-OAR-2014-0827-1271-A1 p.10]

**Response:** EPA has made changes to 40 CFR 1066.110 and 40 CFR 1066.815 that will allow a maximum filter face velocity of 140 cm/s. For single filter per test sampling, flow weighting would be based off of the maximum filter face velocity of 140 cm/s. EPA will note that a maximum of 100 cm/s is recommended, but 140 cm/s is allowed to increase the filter loading to reduce variability. The results of Phase 1 of the CRC E-99 test program, which investigated and compared sampling at up to 150 cm/s to 100 cm/s, were the basis for EPA’s decision.

We do not support the proposed change to 1066.210 - New calculation on road grade -- since the change would be confusing and unnecessary for LD: [EPA-HQ-OAR-2014-0827-1271-A1 p.10]

1) The Preamble states this is for HD only (Part 1037), yet this section does not differentiate applicability and appears to apply to LD as well. This needs to be clarified and the previous equation retained. [EPA-HQ-OAR-2014-0827-1271-A1 p.11]

2) In SAE J2263, if the grade is less than 0.5%, there is no grade correction required (Section 7.4). However, if the grade is known, J2263 does provide a grade correction (Section 11.5). Regulations should follow this technique. [EPA-HQ-OAR-2014-0827-1271-A1 p.11]

3) “Gi = instantaneous road grade, in percent (increase in elevation per 100 units horizontal length)” -- This provision requires (implies) some type of on the road measurement of elevation. It is not clear what
type of equipment would be used to provide instantaneous mapping with accuracy, and whether such equipment is widely available. [EPA-HQ-OAR-2014-0827-1271-A1 p.11]

Response: Equation 1066.210 describes the forces acting on the vehicle during normal driving. This equation is a general example and the addition of the road grade element does not imply that you need to address road grade forces unless the duty cycles in the standard-setting part include road grade. Part 1066 is applicable to both light-duty and heavy-duty vehicles. Since road grade is an element of heavy-duty testing, it needs to be added to this general equation. EPA has revised the equation to simplify the change and has provided direction in the description to Gi that directs you to set it equal to zero if your duty cycle does not include road grade. The reference made to J2263 is not germane as 1066.210 does not deal with coastdowns or grade correction.

We support the proposed changes to 1066.605 and 1066.815. [EPA-HQ-OAR-2014-0827-1271-A1 p.11]

We recommend adding a provision in §1066.815(b), to allow a time-weighted average of PM filter face velocity of 100 cm/s, when using single filter measurement technology as described in (b)(4)& (b)(5). Currently, 1065.170(c)(1)(vi) has a maximum filter face velocity of 100 cm/s. However, the weighting factors used in (b)(4) & (b)(5) reduce the loading on the filter. Allowing a time-weighted average filter face velocity of 100 cm/s greatly improves filter loading and is similar loading of 3 or 4 filter PM techniques. [EPA-HQ-OAR-2014-0827-1271-A1 p.11]

Specifically, we recommend that this provision be added at the end of §1066.815(b): “If you collect PM using the procedures specified in paragraphs (b)(4) or (b)(5) of this section, the residence time requirements in 40 CFR 1065.140(e)(3) apply, except that you may exceed an overall residence time of 5.5 s for sample flow rates below the highest expected flow rate.” [EPA-HQ-OAR-2014-0827-1271-A1 p.11]

Response: EPA has made changes to 40 CFR 1066.110 and 40 CFR 1066.815 that will allow a maximum filter face velocity of 140 cm/s. For single filter per test sampling, flow weighting would be based off of the maximum filter face velocity of 140 cm/s. EPA will note that a maximum of 100 cm/s is recommended, but 140 cm/s is allowed to increase the filter loading to reduce variability. The results of Phase 1 of the CRC E-99 test program, which investigated and compared sampling at up to 150 cm/s to 100 cm/s, were the basis for EPA's decision.

b. Flexibility for PM blank testing

We appreciate the agencies’ flexibility in the current Part 1066 test procedures in running PM blank tests, and allowing averaging of results. However 1066 implies that a separate PM blank emissions test needs to be performed, which is very burdensome, and unwarranted. This PM blank testing could be combined with another diagnostic: propane injections. Performing these two diagnostics together dramatically reduces the time required, yet achieves similar results. However, Part 1066 has one clause (below) which prevents this if an OEM injects propane in the transfer tube, which checks for leaks throughout the entire sampling system, and is more representative of the real vehicle testing environment. Concerns with allowing this dual diagnostic should be minimal, since these blank test corrections are typically a small fraction of the standard, and the amount of PM correction is capped in 1066.110(b)(2)(i)(D) (“Your PM background correction may not exceed 5 μg or 5% of the net PM mass expected at the standard, whichever is greater.”). [EPA-HQ-OAR-2014-0827-1271-A1 p.13-14]
We therefore recommend the following change:

§1066.110 Equipment specifications for emission sampling systems. (b)(2)(i)(B) You may sample background PM from the dilution tunnel at any time before or after an emission test using the same sampling system used during the emission test. For this background sampling, the dilution tunnel blower must be turned on, the vehicle must be disconnected from the laboratory exhaust tubing, and the laboratory exhaust tubing must be capped. You may run this PM blank test in combination with propane injection diagnostic.” [EPA-HQ-OAR-2014-0827-1271-A1 p.14]

Response: EPA test data shows that the propane injection has no effect on the PM tunnel blank results when the tailpipe connection point is HEPA filtered. Our data also shows that if the tailpipe connection point is left open to room air unfiltered, the PM background mass can be biased 1 to 1.5 ug high. Based on these results, EPA will make a change to 1066.110 that allows simultaneous PM background measurement and propane injections as long as the tailpipe connection point is HEPA filtered.

c. Comments with regard to requests for additional clarification

1) Comments on clarification of records retention policies: There continues to be confusing and conflicting language in multiple parts and subparts of the regulations. This needs further clarification with regard to emissions test records so that OEMs have a clear understanding of what needs long-term storage. This data is not all electronic today, nor is it in a common electronic format. Retaining large amounts of supporting, primitive data is burdensome and of little value. The Automakers would like to discuss whether requirements could be clarified and focused on critical data. [EPA-HQ-OAR-2014-0827-1271-A1 p.14]

Response: The commenter did not raise and specific concerns about confusing or conflicting requirements, so we are unable to address that concern. Moreover, we believe the current records retention policy is clear and adequate. We also continue to expect that paper (primitive) records have become uncommon and will only become less common over time. We therefore believe it is appropriate to adopt the simplified eight-year recordkeeping requirement as proposed. The recent enforcement case regarding Volkswagen reinforces the need to keep certification-related records for several years.

2) §1065.590 PM sampling media (e.g., filters) preconditioning and tare weighing. “(j) Substitution weighing involves measurement of a reference weight before and after each weighing of PM sampling media (e.g., filters).” Comment: The regulatory language appears to allow multiple filter mass measurements between pre & post reference filter mass measurements. The sentence in (j) could be clearer by deleting “each” or modifying to “each or multiple.” Doing this substitution weighing before and after “each” filter is very burdensome and unwarranted; manufacturers should be allowed to run a reasonable amount of multiple filters bookended by substitution mass measurements. [EPA-HQ-OAR-2014-0827-1271-A1 p.14]

Response: The substitution weighing procedure in 1065.590(j) is optional. 1065.590(f)(2) clearly states that you may use the procedure in (j) or develop your own procedure. EPA has no intentions to revise the procedure in paragraph (j) as a whole. If manufacturers desire to make changes to the procedure in (j), they are allowed to as described in (f)(2).

EPA notes that the procedure in paragraph (j) reads as though it covers a single filter medium, with the exception of the mention of media in the introductory paragraph to (j). To avoid
confusion, EPA will make the mention of media singular by changing it to medium. Manufacturers are still free to modify the procedure in (j) via (f)(2) to allow its use over groupings of sample media at their own discretion.

3) 1065.341(c)(3) “Select a C3H8 injection port in the CVS. Select the port location to be as close as practical to the location where you introduce engine exhaust into the CVS. Connect the C3H8 cylinder to the injection system.” Comment: The regulatory language should be clarified that this section also allows the option for propane injection in the transfer tube as well. This allows (1) leak checking the entire sampling system from the point where exhaust gas is injected into the transfer tube; (2) supporting The Automakers request to simultaneously run PM blank tests / propane injection diagnostics; and (3) allowing propane leak checking of partial dilution systems like PM or gaseous emissions. [EPA-HQ-OAR-2014-0827-1271-A1 p.14-15]

Response: EPA has addressed the comment by revising 1065.341(c)(3) to read as follows:

(3) Select a C3H8 injection port in the CVS. Select the port location to be as close as practical to the location where you introduce engine exhaust into the CVS, however you may include part of the laboratory exhaust tubing and locate the injection port in this tubing. Connect the C3H8 cylinder to the injection system.

Organization: Daimler Trucks North America LLC

Additional Test Procedure Amendments – The agencies propose to allow NMOG measurements to demonstrate compliance with NMHC standards, and the agencies request comment on whether other forms of hydrocarbon standards (such as VOC) should be allowed for alternative fuels. This seems reasonable. 80 FR 40534. [EPA-HQ-OAR-2014-0827-1164-A1 p.30]

EPA subsequently prepared revised draft regulations to address manufacturers’ concern that ethane emissions from natural gas engines was making it hard to meet standards, even though ethane is generally nonreactive in the atmosphere. This non-reactivity also makes it hard to reduce ethane emissions with conventional aftertreatment technology.

California ARB objected to the suggestion that we should redefine NMHC standards to exclude ethane without accounting for the change in the standard, arguing that this would allow manufacturers to dial in a higher level of toxic hydrocarbon emissions while continuing to comply with the standard.

Response:

EPA’s stationary program has long excluded ethane from hydrocarbon (VOC) emission standards. California ARB’s emission standards for highway and nonroad engines applies reactivity adjustments to reduce the ethane emissions by 72 percent. In line with these programs and policies, we believe it is appropriate to allow manufacturers to subtract ethane emissions from their measured hydrocarbon results. This is especially the case for engines fueled by natural gas and LPG, where fuel ethane can be substantial. Gasoline and diesel fuel contain no ethane, so there is no comparable concern for ethane to make it through the combustion process unoxidized and be emitted into the atmosphere.

We are applying this conclusion to heavy-duty highway engines and all sectors of nonroad compression-ignition engines that are fueled with natural gas and LPG. The one exception is for Category 3 marine compression-ignition engines, which are subject to a hydrocarbon standard of 2 g/kW-hr. The ethane provision is only needed where the emission standard is at a very low level. A standard of 0.19 g/kW-hr is typical for the other types of compression-ignition engines.
We believe manufacturers have no incentive to dial in a higher hydrocarbon emission level to account for the subtracted ethane. Even if they do, the resulting increase of perhaps 0.03 g/kW-hr from the small number of natural gas and LPG engines would be miniscule.

**14.4.8 Amendments Related to Nonroad Diesel Engines in 40 CFR Part 1039 1939**

**Organization:** Truck & Engine Manufacturers Association (EMA)

Comments on the Proposed Technical Amendments to Part 1039

The current provisions of section 1039.135(d)(1) state as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

(d) You may add information to the emission control information label to identify other emission standards that the engine meets or does not meet (such as European standards). You may also add other information to ensure that the engine will be properly maintained and used. [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

EPA is proposing to amend that regulatory language in the following manner: [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

(d) You may add information to the emission control information label as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

(1) If your emission control information label includes all the information described in paragraphs (c)(5) through (10) of this section, you may identify other emission standards that the engine meets or does not meet (such as international standards). You may include this information by adding it to the statement we specify or by including a separate statement. [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

(2) You may add other information to ensure that the engine will be properly maintained and used. [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

(3) You may add appropriate features to prevent counterfeit labels. For example, you may include the engine’s unique identification number on the label. [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

EMA believes that finding space for the items required to be on the emission control information label has always been challenging. In that regard, adding information about which other emission standards the engine meets, such as .” .and California” or .” .and European Union Stage XX” can be very important to those who read the emission control information label, including Customs Inspectors. [EPA-HQ-OAR-2014-0827-1269-A1 p.78]

The information required in 1039.135 (c)(5) through (10) requires a significant amount of space on the emission control information label and is considered to be of lesser importance. In addition, much of that information can easily be found elsewhere, as the regulatory language quoted below indicates. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]
(5) State the engine's displacement (in liters); however, you may omit this from the label if all the engines in the engine family have the same per-cylinder displacement and total displacement. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

(6) State the date of manufacture [DAY (optional), MONTH, and YEAR]; however, you may omit this from the label if you stamp, engrave, or otherwise permanently identify it elsewhere on the engine, in which case you must also describe in your application for certification where you will identify the date on the engine. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

(7) State the FELs to which the engines are certified if certification depends on the ABT provisions of subpart H of this part. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

(8) Identify the emission-control system. Use terms and abbreviations as described in 40 CFR 1068.45. You may omit this information from the label if there is not enough room for it and you put it in the owners manual instead. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

(10) Identify any additional requirements for fuel and lubricants that do not involve fuel-sulfur levels. You may omit this information from the label if there is not enough room for it and you put it in the owners manual instead. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

The information required by paragraph (c)(8) can take up an especially large amount of space on the emission control information label, and provides little value. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

In light of the foregoing, EMA recommends deleting the opening clause of paragraph (d)(1) so that it reads as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

(1) You may identify other emission standards that the engine meets or does not meet (such as international standards). You may include this information by adding it to the statement we specify or by including a separate statement. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

If the Agency feels strongly that information about other standards that the engine meets cannot be added unless information that was omitted based on limited availability of space on the emission control information label is added back, then EMA recommends that only the information required in subparagraphs (c)(5) through (c)(7) and (c)(9) through (c)(10) be required to be added back. As mentioned above, the information required by subparagraph (c)(8) consumes a significant amount of space and is of very limited value. [EPA-HQ-OAR-2014-0827-1269-A1 p.79]

The other change to this section is the addition of a provision which would allow a manufacturer to add features to the label to prevent counterfeit labels (paragraph (d)(3) of the proposed language). EMA agrees with that proposed change. [EPA-HQ-OAR-2014-0827-1269-A1 p.80]

**Response:** We agree with the concern and have revised the regulation to allow manufacturers to omit the specified information “as long as this does not cause you to omit” the other information.
EPA also proposes to add a provision to 40 CFR 1039.205 that would require manufacturers to describe their “normal practice” for importing engines. By way of example, EPA states that this description may include identifying the names and addresses of any agents that a manufacturer authorized to import its engines. [EPA-HQ-OAR-2014-0827-1269-A1 p.80]

This proposed provision is problematic. The vast majority of manufacturers of engines and equipment used in construction, agricultural and industrial markets are multi-national. For a wide variety of reasons, the nonroad engines and equipment they produce are often manufactured in only a few locations around the world, and then shipped to end-user customers in nearly every country and region of the world. As a consequence, a large percentage of manufacturers’ nonroad engines and equipment is shipped around the world, and many are “imported” into the United States. Describing the “normal practice” for importing all of those engines (both loose engines and those installed in equipment) would result in a tremendous burden. [EPA-HQ-OAR-2014-0827-1269-A1 p.80]

In the Preamble to the NPRM, the Agency states that “where a manufacturer’s engines are imported through a wide variety of means, EPA would not require this description to be comprehensive.” EPA goes on to state that “in such cases, a short description of the predominant practices would generally be sufficient.” This additional explanation of what is required of manufacturers provides much needed relief. Accordingly, EMA recommends that EPA include those explanatory statements in the Preamble to the final Phase 2 Rule. [EPA-HQ-OAR-2014-0827-1269-A1 p.80]

Response: As noted, in cases where an engine manufacturer ships loose engines to equipment manufacturers for eventual importation into the United States, we would understand that manufacturers would not need to account for all the different ways that their engines might be imported. The regulation requires that engine manufacturers describe their “normal practice for importing engines,” with the clarification that this may involve naming agents for importation. For engine manufacturers that sell loose engines to a wide range of equipment manufacturers, the manufacturer could fulfill the requirement by describing its business model and perhaps identifying the equipment manufacturers that are expected to import the highest volume of equipment with that engine manufacturer’s engines.

EPA is proposing to make the same revisions to the opening paragraph of §1039.225 as the Agency is proposing to make to the opening paragraph of §1033.225, as discussed above. EMA’s comments and recommendation regarding these proposed changes are largely the same. The specific wording of the proposed revision is as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.80]

Before we issue you a certificate of conformity, you may amend your application to include new or modified engine configurations, subject to the provisions of this section. After we have issued your certificate of conformity, but before the end of the model year, you may send us an amended application requesting that we include new or modified engine configurations within the scope of the certificate, subject to the provisions of this section. Before the end of the model year, you must amend your application if any changes occur with respect to any information that is included or should be included in your application. After the end of the model year, you may amend your application only to update maintenance instructions as described in § 1039.220 or to modify an FEL as described in paragraph (f) of this section. [EPA-HQ-OAR-2014-0827-1269-A1 p.80]
As with the proposed revisions to section 1033.225, the proposed changes to section 1039.225 are unacceptable. In the Preamble explanation for these changes, the Agency again states that the changes at issue are simply 'clarifications' of the existing language. The proposed changes, however, go well beyond being 'clarifications' and represent significant modifications. [EPA-HQ-OAR-2014-0827-1269-A1 p.80-81]

As noted above, the ability to add a new engine configuration and/or amend an existing engine configuration is critical to engine manufacturers and the customers they serve, both during the model year and afterwards. In some cases a change may be needed to make product improvements and/or correct unanticipated product issues. In other cases, new ratings may be required to meet customer needs to enable pieces of equipment powered by the subject engines to perform their intended functions. As some of those changes may be needed to maintain emissions compliance, or to correct emissions-related issues discovered during the course of business, it is in the Agency’s best interest to continue to allow manufacturers the opportunity to request to make such changes. [EPA-HQ-OAR-2014-0827-1269-A1 p.81]

In that regard, it is important to note that such application changes must be submitted to the Agency, and are subject to Agency approval. Consequently, if EPA has an issue with a requested new engine configuration or with a requested amendment to an existing engine configuration, the Agency can address that issue during their review process, and so does not need the proposed revision at issue. [EPA-HQ-OAR-2014-0827-1269-A1 p.81]

Accordingly, and as with respect to the proposed revisions to section 1033.225, EMA recommends that EPA retain the current language of the opening paragraph of section 1039.225, and not finalize the proposed changes to this paragraph. [EPA-HQ-OAR-2014-0827-1269-A1 p.81]

Response: We agree that the proposed change to the regulation would conflict with EPA’s longstanding policy on field fixes. We are removing this proposed change and replacing it with a new paragraph that translates the field-fix guidance into regulation. The expectation is that this regulation codifies the field-fix guidance without changing current policy. The new regulation language reads as follows:

“You may produce engines as described in your amended application for certification and consider those engines to be in a certified configuration if we approve a new or modified engine configuration during the model year under paragraph (d) of this section. Similarly, you may modify in-use engines as described in your amended application for certification and consider those engines to be in a certified configuration if we approve a new or modified engine configuration at any time under paragraph (d) of this section. Modifying a new or in-use engine to be in a certified configuration does not violate the tampering prohibition of 40 CFR 1068.101(b)(1).”

We are adopting this change for all heavy-duty highway engines and vehicles and for all nonroad compression-ignition engines. We also expect to add this same paragraph for nonroad spark-ignition engines and vehicles in due course.

Organization: Daimler Trucks North America LLC

Part 1039 - We accept all changes proposed by the agencies on Part 1039. [EPA-HQ-OAR-2014-0827-1164-A1 p.121]
Amendments Related to Non-road Diesel Engines in 40 CFR Part 1039 – The EPA requested comment on adding SCR diagnostic requirements to nonroad diesel engines. 80 FR 40534. DTNA’s Tier IV engines already comply, so we agree with the EPA’s proposal. 40 CFR Part 1039. [EPA-HQ-OAR-2014-0827-1164-A1 p.132]

Amendments Related to Non-road Diesel Engines in 40 CFR Part 1039 – The EPA requested comment on removing regulatory provisions for Independent Commercial Importers in 40 CFR Part 1039. We think that these rules are obsolete, so we agree with removing them. [EPA-HQ-OAR-2014-0827-1164-A1 p.132]

Response:
We are adopting the provisions as proposed and as supported by the commenter.

Organization:  Volvo Group

REVISIONS TO NONROAD EMISSIONS CONTROL PROVISIONS

Currently, an imported engine manufacturer is permitted to run Selective Enforcement Audit testing at or near their manufacturing location, typically using their engine certification facility. Foreign manufacturers should not be required to provide an additional SEA test site in the United States. The phrase, “in the United States,” should be removed from the proposed change to §1039.205 since it unfairly burdens foreign engine manufacturers with maintaining expensive §1065 compliant test cell capacity in addition to their existing Certification Test Cell capacity. [EPA-HQ-OAR-2014-0827-1290-A1 p.81]

Response:
It has been EPA’s longstanding policy that manufacturers must perform testing at the facility identified by EPA. This may be the manufacturer’s own facility, but it may be any other test facility. The provision requiring the manufacturer to identify a test lab in the United States is simply arranging for an easier path to identify a mutually agreeable test facility if we would want to require testing in the United States. The manufacturer can choose to name a reputable third-party test lab instead of developing complete testing capability in the United States.

Organization:  California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Recording reductant use and other diagnostic functions

CARB staff conceptually supports U.S. EPA and NHTSA’s proposal requiring non-road compression ignition engine manufacturers to incorporate OBD that monitor selective catalytic reduction (SCR) reductant levels and quality, and alert the equipment operator when those levels and quality are out of specification. Advanced notification of compromised or low levels of reductant will help to ensure proper SCR operation in-use, and should help minimize occurrences of the engine entering a derated mode of operation per existing SCR inducement strategies. [EPA-HQ-OAR-2014-0827-1265-A1 p.125]
CARB staff understands that this proposal is not meant to replace SCR inducement policies, but rather to complement them with additional detection capability in an uncomplicated manner. While we generally prefer simple and straightforward approaches as well, diagnostics need the proper balance between simplicity and utility. As such, CARB staff recommends that extra rigor be introduced in 40 CFR 1039.110 to enhance monitoring effectiveness and compatibility. CARB’s “On-Board Diagnostic System Requirements for 2010 and Subsequent Model-Year Heavy-Duty Engines” in Title 13 of the California Code of Regulations (CCR), Section 1971.1, contain reductant level/quality monitoring provisions that could serve as guidelines for a more robust federal mechanism. [EPA-HQ-OAR-2014-0827-1265-A1 p.125]

At a minimum, CARB staff recommends that U.S. EPA and NHTSA adopt standardized fault codes (e.g., SAE Standard J1939 or controller area network (CAN) based), monitoring conditions, malfunction criteria, and fault processing protocols to ensure reasonable and reliable diagnostic system monitoring frequency and malfunction detection performance. Precautions such as these will help ensure that issues related to reductant quality and replenishment are detected and addressed in a timely manner, and will undoubtedly prove useful should matters of in-use compliance and enforcement come into question. For example, there are no timeframes for detection specified in the proposed language; therefore, a manufacturer could theoretically only monitor once per month (or even less frequently) rendering the diagnostic virtually useless. Therefore, we recommend U.S. EPA and NHTSA to clearly define a minimum performance metric such that the monitoring strategy provides detection capability several times per tank fill of reductant, or continuously for the parts of the diagnostic that rely on electrical continuity or out of range type checking. Standardization may also create opportunities for innovative control approaches by third party developers who might otherwise not have access to proprietary diagnostics. [EPA-HQ-OAR-2014-0827-1265-A1 p.125-126]

Additionally, CARB staff recommends that U.S. EPA and NHTSA revise the reductant quality monitoring exemption in 40 CFR 1039.110(a) for vehicles that already possess a diagnostic NOx sensor. The problem with the provision is that it requires a NOx sensor to be present with the capability to monitor reductant quality, but does not necessarily require the sensor to monitor reductant quality in any meaningful way. We recommend that a qualifying statement be appended to the language to address this limitation (see underscored text in paragraph (a) of CARB staff’s revised regulatory text below). [EPA-HQ-OAR-2014-0827-1265-A1 p.126]

CARB staff also recommends the same degree of standardization and robustness mentioned above for any emission-related diagnostic strategy employed per the provisions of 40 CFR 1039.110(b). Taking the time to standardize diagnostic practices now will save valuable resources in the future when more comprehensive OBD requirements are adopted for the non-road compression ignition category. For reference, 40 CFR 1039.110(b) contains the following language: [EPA-HQ-OAR-2014-0827-1265-A1 p.126]

“§1039.110 Recording reductant use and other diagnostic functions.

(a) Engines equipped with SCR systems using a reductant other than the engine’s fuel must have a diagnostic system that monitors reductant quality and tank levels and alert operators to the need to refill the reductant tank before it is empty, or to replace the reductant if it does not meet your concentration specifications. Unless we approve other alerts, use a warning lamp or an audible alarm. You do not need to separately monitor reductant quality if you include an exhaust NOx sensor (or other sensor) that allows you to determine inadequate reductant quality and alert operators when the condition that is indicative of inadequate reductant quality is
present. However, tank level must be monitored in all cases. [EPA-HQ-OAR-2014-0827-1265-A1 p.126]

(b) You may equip your engine with other diagnostic features. If you do, they must be designed to allow us to read and interpret the codes. Note that § 1039.205 requires you to provide us any information needed to read, record, and interpret all the information broadcast by an engine’s onboard computers and electronic control units.” [EPA-HQ-OAR-2014-0827-1265-A1 p.127]

Response: EPA’s objective for nonroad OBD systems in this rule is to adopt requirements that can be adopted with minimal lead time. The most effective way to do this is to copy the OBD provisions that already apply for marine diesel engines under 40 CFR part 1042. We intend to revisit issues related to CARB’s suggested enhancements to the proposed OBD protocol in a future rulemaking. This will allow us to take a broader view of the requirements to make sure we capture the range of concerns for designing OBD systems that are robust and effective, without creating an unreasonable burden or failing to account for possible technical limitations. We would expect to include marine diesel engines in that program review.

We have revised the regulatory text related to NOx sensors as an alternative to DEF concentration monitoring since that clarification is clearly understood to be part of this alternative compliance path. We have made the change for both land-based engines in 40 CFR 1039.110 and marine diesel engines in 1042.110.

Neutral/Provide Additional Information Comment

Comment – Allowing optional content on the emission control label for non-road compression ignition engines

Although CARB staff recognizes that this particular provision merely allows manufacturers to incorporate features on the label that can be used to identify counterfeit labels (which CARB staff supports in principle), CARB staff recommends that U.S. EPA and NHTSA include a provision requiring the case-by-case approval of all manufacturer specific content on the label or any content not specifically identified in the regulations, prior to issuing a Certificate of Conformity. U.S. EPA and NHTSA should retain the right to reject any content that could have unintended consequences regardless of whether or not that content meets the general criteria for the optional label content. In particular, staff is concerned that too much information on the label could be a source of confusion to the end user or to enforcement inspectors in the field. For example, a manufacturer might want to use the labelling provisions of 40 CFR 1039.135(d)(1) to identify an ABT engine, that was originally certified to a family emission limit (FEL) consistent with Tier 3 emission levels, as being compliant with the more stringent Tier 4 emission levels. While this identification may not be inaccurate, it could create a situation for California’s in-use programs in which fleet owners mistakenly purchase these ABT engines believing that they fulfill the owners’ requirements for upgrading the “emissions average” of their fleets. Such a situation could negatively impact both the effectiveness of CARB’s in-use programs and the fleet owners’ costs should penalties be assessed. Other situations could be problematic, such as the inclusion of bar codes or Quick Response® (QR) type matrix codes on the emission control label that would redirect to a manufacturer supported webpage over which U.S. EPA and NHTSA have no control, or which a manufacturer may decide to no longer support at a future date. CARB staff does not have a comparable allowance for optional label content for off-road compression ignition engines, as the CAA prohibits California from regulating farm and construction equipment under 175 hp; therefore, we must rely on U.S. EPA and NHTSA to protect California’s interests in this matter. [EPA-HQ-OAR-2014-0827-1265-A1 p.127-128]
**Response:** EPA considers manufacturer’s proposed label content as part of the review of an application for certification. We intend to be mindful of the concern expressed by California ARB as part of that review process.

### 14.4.9 Amendments Related to Marine Diesel Engines in 40 CFR part 1042 and 1043 1946

**Organization:** GE Transportation

As a general matter, GE supports the proposed technical changes and clarifications to 40 CFR part 1042. [EPA-HQ-OAR-2014-0827-1297-A1 p.1]

Second, as discussed below, GE believes that it is critical for EPA to also apply these technical changes and clarifications to the marine testing requirements in 40 CFR part 1042. [EPA-HQ-OAR-2014-0827-1297-A1 p.1]

**II. APPLICATION OF TESTING CLARIFICATIONS TO MARINE AND STATIONARY ENGINES IN 40 C.F.R. PART 1042**

The same reasons that support the clarification of the proportionality verification for locomotives apply equally to marine and stationary engines. Accordingly, EPA should apply these same clarifications and regulatory language changes (subject to the requested changes noted above) to the testing requirements for marine and stationary engines defined in 40 C.F.R Part 1042. The steady state discrete mode testing procedure for marine and stationary engines contains the same technical issues relating to the verification of proportional sampling when utilizing batch fuel rate measurements that are resolved for locomotive testing by the proposed § 1033.501(a)(4) and (a)(5). These issues will be resolved for testing of marine and stationary engines if provisions similar to the proposed § 1033.501(a)(4) and (a)(5) are incorporated into Part 1042. [EPA-HQ-OAR-2014-0827-1297-A1 p.3]

The proposed Technical Amendment contains no provisions in 40 CFR part 1042, subpart F to accommodate proportional sampling verification when using a batch fuel rate, similar to the amendment of § 1033.501(a)(4) for steady state discrete mode testing. Use of a gravimetric measurement to determine a batch fuel rate for steady state discrete mode testing is the standard by which EPA verifies all other fuel flow meters as provided in § 1065.307(d)(4). It is requested that 40 CFR part 1042 incorporate similar language to § 1033.501(a)(4). [EPA-HQ-OAR-2014-0827-1297-A1 p.3]

GE requests a similar allowance in 40 CFR part 1042 for verification of proportional sampling over grouped test intervals instead of each discrete interval for testing of marine and stationary engines. This ensures consistent test equipment, processes and verification practices between test facilities regardless of the equipment under test (i.e., locomotives, marine engines, or stationary engines). Moreover, it ensures the same metric and degree of proportional sampling in all engine programs irrespective of engine application. [EPA-HQ-OAR-2014-0827-1297-A1 p.3]
Response:  EPA will make the requested changes to 40 CFR part 1042 that are similar to those made in 40 CFR part 1033 and has modified 40 CFR 1042.501(a) by adding four additional subparagraphs to address the concerns over proportional sampling verification for steady-state discrete mode testing.

Organization:  Navy

Our enclosed comments request that EPA consider a revision to the National Security Exemption (NSE) language in its diesel engine regulations to add an exemption for engines used in tactical equipment, vehicles, and vessels required to operate on high sulfur fuels to meet performance requirements in a worldwide deployable environment. [EPA-HQ-OAR-2014-0827-1137-A1 p.1]

Request for Modification to National Security Exemption Language in EPA Engine Regulations

Comment - The Department of Defense (DoD) must deploy and operate weapon systems around the world. The sulfur content in fuel supplies varies greatly at different deployment sites. Accordingly, DoD weapon systems must be able to operate with a wide range of sulfur contents. Current and future Environmental Protection Agency (EPA) compression ignition engine emission standards employ pollution prevention technologies that are intolerant to high levels of sulfur. If operated using high sulfur fuels, these engines suffer power degradation and engine failure. In an operational or tactical environment, engine degradation and failure jeopardizes warfighters’ lives and national security. CAA Section 203(b) provides EPA the authority to exempt these engines for reasons of national security. Accordingly, DoD requests that EPA grant system-specific National Security Exemptions (NSEs) and Blanket NSEs for DoD tactical equipment required to operate on high sulfur fuels. [EPA-HQ-OAR-2014-0827-1137-A1 p.3]

Discussion - EPA has approved all of the DoD’s NSE requests, including Blanket NSEs, exempting all tactical equipment from current non-road EPA emissions standards and tactical vehicles from current motor vehicle EPA emissions standards. EPA has stated that they thoroughly understand this rationale and plan to continue to approve all of the DoD’s NSE requests for DoD tactical equipment and vehicles to operate on high sulfur fuel. Continuing to require submittal of NSE requests to the EPA for approval with this rationale as justification will result in additional time and expense to the taxpayer with no benefit. [EPA-HQ-OAR-2014-0827-1137-A1 p.3]

Recommendation – DoD requests EPA revise the following sections of the Code of Federal Regulations (CFR) to add the requirement to operate on high sulfur fuels as a basis for an exemption from these regulations for purposes of national security. Therefore, no exemption request or approval will be necessary. This change will save considerable time and expense to both the EPA and DoD by eliminating unnecessary paperwork and management of these NSEs. [EPA-HQ-OAR-2014-0827-1137-A1 p.3]

§1042.635 National security exemption.
The standards and requirements of this part and prohibitions in §1068.101(a)(1) do not apply to engines exempted under this section.
(a) An engine is exempt without a request if it will be used or owned by an agency of the Federal government responsible for national defense, where the vessel in which it is installed has armor, permanently attached weaponry, specialized electronic warfare systems, unique stealth performance requirements, or unique combat maneuverability requirements, and/or installed in an auxiliary vessel that has the requirement to operate on high-sulfur fuels (greater than 15 parts per million) to meet performance requirements in a worldwide deployable environment. This applies to both remanufactured and freshly manufactured marine engines. Gas turbine engines are also exempt without a request if they...
Response: We agree with Navy that an automatic exemption is appropriate in cases where a defense agency would be operating (noncombat) compression-ignition engines in areas where ULSD may not be available. We believe the suggested language could be understood to broadly apply to all engines operated by defense agencies. We have adopted a provision tailored to the concern, as follows: “An engine/equipment is automatically exempt if it would need sulfur-sensitive technology to comply with emission standards, and it is intended to be used in areas outside the United States where ultra-low-sulfur fuel is unavailable.” This would not apply for compression-ignition engines that don’t have sulfur-sensitive technologies, and it would not apply for engines that can be expected to have access to ULSD.

In addressing the Navy comment, it became clear that we should draft a single, comprehensive national security exemption in §1068.225 rather than keeping a separate national security exemption for marine engines. The expanded version of §1068.225 includes minor changes. First, we more carefully identify how combat features apply in the context of equipment-based standards. Second, we are making explicit the allowance for engine manufacturers to produce and ship engines that qualify for the exemption.

Organization: Truck & Engine Manufacturers Association (EMA)

Comments on the Proposed Technical Amendments to Part 1042

As discussed above in connection with section 1039.135(c) and (d), the information required in 1042.135 (c)(5) through (9) requires a significant amount of space on the emission control information label and is considered to be of lesser importance. In addition, much of that information can easily be found elsewhere, as the language below indicates. [EPA-HQ-OAR-2014-0827-1269-A1 p.82]

(5) State the date of manufacture [DAY (optional), MONTH, and YEAR]; however, you may omit this from the label if you stamp, engrave, or otherwise permanently identify it elsewhere on the engine, in which case you must also describe in your application for certification where you will identify the date on the engine. [EPA-HQ-OAR-2014-0827-1269-A1 p.82]

(6) Identify the application(s) for which the engine family is certified (such as constant-speed auxiliary, variable-speed propulsion engines used with fixed-pitch propellers, etc.). If the engine is certified as a recreational engine, state: “INSTALLING THIS RECREATIONAL ENGINE IN A COMMERCIAL VESSEL OR USING THE VESSEL FOR COMMERCIAL PURPOSES MAY VIOLATE FEDERAL LAW SUBJECT TO CIVIL PENALTY (40 CFR 1042.601).” [EPA-HQ-OAR-2014-0827-1269-A1 p.82]

(8) State the useful life for your engine family if the applicable useful life is based on the provisions of § 1042.101(e)(2) or (3), or § 1042.104(d)(2). [EPA-HQ-OAR-2014-0827-1269-A1 p.82]

(9) Identify the emission control system. Use terms and abbreviations as described in 40 CFR 1068.45. You may omit this information from the label if there is not enough room for it and you put it in the owners manual instead. [EPA-HQ-OAR-2014-0827-1269-A1 p.82]
The information required by paragraph (c)(9) can claim an especially large amount of space on the emission control information label, and provides little value. [EPA-HQ-OAR-2014-0827-1269-A1 p.82]

In light of the foregoing, EMA requests that EPA not change the current language of paragraph 1042.135(d)(1). [EPA-HQ-OAR-2014-0827-1269-A1 p.82]

If the Agency feels strongly that information about the other standards that the engine meets cannot be added unless the information that was omitted based on the limited availability of space on the emission control information label is added back, then EMA recommends that only the information required in subparagraphs (c)(5) through (c)(8) be required to be added back. As mentioned above, the information required by subparagraph (c)(9) consumes a great deal of space and is of very limited value. [EPA-HQ-OAR-2014-0827-1269-A1 p.83]

The other proposed change to this section is the addition of a provision which would allow a manufacturer to add features to the label to prevent counterfeit labels (paragraph (d)(3) of the proposed language). As noted above, EMA agrees with this change. [EPA-HQ-OAR-2014-0827-1269-A1 p.83]

**Response:** We agree with the comment and have revised the regulation as described in Section 14.4.8.

EPA is proposing to make the same changes to the opening paragraph of §1042.225 as the Agency is proposing to make to the opening paragraphs of §1033.225 and §1039.225. EMA’s comments and recommendation regarding these proposed changes are essentially identical to EMA’s comments discussed above. Accordingly, for the same reasons as set forth above, EMA recommends that EPA retain the current language of the opening paragraph of §1042.225, and not finalize the proposed changes to that paragraph. [EPA-HQ-OAR-2014-0827-1269-A1 p.83]

**Response:** We agree with the comment and have revised the regulation as described in Section 14.4.8.

EPA also is proposing an amendment to section 1042.515(f)(4)(iii). EPA’s proposed technical amendment to this provision would read, as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.83]

(4) You may exclude emission data based on catalytic Aftertreatment temperatures as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.83]

(i) For an engine equipped with a catalytic NOx aftertreatment system, exclude NOX emission data that is collected when the exhaust temperature at any time during the NTE event is less than 250 °C. [EPA-HQ-OAR-2014-0827-1269-A1 p.84]

(ii) For an engine equipped with an oxidizing catalytic Aftertreatment system, exclude HC and CO emission data that is collected when the exhaust temperature at any time during the NTE event is less than 250 °C. Also exclude PM emission data if the applicable PM standard (or family emission limit) is above 0.06 g/kW-hr. Where there are parallel paths, measure the temperature 30 cm downstream of the last oxidizing aftertreatment device in the path with the greatest exhaust flow. [EPA-HQ-OAR-2014-0827-1269-A1 p.84]

(iii) Measure exhaust temperature within 30 cm downstream of the last applicable catalytic Aftertreatment device. Where there are parallel paths, use good engineering judgment to
measure the temperature within 30 cm downstream of the last applicable catalytic aftertreatment device in the path with the greatest exhaust flow. [EPA-HQ-OAR-2014-0827-1269-A1 p.84]

EMA has concerns regarding this amendment. EPA has inexplicably dropped the current language of paragraph 1042.515(f)(4)(iii) which reads “Other parameters. You may request our approval for other minimum or maximum ambient or engine parameter limit values at the time of certification.” That language provides important and needed potential relief and should not be deleted, especially since that relief is only available upon request, and requires EPA approval. [EPA-HQ-OAR-2014-0827-1269-A1 p.84]

Another proposed change to this section is to move the specification of the temperature measurement point as well as the instructions pertaining to how to deal with the situation of parallel exhaust streams to a separate paragraph. However, it appears that EPA inadvertently left a portion of those instructions in revised paragraph (4)(ii). It is redundant and unnecessary to have that instruction in both places. [EPA-HQ-OAR-2014-0827-1269-A1 p.84]

Accordingly, EMA recommends that EPA modify section 1042.515(f)(4) to read as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.84]

(4) You may exclude emission data based on catalytic Aftertreatment temperatures as follows: [EPA-HQ-OAR-2014-0827-1269-A1 p.84]
(i) For an engine equipped with a catalytic NOX aftertreatment system, exclude NOX emission data that is collected when the exhaust temperature at any time during the NTE event is less than 250 °C. [EPA-HQ-OAR-2014-0827-1269-A1 p.84]
(ii) For an engine equipped with an oxidizing catalytic Aftertreatment system, exclude HC and CO emission data that is collected when the exhaust temperature at any time during the NTE event is less than 250 °C. Also exclude PM emission data if the applicable PM standard (or family emission limit) is above 0.06 g/kW-hr. [EPA-HQ-OAR-2014-0827-1269-A1 p.84]
(iii) Measure exhaust temperature within 30 cm downstream of the last applicable catalytic Aftertreatment device. Where there are parallel paths, use good engineering judgment to measure the temperature within 30 cm downstream of the last applicable catalytic aftertreatment device in the path with the greatest exhaust flow. [EPA-HQ-OAR-2014-0827-1269-A1 p.84-85]
(iv) Other parameters. You may request our approval for other minimum or maximum ambient or engine parameter limit values at the time of certification. [EPA-HQ-OAR-2014-0827-1269-A1 p.85]

Response: EPA has removed the redundant text in 1042.515(f)(4). EPA will not add the EMA proposed paragraph (iv) as this section deals with aftertreatment exclusions and not exclusions related to engine temperature. More broadly, we believe there has been enough development and learning for current aftertreatment technologies to allow us to identify certain exclusions without leaving an allowance for creating exclusions for additional items or types of operation that have not yet been identified

14.4.10 Amendments Related to Locomotives in 40 CFR Part 1033

Organization: Truck & Engine Manufacturers Association (EMA)

Comments on the Proposed Technical Amendments to Part 1033

EPA is proposing to make the following amendments to the opening paragraph of section 1033.225:
§1033.225 Amending applications for certification.
Before we issue you a certificate of conformity, you may amend your application to include new or modified locomotive configurations, subject to the provisions of this section. After we have issued your certificate of conformity, but before the end of the model year, you may send us an amended application requesting that we include new or modified locomotive configurations within the scope of the certificate, subject to the provisions of this section. Before the end of the model year, you must also amend your application if any changes occur with respect to any information that is included or should be included in your application. For example, you must amend your application if you determine that your actual production variation for an adjustable parameter exceeds the tolerances specified in your application. After the end of the model year, you may amend your application only to update maintenance instructions as described in §1033.220 or to modify an FEL as described in paragraph (f) of this section. [EPA-HQ-OAR-2014-0827-1269-A1 p.73-74]

As shown in the “track changes” version of the proposed amendment quoted above, EPA is seeking to modify the existing regulatory language to differentiate the items that a manufacturer can request be amended within the model year, on the one hand, and those items that a manufacturer can request be amended only after the end of the model year, on the other hand. In that regard, EPA would continue to allow manufacturers to request new or modified engine configurations (as long as they are within the scope of the certificate and subject to the other provisions of section 1033.225) before the end of the model year. But, after the end of the model year, EPA is proposing to limit amendments that can be requested by a manufacturer to updated maintenance instructions as described in section 1033.220, or FEL modifications as described in section 1033.225(f), thereby disallowing requests for amendments that would add to or modify existing engine configurations, even those that otherwise would be within the scope of the certificate and consistent with the other provisions of section 1033.225. [EPA-HQ-OAR-2014-0827-1269-A1 p.74]

Simply stated, these proposed amendments are unacceptable. In the Preamble explanation for these changes, the Agency states that the changes are merely “clarifications” of the existing language. That is not correct. The proposed revisions go well beyond being “clarifications” and represent significant modifications. [EPA-HQ-OAR-2014-0827-1269-A1 p.74]

The ability to add a new engine configuration and/or amend an existing engine configuration is critical to engine manufacturers and the customers they serve, both during the model year and afterwards. In some cases a change may be needed to make product improvements and/or correct unanticipated product issues. In other situations, new ratings may be needed to meet customer requirements to enable pieces of equipment powered by the subject engines to perform their intended functions. As some of those changes may be needed to maintain emissions compliance, or correct emissions-related issues found in the course of business, it is in the Agency’s best interest to continue to allow manufacturers the opportunity to request such changes. [EPA-HQ-OAR-2014-0827-1269-A1 p.74]

It is important to note that all of the application changes at issue must be submitted to the Agency, and are subject to approval by the Agency. Consequently, if EPA has an issue with a requested new engine configuration or with a requested amendment to an existing engine configuration, the Agency can address that issue during the review process. There is, therefore, no need for this unacceptable amendment. [EPA-HQ-OAR-2014-0827-1269-A1 p.74]

Accordingly, EMA recommends that EPA retain the current language of the opening paragraph of section 1033.225, and not finalize the proposed changes to this paragraph. [EPA-HQ-OAR-2014-0827-1269-A1 p.74]
Response: We agree with the comment and have revised the regulation as described in Section 14.4.8.

In addition to the proposed technical amendments to Part 1033, EPA has requested comments on several other provisions in Part 1033. Specifically, 40 CFR 1033.101(g)(3) provides an allowance for shorter useful lives for non-locomotive-specific engines—that is, engines not specifically designed for use in locomotives. For normal locomotive engines, the minimum useful life is specified in terms of MW-hrs as the product of the rated horsepower multiplied by 7.50. However, the regulations allow manufacturers/remanufacturers of locomotives with non-locomotive specific engines to request a shorter useful life if the locomotives will rarely operate longer than the shorter useful life. EPA has asked for comment regarding the need for additional guidance on applying this provision. [EPA-HQ-OAR-2014-0827-1269-A1 p.74-75]

EMA believes that this is an important regulatory provision, allowing a shorter useful life for certain engines used in locomotive applications. Now that the provision has been in place for several years, and has been utilized by several EMA member companies, EMA recommends keeping the provision as it is and not making any changes. The example default alternative minimum life, which defines a set multiplier less than the standard 7.5 would be especially problematic, as it would remove a key aspect of the current provision which allows engine (and duty cycle) characteristics (characteristics which vary from engine to engine) to define the reduced useful life. [EPA-HQ-OAR-2014-0827-1269-A1 p.75]

Response: As recommended in the comment, we are not adopting a change to useful life provisions of 40 CFR part 1033.

EPA is also seeking comment on whether the Agency should consider notch-specific engine/alternator efficiencies to be confidential business information. Under the current “Class Determination 1-13, Confidentiality of Business Information Submitted in Certification Applications for 2013 and subsequent model year Vehicles, Engines and Equipment,” there are three possible ways such information could be treated: 1) as information not entitled to confidential treatment; 2) as information entitled to confidential treatment until introduction into commerce; or 3) information entitled to confidential treatment. The “Class Determination” document, authored by EPA’s Office of General, provides guidance as to how to determine which of these three treatment options is appropriate for various types of information. [EPA-HQ-OAR-2014-0827-1269-A1 p.75][This section can also be found in section 1.4.6 of this comment summary]

The following table, taken from the Class Determination document, lists the information that can be entitled to confidential treatment. [EPA-HQ-OAR-2014-0827-1269-A1 p.75][This section can also be found in section 1.4.6 of this comment summary]

[Table 3, ‘Manufacturer Information Entitled to Confidential Treatment’, can be found on p.76 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

In accordance with EPA regulations at 40 C.F.R. sections 2.204 and 2.205, information will be entitled to confidential treatment if the manufacturer (1) asserts that the information is entitled to confidential treatment, and (2) has not waived or withdrawn that assertion. Inherent in assertion (1) are the following representations by the manufacturer: (a) they have maintained the information in confidence, (b) the information cannot be readily obtained by other legitimate means, and (c) disclosure of the information to the public both before and after model introduction would be likely to cause substantial harm to the manufacturer’s competitive position. [EPA-HQ-OAR-2014-0827-1269-A1 p.76][This section can also be found in section 1.4.6 of this comment summary]
EPA provides two alternative methods to certify engines used in locomotive applications. Such engines can be certified on an engine dynamometer or alternatively in the locomotive. In the latter case, it is necessary to know the notch-specific engine/alternator efficiencies to ensure that the engine is tested at the appropriate speed and load conditions. [EPA-HQ-OAR-2014-0827-1269-A1 p.76][This section can also be found in section 1.4.6 of this comment summary]

EMA believes that notch-specific engine/alternator efficiency clearly fits within the category “Technical Description Information” on Table 3 above. Accordingly, EMA believes that notch-specific engine/alternator efficiencies readily meets the criteria set forth in 40 CFR 2.204 and 2.205 and should be treated as confidential business information. [EPA-HQ-OAR-2014-0827-1269-A1 p.77][This section can also be found in section 1.4.6 of this comment summary]

Response: We have been unable to prepare a comprehensive policy regarding CBI determinations, so we will continue to respond to any requests for information on a case-by-case basis.

EPA has also requested comment on extending the provisions of 40 CFR 1033.101(i) to Tier 4 locomotives. That provision generally involves a less stringent CO standard coupled with over-complying with the PM standard. Specifically, this option, which currently applies for Tier 2 and earlier locomotives, requires PM emissions be at least 50 percent below the normally applicable PM standard. The existing provisions were developed to provide a compliance path for natural gas locomotives that reflected both the technological capabilities of natural gas locomotives and the relative environmental benefits of their CO and PM emissions. The provision was not applied to Tier 4 locomotives, because the applicable Tier 4 PM standard is already very low (0.03 g/hp-hr). If EPA were to apply a similar provision corresponding to Tier 4 standards, EPA would need to select PM and CO levels that are properly paired to manage this tradeoff. Thus, EPA has requested comment on whether it is appropriate to pursue such alternate standards, and on the specific numerical standards for PM and CO that would represent an equivalent level of stringency relative to the published standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.77]

Alternate CO standards are currently provided for Tier 0, Tier 1 and Tier 2 Locomotives. The pertinent regulatory language is found in 40 CFR Part 1033.101(i), as set forth below: [EPA-HQ-OAR-2014-0827-1269-A1 p.77]

(i) Alternate CO standards. Manufacturers/remanufacturers may certify Tier 0, Tier 1, or Tier 2 locomotives to an alternate CO emission standard of 10.0 g/bhp-hr instead of the otherwise applicable CO standard if they also certify those locomotives to alternate PM standards less than or equal to one-half of the otherwise applicable PM standard. For example, a manufacturer certifying Tier 1 locomotives to a 0.11 g/bhp-hr PM standard may certify those locomotives to the alternate CO standard of 10.0 g/bhp-hr. [EPA-HQ-OAR-2014-0827-1269-A1 p.77]

EMA believes that alternative CO standards for Tier 4 locomotives would allow a compliance path for manufacturers/remanufacturers of locomotives fueled by natural gas and other non-conventional fuels, and EMA recommends that such alternative CO standards be provided. Further, EMA recommends that alternative CO standards also be provided for Tier 3 remanufactured locomotives as well. [EPA-HQ-OAR-2014-0827-1269-A1 p.77]

More specifically, EMA recommends the following alternative sets of standards for Tier 3 and Tier 4 locomotives. On the two tables below - one for Tier 3 remanufactured locomotive, the other for Tier 4
locomotives - the current required set of standards is highlighted in bold and the recommended alternative sets of standards are shown in italics. [EPA-HQ-OAR-2014-0827-1269-A1 p.77]

[Table of Tier 3 and 4 Locomotives can be found on p.78 of docket number EPA-HQ-OAR-2014-0827-1269-A1]

Response:

We are adopting alternate standards for Tier 3 and Tier 4 locomotives, consistent with the alternate standards adopted for earlier tiers of standards. Rather than adopting the graduated approach recommended by EMA, we believe it is appropriate to continue with the policy of establishing an alternate CO standard of 10.0 g/hp-hr, with an increased level of PM control required for the Tier 3 and Tier4 standards to qualify for the CO relief. Since the technologies in question generally correspond with substantial step changes in emissions, we don’t want to create graduated standards suggesting that manufacturers need to dial in a certain level of PM control to earn a corresponding level of relief for CO emissions. These alternate standards are most likely to be relevant for natural gas engines. We believe manufacturers of natural engines can achieve a level of 0.01 g/hp-hr and have set that as the alternate PM standard corresponding to the 10.0 g/hp-hr CO standard for Tier 3 and Tier 4 engines.

Organization:  Association of American Railroads

The Association of American Railroads (“AAR”) appreciates the opportunity to comment on the proposed rule for Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles- Phase 2. 1 AAR generally supports the changes made in the proposal that impact railroad operation directly; however, AAR seeks clarification with regard to §1033.601, General compliance provisions. [EPA-HQ-OAR-2014-0827-1273-A2 p.1]

(f) Multi-fuel locomotives. Subpart C of this part describes how to test and certify dual-fuel and flexible-fuel locomotives. Some multi-fuel locomotives may not fit either of those defined terms. For such locomotives, we will determine whether it is most appropriate to treat them as single-fuel locomotives, dual-fuel locomotives, or flexible-fuel locomotives based on the range of possible and expected fuel mixtures. For example, a locomotive might burn natural gas but initiate combustion with a pilot injection of diesel fuel. If the locomotive is designed to operate with a single fueling algorithm (i.e., fueling rates are fixed at a given engine speed and load condition), we would generally treat it as a single-fuel locomotive. In this context, the combination of diesel fuel and natural gas would be its own fuel type. If the locomotive is designed to also operate on diesel fuel alone, we would generally treat it as a dual-fueled locomotive. If the locomotive is designed to operate on varying mixtures of the two fuels, we would generally treat it as a flexible-fueled locomotive. To the extent that requirements vary for the different fuels or fuel mixtures, we may apply the more stringent requirements. [EPA-HQ-OAR-2014-0827-1273-A2 p.2]

In this section, it is unclear what EPA means by “flexible-fuel” and “dual-fuel” and what technology EPA is referencing with regard to those terms. AAR requests that EPA provide a full definition of “flexible-fuel” and “dual-fuel,” as well as corresponding examples of technology for both engines. In addition, low pressure, dynamic gas blending, and high pressure direct injection are undefined and require explanation. There are many other combinations that need to be addressed and defined. Also, it is unclear whether there are other fuel types besides natural gas and diesel that EPA is including in the definition of flexible-fuel. [EPA-HQ-OAR-2014-0827-1273-A2 p.2]
Also, please explain what EPA means by, “[t]o the extent that requirements vary for the different fuels or fuel mixtures, we may apply the more stringent requirements” and the reason for more stringent requirements.

Response:

The proposed rule included new definitions for flexible-fuel and dual-fuel and the draft text in §1033.601(c) included examples of the corresponding technologies, consistent with the AAR comment. The proposed rule did not include any of the terms AAR suggested would need more explanation. The combination of natural gas and diesel fuel is listed as an example of an engine using two fuels, but there is nothing to suggest that the provisions apply any differently for other fuel combinations.

Most regulatory provisions apply uniformly for different fuels, but there are some places where the regulation describes or prescribes something different for different fuels. If an engine has two fuels, it is subject to requirements that apply for both fuels. As such, it is not enough for the engine to meet the requirements that apply for one fuel, but not for the other. A different way to say this is that the engine must meet the more stringent requirements if they are different.

Organization:  GE Transportation

As a general matter, GE supports the proposed technical changes and clarifications to 40 CFR part 1033.

The proposed technical changes and clarifications help resolve issues related to locomotive testing. These comments provide a few practical enhancements to the testing procedures for locomotives that are important to effectuate the purposes of the proposed amendments.

GE supports the revision to 40 CFR 1033.101, which clarifies that compliance with the numerical hydrocarbon (HC) emission standard is based on non-methane hydrocarbon (NMHC) for dual-fuel and flexible-fuel locomotives.

I. CLARIFICATIONS OF LOCOMOTIVE TESTING REQUIREMENTS IN 40 CFR 1033.501

A. Proportionality Verification for Certain Discrete Mode Tests (40 C.F.R. § 1033.501(a)(4))

Section 1033.501(a)(4) of the proposed Technical Amendment states that locomotive manufacturers should verify proportional sampling by "...using the mean raw exhaust molar flow rate paired with each recorded sample flow rate." This language limits the proportionality verification options in 40 CFR 1065.545 to only § 1065.545(b). In the final rule, EPA should slightly alter the proposal such that if a batch fuel measurement is used to determine raw exhaust flow rate, the batch modal fuel rate would be paired with each recorded modal 1 hertz (Hz) data set. Chemical balance calculations then would be performed at a frequency of 1Hz for the purpose of determining exhaust molar flow rate at 1Hz. These 1Hz raw exhaust flows would already be paired with each recorded sample flow rate and only be used for proportional sampling verification purposes. This approach would include some variation in the determination of modal raw exhaust flow associated with all other recorded data except fuel rate. Thus, both § 1065.545(a) and § 1065.545(b) become viable means to verify proportional sampling.
No changes in determining mass emissions, including drift verification, are being suggested. Those would still be performed utilizing the steady state discrete mode method provided in § 1065.650(e). [EPA-HQ-OAR-2014-0827-1297-A1 p.2]

**Response:** The change that EPA proposed to 1033.501(a)(4) in the NRPM (below) is written generically enough to allow the use of either 1065.545(a) or (b) to verify proportionality, including the scenario proposed by GE. Therefore no change is necessary.

B. Consistent Use of “Phase” and “Interval” (40 CFR 1033.501(a)(5)) [EPA-HQ-OAR-2014-0827-1297-A1 p.2]

The proposed Technical Amendment replaces “phase” with “interval” throughout 40 CFR part 1033. However, “phase” is still used in § 1033.501(a)(5). The word “phase” should be replaced with “group” in § 1033.501(a)(5) to be consistent with respect to terminology used elsewhere in the proposed Technical Amendment. [EPA-HQ-OAR-2014-0827-1297-A1 p.2]

**Response:** We agree with the comment and have revised the regulation accordingly.

Section 1033.501(j)(2) of the proposed Technical Amendment states that manufacturers must “invalidate a smoke test if active regeneration starts to occur during the test.” [EPA-HQ-OAR-2014-0827-1297-A1 p.2]

Currently, sections 1033.515(c)(4) and 1033.520(e)(4) require measurement of smoke and emissions concurrently, with no allowance for measuring smoke separately from other emissions. [EPA-HQ-OAR-2014-0827-1297-A1 p.2]

We recommend that EPA amend Part 1033 to provide an option to perform smoke measurements and other regulated emissions measurements in separate test sequences, similar to the existing provision in 40 CFR 92.124(f). Section 1033.501(j)(2) of the Technical Amendment should explain the means with which to treat smoke and emissions measurements if active regeneration of aftertreatment occurs during either portion of the test. [EPA-HQ-OAR-2014-0827-1297-A1 p.2-3]

**Response:** EPA will make the following changes regarding smoke measurement to address the concern expressed in the comment:

1033.515(c)(4) If applicable, begin the smoke test at the start of the test mode A. Continue collecting smoke data until the completion of test mode 8. You may perform smoke measurements independent of criteria pollutant measurements by rerunning the test over the duty-cycle. If you choose this option, the minimum time-in-notch is 3.0 minutes for duty-cycles in which only smoke is measured. Refer to §1033.101 to determine applicability of smoke testing and §1033.525 for details on how to conduct a smoke test.

1033.520(e)(4) If applicable, begin the smoke test at the start of the first test interval of the applicable ramped modal cycle. Continue collecting smoke data until the completion of final test interval. You may perform smoke measurements independent of criteria pollutant measurements by rerunning the test over the duty-cycle. If you choose this option, the minimum time-in-notch is 3.0 minutes for duty-cycles in which only smoke is measured.
III. NMHC MEASUREMENTS FOR DUAL-FUEL AND FLEXIBLE-FUEL LOCOMOTIVES

The proposed revisions to §1033.101(f)(1)(i) would clarify that the numerical emission standard for hydrocarbon (HC) is based on non-methane hydrocarbon (NMHC) for dual-fuel and flexible-fuel locomotives. GE supports this clarification. [EPA-HQ-OAR-2014-0827-1297-A1 p.4]

Regulations governing emissions from locomotives have always stated that the numerical standard for HC shall be based on NMHC for gaseous-fueled locomotives (§92.8(a)(1) and §1033.101(f)(1)(ii)). This is appropriate because a large portion of natural gas is methane, but EPA has previously excluded methane from the definition of Volatile Organic Compounds (VOC) under 40 CFR 51.100(s), given methane’s negligible photochemical reactivity. [EPA-HQ-OAR-2014-0827-1297-A1 p.4]

Dual-fuel and flexible-fuel locomotives that use a combination of diesel fuel and natural gas are likely to be configured such that during a majority of the locomotive’s operating time, they will use a mixture of diesel and natural gas simultaneously injected into the cylinders. On average, the locomotive will burn more natural gas than diesel; thus, it is appropriate to regulate such a locomotive on measurements of NMHC. [EPA-HQ-OAR-2014-0827-1297-A1 p.4]

Response: In the final rule, we specify that the hydrocarbon standard for gaseous-fueled locomotives excludes ethane, much like we have established for methane, as describe in Section 14.4.7.

IV. AMENDMENTS TO CERTIFICATE APPLICATIONS AND EPA DECISIONS

In proposed §1033.225, the Technical Amendment would clarify that after the end of the model year for a given certificate of conformity, manufacturers “may amend [their] application only to update maintenance instructions ... or to modify an FEL.” [EPA-HQ-OAR-2014-0827-1297-A1 p.4]

In the past, EPA has utilized the mechanism of a “field fix” in order to apply changes to prior year certificates, as described in Field Fixes Related to Emission Control-Related Components, Advisory Circular 2B, (Mar. 17, 1975) (“Field Fix Circular”). The Field Fix Circular defines a field fix as follows: [EPA-HQ-OAR-2014-0827-1297-A1 p.4]

In the context of this Advisory Circular, a field fix is defined as: A modification, removal or replacement of an emission-control related component by a manufacturer or dealer, or revision by a manufacturer for implementation by dealers to specifications or maintenance practices for emission-control related components on vehicles that have left the assembly line. [EPA-HQ-OAR-2014-0827-1297-A1 p.4]

It is common practice in the locomotive industry for manufacturers to develop improved emission-control related components for incorporation into current model year locomotives, with the intent to also incorporate such components into prior model year locomotives of similar design. For example, a manufacturer could develop a modification to a locomotive’s originally-certified fuel injector that improves the reliability of the injector. In this example, under current practice, a field fix is used to notify EPA of the manufacturer’s intent to incorporate the improved injector into prior model year locomotives. The proposed rule revision creates uncertainty as to whether EPA is planning a new approach of amending prior years’ certification applications or whether EPA intends to continue using...
the field fix approach. It is important for EPA to make clear how it intends manufacturers to proceed. In addition, if applications are to be amended, it is unclear whether EPA would subsequently “act” on those applications and how the certificate would be amended (or if amendment would occur automatically). In short, to the extent EPA intends to eliminate the field fix mechanism, what will be the mechanism for manufacturers to use in order to update prior model year applications for updates to emission-control related components (including AECDs)? [EPA-HQ-OAR-2014-0827-1297-A1 p.5]

Response: We agree with the comment and have revised the regulation as described in Section 14.4.8.

In proposed §1033.255(c)(2), EPA states that it “may deny [an] application or suspend or revoke [a] certificate if [a manufacturer does] any of the following ... Submit false or incomplete information ... This includes doing anything after submission of [an] application to render any of the submitted information false or incomplete.” [EPA-HQ-OAR-2014-0827-1297-A1 p.5]

GE is concerned that use of the phrase “doing anything” is overly broad and does not clearly indicate to manufacturers the specific actions that EPA is trying to address with this provision. Using the example in above paragraph IV.B, if a manufacturer develops an improved fuel injector for incorporation into prior model year locomotives, but the revised provisions in §1033.225 preclude amending the application to include this improved fuel injector, would that manufacturer be in violation of this provision? The language EPA has drafted appears to be overbroad, and it needs to be clarified so that EPA can provide adequate notice to regulated entities of the actions that could call their certificates of conformity into question. [EPA-HQ-OAR-2014-0827-1297-A1 p.5]

EPA should clarify and narrow this provision in the final rule and should explain clearly the actions that would implicate the provision. Otherwise, the provision is impermissibly broad and vague. [EPA-HQ-OAR-2014-0827-1297-A1 p.5]

Organization: GE Transportation

GE requests clarification on language in the Technical Amendment concerning amendments to certificate applications (40 CFR 1033.225) and certain EPA decisions (40 CFR 1033.255). The proposed regulatory language should be revised to address the specific situation that is of concern to ensure that the provision gives adequate notice to regulated entities of the types of activities that could jeopardize their certificates of conformity. [EPA-HQ-OAR-2014-0827-1297-A1 p.1]

Response:

As noted in the previous section, we are not adopting the proposed change to §1033.225. Some examples of making applications incorrect would include (1) Naming an agent for service in the application, then deciding later to no longer rely on that agent for managing communications with EPA, (2) changing engine designs for production engines in a way that is not covered by the application (adjustable parameters, emission control features, etc.), and (3) Recommending a revised time to remanufacture that is longer than the locomotive’s useful life. We address the question regarding §1033.225 in Section 14.4.8.
Appendix A to Section 14 - Sensitivity Analysis of Glider Impacts

EPA is restricting the number of gliders that may be produced using engines not meeting current standards. Current standards for NO\textsubscript{X} and PM (which began in 2007 and took full effect in 2010) are at least 90 percent lower than the most stringent previously applicable standards, so the NO\textsubscript{X} and PM emissions of any glider vehicles using pre-2007 engines are at least ten times higher than emissions from equivalent vehicles being produced with brand new engines.\textsuperscript{248} However, most gliders being produced today use engines originally manufactured before 2002. Since these pre-2002 engines lack both EGR and exhaust aftertreatment, they would have NO\textsubscript{X} and PM emissions 20-40 times higher than current engines. If miscalibrated, emissions could be even higher. Thus, each glider vehicle using an older engine that is purchased instead of a new vehicle with a current MY engine results in significantly higher in-use emissions of air pollutants associated with a host of adverse human health effects, including premature mortality (see Section VIII of the FRM Preamble).

These emission impacts have been compounded by the increasing sales of these vehicles. Estimates provided to EPA indicate that production of glider vehicles has increased by an order of magnitude from what it was in the 2004-2006 time frame – from a few hundred each year to thousands.\textsuperscript{249} Glider vehicle production is not currently being reported to EPA, but we estimate that current production is close to 10,000 each year. Some commenters to the proposed rule indicated that the volume may be higher still. Volvo provided evidence that current sales have grown to 10,000 or more per year. Even some commenters who produce glider vehicles and opposed EPA’s proposal acknowledged that glider sales are now over 10,000 units annually. See Section XIII.B.(3) of the Preamble and Section 14.2 of this RTC.

For the final rule, EPA has updated our analysis of the environmental impacts of gliders.\textsuperscript{250} The updated analysis used the MOVES model, which is the same emissions modeling tool used to estimate the emissions impacts of the rule, described in Sections VII and VIII of the FRM. EPA performed two analyses which are described below. The first projected future fleetwide emissions for a control scenario based on the proposal (which is similar to the final rule). The second projected per-vehicle emissions for MY 2017 gliders. Both analyses focused on NO\textsubscript{X} and PM emissions and assumed that these gliders emit at the level equivalent to the engines meeting the MY 1998-2001 standards, since most glider vehicles currently being produced use remanufactured engines of this vintage. See Section XIII.B.(3) of the Preamble and Section 14.2 of this RTC. We did not attempt to account for any miscalibration of these engines or other factors that would cause emissions to be higher than 1998 engines. Finally, the analyses made the simplifying assumption that all gliders are tractors. Although not entirely correct, the vast majority of glider vehicles currently being produced are tractors, so this assumption still allows impacts to be reasonably approximated.

\textsuperscript{248} The NO\textsubscript{X} and PM standards for MY 2007 and later engines are 0.20 g/hp-hr and 0.01 g/hp-hr, respectively. The standards for MY 2004 through 2006 engines were ten times these levels, and earlier standards were even higher.

Fleetwide Emission Projections

Based on public comments, EPA is estimating that approximately 10,000 gliders will be produced in 2016. Consistent with this, the modeling of gliders discussed here assumed annual glider sales of 10,000 for 2015 and later. As noted above, the modeling assumed that these gliders emit at the level equivalent to the engines meeting the MY 1998-2001 standards without miscalibration.

Figure A-1: Glider vehicle production projected for fleetwide analysis without new provisions

We modeled impacts on NOx and PM inventories with and without restrictions for two calendar years: 2025 and 2040. The restrictions were modeled as limiting sales in 2018 and later to 1,000 new gliders each year. This control case roughly approximates the restrictions being adopted for 2018 and later, and is consistent with the proposed requirements. The total number of vehicles was held constant by increasing the number of fully compliant vehicles (i.e., vehicles with engines meeting 2017 and later standards for NOx and PM) by 9,000 for each model year after 2017. However, we recognize that the actual number of gliders produced annually under the control case may vary by year and/or be higher or lower than 1,000. The results are shown below. This control scenario does not reflect the restrictions being adopted for 2017. See the model year analysis below for the impacts of model year 2017 glider vehicles.

The model projects that if glider vehicle production remains at 10,000 per year, there would be 128,750 glider vehicles on the road in 2025 and that they would emit 295,000 tons/year of NOx in 2025 and 7,817 tons/year of PM$_{2.5}$. This means the average glider on the road in 2025 would emit 4,583 pounds of NOx and 121 pounds of PM$_{2.5}$ for that single year.\(^{251}\)

Model Year Analysis

EPA also modeled the lifetime emissions of a single model year. The analysis estimated per-vehicle emissions, as well as the emission reductions associated with restricting the number of glider vehicles that could be produced in 2017 using older engines not meeting the current criteria pollutant standards. As with the fleetwide analysis, the model year analysis assumed that these gliders emit at the level equivalent to the engines meeting the MY 1998-2001 standards without miscalibration. Although presented for model year 2017, similar results would be expected for later years as well. The per-vehicle results are shown in the figures below (gray bars for glider vehicles). These figures also show the corresponding emissions projected for conventional model year 2017 vehicles with fully compliant engines (small blue bars).

\(^{251}\) This estimate is for the projected number of vehicles on the road, and does not include vehicles projected to have been scrapped from the population.
Figure A-2: Annual Per-Vehicle NOx Emissions (tons/year)  
For Model Year 2017 Glider Vehicles and Other New Vehicles

Figure A-3: Annual Per-Vehicle PM Emissions (tons/year)  
For Model Year 2017 Glider Vehicles and Other New Vehicles
Emissions are shown normalized to the initial number of model year 2017 vehicles.\textsuperscript{252} The trends shown in these figures largely reflect three phenomena: deterioration, scrappage, and declining use. Emissions initially increase due to deterioration of the engines (and deterioration of aftertreatment controls for the fully compliant engines). Then the average per-vehicle emissions decline as the projected annual mileage accumulation rates decline and some fraction of the vehicles are removed from service. Model year lifetime emissions are shown below per thousand glider vehicles.\textsuperscript{253}

| Table A-3: Lifetime NOx and PM Emissions (tons) For Model Year 2017 Glider Vehicles and Other New Vehicles |
|---------------------------------------------------------------|---------------------------------------------------------------|
| Model Year 2017 Glider Vehicles                               | Model Year 2017 Fully Compliant Vehicles                      |
| NOx Lifetime Tons per 1,000 Vehicles                         | PM\textsubscript{2.5} Lifetime Tons per 1,000 Vehicles       |
| 43,800                                                       | 710                                                          |
| 2,300                                                       | 30                                                           |
| Difference                                                   |                                                               |
| 41,500                                                      | 680                                                          |

As shown in this table, even a small number of glider vehicles has a very large emission impact. Even without any projections of miscalibration, glider vehicles are projected to emit about 20 times as much NOx and PM as the same number of fully compliant vehicles.\textsuperscript{254} Moreover every 1,000 glider vehicles that are produced instead of fully compliant vehicles results in 41,500 tons of additional NOx and 680 tons additional PM emitted into the atmosphere. Although we do not have precise historical production rates for glider vehicles, we are confident that they were less than 5,000 per year prior to 2015. Without controls, it is reasonable to assume that glider vehicle production for 2017 would be 10,000 to 15,000.\textsuperscript{255} Thus, the restriction on 2017 production that is being adopted is projected to prevent the use of high polluting engines in 5,000 to 10,000 glider vehicles. This would prevent the emission of 207,500-415,000 tons of NOx and 3,400-6,800 tons of PM.

\textsuperscript{252} These numbers differ from per-vehicle estimates from the fleetwide analysis because they are normalized to the total number of model year 2017 vehicles produced rather than those still in the fleet for a given calendar year.\textsuperscript{253} The maximum lifetime assumed for these vehicles is 30 years; however, MOVES models most vehicles as being removed from service after much less than 30 years. MOVES projects that nearly 80 percent of lifetime emissions will occur within the first 15 years of a vehicle’s life.\textsuperscript{254} EPA has separately estimated that glider emissions could be as much more than twice as high as this (or producing more than 40 times as much NOx and PM as current engines) if the engines are miscalibrated, incompletely/improperly rebuilt, and/or were originally manufactured before 1998.\textsuperscript{255} 2016 production is projected to be approximately 10,000 glider vehicles. Given the trend of ever-increasing sales over the last several years, combined with the likelihood of some pre-buying occurring based on the proposed restrictions for 2018, we believe that 2017 production could have been 15,000 or more without the production limit for 2017.
Benefits of Controlling Emissions from Glider Vehicles

Reducing the number of glider vehicles produced using older engines will yield substantial improvements in public health. For example, using incidence-per-ton estimates, the number of PM$_{2.5}$-related premature mortalities caused by glider vehicles can be estimated from the lifetime reductions in both NO$_X$ (which forms nitrate PM in secondary reactions) and directly emitted PM$_{2.5}$. Using benefit-per-ton values (described in Section IX.H of the FRM Preamble), the present value of total monetized PM$_{2.5}$-related benefits associated with these lifetime emission reductions can also be calculated. These health-related benefits are presented in the table below. Cases of premature mortality avoided are presented as a range based on results derived from two studies (the American Cancer Society cohort study - Krewski et al., 2009, and the Harvard Six-cities study - Lepeule et al., 2012). Monetized benefits are presented as net present values in 2013$, assuming a 30-year vehicle lifetime and a 3% and 7% discount rate. Both premature mortalities and benefits are shown for model year 2017 glider vehicles based on the increase in lifetime emissions over a fully compliant model year 2017 vehicle. Note, as discussed below, there would be additional benefits that have not been quantified.

| Increased Lifetime NOx Emissions per 1,000 Glider Vehicles | 41,500 Tons |
| Increased Lifetime PM$_{2.5}$ Emissions per 1,000 Glider Vehicles | 680 Tons |
| Premature Mortalities per 1,000 Glider Vehicles | 70-160 Persons |
| Monetized PM$_{2.5}$-related Benefits Associated with Reducing Glider Production by 1,000 Vehicles | $0.3-1.1 Billion |

As noted above, the restriction on 2017 production that is being adopted is projected to prevent the use of high polluting pre 2002-engines in 5,000 to 10,000 glider vehicles, and would prevent the emission of 207,500-415,000 tons of NOx and 3,400-6,800 tons of PM over the lifetime of those vehicles and engines. This is estimated to prevent 350 to 1,600 premature mortalities (and achieve $1.5 to 11.0 billion in monetized PM$_{2.5}$-related benefits).

Several commenters argued that EPA is precluded from adopting any controls on installation of high polluting engines in glider vehicles until MY 2021. This could mean the production of 30,000 to 40,000 additional glider vehicles using the older high polluting engines. Using the same assumptions as above, these three additional model years of production are estimated to result in an additional 2,100 to 6,400 premature mortalities, incremental to the premature mortalities.

As described above, this sensitivity analysis uses estimates of the benefits from reducing the incidence of PM$_{2.5}$-related health impacts. These estimates, which are expressed per ton of PM$_{2.5}$-related emissions eliminated by adopting glider vehicle controls, represent the total monetized value of quantified human health benefits (including reduction in both premature mortality and premature morbidity) from reducing each ton of directly emitted PM$_{2.5}$, or its precursors (e.g., NO$_X$), from on-road mobile sources. Ideally, the human health benefits would be estimated based on changes in ambient PM$_{2.5}$ as determined by full-scale air quality modeling. However, the length of time needed to prepare the necessary emissions inventories, in addition to the processing time associated with the modeling itself, has precluded us from performing air quality modeling for this analysis.
The benefit per-ton technique has been used in previous analyses, including EPA’s 2017-2025 Light-Duty Vehicle Greenhouse Gas Rule, the Reciprocating Internal Combustion Engine rules, and the Residential Wood Heaters NSPS. The table below shows the quantified PM$_{2.5}$-related benefits captured in the per-ton estimates, as well as unquantified PM$_{2.5}$ effects the per-ton estimates are unable to capture.

This sensitivity analysis uses per ton benefits estimates taken from the "Technical Support Document Estimating the Benefit per Ton of Reducing PM2.5 Precursors from 17 Sectors," U.S. Environmental Protection Agency, Office of Air and Radiation, Office of Air Quality Planning and Standards, Research Triangle. The procedure for calculating benefit per ton coefficients follows three steps, shown graphically in Figure A-4 below:

---

1. Use source apportionment photochemical modeling to predict ambient concentrations of primary PM$_{2.5}$, nitrate and sulfate attributable to each of 17 emission sectors across the Continental U.S., including on-road mobile sources. The on-road mobile source sector contribution to PM$_{2.5}$ concentrations was estimated using the peer-reviewed model CAMx version 5.30, which includes numerous science modules that simulate the emission, production, decay, deposition and transport of organic and inorganic gas-phase and particle-phase pollutants in the atmosphere (Baker and Scheff, 2007; ENVIRON, 2010; Nobel et al., 2001; Russell, 2008). Particulate matter source apportionment technology (PSAT) implemented in CAMx estimated the contribution from on-road mobile sources to primarily emitted PM$_{2.5}$ and to secondarily formed PM$_{2.5}$ (e.g., nitrate) using reactive tracers to capture nonlinear formation and removal processes (Baker and Foley, 2011; ENVIRON, 2010; Wagstrom et al., 2008). Mobile source contributions were estimated in CAMx for domains covering the eastern and western United States with 12 km square sized grid cells. The emissions data used in the air quality modeling were based on EPA’s 2005 v4 platform.

2. For each sector, estimate the health impacts, and the economic value of these impacts, associated with the attributable ambient concentrations of primary PM$_{2.5}$, sulfate and nitrate PM$_{2.5}$ using the environmental Benefits Mapping and Analysis Program (BenMAP v4.0.66). BenMAP is a peer-reviewed Geographic Information System (GIS)-based tool that takes air quality input data (i.e., the CAMx data described in step 1), overlays that with population to estimate exposure, and uses that information to estimate changes in health effects using “health impact functions” derived from the published epidemiology literature.

3. For each sector, divide the PM$_{2.5}$-related health impacts attributable to each type of PM$_{2.5}$, and the monetary value of these impacts, by the level of associated precursor emissions. That is, primary PM$_{2.5}$ benefits are divided by direct PM$_{2.5}$ emissions, and nitrate benefits are divided by NO$_X$ emissions.

269 https://www.epa.gov/benmap.
270 In this stage we estimate the PM$_{2.5}$-related impacts associated with changes in directly emitted PM$_{2.5}$ and nitrate separately, so that we may ultimately calculate the benefit per ton reduced of the corresponding PM$_{2.5}$ precursor, or directly emitted PM$_{2.5}$, in step 3. When estimating these impacts we apply effect coefficients that relate changes in total PM$_{2.5}$ mass to the risk of adverse health outcomes; we do not apply effect coefficients that are differentiated by PM$_{2.5}$ specie.
The process described above yields per-ton estimates that relate emission changes to health impacts and monetized benefits. We recommend readers refer to pp. 142-144 of Fann et al. (2012) for a detailed description of the benefit-per-ton methodology.

In this sensitivity analysis, using benefit-per-ton values, EPA only estimates the economic value of the human health benefits associated with the resulting reductions in PM$_{2.5}$ exposure. For example, we do not estimate the change in health risk associated with reductions in diesel PM based on current limitations in methods and available data. Thus, the per-ton estimates do not reflect cancers attributable to exposure to diesel PM exhaust, a likely human carcinogen. See Preamble Section VIII.A.6. However, we capture other benefits related to reductions in diesel PM (chiefly, benefits related to cardiovascular health endpoints) to the extent that diesel PM is included in measured PM$_{2.5}$. Furthermore, due to analytical limitations with the benefit per ton method, this analysis does not estimate reductions in premature mortality and other benefits resulting from reductions in population exposure to other criteria pollutants such as ozone. The air quality modeling that underlies the PM-related benefit per ton values also produced estimates of ozone levels attributable to each sector. However, the complex non-linear chemistry governing ozone formation prevented EPA from developing a complementary array of ozone benefit per ton values. This limitation notwithstanding, we anticipate that the ozone-related benefits associated with reducing emissions of NOx and VOC emitted by glider vehicles using high polluting engines are substantial. Refer to RIA Appendix 8.A for the ozone benefits results from the supplemental CY benefits analysis. Finally, the benefits per-ton method does not monetize all of the potential health and welfare effects associated with reduced concentrations of PM$_{2.5}$.

15 Other Comments

15.1 General Other Comments

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Modification of the minimum and maximum allowable test vehicle accumulated mileage for BEVs and plug-in hybrid electric vehicles (PHEV)

CARB staff agrees that it would be appropriate to increase the maximum allowable test vehicle accumulated mileage for BEVs and PHEVs. Note that this proposed modification does not appear to be included in the NPRM or redlined regulatory language, only in the RIA. [EPA-HQ-OAR-2014-0827-1265-A1 p.96]

Response:

The agencies appreciate the response to our request for comment on increasing the maximum allowable test vehicle accumulated mileage for EVs and PHEVs. We do not plan to increase the mileage at this time, as it is not clear what the mileage level should increase to as we were given no supporting data or suggestions from commenters.

Organization: National Zephyr Research, NZR Conversions and Equipment Sales, Inc.

We respectfully offer our contribution to the above EPA initiative and are pleased to introduce EPA, NHTSA to a new iteration for Semi-trailers which may assist with emission standards. The NEW ‘ACCORD-Semi-trailer’ with '5th Wheel Compound Hitch' tractor package. This universal design will advance the existing 53’ or long configuration with improved aerodynamic characteristics and includes the following model designations for your consideration. [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

- Silver-Diamond 53’ ACCORD Semi-trailer (Conversions) [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

These 'Accordion' or 'Stinger' Semi-trailers have one thing in common; they are rigidly coupled to the tractor and do not articulate at the tractor 5th wheel. A patented 5th wheel compound hitch system is designed to restrict 5th wheel rotation and force the trailer to articulate at the stinger position approx. 20' behind the kingpin. A patented design the ACCORD semi-trailer when used in conjunction with the patented d-TRAIN 5th wheel compound hitch tractor package offers a new and advance on existing semi-trailers with many advantages that may be of interest to EPA some of which are as follows: [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

- Tractor will not articulate and will never be involved is a full jackknife [EPA-HQ-OAR-2014-0827-0947-A1 p.1]
Zero 'GAP' from BOC to the trailer (approx. 6') aerodynamics saving fuel [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

Length of Semi-trailer is increased min. 18% to increase productivity [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

Forward lengths dimensions are reduced [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

Maneuverability is improved by 50% [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

Most existing Semi-trailers and tractor may be converted [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

Tractors remain universal even when converted to d-TRAiN hitch system [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

We are suggesting that these trailers be tested and evaluated and are confident the results will prove significant. And new design option for OEMs willing to become a licensed. This technology is offered to OEM and Service Shops across the nation. [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

However, this project needs funding to build concept OEM or conversion trailers. With EPA, DOE and NHTSA assistance we would willingly co-operate with licensees throughout the US to confirm these findings. Incidentally, There is ample proof of concept provided by Auto-hauler transporters presently operating on US and Canadian roads and which have been successfully shipping cars and trucks throughout the US and Canada for at least thirty years. To view animation of this concept and view drawings Goto: www.nationalzephyrresearch.wordpress.com [EPA-HQ-OAR-2014-0827-0947-A1 p.1]

Response:

Thank you for the information provided on these technology packages. We appreciate your innovation; however, the agencies are not funding the development of technologies in the Phase 2 program.

Organization: Daimler Trucks North America LLC

Paperwork Reduction Act - The agencies request comments on the collection of information for the Phase 2 regulations, including the accuracy of the agencies' burden estimates and any suggested methods for minimizing respondent burden. 80 FR 40541. We understand that the agencies need to collect information under the Phase 2 regulations for certification and end of year reporting purposes. But we think that, rather than simply tally the amount of burden imposed on manufacturers, the agencies could work with manufacturers to reduce some of the burden. In particular, the agencies require dozens of redundant applications for certification; this redundancy could be eliminated. The agencies require unnecessary estimates of ten vehicles' GEM scores per regulatory sub-category as a means of characterizing the Certificates of Conformity as test-based; the agencies could use the last year's or previous year's end-of-year report (which contains much more detailed and accurate information) as meeting that requirement, thus eliminating some burden on manufacturers. The agencies require extensive paperwork for off-cycle technology certifications, as we learned in Phase 1 when we had to submit documents for upwards of a year for a technology that has proven extremely fuel-saving on the road and on our Super Truck vehicle; this burden could be reduced. In short, we would like to work with the EPA and NHTSA to get the agencies what they need while minimizing burden on us--as there is a long way to go. [EPA-HQ-OAR-2014-0827-1164-A1 p. 132-133]

Response:
The agencies have had extensive outreach with the manufacturers to understand their concerns and will continue to work to minimize burden while maintaining a robust compliance program. The agencies have also tailored aspects of the program to facilitate easier compliance demonstrations (e.g., use of GEM equation for trailer compliance; design standards for non-box and non-aero trailers; modification of proposed provisions related to delegated assembly). Concerns about the burden associated with specific aspects of the compliance program are addressed in earlier sections of this RTC.

Organization: Driversgripe.com

Hello, I currently run www.driversgripe.com and I understand that you are mandating trucking monitor devices in 2017 of January and want you to know this is an invasion of our privacy under the constitution and would like to say there is no proven facts of these devices working. Look at FedEx and other trucks that have the device and have a high rate of accidents. There is nothing wrong with these devices being installed if a driver has multiple violations and allowed to remove them once there is no further violations but to force one to do so is not right according to the constitution and to all the good truck drivers that have no violations or have minor fractions. Remember one thing without trucks you would not have your car, house, supply’s to build highways, etc. It is not fair to publish all truck drivers to an negligence of a few.

Response:

This rulemaking does not mandate the use of specific technologies (with the exception of design standards for certain limited types of trailers). Rather, the standards are performance based and allow manufacturers to choose the technology mix that most fits their customers’ needs. With respect to “trucking monitoring devices” in particular, the agencies have included no such requirement in this rulemaking.

15.2 Comments on International Harmonization

Organization: Daimler Trucks North America LLC

14. Alignment with Canada

Alignment with Canada - We applaud the agencies on working with the Environment Canada for a unified program. 80 FR 40150. The continuation of this strategy will continue the shared set of procedures and common model for demonstrating compliance and shared target for any vehicle category. Our concern from GHG Phase 1 still resonates in the fact that there is a different sales mix in the different countries, and with compliance based upon a manufacturer’s sales mix, common numerical CO2 or fuel consumption targets would result in different levels of stringency in the two countries. As stated in Phase 1, the US agencies should work with Environment Canada to define achievable target penetrations of the various technologies that are appropriate for Canada and calculate the numerical targets based on these penetration rates. [EPA-HQ-OAR-2014-0827-1164-A1 p.133] As noted in the April 2015 white paper from the International Council on Clean Transportation, “Heavy-Duty Vehicle Fuel Efficiency Simulation: A Comparison of U.S. and EU Tools,” a key area for harmonization is the alignment of test procedures to quantify a technology’s performance or efficiency benefit. For example, it would be ideal to conduct a single axle-efficiency test to create an input map for both the U.S. and EU regulatory models. [EPA-HQ-OAR-2014-0827-1254-A1 p.2]

Organization: Meritor, Inc.
Maintain Broad Regulatory Framework - Nationally and Internationally

Meritor supports the proposed nationwide regulatory framework as demonstrated in Phase 1 and proposed for Phase 2. We encourage the agencies to resolve any open issues with state regulatory bodies to ensure a unified, national regulation. As a global company, we also encourage the agencies to take a leadership role and collaborate internationally so that the final regulation may harmonize with global actions that are proposed or already completed. Addressing the global issue of reducing greenhouse gas on a state-by-state or a country-by-country level will contribute to proliferation which increases cost and requires that limited resources be dedicated to compliance rather than the pursuit of technologies that will further drive greenhouse gas reduction. Although we recognize the feasibility limitations of global regulatory standards, we encourage the agencies to continue efforts to commonize global regulation where possible. [EPA-HQ-OAR-2014-0827-1254-A1 p.2]

Organization: Motor & Equipment Manufacturers Association (MEMA)

Harmonization should be the driving goal of regulations like this – whether it is between the federal and state entities or between the U.S. and European Union – particularly for greenhouse gas (CO2) emissions, which are a global. While global harmonization is outside the scope of this particular proposed rule, MEMA reminds the agencies about the significant consequences resulting from multiple compliance regimes, testing protocols, conflicting and overlapping or competing regulations. For example, it is desirable that emerging European regulations be compatible with the testing procedures outlined in the proposal. Given that the developing state of EU regulatory processes may benefit from regulatory models and structure being promoted by the EPA and NHTSA, we urge the agencies to continue outreach to their EU counterparts about the U.S. procedures development and, to the extent possible, for the U.S. procedures to be mirrored in the European context. This would be especially important in areas like engine fuel maps, transmission representation and axle efficiencies. [EPA-HQ-OAR-2014-0827-1274-A1 p.3]

Organization: International Council on Clean Transportation (ICCT)

International context

Finally, this rulemaking is key in establishing the U.S. as a global leader on freight truck efficiency. The governments of Canada, China, Europe, India, Japan, Mexico, and others are also considering their next policy actions to similarly ensure greater efficiency technology deployment for heavy-duty vehicles (Sharpe, 2015b; Kodjak, 2015). Assessment of technology potential across markets, as well as alignment opportunities for regulatory testing, modeling, and compliance and protocols are all important areas for international collaboration (see, e.g., Langer and Khan, 2013). We recommend that the agencies make a commitment within the rulemaking to collaborate with their counterparts around the world to ensure that the experiences are shared and leveraged, and the potential climate and energy benefits increased, from their respective heavy-duty vehicle rulemakings. [EPA-HQ-OAR-2014-0827-1180-A4 p.18]

Response:

The agencies believe that the Phase 1 program, this Phase 2 rulemaking, and the many other actions called for in the President’s 2013 Climate Action Plan are critical for supporting United States leadership to encourage other countries to also achieve meaningful GHG reductions and fuel conservation. In the development of the Phase 2 program, EPA and NHTSA staff also met with regulatory counterparts from several other nations who either have already or are considering establishing fuel consumption or GHG
requirements, including outreach with representatives from the governments of Canada, the European Commission, Japan, and China.

As noted in the Preamble (Section I), on March 13, 2013, Environment and Climate Change Canada (ECCC), which is EPA’s Canadian counterpart, published its own regulations to control GHG emissions from heavy-duty vehicles and engines, beginning with MY 2014. These regulations are closely aligned with EPA’s Phase 1 program to achieve a common set of North American standards. ECCC has expressed its intention to amend these regulations to further limit emissions of greenhouse gases from new on-road heavy-duty vehicles and their engines for post-2018 MYs. As with the development of the current regulations, ECCC is committed to continuing to work closely with EPA to maintain a common Canada–United States approach to regulating GHG emissions for post-2018 MY vehicles and engines. This approach will build on the long history of regulatory alignment between the two countries on vehicle emissions pursuant to the Canada–United States Air Quality Agreement.1 In furtherance of this coordination, EPA participated in a workshop hosted by ECCC on March 3, 2016 to discuss Canada’s Phase 2 program.2 The Government of Canada, including ECCC and Transport Canada, has also been of great assistance during the development of this Phase 2 rule. In particular, the Government of Canada supported aerodynamic testing, and conducted chassis dynamometer emissions testing.

In a joint statement from the U.S. and Canada on March 10, 2016,3 both nations committed to “work together and with other countries to encourage robust leader-level G-20 commitments to improve the environmental performance of heavy-duty vehicles, including through the implementation of stringent domestic regulations on fuel efficiency and/or greenhouse gas emissions, air pollutant emissions and low-sulfur fuels and green freight programs.”

15.3 NAS Recommendations 1973

Organization: American Iron and Steel Institute

In this regard, it should also be noted that the National Academy of Sciences Committee recommended that EPA and NHTSA develop a separate standard for natural gas vehicles and that the agencies assemble a best estimate of ‘well-to-tank GHG emissions to be used for developing future rulemakings.’ The Preamble indicates that the agencies are not developing such a standard primarily because the low market share of such vehicles means that imposing standards will have little impact on the overall GHG reductions from the program. The agencies take a similar position with respect to assessing the life cycle impact of electric vehicles.41 While the agencies also cited uncertainty in methane estimates and leakage, they did not consider this uncertainty to be of such a degree as to prevent them from moving forward.42

Since materials affect the construction of all vehicles, EPA and NHTSA cannot use the same rationale for its ‘wait and see’ approach to natural gas and electric vehicles. Utilizing a life cycle analysis of materials in this rulemaking would not suffer from most of the constraints that the agencies have identified for natural gas or zero-emission vehicles. Changes to materials would much more likely be made across
many different vehicles at the same time versus through the sale of individual alternatively fueled vehicles. [EPA-HQ-OAR-2014-0827-1275-A1 p.14]

41 EPA also is proposing to maintain a zero emissions rate for electrically charged vehicles, even though upstream emissions will vary depending on electricity source. Id. at 40,331, 40,389. Again, however, a main part of the rationale for not imposing lifecycle standards in this rulemaking is not methodological but rather based on the agencies assessment of the very small market and emissions impact of these vehicles.

42 Instead, the agencies expressed a desire to take a holistic approach for incorporating well-to-tank emissions into future rulemakings. 80 Fed. Reg. at 40,516.

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Tire testing and the need for a reference machine for calibration of truck tire characterization equipment**

The NPRM proposes to carry over tire testing provisions adopted in International Organization for Standardization (ISO) 28580 for the Phase 1 program into Phase 2. CARB staff supports this proposal. [EPA-HQ-OAR-2014-0827-1265-A1 p.134]

The NPRM also requests comment on the need to develop a reference machine for calibration of truck tire characterization equipment, and on whether tire test facilities are interested in and willing to commit to developing a reference machine. CARB staff supports this effort to consider the need for a reference machine to ensure accurate correlations of coefficient of rolling resistance (Crr) measurements within the tire industry. CARB staff believes this effort is critical to ensuring reliable comparisons between tire models and manufacturers, and is pertinent to providing rolling resistance data to assist consumers in purchasing replacement tires with Crr levels equivalent to original equipment manufacturer (OEM) tires. [EPA-HQ-OAR-2014-0827-1265-A1 p.134-135]

One of the findings in the National Academy of Sciences (NAS) Committee on Technologies and Approaches for Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles, Phase Two, interim report was that tire Crr measurements need to be precise, given the relatively modest fuel savings achieved with LRR tires. Further, while the ISO 28580 test procedure has received high grades from the tire industry, there is not yet a robust cross-correlation for machines used in commercial tire testing. Based on this finding, the NAS Committee recommended that NHTSA, supported by U.S. EPA, implement a mechanism for obtaining accurate tire rolling resistance data, including establishing a tire alignment laboratory and mandating the use of that laboratory.49 [EPA-HQ-OAR-2014-0827-1265-A1 p.135]

Based on public comment during Phase 1 development and to address the NAS Committee’s specific recommendation to establish a tire alignment laboratory, U.S. EPA and NHTSA evaluated test data from U.S. EPA’s Phase 1 tire test program conducted at two independent tire test labs, Standards Testing Lab (STL) and Smithers-Rapra (Smithers), and concluded that any lab-to-lab variation between STL and Smithers has little effect on measured rolling resistance values.50 As such, U.S. EPA and NHTSA consider STL or Smithers as acceptable for use as the reference test laboratory in correlating results of tire testing performed by vehicle manufacturers intended for use as GEM inputs. The Phase 2 proposal,
however, does not go so far as to require vehicle manufacturers to use a reference laboratory, and instead carries over the provisions from Phase 1 that allow vehicle manufacturers to also perform their own testing or obtain test results from the tire manufacturer or another third party. [EPA-HQ-OAR-2014-0827-1265-A1 p.135]

Given the proposal’s lack of a provision mandating the use of a reference laboratory, CARB staff believes it is important that NHTSA and U.S. EPA work with the tire test industry in developing a reference machine. [EPA-HQ-OAR-2014-0827-1265-A1 p.135]

Oppose/Requested Change Comment

Comment – Develop rolling resistance performance standard for replacement tires

The Phase 2 proposal continues the Phase 1 requirement for GEM inputs for steer tire and drive tire rolling resistance. As with the Phase 1 program, the Phase 2 proposal contains no mechanism to ensure that rolling resistance of replacement tires is the same as the OEM tires simulated during GEM vehicle certification, even though vehicle tires will likely be replaced at the discretion of the vehicle owner at multiple points over the actual lifetime mileage of the vehicle. For example, U.S. EPA and NHTSA estimate a tire replacement interval of about 200,000 miles for tractors (page 7-36 of the RIA). For a class 8 tractor, the regulatory useful life in regards to GHG emissions is 10 years/435,000 miles (page 40215 of the NPRM) but this mileage value is considerably less than the actual lifetime mileage for a class 8 truck. Without a mechanism to ensure replacement tires have Crr values equivalent to OEM tires, there is no assurance a vehicle will maintain its allowable GHG vehicle emission levels demonstrated through GEM. [EPA-HQ-OAR-2014-0827-1265-A1 p.136]

As such, CARB staff strongly supports the NAS Committee recommendation51 for NHTSA, in coordination with U.S. EPA, to quantify the rolling resistance of new tires, especially those sold as replacements, and to adopt a regulation establishing a LRR performance standard for all new tires designed for tractors and trailers (if additional cost-effective fuel savings can be achieved), and encourages NHTSA to act as expeditiously as possible. [EPA-HQ-OAR-2014-0827-1265-A1 p.136]

Oppose/Requested Change Comment

Comment – Publication of tire Crr levels and development of tire Crr database

The NPRM states that U.S. EPA and NHTSA are considering publishing Crr levels from GHG and fuel efficiency program compliance data (which is submitted by vehicle manufacturers, not by tire manufacturers), although the data could vary for a given tire model among vehicle manufacturer submissions or lag when tires are redesigned. CARB staff supports this as a first step in providing buyers information on Crr levels for the universe of tires utilized under the Phase 2 program in order to facilitate tire replacements with equivalent Crr levels. [EPA-HQ-OAR-2014-0827-1265-A1 p.137]

Nonetheless, U.S. EPA and NHTSA cite the data limitations described above as the rationale for not proposing to establish a public database containing heavy-duty vehicle tire LRR information at this time. While CARB staff acknowledges this concern, the NAS Committee recommends,52 and CARB staff strongly encourages, that U.S. EPA and NHTSA develop a mechanism to maintain accurate information on LRR levels in a public database (or other web-based medium). Commercial tires are not sidewall labeled with Crr values, or another standardized metric, to assist truck owners in purchasing replacement tires with Crr values equivalent to the OEM tires, or to assist vehicle builders with tire selection based on their fuel savings benefits. The NPRM itself acknowledges the inability of vehicle buyers to obtain
reliable information on the fuel savings, reliability, and maintenance costs of technologies that improve
fuel efficiency (page 40436 of the NPRM). For the near-term, CARB staff believes that a public database
is necessary to provide truck owners and vehicle builders with access to accurate information on tire LRR
and fuel savings benefits associated with Crr values. [EPA-HQ-OAR-2014-0827-1265-A1 p.137]

For the longer-term, CARB staff recommends that NHTSA coordinate with the tire industry to develop
standardized sidewall labeling parameters that include Crr values, or other standardized accepted metrics
for determining Crr values, and undertake a rulemaking to require such sidewall labeling. [EPA-HQ-

Gas Emissions of Medium- and Heavy-Duty Vehicles, Phase 2, First Report,” Washington, D.C. National

50 Summary of test results is described in U.S. EPA Heavy-Duty Tire Evaluation Memorandum by L.
Joseph Bachman, July 18, 2011.

Gas Emissions of Medium- and Heavy-Duty Vehicles, Phase 2, First Report,” Washington, D.C. National

Gas Emissions of Medium- and Heavy-Duty Vehicles, Phase 2, First Report,” Washington, D.C. National

Organization: National Automobile Dealers Association (NADA)

SECTION 102 OF EISA

NADA/ATD actively supported the 2007 enactment of Section 102 of EISA, which detailed a
Congressionally-mandated national program for the first-time-ever regulation of commercial vehicle fuel
efficiency. As required by EISA, the National Academy of Sciences (NAS) completed its first study on
this topic in March 2010. The following year, a joint NHTSA/EPA Phase 1 rule was published, some 5
months before the statute’s 24 month deadline. The Phase 1 rule required manufacturers to begin
compliance with EPA’s GHG mandates effective with model year (MY) 2014, but made NHTSA’s
mandates “voluntary” until MY 2016. The Phase 1 mandates take full effect with MY 2018. [EPA-HQ-
OAR-2014-0827-1309-A1 p.2]

NADA/ATD is fully supportive of continuous improvements in commercial truck FE/GHG performance.

Consistent with that support is the fact that no variable cost is more critical to truck dealership customers
than fuel, leading the overwhelming majority of customers to focus on fuel efficiency performance when
ordering new commercial vehicles. NADA/ATD questions the need for a Phase 2 rule, except perhaps as
a backstop to the mandates set out in the Phase 1 rule. [EPA-HQ-OAR-2014-0827-1309-A1 p.2-3] [[This
comment can also be found in EPA-HQ-OAR-2014-0827-1372, p.70.]]

NADA/ATD believes that improvements in commercial truck, tractor and trailer FE/GHG should be
However, in February of 2014, the President called upon NHTSA and EPA to move forward with a Phase II rule. In April 2014, the NAS issued a second (interim) report outlining several recommendations addressing technical and policy matters to be considered in the context of a Phase 2 FE/GHG rule for commercial vehicles. The Phase 2 proposal appears to reflect the consideration of many of those recommendations. What is less clear is the degree to which the Phase 2 proposal fully takes into account the key constraints identified by the NAS and the statutory mandate that any FE/GHG rules be “appropriate, cost-effective and technologically feasible.” These critical constraints inherently reflect the reality that federal FE/GHG mandates only apply to the manufacture of new motor vehicles and engines and not to their purchase. Consequently, unless FE/GHG rules are “appropriate, cost-effective and technologically feasible,” prospective customers will avoid purchasing the new vehicles and engines they govern, electing instead to hold onto the used vehicles they own or lease, or turn to the used vehicle market. Either way, commercial truck dealerships lose potential new vehicle sales, with no benefit to the environment or to energy security. [EPA-HQ-OAR-2014-0827-1309-A1 p.3]

With its passage of EISA, Congress amended the Energy Policy and Conservation Act, which contains a clear-cut prohibition against the adoption or enforcement of state laws related to fuel economy. Avoiding a patchwork of state laws in this area is critical to the for-hire carriers, private companies, public fleets, and individuals who operate trucks and tractors in every state in the nation. The final Phase 2 rule must acknowledge the critical importance of avoiding duplicative and non-identical state rules that could impose untenable burdens on dealerships, on new truck and engine manufacturers, and on prospective purchasers. Above all, the Phase 2 rule should constitute a single federal commercial vehicle FE/GHG program. [EPA-HQ-OAR-2014-0827-1309-A1 p.3]

3 EISA requires that:

1. The National Academy of Sciences (NAS) conduct and publish a study of potential commercial vehicle fuel efficiency improvement strategies, and

2. NHTSA, in consultation with the Secretary of Energy (DOE) and EPA, examine the fuel efficiency of commercial medium- and heavy-duty on-highway vehicles and work trucks and determine:

(A) the appropriate test procedures and methodologies for measuring the fuel efficiency of such vehicles;

(B) the appropriate metric for measuring and expressing fuel efficiency performance, taking into consideration, among other things, the work performed by such vehicles and the types of operations in which they are used;

(C) the range of factors, including, without limitation, design, functionality, use, duty cycle, infrastructure, and total overall energy consumption and operating costs that affect the fuel efficiency of such vehicles; and

(D) such other factors and conditions that could have an impact on a program to improve the fuel efficiency of such vehicles.

3. Not later than 24 months after completion of the NAS study, NHTSA consult with DOE and EPA and determine by rulemaking how to implement a commercial medium- and heavy-duty on-highway vehicle and work truck fuel efficiency improvement program designed to achieve the maximum feasible improvement, and adopt and implement appropriate test methods, measurement metrics, fuel economy
standards, and compliance and enforcement protocols appropriate, cost-effective, and technologically feasible for such vehicles, prescribing as appropriate separate standards for different classes of vehicles. Such rules were to provide for not less than 4 full model years of regulatory lead-time and 3 full model years of regulatory stability.

49 USC '32902(k).

4 Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicle, (NAS, 2010).

6 Neither EISA nor the CAA mandates a Phase 2 rule (or any commercial truck GHG/FE program beyond Phase 1).

8 The NAS recognized the following constraints on commercial truck fuel efficiency and GHG reduction improvements: (a) holding life-cycle cost of technology change or technology addition to an acceptable level; (b) holding capital cost of acquiring required new technology to an acceptable level; (c) acknowledging the importance of employing a balance of energy resources that offers national security; (d) avoiding near-term, precipitous regulatory changes that are disruptive to commercial planning; (e) ensuring that the vehicles offered for sale remain suited to their intended purposes and meet user requirements; (f) ensuring that the process used to demonstrate compliance is accurate, efficient, and not excessively burdensome; and (g) not eroding control of criteria pollutants or unregulated species that may have health effects. Report at p. ix.

9 49 USC '32919.

Organization: National Waste & Recycle Association

The trucks used by our industry are in the “vocational vehicle” category in both the Phase 1 rule and the Phase 2 proposal. As they did with the Phase 1 proposal, EPA and NHTSA continue to ignore the advice of the National Academies of Science (NAS). In its study, “Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-duty Vehicles” (2010), NAS highlighted the wide differences between different types of vocational vehicles. In the press release accompanying the release of the study, NAS pointed out that “NHTSA will need to establish standards tied to the task associated with a particular type of vehicle; garbage trucks might be held to a different standard than transit buses, for example.” The failure of the agencies to heed that advice and to instead lump all vocational vehicles together with only minimal differences in regulatory approach, results in a proposal that fails to recognize their differences and that will accomplish far less than an approach tailored to each different kind of vocational vehicle. [NHTSA-2014-0132-0071-A1 p.6][This comment can also be found in section 6.1 of this comment summary]

Response:

The NAS HD Phase 2 First Report contains more than 40 recommendations to the agencies. The agencies have carefully considered all of the Committee’s recommendations, and incorporated many of them in the Phase 2 standards. In some instances, the agencies have chosen a different course (with explanation) from the one charted by the NAS Committee’s recommendations. See Section XII of the NPRM for a detailed
discussion of these recommendations and the agencies’ response to those recommendations (80 FR 40512).

**Life Cycle Emissions for Natural Gas Vehicles**

While AISI cited the NAS recommendation to estimate life cycle emissions from natural gas vehicles, AISI did not comment as to whether or not the agencies should follow that recommendation. Rather, its comments addressed life cycle emissions for material substitution. These were addressed in RTC Section 1.8 and also in section I.F of the Preamble to the final rule.

**Reference Test Lab for Tire Rolling Resistance**

CARB supported the NAS recommendation to establish a reference laboratory for tire rolling resistance. We largely share this goal, and expect to continue working toward it with industry and other interested stakeholders.

CARB also commented that Phase 2 “contains no mechanism to ensure that rolling resistance of replacement tires is the same as the OEM tires” and should adopt a performance standards for replacement tires. However, we did not propose such standards and consider them to be outside the scope of this current rulemaking. Additionally, we believe CARB overstates this concern. The regulations do include a regulatory prohibition against disabling emission controls including tire-related improvements.

Similarly CARB commented in support of standardized sidewall labeling for rolling resistance. However, that is also outside the scope of this rulemaking.

**Vocational Vehicle Segmentation**

NWRA commented that the agencies should have more closely followed the NAS recommendations related to vocational vehicle segmentation. They argued that the proposal “fails to recognize their differences and that will accomplish far less than an approach tailored to each different kind of vocational vehicle.” However, this position ignores the burden it would place on manufacturers to separately track vehicles by final application. The approach being finalized balances these competing interests by allowing manufacturers to select from a limited range of duty-cycles. This will allow vehicles to be evaluated similarly (although not identical) to how they are likely to be used.

### 15.4 Small Business Impacts 1979

**Organization:** American Reliance Industries, Co. (ARI)

**ARI’s Procedures under Phase 1**

ARI has worked directly with EPA’s designated compliance officer to ensure compliance with the procedural requirements relevant to ARI under Phase 1. ARI qualified for the small business exemption under 40 C.F.R. § 1037.150(c). ARI notified the designated compliance officer each model year prior to introducing any heavy duty vehicles for that model year into commerce that included cab sleeper modifications made by ARI. ARI places a permanent label on each heavy duty vehicle improved by ARI that states: “THIS VEHICLE IS EXCLUDED UNDER 40 CFR § 1037.150(c).” [EPA-HQ-OAR-2014-0827-1300-A1 p.2]
When qualifying for the small business exemption, ARI had to ensure that it qualified as a small business under 13 C.F.R. § 121.201. ARI operates in a unique niche market that is not properly reflected in NAICS Code system. There is not a NAICS Code that directly identifies ARI’s line of business. ARI has been using NAICS Code 336120, Heavy Duty Truck Manufacturing, when qualifying for the small business exemption because this is the type of vehicle that it primarily improves. ARI has always fallen far below the threshold for qualifying as a small business under 13 C.F.R. § 121.201. ARI is also a very low volume producer in comparison to others who are more suitably designated under NAICS Code 336120, Heavy Duty Truck Manufacturing. [EPA-HQ-OAR-2014-0827-1300-A1 p.2]

Evaluation of the Phase 1 Small Business Exemption Impact by EPA and NHTSA

The following statement was made by the agencies when assessing whether to include the small business exemption in Phase 1: “The proposed exemption from the standards established under this proposal would have a negligible impact on the GHG emissions and fuel consumption reductions otherwise due to the standards.” Draft Reg. Impact Statement, EPA NHTSA (October 2010). [EPA-HQ-OAR-2014-0827-1300-A1 p.2]

Alternative Options

ARI believes that two simpler alternative methods exist for providing an exemption to small businesses that are second stage manufacturers performing cab sleeper modifications. EPA and NHTSA could select to carry over the small business exemption from Phase 1 and finalize it as a permanent flexibility. Alternatively, EPA and NHTSA could add a section comparable to the current 40 C.F.R. § 1037.150(c), but limited to small businesses that are second stage manufacturers performing cab sleeper modifications. Under either approach, ARI recognizes that EPA and NHTSA may want to have a notification requirement and a labeling requirement. ARI encourages the agencies to make any labeling requirement be added in addition to the original certification label. ARI also encourages the agencies to make any required label identify that “AFTER THE ORIGINAL CERTIFICATION OF THIS VEHICLE, A SMALL BUSINESS MADE CAB SLEEPER MODIFICATIONS WHICH ARE EXCLUDED UNDER 40 C.F.R.______.” ARI recognizes that under any approach, the term “cab sleeper modifications” may need to be defined in order to ensure that it includes the possibility of adding aerodynamic technologies as described above. ARI is interested in working with EPA and NHTSA to help develop a definition that is acceptable to the agencies and applicable to the industry. [EPA-HQ-OAR-2014-0827-1300-A1 p.5]

ARI requests that the agencies either carry over the small business exemption from Phase 1 or make a specific small business exemption for second stage manufacturers performing cab sleeper modifications. [EPA-HQ-OAR-2014-0827-1300-A1 p.7]

Response:

The agencies proposed and are finalizing provisions to include small business manufacturers in our Phase 2 program. It is not clear from the comment if ARI exclusively produces new custom sleeper tractors as a secondary manufacturer, or if they also provide glider kits or glider vehicles for customers that wish to use older engines in a new custom sleeper body. In either case, the agencies are adopting flexibilities for both glider manufacturers (40 CFR 1037.150(t) and 1037.635) and custom sleeper manufacturers (40 CFR 1037.150(r) and 1037.622).

Under our interim provision in 40 CFR 1037.150(t), glider manufacturers may produce up to 300 exempt vehicles per calendar year. Any production beyond 300 units would meet the requirements outlined in 40
CFR 1037.635, including use of an engine that meets GHG and criteria pollutant standards for the engine model year corresponding to the vehicle’s date of manufacture.

We are adopting an interim provision in 40 CFR 1037.150(r) to allow small business secondary manufacturers to convert low- and mid-roof tractors to mid or high-roof configurations without recertification for the purpose of building a custom sleeper tractor. Also noted in 40 CFR 1037.622, small business custom sleeper manufacturers may modify complete or incomplete vehicles certified as tractors, as long as they do not modify the vehicle body in front of the b-pillar or increase the effective frontal area of the certified configuration, including consideration of the frontal area of the standard trailer. For high-roof tractors, this would generally mean the added sleeper compartment may not be more than 102 inches wide or 162 inches high (measured from the ground), which are the dimensions of the appropriate standard trailer under this part.

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Small business impacts**

The NPRM requests comment on additional provisions for small businesses. In California, small businesses play an important role in the economic vitality of the state, representing 3.5 million businesses and 50 percent of the private-sector labor force. CARB staff supports additional research on the impact of the proposed rulemaking on small businesses, specifically in regards to potential impacts on employment. [EPA-HQ-OAR-2014-0827-1265-A1 p.187]

**Response:**

The agencies evaluated the potential economic impact of this rulemaking and do not believe it will have a significant economic impact on small businesses. We estimated the number of hours these rules will require from the individual sectors and the heavy-duty industry as a whole, but cannot distinguish if these additional hours would necessitate additional hiring, since it is possible that companies will assign current staff to fulfill their needs.

**Requested Clarification**

**Comment – Small Manufacturer Provisions**

Small manufacturers were exempt from Phase 1 GHG rules, but must comply with Phase 2, under a delayed schedule. The small manufacturer delays apply to engine manufacturers (page 40161 of the NPRM), trailer manufacturers (page 40285 of the NPRM), and small engine converters (page 40545 of the NPRM). Alternate fuel engines, defined as those fueled with any fuel other than gasoline, E85, or diesel, have an additional year to comply with each new standard. CARB staff supports the inclusion of small manufacturers into Phase 2 of the GHG regulations. CARB staff recommends clarification on whether this alternate fuel delay noted in 40 CFR1036.150 (d) and 86.1819 – 14 (j) (5) is in addition to the small manufacturer delay (resulting in a delay of up to 2 years for an alternative fuel engine manufactured by a small manufacturer), and whether the alternative fuel delay is available to manufacturers who are not small manufacturers. [EPA-HQ-OAR-2014-0827-1265-A1 p.191]

**Response:**
We have revised the regulation to clarify that the one-year delay applies only for small manufacturers, and that it is not a two-year delay for the initial round of Phase 2 standards.

**Organization:** CALSTART

**Regulatory Flexibility for Small Manufacturers**

Much of the innovation in idle reduction, electric drive, hybridization and even new novel engine and waste heat recovery systems is occurring among the supplier industry and small, innovative manufacturers. To encourage this innovation, it is very important to both find ways to include these innovators in the rule and to minimize the regulatory burden of involvement in the regulation. California has been grappling with this conundrum which it recognizes is creating a barrier to innovation at the time it most needs to encourage it. Indeed, the HD-OBD requirements, while understandable, did not provide any flexibility for low volume, low risk technologies to proceed – they faced the same burden as fully mature, high-volume approaches. It is certainly a key factor, among several, that stalled early hybrid technology. [EPA-HQ-OAR-2014-0827-1190-A1 p.8]

The California Air Resources Board (CARB) currently is redesigning a structure to try and better encourage the deployment of these advanced technologies under its Innovative Technology Regulation. The concurrent timing of the Phase 2 rules can provide an opportunity to work with CARB to harmonize the federal and California policy approaches around new concepts to minimize the regulatory burden on small manufacturers and provide clarity for future deployment. The California draft rule is envisioning a phased or stair-stepped, staged approach to regulatory compliance that is tied to production volume. In other words, it would possibly allow low volume, early stage technology to face a reduced regulatory and compliance burden than higher volume, mature technology. As the technology ramps up in market volume and penetration it would face increasing tiers of regulatory compliance, ending in full compliance. We can envision a productive use of this approach for advanced technologies and some off cycle technologies in Phase 2. [EPA-HQ-OAR-2014-0827-1190-A1 p.8]

Because the Phase 2 proposed regulations are forward-looking and provide significant lead-time, the rule should be designed in a way that captures all of the potential fuel consumption reduction technologies, including those of innovative secondary manufacturers. The Phase 1 standards allowed small, final stage or aftermarket technology providers to participate in the regulations only as certifying manufacturers. For many reasons, including the stringency and structure of the regulation as well as the disproportionate burden it would place on small-volume manufacturers, this has limited participation in the current regulations, meaning that the fuel consumption reductions currently achieved by end users of these systems are not reflected in the Phase 1 certified fleet. It is worth noting that the stringency levels of Phase 1 did not drive OEMs to seek such approaches or the reductions (or credits) they could provide. Phase 2 provides an opportunity to rectify this and encourage innovation across the certified vehicle fleet. [EPA-HQ-OAR-2014-0827-1190-A1 p.8]

**Response:**

The agencies provide a means to evaluate innovative technologies in our off-cycle provisions for Phase 2. See responses to comments on innovative and off-cycle technologies at Section 1.4.2. We also discuss some possible roles of secondary manufacturers in Section 1.4.4. A certificate holder should be an entity willing and able to be responsible for compliance for all aspects of the vehicle covered by the certificate. This is generally an engine or chassis manufacturer. Suppliers and other unregulated manufacturers are encouraged to work with OEMs to integrate their technologies.
Organization: Competitive Enterprise Institute et al.

The rule threatens the economic viability of small trucking firms, hundreds of which have gone out of business due to increasing regulatory costs. The proposal says not one word about the plight of small truckers or the greater relative burdens it will place on them. [EPA-HQ-OAR-2014-0827-1251-A2 p.1]

The rule threatens the economic viability of small trucking firms.

In scores of places, the rule acknowledges that regulations impose a greater relative burden on small firms than on large. Accordingly, pursuant to the Small Business Regulatory Enforcement Fairness Act (SBREFA), EPA convened a Small Business Advocacy Review (SBAR) Panel to consider “flexibility provisions . . . specific to small businesses.” However, in every instance, the entities in question are small manufacturers, not vehicle owners and operators. [EPA-HQ-OAR-2014-0827-1251-A2 p.2]

Specifically, the agencies propose regulatory flexibilities for manufacturers of box trailers, non-box trailers, non-highway trailers, alternative fuel converters, emergency vehicle chassis, custom chassis, off road vocational vehicle chassis, and gliders. Not once does the 627-page proposal mention small trucking firms. [EPA-HQ-OAR-2014-0827-1251-A2 p.2]

[Table XV-2, 'Primary Small Business Categories Potentially Affected by the Regulation', can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1251-A2]

We recognize that the rule’s requirements apply to manufacturers, not customers. Nonetheless, small business truckers are an important category of stakeholders. As a recent Wall Street Journal article observes, small operators “make up the vast majority of the roughly 470,000 for-hire fleets on the road today.” Indeed, companies “operating six or fewer trucks . . . make up 89% of all fleets.” Although large firms are increasing wages and hiring drivers, new regulations, “including rules capping emissions and limiting drivers’ hours on the road,” are making it harder for small firms to hire workers, raise wages, or even survive; [EPA-HQ-OAR-2014-0827-1251-A2 p.3]

Response:

Our official analysis of small business impacts through our Small Business Regulatory Enforcement Fairness Act (SBREFA) obligations is limited to small entities that would be regulated under the proposed rulemaking (i.e., engine and vehicle manufacturers). We did not calculate the economic impact that other related small industries, including small trucking firms, may experience and are not required to do so. Coalition for Responsible Regulation v. EPA, 684 F. 3d 102, 129 (D.C. Cir. 2012). However, unlike many other regulations promulgated by the agencies, the technologies that provide the basis for these regulations will pay for themselves with use. Payback for the initial cost of technologies for these rules are an average of four years or less. These technologies are expected to increase the up-front cost of these regulated vehicles, which we recognize can be difficult to justify for small firms or individual owner-operators, but these customers are also likely to own their vehicles longer than larger firms.
OOIDA’s example refers to owning a truck for 10 and 7 years, which would suggest that these technologies would conservatively provide three years of direct savings to the owner.

**Organization:** Autocar, LLC

Autocar submits this letter and comments to the Proposed Regulations (the “Comments”) and respectfully requests that the Company not be subject to the Proposed Regulations for two reasons: [EPA-HQ-OAR-2014-0827-1233-A1 p.2]

First, Autocar’s products are of a particular vehicle type (low-speed, frequent-stop, stationary-application trucks) that will not produce the environmental benefits intended by the proposed technologies, beyond the use of an emissions-compliant engine. [EPA-HQ-OAR-2014-0827-1233-A1 p.2]

Second, Autocar is a small business that should be exempt from Phase 2. In 2011, the agencies determined that its small size justified a deferral from compliance from the **Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 1** regulations (“Phase 1”) for Autocar. The relevant facts remain the same, and Autocar’s size, volume and product lines continue to justify an exemption or different standards for its vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.2]

1.1 Autocar is a small business that has demonstrated leadership in the alternative fuel vocational truck market. Autocar has 293 employees located in east central Indiana in Wayne County, at one plant in Hagerstown, Indiana (population 1,787), an area that historically has struggled during economic downturns. Autocar annually produces approximately 2,000 refuse truck chassis and 500 other trucks and chassis, marketed and sold under three product lines: (A) heavy heavy-duty class 8 vocational truck cab and chassis, primarily for use as refuse trucks; (B) heavy heavy-duty class 8 terminal tractors (yard hostlers); and (C) medium heavy-duty class 7 vocational truck chassis, primarily for use as street sweepers and refuse trucks. Unlike most other chassis makers, who design, stamp and fabricate many of their trucks’ components, Autocar purchases parts, modules and components from its suppliers, and assembles its cabs and chassis. Autocar does not manufacture engines nor is it affiliated with any engine manufacturer. [EPA-HQ-OAR-2014-0827-1233-A1 p.6]

1.2 Autocar exemplifies the Federal Government’s desire to safeguard competition in the specialty vehicle markets. Autocar not only supports sound GHG emissions and fuel efficiency standards policy, but is also aligned with the Federal Government’s efforts to promote competition in the specialty vehicle markets. As the longest-standing continuous truck brand in the United States, Autocar was at risk of being eliminated when its then-owner, AB Volvo, acquired another heavy-duty Class 8 low cab over engine (“LCOE”) chassis manufacturer, Mack Trucks, Inc., in 2000. The United States Department of Justice (“DOJ”) (under Presidents Clinton and Bush), concerned with the potential effects of reduced competition in the refuse market, and finding there was no reasonable substitute for a heavy LCOE chassis, ordered Volvo to divest itself of one of its LCOE lines (U.S. v. AKTIEBOLAGET VOLVO, et al., Competitive Impact Statement, February 7, 2001, and Final Judgment, entered April 30, 2001). [EPA-HQ-OAR-2014-0827-1233-A1 p.7]

As a result, Volvo sold the assets of the Autocar division to Autocar’s current owner, and Autocar built a factory, hired employees, secured suppliers and began production in Hagerstown in 2003. Autocar would not exist as an independent small business had the Federal Government not taken steps to preserve it, and Autocar’s existence has, in fact, generated the pro-competitive effects the Department of Justice sought. The agencies should not now undermine the DOJ’s efforts at promoting competition by implementing requirements that would threaten Autocar’s continued viability. [EPA-HQ-OAR-2014-0827-1233-A1 p.7]
As a Small Business, Autocar Should be Exempt from the Phase 2 Regulations.

3.1 Autocar was exempt from Phase 1 as a small business, and compliance with Phase 2 would be unsustainable. As noted above, Autocar is a small, privately owned assembler. Autocar already has a high concentration of its employees working in product development and dedicated to continuous product improvement in the areas of safe operation, cost and fuel economy. Allocation of resources is a delicate balance when the Company has only 293 workers, and Autocar cannot reasonably locate, recruit, retain and pay for additional personnel and other resources to work toward achieving the standards required under the Proposed Regulations (Appendix A addresses development work that Autocar would need to complete if it is not exempt). [EPA-HQ-OAR-2014-0827-1233-A1 p.9]

Autocar does not build or install its own engines, but works closely with powertrain makers to find ways to achieve fuel efficiencies and lower emissions on Autocar’s vehicles. The Company’s success depends on delivering these improvements year after year. [EPA-HQ-OAR-2014-0827-1233-A1 p.9-10]

The agencies recognized these facts when they exempted Autocar from the Phase 1. Autocar did not use its exemption to shirk environmental responsibility, but instead continued to drive improved emissions through increased penetration of CNG and hybrid-powered trucks in its industry segments. Through delegated assembly, all Autocar vehicles are compliant with the latest emission standards. [EPA-HQ-OAR-2014-0827-1233-A1 p.10]

Autocar assembles trucks that move through the air slowly and perform significant functions while stopped. If Autocar is required to apply the technologies suggested in the Proposed Regulations, the agencies’ desired environmental benefits would not be achieved on these mostly low-speed trucks, and Autocar resources would be diverted from work on accepted, proven-effective alternative fuel vehicles useful for Autocar’s trucks’ applications. [EPA-HQ-OAR-2014-0827-1233-A1 p.10]

3.2 Autocar’s vehicles are highly customized and are sold in a fixed-size market, making additional regulatory compliance unduly burdensome on this small business. Autocar’s customers require customized products. Because each neighborhood in America demands a differently-configured truck to collect its trash and sweep its streets, Autocar’s business model is to assemble high-quality chassis with customized specifications and components specifically suited to each truck ordered by its customers. Autocar’s customers include municipalities such as the City of Charlotte and the City of San Antonio, private and public waste haulers, airports and construction companies, and Autocar’s small size enables it to work very closely within this narrow set of vocations. [EPA-HQ-OAR-2014-0827-1233-A1 p.10]

For the last 10 years, the American annual market segment size for refuse trucks and street sweepers has consistently remained less than 6,000 units, requiring Autocar to operate leanly and efficiently. The Company minimizes research and development costs by sourcing adaptable, off-the-shelf components whenever possible. We integrate, rather than manufacture in the typical fashion. For these reasons, the burden of compliance with the Proposed Regulations poses a unique threat to Autocar’s ability to continue its business. [EPA-HQ-OAR-2014-0827-1233-A1 p.10]

3.3 Unlike a large, diverse, vertically-integrated manufacturer, a small business such as Autocar cannot reasonably absorb new regulatory development and compliance cost. Without continuing the small business deferral that EPA and NHTSA provided in Phase 1, manufacturers meeting Small Business Administration size criteria (see Note 1 above) would be forced to raise prices of their products. Small businesses cannot adequately realize the advantages of averaging and spreading costs afforded large manufacturers; without an exemption, the compliance burden would be disproportionately high. In fact, even with the compliance deferral granted in Phase 1, a number of the small businesses the agencies
exempted were sold, bankrupt or dissolved in the four years since. [EPA-HQ-OAR-2014-0827-1233-A1 p.11]

Moreover, small businesses exempted from Phase 1 have not, and cannot, reasonably marshal the resources necessary for compliance, including engineers experienced with GEM testing and personnel dedicated to maintaining records and executing the processes necessary to obtain EPA and NHTSA certification (see the chart below presented by EPA in 2012 to summarize the substantial work needed to certify). Notwithstanding the burden, Autocar would be at a distinct disadvantage in attracting and affording such talent now. Even if a small business could build such a compliance organization, it could not reasonably match such costs with benefits, because as the agencies themselves noted, “[A]veraging is not of practical value as a compliance flexibility” for manufacturers offering a narrow range of products, and such manufacturers do not have “large sales volumes over which to distribute technology development costs.” 80 Fed. Reg. at 40,294. Exempting small businesses would be consistent with the Small Business Advocacy Review Panel’s recommendations. [EPA-HQ-OAR-2014-0827-1233-A1 p.11]

[Graphic, Steps in EPA/NHTSA Certification Process, can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1233-A1]

3.4 Exempting small manufacturers would support other small businesses and preserve competition that benefits customers. In support of the agencies’ examination of the effect of their regulations on small businesses, Autocar notes that, should it be forced to comply with the Proposed Regulations, other small businesses, including the small governmental entities the agencies specifically identified as being potentially impacted (80 Fed. Reg. at 40,542-40,543), would similarly suffer negative downstream effects. [EPA-HQ-OAR-2014-0827-1233-A1 p.12]

Without the benefit of compliance flexibilities and without an exemption, Autocar and other small manufacturers—and their customers—would face potential disruption to their businesses due to production delays, lost sales, upfront cost increases and increased maintenance costs. Increased costs of ownership would negatively impact customers’ payback analysis, causing them to use existing vehicles longer, and delay the purchase of new equipment, due to higher acquisition and maintenance costs. Many of these customers are other small businesses (for example, municipalities and independent “mom-and-pop” waste management companies) that would be negatively impacted by such additional costs and market disruptions. And if Autocar was forced from the marketplace, customers would have fewer companies competing for their business, which would otherwise support lower prices and improved product features, in contravention of the DOJ’s objectives. [EPA-HQ-OAR-2014-0827-1233-A1 p.12]

Additionally, many body builders that install important vocational equipment onto Autocar’s cabs and chassis are small businesses (as the agencies specifically noted at 80 Fed. Reg. 40,286) and these firms are able to sell more of their products when they have several viable chassis makers participating in their market. [EPA-HQ-OAR-2014-0827-1233-A1 p.12]

Autocar is a small company with small volumes in niche markets. The unsustainable and disproportionate efforts that would be required for Autocar to achieve compliance with the Proposed Regulations would yield only minimal impact on the reduction of GHG emissions. If given the ability to continue to pursue other proven and accepted environmentally-friendly technologies such as CNG and hybrid drive, Autocar, and likely other small players, have a chance to generate more than a small impact on GHG emissions. [EPA-HQ-OAR-2014-0827-1233-A1 p.16-17]

Autocar requests that the final rules reflect an exemption for small business manufacturers or an exemption for low-speed and stationary or high-frequency-stop vocational vehicles. Alternatively, but
with caution, Autocar supports modified standards and simplified compliance for small custom chassis manufacturers of low-speed and stationary or high-frequency-stop vocational vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.17]

6 In its comments on the Phase 1 proposed regulations, Volvo argued that a small business exemption would incentivize big companies to divest themselves of small truck making divisions with the hope of creating exempt entities, and would discourage body builders from doing business with non-exempt entities such as Volvo. See Comments of the Volvo Group on the proposed rule, Greenhouse Gas Emission Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles, 74 FR 74152 (November 30, 2010) dated January 31, 2010. To Autocar’s knowledge, none of Volvo’s concerns materialized as a result of the Phase 1 small business deferral – market shares were not directly affected; body builders did not change their product mix or their business relationships with chassis manufacturers; large manufacturers did not restructure their business units to get around the regulations (nor could they effectively, under the SBA criteria).

Organization: Autocar, LLC

3. Autocar is Small and will be Adversely Affected by the Compliance Scheme Proposed in the EPA’s Vocational Custom Chassis Memorandum.

3.1 Autocar was Exempt from Phase 1 Compliance. When the agencies exempted Autocar from compliance with Phase 1,¹² they recognized its small size and production volume compared to its competitors.¹³ As a result, Autocar was exempt from a compliance structure that would otherwise have involved the use of full GEM and whole-vehicle certification and compliance (with LRR tires being the only required technology). What is being considered now for Phase 2 compliance would thrust Autocar into the realm not only of GEM, but of two levels of GEM. Compliance would require Autocar to rely on third parties to invent and supply technologies, some of which do not currently exist, and some which will not be effective for the industry segments in which Autocar participates. The negative impact of the regulations on Autocar will be enormous, and the positive impact on GHG emissions, through the regulation of Autocar’s 2,500 trucks per year, will be miniscule. If the agencies adopt the compliance scheme suggested in the Memorandum, Autocar will have approximately 18 months to source, integrate, market and certify new technologies, through full GEM for some of its chassis applications and Simplified GEM for its refuse chassis. To proceed as suggested by the Memorandum would force an unanticipated, costly and unnecessary compliance pathway on Autocar. [EPA-HQ-OAR-2014-0827-1885-A1 p.9]

3.2 Small Manufacturers Face Multiple Threats to Survival. Small manufacturers in the United States face daunting challenges to stay in business and are declining in number.¹⁴ In fact, many of the small businesses exempted in Phase 1 no longer operate independently, having either filed for bankruptcy or been absorbed by larger companies (see Figure 2 on the following page). While capitalizing on the benefits of being small, such as agility and staying close to customers, when compared to their giant competitors with deep resources, small businesses in the motor vehicle industries struggle more, with employee turnover, recruiting, financing, leverage with suppliers and access to new technology. The threat that these challenges post to the survival of small businesses is the reason the agencies are required...
to make accommodations for small businesses in rulemaking under the Regulatory Flexibility Act. The agencies have failed under SBREFA to provide adequate consideration to small business concerns, specifically by failing to subcategorize for custom chassis makers, especially for refuse and other specialty applications. [EPA-HQ-OAR-2014-0827-1885-A1 p.9-10]

[Figure 2 can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1885-A1]

3.3 The Small Business Advocacy Review Panel Specifically Recognized the Potential Impact on Manufacturers like Autocar and Recommended an Exemption, but the agencies are Taking a Different Approach. In its Final Report on the Proposed Regulations’ impact on small businesses, the Small Business Advocacy Review Panel (the ‘Panel’) recommended ‘proposing a low volume exemption based on the volume of sales’ for vocational custom chassis manufacturers like Autocar. Although the agencies followed the Panel’s recommendation in requesting comment on this topic in the Proposed Regulations, the next official communications from the agencies were the Memorandum, which made no mention of a small volume exemption, and the NODA, which stated that Phase 2 would build on Phase 1 by ‘including vehicles produced by small business manufacturers.’ The agencies have neglected their obligation to minimize the regulations’ impact on small businesses. And if the agencies are not inclined to use the size of a vehicle manufacturer’s business as grounds for exemption, then a more appropriate factor in determining the exemption is low volume, as recommended by the Panel. [EPA-HQ-OAR-2014-0827-1885-A1 p.10-11]

3.4 The Impact of the Regulations Will Be Disproportionate. The compliance requirements proposed in the Memorandum will impose burdens disproportionately high for a company such as Autocar that assembles small volumes of customized chassis and no other product lines, limiting both the ability to benefit from averaging, as well as the ability to spread development and compliance costs across many vehicles. Autocar’s development and compliance costs will be concentrated across its current volume of 2,500 vehicles annually, while Autocar's competitors will spread those costs across tens of thousands of vehicles. Autocar's competitors have had the opportunity to build internal GEM compliance teams, while Autocar is just now getting its first exposure to the model. And with vertical integration and massive purchasing power, the competition will gain additional advantage over their Indiana rivals, as illustrated in Figure 3. [EPA-HQ-OAR-2014-0827-1885-A1 p.11]

[Figure 3 can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1885-A1]

3.5 Some Small Businesses Received Greater Flexibilities. In the Memorandum, EPA exempted manufacturers of emergency vehicles and cement mixers from compliance with Phase 2, requiring only that they install LRR tires on their vehicles. Manufacturers of recreational vehicles also have a lesser compliance burden than other vocational vehicle types. Neither the Memorandum nor the documents included in the NODA explain why emergency vehicles, cement mixers and recreational vehicles should be exempt, but not refuse vehicles. Moreover, Autocar and other small volume manufacturers assemble custom chassis in other heavy-duty vocational applications that are not addressed in the Memorandum, such as conventional (non-cab-over-engine) refuse trucks, concrete pumbers, street sweepers, tank trucks and sewer cleaners. Without explanation, these similar applications have been excluded from the proposed Simplified compliance scheme, and presumably require full GEM certification. This bifurcated approach will further unnecessarily burden small businesses. [EPA-HQ-OAR-2014-0827-1885-A1 p.12][This comment can also be found in section 6.2 of this comment summary]

3.7 Phase 2 May Put Autocar Out of Business or Cause it to Exit Certain Product Lines. Autocar is not equipped to handle the design, implementation, procurement, sales and marketing obligations that will be necessary for compliance with Phase 2, and it cannot bear the increased cost of these obligations and still
continue to operate its business as it does today. If certain product lines are subject to full GEM, those
product lines may have to be discontinued, stressing Autocar further. The agencies must not restrain trade
by eliminating competition through regulation. Autocar already competes with some of the largest
manufacturers in the world. Regulatory actions that favor large competitors by allowing them to average,
bank and trade credits - advantages of which Autocar cannot avail itself - and favor large competitors by
distressing their small competitors, are inappropriate and unfair. As discussed in detail in Autocar's
October 1, 2015 Comments, Autocar would not exist as an independent small business had the Federal
Government not taken steps to preserve it, and Autocar's existence has, in fact, generated the pro-
competitive effects the Department of Justice sought. The agencies should not now undermine the
Department of Justice's efforts at promoting competition by implementing requirements that would

5. Conclusion

Fifteen years ago, at the request of the Department of Justice, the management and owners of Autocar
chose to hire 200 people and start a small business in Hagerstown, Indiana, in an industry where its
competitors employ hundreds of thousands of people all over the world. Frankly, we wouldn't have it any
other way. But after all the hard work put into Autocar to make it competitive, the agencies must not
inject Autocar into a regulatory scheme designed for companies that can 'average, bank and trade' and
'spread compliance cost over multiple vehicle types.' These are concepts that exclude small business by
their very nature. The agencies are required to provide flexibilities to accommodate small business, and
the only flexibility that will be effective for Phase 2, like Phase 1, is a small business or low volume
exemption. Autocar outlined the suggested parameters of these exemptions in its October 1, 2015
comments, and reiterates its request that such an exemption be included in the final Phase 2 rule. [EPA-

12 Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty

13 See Figure 3 for details.

14 Bureau of Labor Statistics, Business Employment Dynamics, Business Establishment Age and

15 5 U.S.C. 601-612, as strengthened by the Small Business Regulatory Enforcement Fairness Act of

16 Final Report of the Small Business Advocacy Review Panel on EPA's Planned Proposed Rule,
Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and
Vehicles: Phase 2, at 42 (Jan. 15, 2015).

17 81 Fed. Reg. at 10825

18 Any number of methods could be used to determine which manufacturers should be exempt per the
SBREFA Panel's recommendation. Autocar previously proposed and continues to support a 5,000-vehicle
limitation on the number of vehicles that a small chassis manufacturer may produce under an exemption
annually, consistent with the small-volume vehicle manufacturer exemption for NHTSA's TREAD
reporting.
Autocar is interested in pursuing ways to offset these development costs, such as taking advantage of any incentives or development funding that the agencies could offer, or perhaps purchasing environmental credits from outside of the medium- and heavy-duty engine and vehicle industries if the agencies would allow.

After learning of EPA’s proposed approach in the Memorandum, Autocar contacted several consulting firms as well as other vehicle manufacturers to attempt to retain a GEM consultant, to assist in understanding and potentially implementing the GEM compliance model. Most manufacturers have had in-house GEM experts since Phase 1 and could not provide GEM simulation services. One outside consultant Autocar located charges $145 per hour for Phase 1 services and has yet to work with Phase 2 GEM.

Response:

Small businesses producing heavy-duty vehicles are not subject to Phase 1 heavy-duty GHG and fuel consumption standards because of a deferral, not a permanent exemption. Before proposing regulations that would apply to small businesses in Phase 2, we conducted an official analysis of small business impacts under the Small Business Regulatory Enforcement Fairness Act (SBREFA). In response to the recommendations of the SBREFA panel as well as public comments, the agencies are adopting provisions that will reduce the compliance burden for small businesses. Primarily, we are including a one-year delay in implementation for all small businesses that will allow them additional time to become familiar with the compliance process, address staffing concerns, and evaluate technologies.

In the vocational vehicle sector, the agencies have identified nearly 40 chassis manufacturers likely to be subject to the Phase 2 standards, where nearly half of them are small businesses based on number of employees. In consideration of current market dynamics where many of these small businesses compete directly with large diversified manufacturers, as well as comments stating it would be unfair to make less stringent standards available solely on the basis of sales volume, the agencies are not finalizing a broad sales volume threshold below which a vocational chassis manufacturer would have a different set of requirements. See discussion in Section 6.4 of this RTC.

We are adopting a custom chassis program where eligibility is not limited to small entities. Manufacturers will have the option to designate the following applications as custom chassis: coach (intercity) bus, motor home, school bus, transit bus, refuse truck, cement mixer and emergency vehicle. See Section 6.2.3 for responses to other comments on the custom chassis program. Chassis so designated may be certified with a default engine map and other default parameters so that manufacturers choosing this option will have fewer technologies to evaluate, and will have unique standards for each vehicle type that reflect use of appropriate technologies. Further, the agencies are adopting a non-GEM design standard option for motor home, cement mixer, and emergency vehicle chassis, because we have determined these vehicles to have the least number of feasible technologies that can be applied in Phase 2. As discussed in Section 6.4.1, we were unable to identify other custom chassis technology packages that we believed could be applied at a 100% adoption rate; thus, averaging (and use of GEM) was deemed necessary for other vehicles. Cement mixers have been determined by the agencies to essentially need only apply low rolling resistance tires, certified engines, and low leakage air conditioning systems (i.e. the final optional standard is predicated on performance of only these technologies). Where a manufacturer of these vehicles is able to apply the same technology on all of its production without averaging, we offer the non-GEM option as a compliance flexibility to avoid the certification burden associated with running GEM.
In response to comments, we are also revising some of the low-speed and off-road vehicle exemptions that are carrying forward from Phase 1. See Section 6.4.2 for responses to these comments, including some revisions in Phase 2 that may provide a pathway for a reduced certification burden for some of commenter’s other products.

In part to address the commenter’s concern about large companies having a business advantage over small, non-diversified businesses, the agencies are adopting a more restricted approach to averaging, banking and trading (ABT) for custom chassis, allowing averaging within each subcategory, but no banking or trading for vehicles certified to the optional standards, except that small businesses may use traded credits to comply with the optional custom chassis standards. This recognizes that small businesses may have fewer opportunities than large companies to over-comply with the final standards. If a manufacturer wishes to generate tradeable credits from sales of these vehicles, one or more families may be certified to the primary vocational vehicle standards.

**Organization:** Innovus Enterprise LLC

Innovus Enterprise, LLC is a certified Service-Disabled Veteran-Owned Small Business. We have been working for over two years preparing to participate in a niche US truck market with new medium-heavy-duty diesel engines in our class 6, 7 and 8 high-mobility specialized vehicles. During this time-frame, we have made visits with the EPA diesel engine certification officials in Washington DC and in Ann Arbor, MI. We are a registered manufacturer in the Verify database and have submitted our letter of intent to certify this new engine family. We have had numerous conference calls with EPA officials concerning certification and continue to converse in order to identify potential options for our small volume/small business. Our anticipated US sales for year-1 are in a low two-digit figure and forecasted to grow at approximately 15% year-on-year. An exceptionally high volume of sales for our business would be in a low three-digit figure. [EPA-HQ-OAR-2014-0827-1116-A1 p.2]

Our business operating model is strong. However, relative to industry standards and market realities, we are without question an ultra-low volume producer. From a quantity of sales perspective, we are not organized nor have the capability to disrupt this heavy-duty market segment; and this is not our intention. Additionally, we understand and respect the tough mandate given to our government agencies with respect to mobile source pollution control and fuel efficiency. We accept the challenge to be part of the solution to help achieve our national GHG program goals. [EPA-HQ-OAR-2014-0827-1116-A1 p.2]

We have analyzed our system, emissions and performance data. From an engineer’s standpoint, we have a very high degree of confidence, using quantitative data, our products emissions and fuel performance characteristics will fall within allowable emissions tolerances and positively influence the GHG mandate albeit so small and within the realm of a small business environment. That said, we now face a tremendous hurdle; NHTSA and EPA certification. [EPA-HQ-OAR-2014-0827-1116-A1 p.2]

The current and projected costs (technical, legal, accounting and consulting) we will burden to obtain and hold NHTSA/EPA/CARB certificates for our products are enormous given our small scale business model. The cost of certification is a defining moment for our business. If we are not afforded relief with some form of certification flexibility (possibly using regulatory alternatives) we will in all probability not be able to continue our business in this industry. [EPA-HQ-OAR-2014-0827-1116-A1 p.2]

We find our options extremely limited as we seek to justify this certification burden or soundly amortize it over our low volume of vehicle sales per year. Most certainly, large diesel engine and truck manufacturers in this same industry are fortunate to spread these certification and compliance costs out over the tens of thousands of units they sell; and they most often have dedicated staff to manage the
process. From our position, it really is a disproportionate compliance burden for us. Being a small business and understanding there are provisions for such situations, we would like to suggest some potential regulatory alternatives. These alternatives will achieve the agency’s goals while minimizing the burden on small businesses who participate in this industry sector or who would like to enter it. Before we begin with our suggestions and comments, we need to first talk about some of our vehicle/engine characteristics and other defining factors that make our situation a special case. [EPA-HQ-OAR-2014-0827-1116-A1 p.2-3]

Technology, Characteristics and Operating Parameters: Our vehicles are high mobility and compact multi-role class 6, 7 and 8 platforms which are often re-configured with a variety of heavy-duty work implements depending on the season and required function. The vehicles are designed for extreme terrain operations in all seasons performing a variety of highly specialized work tasks. The vehicle’s MHDD engine is equipped with the latest emissions control technology and is not only for propulsion but to simultaneously power the various vocational attachments and implements by utilizing the unit’s various power systems (24V electrics, multi-circuit hydraulics, multi-range/multi-speed PTO’s). The vehicle’s chassis and body are engineered to quickly accommodate a variety of these remove-and-replace implements to perform various functions on a day-to-day basis depending on situation or role. [EPA-HQ-OAR-2014-0827-1116-A1 p.3]

Our vehicles have special engineering and costly components for high mobility, off-road use and cross functionality. These features add great expense to the vehicle and its flexibility but consequently render it undesirable and impractical for general transportation use. Some of the vehicle’s technological features include: [EPA-HQ-OAR-2014-0827-1116-A1 p.3]

- Portal axles with hub reduction gears/planetary reduction axles: Exceptional high ground clearance; reduced axle torque; maximum power to drive system.
- Permanent all-wheel drive/4-mode differential locks: Superior off-road traction and mobility in austere conditions.
- Multiple crawler/working gear configurations with constant speed engine control; electronic quick reverse; opt hydrostatic drive: Operation on difficult terrain; drive high-power implements; continual operation under steady engine speed settings.
- Extreme high angles of approach/departure: Off-road operations with steep incline/declines as well as obstacle avoidance.
- High break-over and tipping angles: Essential for safely navigating off-road/mountainous terrain.
- Single wheel/aggressive tread lug tires: Maximum traction as the rear wheels run in the tracks of the front wheels.
- Central Tire Pressure Control System: Cockpit selected increase/decrease depending on surface conditions (mud, sand, snow, gravel) and weight load.
- Fording ability: Safe design/protected components; up to 47 inches; for operations in flood waters. [EPA-HQ-OAR-2014-0827-1116-A1 p.3]

Our vehicles have a multitude of functional capabilities and set up for quick interchange of implements. Some examples: In summer, the vehicle could be configured for fighting wild fires, controlling large
swaths of vegetation, or forestry work; in fall for high-pressure water/rotary brush tunnel and industrial cleaning; in winter for extreme snow cutting/blowing, clearing a mountain pass or plowing; in spring for agricultural tasks; flood water response or possibly a hazardous spill response in a remote location. Customers often use our vehicles with many other attachable implements such as a heavy duty knuckle-boom crane, PTO driven compressor or electric generator/welder, excavating or drilling equipment, road improvement/grader, or a boom bucket for utility companies needing to reach elevated work in remote locations. [EPA-HQ-OAR-2014-0827-1116-A1 p.3-4]

Comment to the Small Business Advocacy Review Panel: It appears the panel did not have opportunity, or possibly did not see the need to evaluate the Proposed Amendments Related to Heavy-Duty Highway Engines and Vehicles - Alternate Emission Standards for Specialty Heavy-Duty Vehicles, introduced on page 40522. As a small business producing ultra-low volumes of heavy-duty diesel engines, gaining an EPA and CARB certificate of conformity is our most challenging task. Indicative of small business, we are always thinking of ways to do things more efficiently and effectively. [EPA-HQ-OAR-2014-0827-1116-A1 p.5]

President Obama has stated on numerous occasions that the goals and standards of the US and EU vehicle emissions programs are near identical and that our pollution/pollutant standards are relatively the same. He states: There is no reason we should not have mutual recognition of vehicle emission standards. Hearing President Obama makes us think; why can’t we use the ECE-EURO VI certification data, to which we have access, to help achieve certification here in the US? We are certain we are not the only small business trying to find ways to overcome the huge financial and logistical burden for certifying engines and vehicle OBD systems. [EPA-HQ-OAR-2014-0827-1116-A1 p.5]

As such, we propose to open a roundtable discussion, maybe just within the realm of your board experts or maybe you have suggestions or contacts for us. The discussion would be; can quantitative data from like emission systems and testing regimens be used along with engineering design to make high reliability predictions for performance in other regimens. For example, if we have an EURO VI HDD OBD certified system with all certification and testing parameters documented by a third party certification official, why could we not use this to reduce the OBD testing burden for US small business trying to get EPA and CARB certificates? Of course the systems are not mirror image and approving officials need to think somewhat outside the box. The overall objective of the program and its goals should be at the forefront. [EPA-HQ-OAR-2014-0827-1116-A1 p.5-6]

Additional Comments: On page 40295, there is a discussion about chassis manufacturers, small volume manufacturers and small businesses and a request for comments on alternate approach and sales volume threshold. We can say this: There is often a convolution of the terms “small volume” and “small entity.” There are cases where a large manufacturer, with resources normally far exceeding that of the small business, is as a small volume producer, offered flexibility on compliance issues. We are of the opinion that only small volume producers who also qualify as a small entity be the thrust for regulatory flexibility. [EPA-HQ-OAR-2014-0827-1116-A1 p.7][This comment can also be found in section 6.4 of this comment summary]

A request for comment was posed asking for a means to determine what would constitute the correct quantity that amounts to “small volume.” We suggest using a formula based on a percentage of market sales in that particular industry; industry being the particular one that a certificate is sought. Actually, it seems the same question is posed every time small volume flexibility is posed - what is the correct or fair quantity? We have developed such a formula and parameters for a program which could apply to all small volume conditions throughout the CAA program. We can share this with the Agency and further discuss
if they are interested. [EPA-HQ-OAR-2014-0827-1116-A1 p.7][This comment can also be found in section 6.4 of this comment summary]

On page 40545, paragraph (x) Custom Chassis Manufacturers, a request is made for suggestions as to a low volume exception. We are fully supportive of this exemption for small entity/small volume custom chassis manufacturers. We feel that a volume of 200 vehicles per year could be adequate since it is consistent with the other like categories. Additionally, we think there could also be some qualifying factor such as: The exemption is warranted when the feasibility to employ fuel saving and emission reduction technologies are beyond the capability of the small entity to reasonably engineer. Or, the vehicles operate in a manner essentially making them incompatible with fuel saving and emission reduction technologies. The recordkeeping, reporting and labeling could follow along the line of that in 1037.631. [EPA-HQ-OAR-2014-0827-1116-A1 p.7][This comment can also be found in section 6.4 of this comment summary]

Comment to the Small Business Advocacy Review Panel: On page 42 of your Final Report dated January 15, 2015 for this proposed rule, in reference to the 9.5.3.2 Off-Road Vocational Vehicle it states: “The Panel believes this exemption is sufficient to cover the small business chassis manufacturers who design chassis for off-road vocational vehicles.” As §1037.631 is currently proposed, our small business and our off-road vocational vehicles would not necessarily be exempted unless our suggestion is accepted (see suggestion above). It is very hard to imagine our purposely engineered high mobility/off road vocational vehicles not fitting this term. Then again, maybe there is a means for our situation to fall within the custom chassis realm. Of course we continue to advocate for remaining within the spirit and intent of the exemption along with the flexibilities often afforded small entities. [EPA-HQ-OAR-2014-0827-1116-A1 p.7-8]

Comment to the Small Business Advocacy Review Panel: On page 15 of your Final Report for this GHG ruling dated January 15, 2015, you mention in reference to OBD; “Small businesses in particular, who don’t have a direct connection with the large manufacturers, will have a difficult time writing new algorithms without access to the diagnostics from the OEM.” You go on to present issues and potential solutions. In 40 CFR 86.094-14, 86.095-14, or 86.098-14, Small-volume manufacturer’s certification procedures, there is a compilation of flexibilities and standards required for SVM certification but exclude any mention of -17 or -18 OBD requirements. [EPA-HQ-OAR-2014-0827-1116-A1 p.8-9]

Having researched EPA’s promulgation of heavy-duty OBD, there appears to be no discussion as to small entity impact assessment or Regulatory Flexibility Analysis with the exception in the justification statement that the rule was not going to impact small entities only large manufacturers. We know this is not the case and therefore... Our suggestion: Move to include the -17/-18 OBD requirement to the listing of applicable certification standards along with the other requirements in the -14. At least then maybe there can be a proper discussion as to how small entities are impacted by this requirement and if there are any means for flexible alternatives. [EPA-HQ-OAR-2014-0827-1116-A1 p.9]

Response:

Innovus raised a variety of substantive and procedural concerns about the current rulemaking as it relates to policy development and their ability to meet the range of requirements that apply now and in the future. We believe we have included provisions in the final rule that effectively address all these concerns. Most noteworthy is the provisions allowing manufacturers of specialty heavy-duty vehicles to use engines certified to alternative highway standards that are based on nonroad certification requirements. This applies for annual production volumes of up to 200 vehicles, including a specific allowance for applying those provisions to the all-terrain vehicles that Innovus produces. This allows for substantially simplified
OBD requirements and a much wider selection of candidate engines. The specialty vehicle provisions are described in detail in Section 14.3.1.

The procedural concerns are secondary to the substantive items addressed above, but these points also warrant mention:

- We have clarified the small-business provisions in § 86.094-14 to clarify that there is no blanket exemption from OBD requirements for small manufacturers. We believe this is more appropriately addressed based on the technology limitations of the vehicle applications than on the type of company making the engine. Moreover, since the OBD requirements apply to engine manufacturers, it would be impractical to create an exemption from OBD requirements for engines installed by small vehicle manufacturers.

- The regulations include several allowances to use test data from procedures other than those we specify (see 40 CFR 14065.10(c)). These variances are all premised on the expectation that manufacturers may use measurement procedures that are equivalent to or better than the specified procedures, or that they may measure emissions in a way that better represents in-use operation. Test data measured using current European testing and certification procedures would not be useful for demonstrating compliance with EPA standards. We believe the more effective way to address this concern is to adopt standards and measurement procedures based on EPA’s nonroad programs. This approach allows vehicle manufacturers to get past the particularly limiting aspects of the heavy-duty highway engine standards.

- The provisions of § 1037.605 and 1037.631 are not limited to small manufacturers, so using these provisions does not depend on meeting some specified criteria.

- Other companies as part of the rulemaking process. We believe the final rule properly balances environmental concerns with the technical and financial limitations described in the comments.

**Organization:** Motiv Power Systems

One further method to encourage small, innovative manufacturers is to reduce the regulatory burden, especially when those companies focus on zero-emission technology. [EPA-HQ-OAR-2014-0827-1184-A1 p.2]

For small, innovative manufacturers, it is very important to minimize the regulatory burden of any regulation. As a small company, we focus on technology first – and without clear regulations that can be easily complied with, regulations that serve a wonderful end goal can be cumbersome. California has been a leader in hybrid and electric vehicle deployment to-date as part of the state’s commitment to a low-carbon future—the California Air Resources Board (CARB) currently encourages the deployment of these advanced technologies under its Innovative Technology Regulation. As a partner with the EPA and NHTSA under the Clean Air Act, the agencies should work closely with CARB to harmonize the federal and California policies as much as possible to minimize regulatory burden on small manufacturers and provide clarity for future deployment. The success in California has allowed small companies such as Motiv to bring products to market that reduce vehicle emissions, and we strongly support using this model at a national level. [EPA-HQ-OAR-2014-0827-1184-A1 p.2]

**Response:**
The agencies are continuing in Phase 2 the simplified compliance strategy for manufacturers of zero-emission vehicles that is currently in place for Phase 1. They are not required to use our GEM vehicle simulation tool. Instead, they simply submit a report describing their technology, their sales and other relevant information to EPA for compliance. Hybrid systems will require some additional compliance steps (e.g., a powertrain test) to evaluate the performance. The comments related to OBD are addressed in our responses in Section 14.3.3. Note that vehicles that qualify for our alternate engine standards for specialty heavy-duty vehicles have alternate diagnostic requirements. California’s authority under the CAA differs from EPA, and EPA cannot always align national standards with requirements in California.

Organization: National Propane Gas Association (NPGA)

**Definition of Small Manufacturers**

We request that the agencies revise the proposed definition for ‘small manufacturer’ to avoid inconsistency based on engine type. The agencies define ‘small manufacturer’ according to the code of the North American Industry Classification System (NAICS) with distinctions for manufacturers of vehicles versus alternative fuel businesses that perform engine conversion. The result of the proposed definition is separate classes of small manufacturers that are measured by different criteria. We ask the agencies to apply the same definition of ‘small manufacturer’ that the agencies implemented in the Final Rule for Light-Duty Vehicle Greenhouse Gas Emissions and Corporate Average Fuel Economy Standards, which is a company with 1,000 or fewer employees. We believe that extension of the same definition from light-duty through heavy-duty vehicle regulations provides consistency and clarity that is valuable for businesses. Additionally, the same definition irrespective of the type of engine permits businesses to diversify engine production without regulatory confusion. [EPA-HQ-OAR-2014-0827-1272-A1 p.4]

28 Supra note 6, at 40563.

29 Id. For example, the NAICS code defines small manufacturers of gasoline engines according to the number of employees, whereas small manufacturer businesses that convert engines are defined by revenue. See U.S. Small Business Administration, Table of Small Business Size Standards Matched to North American Industry Classification System Codes (2014), at 18; see also id. at 38.

Response:

Our industry-specific definitions of small entity are based on the definitions recommended by the Small Business Administration (SBA), who is represented in our Small Business Advocacy Review Panel. Production volume is not consistently proportional to the number of employees for vehicle and engine manufacturers in the heavy-duty industry and the agencies cannot apply a universal threshold to diverse
sectors. We are adopting the SBA small business thresholds updated in February 2014 for our final small business flexibilities.

Small Manufacturer Definition

The EPA regulation of small businesses refers to 13 CFR 121.201. This is spelled out in section 1036.150 (d) of the EPA regulations. That section also provides, with respect to 13 CFR 112.201, the following: “NAICS code 336310 for engine manufacturers with respect to gasoline-fueled engines, 336318 for engine manufacturers with respect to other engines, and 811198 with respect to fuel conversions with engines manufactured by a different company.” Unfortunately this means that very different rules apply to gasoline engines, diesel engines and alternative fuel conversions. For gasoline engine manufacturers, a small business is a company that has 750 or fewer employees, for manufacturers of other engines (presumably including diesel engines and new natural gas engines) it is 1,000 or fewer employees, and for conversions of engines manufactured by a different company the cutoff is based on revenues of $7.5 million or less. [EPA-HQ-OAR-2014-0827-1270-A1 p.6-7]

We do not believe that there is ample justification for establishing different treatment of businesses that produce gasoline, diesel or natural gas engines. The rules obviously make it more difficult for alternative fuel converters to take advantage of the small business exemption, which we do not believe is intended or rational. We would recommend that the defining criteria for alternative fuel conversion manufacturers be 1,000 or fewer employees and note that this is the figure used for exempting small businesses from EPA rules for light and medium duty greenhouse gas regulations.1 For consistency, rules for the light, medium and heavy duty conversions should use the same figure. [EPA-HQ-OAR-2014-0827-1270-A1 p.7]

---

Response:

The agencies defer to the Small Business Administration (SBA) for appropriate business sizes for small entity classification. See 3 above reproduced in our response to the National Propane Gas Association. The employee thresholds have been updated to reflect SBA’s updated criteria as of February 2016. We have removed reference to alternative fuel converters, because the agencies did not establish standards for converted in-use engines in Phase 2. Instead, these businesses must meet tampering provisions outlined by EPA and we do not provide any small business flexibilities exclusively for converters in this rulemaking. The agencies did establish standards for CI and SI engines. Any small businesses (according to SBA’s criteria) that manufacture CI or SI engines are eligible for a 1-year delay at the beginning of the program. Small businesses that manufacturer alternative fuel engines, including secondary manufacturers that modify CI or SI engines to run on alternative fuels before they enter into commerce, are eligible for an additional 1-year delay for each increase in stringency. See Section 12 for additional information about applying GHG-related requirements for aftermarket conversions.

Organization: Newell Coach Corporation

Although we were exempt from the Phase 1 GHG requirements (because we qualified for the small business exemption that was included in the rule), we use and will continue to use components that reduce GHG emissions, including lower GHG-emitting engines and low rolling resistance tires. Thus, despite being exempt, our vehicles achieve the GHG reductions mandated by the Phase I regulations. [EPA-HQ-OAR-2014-0827-1319-A1 p.1]

As is the case today, we will receive lower GHG-emitting engines and tires regardless of requirements placed upon us. Thus, requiring very small companies like ours to actually ‘certify’ compliance using the GEM model will yield no environmental benefit. It will only add unnecessary costs and increase the work load on Newell's small staff and EPA’s. [EPA-HQ-OAR-2014-0827-1319-A1 p.1-2]

Given the above, we respectfully request an extension of the current SBA exception for small manufacturers. In our view, a continuation of the current exemption for small businesses, if not for all small businesses then at least for motorhome chassis, would be the simplest solution for small companies like ours, and for EPA. However, if the EPA should conclude that a continuation of the SBA exemption for motorhome chassis manufacturers is not appropriate, we believe that companies who annually manufacture 500 or fewer Class 8 - HHD motorhome chassis should be provided the opportunity to certify their chassis to a less stringent standard (similar to that which has been proposed for emergency vehicles). [EPA-HQ-OAR-2014-0827-1319-A1 p.2]

Response:

Small businesses producing heavy-duty vehicles are not subject to Phase 1 heavy-duty GHG and fuel consumption standards because of a deferral, not a permanent exemption. Before proposing regulations that would apply to small businesses in Phase 2, we conducted an official analysis of small business impacts under the Small Business Regulatory Enforcement Fairness Act (SBREFA). In response to the recommendations of the SBREFA panel as well as public comments, the agencies are adopting provisions that will reduce the compliance burden for small businesses. Primarily, we are including a one-year delay in implementation for all small businesses that will allow them additional time to become familiar with the compliance process, address staffing concerns, and evaluate technologies.

In consideration of current market dynamics where many small businesses compete directly with large diversified manufacturers, as well as comments stating it would be unfair to make less stringent
standards available solely on the basis of sales volume, the agencies are not finalizing a broad sales volume threshold below which a vocational chassis manufacturer would have a different set of requirements. See discussion in Section 6.4 of this RTC.

Based on public comment and extensive stakeholder outreach, the agencies have identified over a dozen chassis manufacturers serving the U.S. vocational market who produce a narrow spectrum of vehicles for which many technologies underlying the primary standards will either be less effective than projected, or are infeasible. We are adopting optional custom chassis standards for these manufacturers, including significant flexibility for motor homes. Manufacturers will have the option to designate the following applications as custom chassis vehicles: coach (intercity) bus, motor home (the type of chassis produced by the commenter), school bus, transit bus, refuse truck, cement mixer and emergency vehicle. See Section 6.2.3 for responses to other comments on the custom chassis program. Chassis so designated may be certified with a default engine map and other default parameters so that manufacturers choosing this option will have fewer technologies to evaluate, and will have unique standards for each vehicle type that reflect use of appropriate technologies.

Further, the agencies are adopting a non-GEM design standard option for motor homes, cement mixers, and emergency vehicle chassis, because we have determined that these vehicles have the least number of feasible technologies that can be applied in Phase 2. Motor homes, for example, have been determined by the agencies to essentially need only apply low rolling resistance tires, certified engines, low leakage air conditioning systems, and tire pressure systems. Where a manufacturer of these vehicles is able to apply the same technology on all of its production without averaging, we offer the non-GEM option as a compliance flexibility to avoid the certification burden associated with running GEM. As discussed in Section 6.4.1, we were unable to identify other custom chassis technology packages that we believed could be applied at a 100% adoption rate; thus, averaging (and use of GEM) was deemed necessary for other vehicles.

We are not restricting the optional custom chassis program to small businesses. Because we are allowing diversified manufacturers to certify some vehicles to the optional custom chassis standards, but some large manufacturers may not have a system for tracking what the final build of a vehicle is, we are adopting compliance procedures to assure that the final intended build will be one of the defined vehicle types. This approach is intended to level the playing field by allowing large manufacturers to choose this option where their tracking (and/or controls imposed on the vehicle) is sufficient to know at the time of certification what the final build will be.

Organization:  XL Specialized Trailers

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 205.]

As a small business entity, XL Specialized Trailers must consider the potential burden imposed on us by the proposed regulations. Additional pre-production reporting, new compliance and equipment labeling, government mandated warranty requirements not normally seen in this industry, user manual equipment requirements, compliance submissions and record keeping, will create additional burdens to an already cost sensitive industry. As the proposed regulations are presented, this burden will exist whether a company produces a fee regulated product or many.

Response:
The final trailer program significantly reduces the number of regulated trailers by limiting the non-box trailer program to tanks, flatbeds and container chassis only, which removes more than 80 trailer manufactures (73 that qualify as small businesses) from the program. The compliance burden on the remaining non-box trailer manufacturers is limited to evaluating and marketing appropriate LRR tires and tire inflation systems, installing a label to indicate that the trailers have these technologies installed, and reporting the use of those technologies to EPA. The annual economic burden of this compliance process is estimated to be less than $20,000 per manufacturer. We have provided a memo to the docket outlining the compliance burden estimated for small manufacturers.

15.5 Public Participation

In the four years since the Environmental Protection Agency (“EPA”) and the National Highway Traffic Safety Administration (“NHTSA”) finalized the Phase 1 standards for model years (“MYs”) 2014-2018, Allison has met several times with both agencies concerning the development of the Proposed Rule. Allison also collaborated on testing conducted on transmissions in preparation for the Proposed Rule and has sought to continue a productive dialogue with both agencies on the GHG and fuel efficiency effects of various transmission systems. [EPA-HQ-OAR-2014-0827-1284-A1 p.1]

Since the development of the Phase 1 rule, Allison has worked cooperatively with EPA and NHTSA on the development of a Phase 2 rulemaking for MD/HD engines and vehicles. As indicated at the beginning of these comments, we have been pleased at the receptiveness of the agencies to consider technical input and to undertake additional testing and evaluation of different transmission architectures in support this rulemaking effort. Provided that both agencies act on the basis of verifiable data as well as in accordance with their legal authority, Allison supports the goal of making additional progress in reducing GHGs and improving the fuel efficiency of MD/HD vehicles. Such progress would inure to the benefit of both our customers and the environment. [EPA-HQ-OAR-2014-0827-1284-A1 p.64]

At the same time, EPA and NHTSA must realize that there are legal and practical constraints that prevent the finalization of standards more stringent than Alternative 3. In addition, our comments have pointed out several flaws in the record for this rulemaking with regard to technology penetration rates, cost estimates, various aspects of GEM and the crediting of transmission technologies. Allison has also offered several recommendations for GEM improvements, expansion of off-cycle programs and hybrid vehicles. In particular, EPA and NHTSA must assure that any final rule accurately assess and account for the GHG and fuel efficiency benefits of ATs versus other transmissions, including benefits that accrue with respect to how the operation of the transmission, engine and vehicle is controlled. [EPA-HQ-OAR-2014-0827-1284-A1 p.64]

EPA and NHTSA must work to resolve these and other concerns prior to promulgation of a final rule, allowing for additional public input where needed. This rulemaking will serve to define how different engines, transmissions and vehicles are assessed for compliance with new GHG and fuel efficiency regulatory standards that extend well into the next decade. Thus, accurate information and supporting analysis is essential and we look forward to continued engagement with the agencies. [EPA-HQ-OAR-2014-0827-1284-A1 p.64]

During the public hearing the agencies held in Chicago on August 6, 2015, Allison outlined several deficiencies in the Greenhouse Gas Emission Model (“GEM”) as it existed at the time of the proposed Phase 2 Rule. These deficiencies ranged from relatively small issues, like coding errors, to larger issues with respect to how GEM reflected the operation of automatic transmission systems. Given the vital
importance of the GEM to the final rule, we recommended that EPA and NHTSA either extend the period for public comment, reopen the public comment period at a future date, or explore other options, including the issuance of a Notice of Data Availability (“NODA”). [EPA-HQ-OAR-2014-0827-1892-A1 p.1]

**Organization:** American Automotive Policy Council

AAPC looks forward to continuing its cooperative efforts with the agencies to develop harmonized nationwide fuel consumption and greenhouse gas regulations for the 2019-27 model years that enable motor vehicle manufacturers to build a single fleet of vehicles in these classes capable of complying with all regulations. [EPA-HQ-OAR-2014-0827-1898-A1 p.3]

**Organization:** American Bus Association (ABA)

The American Bus Association (ABA) respectfully requests an extension of the time period for filing comments to the Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium-and Heavy-Duty Engines and Vehicles—Phase 2 proposed rule (GHG-2) issued jointly by the U.S. Environmental Protection Agency (EPA) and the U.S. Department of Transportation’s National Highway Traffic Safety Administration (DOT/NHTSA), [Docket ID Nos. EPA-HQ-OAR-2014-0827 and NHTSA-2014-0132–Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2]. ABA requests a 120-day extension to file comments, based on the following: 1) the length and complexity of the rule proposal; 2) the limited resources the Motorcoach industry has at its disposal to analyze the proposal; and 3) the failure of the agencies to engage with motorcoach manufacturers or the motorcoach industry, in any meaningful way, even after an explicit request by ABA to meet, prior to publication of the proposal in August 2015. [EPA-HQ-OAR-2014-0827-1139-A1 p.1]

**1. Length and Complexity of Proposal.**

The GHG-2 proposal, as published in the Federal Register is over 600 pages long, not including NHTSA’s Environmental Impact Statement (EIS). The original public comment period provided for this proposal was 60 days, which has since been extended for another 20 days. It involves highly technical expertise and resources to interpret the proposal, not readily available to small industries such as the motorcoach industry. [EPA-HQ-OAR-2014-0827-1139-A1 p.2]

In comparison, the two federal agencies involved in this proposal have employed dedicated teams, including numerous economists, scientists, engineers and others, to work on this proposal over the span of at least the past 6 years, including the time spent on the Phase 1 proposal from which this proposal evolved. It is simply unreasonable for these federal agencies to expect those businesses affected by the rule to be in a position of providing thoughtful and functional comments on an extremely complex proposal within this short of time period, particularly if these businesses have not been involved in prior discussions or regulated by previous regulatory proposals of the same nature. [EPA-HQ-OAR-2014-0827-1139-A1 p.2]

Further, significant rulemaking proposals of this nature, especially involving this level of complexity and length, and affecting such a broad swath of industries, at a minimum provide a 120-day comment period. It is beyond reason that EPA and NHTSA would make such a complex proposal as the GHG-2, with an initial comment period of only 60 days. [EPA-HQ-OAR-2014-0827-1139-A1 p.2]
If not provided adequate time during the comment period, as originally proposed, agencies often receive and grant requests for extensions as we have already seen requested in this case. This is done in recognition and interest by the agencies, in order to ensure proper input as intended under the Administrative Procedures Act (APA) and full participation of the community affected. It is reasonable under the APA, considering the nature, length, magnitude, and scope of this rule to allow for 120 days to enable all affected interests of this proposal to properly consider it and provide thoughtful comments. Even if the original proposed period was only 60 days, it is not unusual or unreasonable for agencies to grant extensions well beyond the original proposal. [EPA-HQ-OAR-2014-0827-1139-A1 p.2]

2. Motorcoach Industry Resources

The motorcoach industry is a relatively small industry, in terms of the entire transportation sector industry (can we provide a general figure on that annual income of the industry). It is not heavily subsidized in any significant scale by the Federal Government. Of the approximately 3,400 motorcoach companies currently in operation in the U.S., operating nearly 32,000 motorcoaches, over 90% are small fleets or operating 10 vehicles or less. In addition, while there are 4 major motorcoach vehicle manufacturers who serve the private U.S. motorcoach industry, all but one of these manufacturers are foreign companies, who have not been eligible to participate in the previous “credit” programs provided under Phase 1 and continued under the Phase 2 proposal. Indeed, the motorcoach industry is the “small business” model for the transportation sector – no other transportation mode, aside from automobiles, can compare in terms of the dollar investment for providing a transportation service. This can be both a blessing as well as a curse, however, as demonstrated by this rulemaking. [EPA-HQ-OAR-2014-0827-1139-A1 p.3]

As previously mentioned, this lengthy rule proposal is both complex and a relatively new subject for the motorcoach industry. It requires resources and time to properly analyze the proposal and provide any meaningful comments to the agencies. Such resources are in limited supply to the motorcoach industry for this this purpose, and the short comment period designated by the agencies only exacerbates this problem. If it is truly EPA and NHTSA’s goal to continue to “work collaboratively with stakeholders,” as the GHG-2 proposal repeatedly states, then the agencies should extend the comment period to accommodate the needs of smaller businesses and businesses who do not have the relative expertise or familiarity with the issues addressed in the proposal. [EPA-HQ-OAR-2014-0827-1139-A1 p.3]

3. Stakeholder Outreach.

The Preamble of the GHG-2 proposal includes numerous statements on how EPA and NHTSA have “worked with industry” and had “robust collaboration with stakeholders” in preparing not only this proposal, but previous proposals to address greenhouse gas emissions and fuel efficiency. In fact, the Preamble references specifically: the public, heavy-duty vehicle and engine manufacturers, technology suppliers, trucking fleets, truck drivers dealerships, environmental organizations, and state agencies. Noticeably missing from this list are motorcoach or bus manufacturers, motorcoach or bus operators, or motorcoach or bus drivers. [EPA-HQ-OAR-2014-0827-1139-A1 p.3]

However, in anticipation of this rulemaking ABA initiated outreach to its members and specifically requested a meeting with NHTSA on the parameters and information gathering used in the formulating of this proposal. Our request was denied. Nonetheless, we have continued to reach out to ABA members, in an effort to conduct some form of analysis; however, we need more time. The feedback that we have received to date is very limited due to the length and complexity of the rule proposal. [EPA-HQ-OAR-2014-0827-1139-A1 p.4]
The motorcoach industry has a strong record on gas emissions and fuel efficiency. In a study that compared emissions and fuel efficiency by mode, “motorcoaches on average used the least amount of energy and produce the lowest carbon dioxide emissions per passenger mile of any of the transportation modes analyzed.”\textsuperscript{2} [EPA-HQ-OAR-2014-0827-1139-A1 p.4]

Based on the motorcoach industry’s vitality to the national transportation network and its contribution to promoting fuel efficient and environmentally friendly transportation options, we believe the motorcoach industry should be permitted the opportunity to provide thoughtful and meaningful input to this rulemaking. In light of little to no “stakeholder outreach” by the EPA and/or NHTSA to the motorcoach industry, along with the denial of ABA’s request to meet prior to the publication of the rule proposal, ABA believes an extension of the comment period is warranted. [EPA-HQ-OAR-2014-0827-1139-A1 p.4]

Based on the three reasons outlined above, ABA respectfully requests EPA and NHTSA to extend the comment period for the GHG-2 proposal for an additional 120 days.

**Organization:**  American Trucking Associations (ATA)

The American Trucking Associations (ATA) is hereby requesting a time extension of 90-days beyond the September 17, 2015 comment period deadline on the EPA and NHTSA Proposed Rule: Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles - Phase 2 (Phase 2). The magnitude of this rulemaking, both in terms of cost and uncertainty to trucking fleets for decades to come, does not warrant setting artificial and expedited timelines that are neither required by legislation nor legally mandated by the courts. While ATA supports the aims under the Phase 2 Rule, the trucking industry wants to ensure that the final rule is affordable and technologically practical to fleets, manufacturers, and suppliers alike. [EPA-HQ-OAR-2014-0827-0923-A1 p.1]

While a few select stakeholders have established teams to read and analyze the Proposed Rule and the thousands of pages of technical support documents and complex modelling formulations, few throughout the industry have been able to fully review and evaluate how Phase 2 will impact their operations and business plans. This especially holds true for most trucking fleets. ATA and other impacted stakeholders are currently dialoguing, conducting surveys, and gathering data to further assess and develop a sound and achievable regulation that will not result in market disruptions or unattainable goals. [EPA-HQ-OAR-2014-0827-0923-A1 p.2]

Given that fuel is one of the top operating expenses for trucking companies, ATA supports the aims of improving fuel efficiency and reducing the industry’s carbon footprint. However, ATA and its diverse membership seeks additional time to complete its reading to fully understanding this extremely complex and far-reaching rule which will directly impact and transform fleet operations for decades to come. Moving ahead, ATA looks forward to continued cooperative efforts with both EPA and NHTSA in crafting a rule that is both technologically and economically achievable. Thank you for your consideration of this time extension request. [EPA-HQ-OAR-2014-0827-0923-A1 p.2]
Autocar is a small volume manufacturer, and is not subject to existing greenhouse gas standards pursuant to 40 C.F.R. § 1037.150(c). Under the recent proposal, small manufacturers such as Autocar would be newly subject to greenhouse gas emissions standards. Autocar therefore needs ample time to thoroughly review, analyze, understand and respond to the sizable and complex proposal and supporting documents. Although Autocar has begun this process, the 60-day comment period (now extended by six days) is simply inadequate to fully accomplish the task. [EPA-HQ-OAR-2014-0827-0761-A1 p.1]

Autocar respectfully requests that EPA and NHTSA extend the comment deadline for the Phase 2 proposal by a minimum of 90 days, and preferably six months. This extension will allow entities such as Autocar that would be newly subject to the regulations the opportunity to fully consider, and provide informed comment on, the proposal. [EPA-HQ-OAR-2014-0827-0761-A1 p.1]

On behalf of our client Autocar, LLC and Autocar Industries, LLC (“Autocar”), we respectfully request that the Environmental Protection Agency (“EPA”) and the Department of Transportation (“DOT”) extend the comment period for the proposed Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2 (“Phase 2 rulemaking”). Autocar also requests that the agencies formally provide an opportunity for public comment on an important document placed in the public docket for this rulemaking. [EPA-HQ-OAR-2014-0827-1869-A1 p.1]

On March 2, 2016, the Environmental Protection Agency and the Department of Transportation issued a notice of data availability (“NODA”) indicating that the agencies had made available new information related to the proposed Phase 2 rulemaking and announced a new 30-day comment period. 81 Fed. Reg. 10,822, 10,822 (March 2, 2016). As described in Section 1 below, Autocar believes that an extension is necessary to ensure that it and other interested stakeholders have a full and fair opportunity to review and analyze documents included in the NODA, and thereafter provide all relevant information to the agencies so that they may make an informed, reasoned, and defensible decision with respect to the rulemaking. As discussed in Section 2 below, Autocar also believes that the agencies must provide for public comment on a critical document placed in the rulemaking docket, “Vocational Vehicle Technology Packages for Custom Chassis.” [EPA-HQ-OAR-2014-0827-1869-A1 p.1-2]

1. Extension of Time

Autocar seeks the current extension in order to respond to two new and material items about which the agencies requested public comment. First, the extension could afford Autocar an opportunity to assess the Greenhouse Gas Emissions Model (“GEM”) P2v2.1. EPA-HQ-OAR-2014-0827-1626, NHTSA-2014-0132-0181. Second, an extension would enable Autocar—and similarly situated stakeholders—to provide EPA and DOT relevant information responsive to the draft report produced by the National Renewable Energy Laboratory (“NREL”) entitled “The Development of Vocational Vehicle Drive Cycles and Segmentation.” EPA-HQ-OAR-2014-0827-1621, NHTSA-2014-0132-0187. EPA requested comment on both these items. See 81 Fed. Reg. at 10,825. [EPA-HQ-OAR-2014-0827-1869-A1 p.2]

An extension of the comment window would also enable Autocar to attempt simulations using the GEM program and compare those findings with the conclusions of the NREL study. The extension would ensure that Autocar and other similarly situated entities have a full and fair opportunity to respond to the newly docketed materials and, thereafter, provide to the agencies all necessary and relevant information. [EPA-HQ-OAR-2014-0827-1869-A1 p.3]

3. Conclusion
Autocar respectfully requests that EPA and DOT release the underlying data relevant to the NREL report, extend the comment deadline for the information covered by the NODA by a minimum of 60 days after that data is released, and specifically open the vocational vehicle technologies memorandum to comment. These steps will allow entities such as Autocar to fully analyze the recently developed information and provide informed comment to the agencies. Thank you for your consideration of this request. [EPA-HQ-OAR-2014-0827-1869-A1 p.4]

**Organization:** Bendix Commercial Vehicle Systems, LLC

Bendix OEM customers make many of our products available as standard or optional equipment and we respect their expertise and position on Phase 2 standards proposed by EPA and NHTSA, as they will be responsible for implementation of technologies to meet the new standards. Their perspectives merit strong consideration by the agencies in ensuring a responsible standard that is realistically implementable in the timeframes under consideration. [EPA-HQ-OAR-2014-0827-1241-A1 p.1]

Bendix commends the agencies for their open and collaborative approach, and their receptiveness to stakeholder suggestions. Collaboration between government officials and a wide variety of stakeholders is key to the success of such a significant and complex technical regulation. We appreciate the opportunity to present our comments and urge the agencies to consider our positions on the following topics. [EPA-HQ-OAR-2014-0827-1241-A1 p.1]

**Organization:** CALSTART

EPA and NHTSA staffs have been and remain highly collaborative with industry in developing these important rules and we look forward to continuing to work with both staffs to finalize the regulations by next spring/summer. [EPA-HQ-OAR-2014-0827-1190-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.150-151.]]

**Organization:** California Air Resources Board (CARB)

Over the past two years, CARB staff has worked closely with the staff of U.S. EPA and NHTSA to develop the technical analyses intended to inform the stringencies of the federal Phase 2 proposal. We commend and appreciate your agencies’ significant efforts to build on the success of current Phase 1 standards for the purpose of establishing a strong, national Phase 2 program, particularly one that will support California in achieving its unique climate and petroleum reduction targets. [EPA-HQ-OAR-2014-0827-1265-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.150-151.]]

CARB has appreciated the opportunity to work collaboratively with both U.S. EPA and NHTSA in developing the federal Phase 2 proposal. My hope is that U.S. EPA and NHTSA will seriously consider our comments in the spirit they are provided: as an opportunity for our agencies to continue our collaborative efforts to finalize a strong, national Phase 2 program that maintains this country's global leadership role in addressing climate change. [EPA-HQ-OAR-2014-0827-1265-A1 p.5]

**Organization:** Caterpillar Inc., et al.

The major heavy-duty vehicle manufacturers appreciate the time the agencies have given to receive our feedback, through face-to-face meetings and other regular exchanges, through our trade associations, and through our various comment submittals. All stakeholders depend upon a continued good faith
collaboration to see this rule to its successful conclusion, considering all aspects of the public
rulemaking process, and we remain hopeful that the agencies will, at all levels, be available to hear our
concerns and proposals. Without this open dialogue, the regulation risks being finalized in a way that
will not be effective, and will have adverse impacts on the environment and on the users of commercial

This industry is committed to continuous improvement of heavy-duty vehicle fuel efficiency and
greenhouse gas reductions. Heavy-duty truck OEMs and other stakeholders are committing tremendous
time and resources toward a successful evolution of this important regulation, one that brings significant
reductions through assured market success with minimal unintended consequences. We will continue to
work with the agencies to secure the win-win that’s available to all of us in the attainment of our shared
goals. [EPA-HQ-OAR-2014-0827-1215-A1 p.10]

The proposal requires significant revisions to be feasible. The protocols in the draft regulation have
artificially inflated the required greenhouse gas reductions by nearly 50% in some cases, far beyond the
targeted levels reported in the agencies’ overview announcements. The agencies are refining the
proposed test procedures, often in ways that differ considerably from the base proposal. While we
acknowledge that many of these adjustments are necessary and appropriate, the current level of
uncertainty around the means by which products will be assessed to determine their GHG emissions and
fuel efficiency, as well as the continued post-proposal adjustments to stringency targets, renders it
impossible for manufacturers to assess their technical and commercial capability to comply with this
rule. The expedited timeline of this regulation precludes the opportunity to address this issue in the best
way, which would be for the agencies to identify within the public process a means, such as a
Supplemental Notice of Proposed Rulemaking, by which stakeholders could formally comment on a
more firm proposal, with the latest version of the GEM vehicle simulation tool. This opportunity being
unworkable on the current timeline makes close collaboration between the agencies and the industry up
to the point of the final rule absolutely essential. It’s important in this collaborative process that the
procedural and audit provisions are firmed up in a timeframe that still leaves a window of time for the
agencies to receive our feedback on the resultant stringency implications of the rule once those issues
are settled. We believe that this follow-on process will be critical to the rule’s success. [EPA-HQ-OAR-
2014-0827-1215-A1 p.9-10]

Organization: Con-way Inc.

Con-way respectfully requests that EPA and NHTSA extend the comment deadline for the Phase 2
proposal by a minimum of 90 days, and preferably six months, to allow Con-way and other interested
parties a sufficient opportunity to comment on the proposal. The current timeline for submitting
comments does not provide adequate time for industry to review and comment on this complex and
important rulemaking. [EPA-HQ-OAR-2014-0827-0924-A1 p.1]

Organization: Eaton Vehicle Group

Eaton appreciates the open and collaborative approach taken by both the US EPA and NHTSA to
engage a broad array of stakeholders for in-depth technology discussions throughout the development of
Phase 2 NPRM. It cannot be said that the agencies did not listen to the thoughts and concerns of
industry and other stakeholders. [EPA-HQ-OAR-2014-0827-1194-A1 p.4]

Organization: FedEx Corporation
Before discussing the proposal itself, we wish to express our appreciation to the EPA’s Office of Transportation and Air Quality (OTAQ) and the NHTSA Fuel Economy Division for the collaborative actions undertaken with stakeholders by the agencies throughout the process. FedEx has been pleased to be a stakeholder to help inform with regard to more fuel-efficient and lower-emitting commercial vehicles. We have done so for the same reasons that we focus on improving our own fleet of vehicles – because we feel there is the opportunity to obtain even more fuel efficiencies and lower greenhouse gas emissions from vehicles – but doing so at a national level so that the nation has a comprehensive, harmonized approach that applies to all commercial vehicles. [EPA-HQ-OAR-2014-0827-1302-A1 p.1-2]

**Organization:** Great Dane

We at Great Dane support reductions in Greenhouse Gas emissions and improved energy efficiencies in transportation. However, we note that trailers have not been previously regulated with regard to Greenhouse gas emissions, so the trailer regulatory issue is new to the EPA, NHTSA, and the trucking industry. [EPA-HQ-OAR-2014-0827-0907-A1 p.1]

The issue of Greenhouse Gas (GHG) regulations affecting semi-truck trailers is a complex matter. Trailer designs and specifications vary widely from customer to customer and even within a given customer’s fleet based on their operational needs. [EPA-HQ-OAR-2014-0827-0907-A1 p.1]

Great Dane requests a 90-day extension of the September 17, 2015 deadline for comments. This extension will allow Great Dane additional time to understand the NPRM and to interact with the EPA, NHTSA and stakeholders who have valuable information requested in the NPRM. Additionally, a 90-day extension of the formal comment period will allow stakeholders time to respond properly to the proposed regulations. [EPA-HQ-OAR-2014-0827-0907-A1 p.1-2]

Great Dane looks forward to working with both EPA & NHTSA to help answer the questions posed in the NPRM and to develop the best and most appropriate regulations for the industry. We appreciate your consideration of these matters. [EPA-HQ-OAR-2014-0827-0907-A1 p.2]

**Organization:** Innovus Enterprise LLC

1. We are grateful former Congressional Leaders provided the public a vehicle to voice concerns and comments on Agency regulatory development. We also thank the EPA and the NHTSA for following through on these mandates. As Small Business Leaders, we do not take this opportunity for granted and feel it as our duty to contribute positively by keeping a balanced perspective. [EPA-HQ-OAR-2014-0827-1116-A1 p.1]

2. We have diligently studied this proposed ruling; proceeding rulings, as well as support items in the associated dockets. We strongly feel our comments and concerns for the *Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles Phase 2* proposed rules will further the Agency’s goals as well as those of our small business community. Along with this confidence, we feel our suggestions are well within the allowances of the Regulatory Flexibility Act and those powers afforded by Congressional Act to the NHTSA and EPA Administrators. [EPA-HQ-OAR-2014-0827-1116-A1 p.1]

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)
We commend the EPA and NHTSA for their diligent work in crafting this proposal and working closely with the California Air Resources Board (CARB). We also appreciate the agencies’ willingness to engage meaningfully with the UAW, our members, and other stakeholders on this important matter. This is a complex industry and crafting new greenhouse gas emissions and fuel efficiency standards for medium and heavy-duty engines and vehicles is an extremely difficult task. [EPA-HQ-OAR-2014-0827-1248-A2 p.1]

Organization: Meritor, Inc.

Meritor values the professional relationship that has been developed between members of our company and the U.S. EPA and NHTSA as we have worked collaboratively on the content of this proposal.

Organization: Motor & Equipment Manufacturers Association (MEMA)

MEMA and the motor vehicle supplier industry are committed to policies that enable the introduction of new technologies needed to support sustainable mobility and we appreciate our engagement with the EPA and NHTSA over the years as the agencies developed and refined their Phase 2 proposals. MEMA commends the agencies for their open and collaborative approach, and their receptiveness to stakeholder suggestions. Collaboration between government officials and a wide variety of stakeholders is key to the success of such a significant and complex technical regulation. [EPA-HQ-OAR-2014-0827-1274-A1 p.2]

[The following comments were submitted as testimony at the Long Beach, California public hearing August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 192.]

MEMA recognizes and respects how important it is for the agencies to meet the administration’s deadlines in promulgating this rulemaking. But we also believe it is critical to ensure that all stakeholders have as much time as possible to digest this complex rule and to provide substantive, useful feedback to the agencies. Any additional time the agencies can afford to add to the comment period, even a short-term extension of one or two weeks, would be appreciated.

Organization: NAFA Fleet Management Association

NAFA respectfully requests that EPA and NHTSA extend the comment deadline for the Phase 2 proposal by 90 days. This extension will allow NAFA and our members the opportunity to fully consider and provide informed comment on the proposal. [EPA-HQ-OAR-2014-0827-0916-A1 p.1]

Organization: National Automobile Dealers Association (NADA)

Earlier this year, NHTSA and EPA solicited comment on a Phase 2 proposal for medium-and heavy-duty engine and truck fuel efficiency and greenhouse gas (GHG) emissions standards. 80 Fed. Reg. 40138, et seq. (July 13, 2015). At some 627 Federal Register pages in length, the proposal is more than twice as big as that for Phase I, huge even by NHTSA and EPA standards. In addition, as of today, the EPA docket contains 732 supporting documents totaling thousands of pages in length and the NHTSA docket contains an additional 9 supporting documents totaling well over 1000 pages. [EPA-HQ-OAR-2014-0827-0909-A1 p.1]

Recognizing the crucial and complex nature of the Phase 2 program and its potential impact on truck dealerships, ATD is devoting considerable staff resources to analyze the proposal and the supporting
documents and to prepare and submit hearing testimony and written comments. Moreover, ATD is engaged in dialogue with truck, component, and equipment manufacturers to better understand the technical issues and concerns raised by the proposal. [EPA-HQ-OAR-2014-0827-0909-A1 p.1]

Supportive of continuous improvements in commercial truck fuel economy and greenhouse gas performance, ATD nonetheless is concerned about numerous issues in the proposal that could dramatically impact vehicle cost, vehicle performance, and/or vehicle reliability. An adequate review and analysis of the proposal’s potential impact on dealership truck and tractor sales and parts and service operations requires time. Moreover, an adequate opportunity for notice and comment is critical to the development of technologically feasible and economically practical rules designed to achieve public policy objectives in a timely manner.¹ [EPA-HQ-OAR-2014-0827-0909-A1 p.2]

Fortunately, NHTSA and EPA were not constrained by a statutory deadline dictating when the Phase II proposal had to be published. In fact, as noted in NHTSA’s notice to prepare an environmental impact statement for Phase II, the stated goal was to publish a proposal by March of 2015, some four months earlier than what eventually transpired. 79 Fed. Reg. 38842, 38844 (July 9, 2014). Fortunately too, no statutory deadline constrains by when a final rule must be published. Consequently, NHTSA and EPA are not statutorily constrained in their ability to provide for an adequate notice and comment opportunity. [EPA-HQ-OAR-2014-0827-0909-A1 p.2]

The proposal set out a comment deadline of September 11, 2015, which was extended to September 17, 2015 in a subsequent hearing notice. 80 Fed. Reg. 44863-4. (July 28, 2015). Appreciative of these six extra days, ATD nonetheless submits that a comment period of a little over 60 days is insufficient given the volume of documents, the complexity of issues, and the 10-year implementation period involved. Consequently, ATD urges EPA and NHTSA to extend the comment period deadline until December 7, 2015. [EPA-HQ-OAR-2014-0827-0909-A1 p.2]

¹ In addition, the due process inherent in a sufficient notice and comment opportunity is a constitutional and statutory requirement for federal agencies engaged in rulemaking of this sort.

**Organization:** Navistar, Inc.

Adequate Notice and Comment

Agencies must provide for adequate notice and opportunity for comment when developing a rule. This means that the public should both be notified of the content of the rule and also be given an adequate opportunity to comment on the rule. There are several areas, covered in more depth below, where the NPRM contains proposals that do not appear to be in final form. Navistar is concerned that the Proposed Rule as published in the NPRM is not sufficiently definite to allow adequate opportunity to comment. This will be explained more fully below as it pertains to specific areas. [EPA-HQ-OAR-2014-0827-1199-A1 p.4]

However, in this respect our most significant concern relates to GEM and the opportunity Navistar, and the public in general, have been given to analyze and comment on this key aspect of the Proposed Rule. GEM, including its source code, should be considered a rule and subject to the same notice and comment process as the text in the Code of Federal Regulations. GEM is the sole means by which an emission level is set for a particular vehicle. There is no alternative to the use of GEM. Nor is it, like some modeling tools used in various compliance contexts, a tool used in the process of assessing a facility permit, for example. Instead, this software directly functions as the rule. If there is a variation
between what is said in the text of the Code of Federal Regulations and the result or process in the software, the software essentially wins since it sets the result for a particular vehicle. [EPA-HQ-OAR-2014-0827-1199-A1 p.4]

The source code that underlies GEM is as much a part of the rule as the regulatory language in the Code of Federal Regulations. For instance, executable file version 1.1 of GEM was posted to the docket on August 19, 2015. However, that was not the end. As of this writing, EPA had reached GEM executable file version 1.6. Since version 1.1 was posted, there have been at least five subsequent versions to GEM that have not yet been posted to the docket. Furthermore, there is no indication in the docket that the source code was posted at all, certainly not for versions subsequent to version 1.1. Navistar did receive a copy of the source code for version 1.1 on August 20. A notice to the docket relating to the availability of the source code for version 1.1 was posted as well, but that has been the last publicly released document. [EPA-HQ-OAR-2014-0827-1199-A1 p.4-5]

There is a significant difference between the source code and the executable file. With access to the source code one can analyze the actual functions of the application in much greater detail than simply through access to the application itself. One can also isolate the functions of particular systems within the application and determine where changes in the emission results are impacted by those functions. Without such access, by contrast, a result can be seen from a particular set of inputs, but there is no way to see what specific input is driving what portion of the result. Without the source code there is also little way to tell whether the GEM result matches the language in the NPRM or the CFR itself. [EPA-HQ-OAR-2014-0827-1199-A1 p.5]

Moreover, the GEM executable file, a key element of the compliance mechanism and therefore a key element of the rule, was issued with the NPRM. However, it has continued to evolve even during the comment period. A number of the concerns we express below seem only capable of being addressed through modifications to the GEM. EPA acknowledged during the comment period that there will several additional changes. Again, GEM is the mechanism for determining a vehicle’s emission level. As such it is probably the single most important aspect of this rulemaking. Despite that, it appears not to be fully ready and to be in the midst of development. GEM also has significant errors, which we will discuss more fully below, including to the baseline assumptions on which the proposed emission standards are built. Full access to the source code, from the first, with sufficient time to analyze, is what is required for a meaningful opportunity to comment. [EPA-HQ-OAR-2014-0827-1199-A1 p.5]

There are other examples where key elements of the Proposed Rule are not fully explained. For example, in the vocational vehicle standards the NPRM used a “normalization” process to change would be what the ordinary starting point, the 2017 standards by adjusting those standards according to a presumed vehicle population by broad use category. This element of the rule is not fully explained. It appears to Navistar to be largely arbitrary, although we cannot tell since there is no in-depth explanation of this normalization factor. Other elements of the vocational rule also appear to be in a fairly rudimentary state, as discussed more fully below. [EPA-HQ-OAR-2014-0827-1199-A1 p.5]

The opportunity to comment has to be meaningful. That is, it needs to be more than just a general awareness of the areas in which the agencies propose to regulate. The Proposed Rule is of such complexity, and carries such widespread ramifications for the industry, that we believe the burden of adequate notice and comment is increased commensurately and that EPA has met its burden in a number of areas in the Proposed Rule. [EPA-HQ-OAR-2014-0827-1199-A1 p.5]

In particular, we believe that GEM is a key portion of the Proposed Rule, and should be subject to notice and comment to the same extent as the language in the Code of Federal Regulations since it
directly sets the regulatory fuel efficiency (gallons per thousand ton-mile) level for the vehicle, which determines whether the vehicle is compliant or not. We do not think that adequate notice and comment procedures have been followed with regard to GEM because, among other reasons, the source code has not been posted for public comment or provided for each version of the executable GEM file. [NHTSA-2014-0132-0094-A1 p.3]

5 In fact, despite the notation in the NPRM, the normalization process is only briefly explained over the course of two pages. RIA at 2-116-17 and discussion below.

Organization:  Nissan North America, Inc.

The GHG and fuel efficiency programs for medium duty and heavy duty classes have been driven by collaboration between EPA, NHTSA, the California Air Resources Board (CARB), and Original Equipment Manufacturers (OEMs or vehicle manufacturers). [EPA-HQ-OAR-2014-0827-1026-A1 p.2]

Organization:  North American Die Casting Association (NADCA)

While NADCA believes the Administration did not provide sufficient time for the public to provide input given the length and scope of the proposal, the Association hereby submits these abbreviated comments on the die casting industry’s capabilities and role in improving efficiency performance. [EPA-HQ-OAR-2014-0827-1283-A1 p.1]

Organization:  Owner-Operator Independent Drivers Association (OOIDA)

As the representatives of our nation’s small business and independent truckers and professional truck drivers, the Owner Operator Independent Drivers Association (OOIDA) greatly appreciates the outreach which has been demonstrated leading up to the publishing of the Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles; Phase 2 Notice of Proposed Rulemaking (Phase 2 NPRM). The engagement from your agencies has been a significant increase from the Phase 1 process. [EPA-HQ-OAR-2014-0827-0738-A1 p.1]

OOIDA notes the decision by the EPA and NHTSA to extend the comment period for Phase 2 to September 17, 2015. This is an extremely complex proposal, and a longer comment period ensures that OOIDA and other stakeholders, as well as our membership of small business owners and professional truck drivers, has ample opportunity to review the proposal and comment. While extending the comment period 30 days beyond the last planned public meeting is a laudable decision, it does not adequately provide for sufficient time. [EPA-HQ-OAR-2014-0827-0738-A1 p.1]

OOIDA’s members are primarily small business owners and they collectively own and operate more than 200,000 individual heavy-duty trucks. They will be greatly impacted by this proposed rule along with the majority of truck owners. With 90 percent of carriers being comprised of six trucks or less this concern is substantial. As such we have the responsibility to thoroughly assess the over 2,000 pages of documents in order to produce adequate comments for the rulemaking. [EPA-HQ-OAR-2014-0827-0738-A1 p.1]

This entails a great deal of time in order to read the proposed rule, while continuing with our additional duties to our members. In addition we require the opportunity to compile our findings and share those
with our members, as well as time to elicit feedback from our members. OOIDA members consist of individuals who have very full schedules on a daily basis. To complete this process properly and provide useful feedback to the EPA we require sufficient time. Despite the 6 day extension to September 17, 2015 allotted for this proposed rule, additional time is necessary to ensure that all issues and aspects of EPA’s proposal are adequately understood. Given these concerns we respectfully request an additional 90 days for comment submission. [EPA-HQ-OAR-2014-0827-0738-A1 p.1]

OOIDA further understands that the agencies will be conducting two public hearings in regards to this proposal. One will be at the Palmer House Hilton Hotel, 17 East Monroe Street, Chicago, Illinois on August 6, 2015 and the second will be at the Westin Hotel Long Beach, 333 East Ocean Boulevard, Long Beach, California on August 18, 2015. [EPA-HQ-OAR-2014-0827-0738-A1 p.1]

We are concerned that the Chicago hearing provides limited opportunities for truck drivers to attend and participate given the significant restrictions on truck access and parking in downtown Chicago. Even legal and available truck parking outside the downtown core of Chicago does not provide easy access to public transportation. This was a similar concern raised by OOIDA during the Phase I process, where one of the three public hearings was held at a similar downtown Chicago hotel and the other two were held in Washington, DC and Cambridge, MA. Despite the fact that they were concernning a regulation impacting truck owners, none of these locations had nearby truck parking. [EPA-HQ-OAR-2014-0827-0738-A1 p.1-2]

OOIDA is hopeful that the proximity of the location for the Long Beach hearing to a convention center will allow for adequate truck parking for attendees. That said, OOIDA is concerned that by only holding two hearings in the downtown areas of major cities, the agencies will not have the benefit of hearing directly from the long-haul/over-the-road segment of the trucking industry. Long-haul truckers largely avoid traveling into downtown areas of cities due to restrictions on their vehicles, lack of parking, and a desire to limit exposure to the added accident risk that comes with congested urban areas. [EPA-HQ-OAR-2014-0827-0738-A1 p.2]

As such, we encourage the agencies to add a third public hearing at a location that is more focused on this segment of trucking. For instance, there are several large truck stops located throughout major freight corridors that would be able to accommodate a trucker-focused public hearing at a likely limited cost to the agencies. Or, if the agencies would prefer to conduct its hearings in downtown areas, conducting a hearing to coincide with the Great American Trucking Show (GATS) in Dallas, Texas should be considered. This event, which runs from August 26-30, 2015, already accommodates hundreds of trucks every year in downtown Dallas due to existing arrangements with the City and parking providers. In addition to thousands of truck drivers and fleet owners, others within the commercial vehicle industry will be in attendance. GATS is also host to the annual Commercial Vehicle Outlook Conference, another opportunity for the agencies to gain insight for a wide group of experts. [EPA-HQ-OAR-2014-0827-0738-A1 p.2]

Organization: PACCAR, Inc.

PACCAR recognizes that EPA and NHTSA have had ongoing discussions with the industry on some aspects of the proposed rule. PACCAR appreciates this opportunity to engage with the agency to identify the most appropriate way to craft and implement the Phase 2 standards. We further request the opportunity to comment on the record is provided for any provisions that the agencies intend to finalize that were not anticipated at the time of publication of the NPRM. [EPA-HQ-OAR-2014-0827-1204-A1 p.1]
The Open Rulemaking Process has Produced a Smarter Rule

SABIC commends the agencies for their open and collaborative approach to public input, and their receptivity to stakeholder suggestions. As the agencies note, more than 200 meetings took place with manufacturers, suppliers, trucking fleets, dealerships, state air quality agencies, non-governmental organizations (NGOs), and other stakeholders to understand the opportunities and challenges involved in Phase 2. SABIC was pleased to participate in this dialogue, both directly and through industry trade associations. We believe the agencies’ engagement with stakeholders has led to a proposal that better recognizes the mileage and emission benefits of lightweighting and aerodynamic technologies, thereby providing OEMs with cost-effective pathways to Phase 2 compliance. [EPA-HQ-OAR-2014-0827-1207-A1 p.2]

Organization: Truck & Engine Manufacturers Association (EMA)

- The agencies are still revising the GEM inputs for vocational vehicles, which means that GEM still is not suitable for assessing the Phase 2 vocational vehicle program. [EPA-HQ-OAR-2014-0827-1891-A1 p.3]
- Only on March 25, 2016, (just one week ago), did the agencies provide access to the necessary “baseline” vehicle data (including the baseline vehicles’ GHG technology packages and “default” fuel-efficiency percentage improvement values) that the agencies are using to model and derive the various Phase 2 vehicle stringency standards at issue. This last-minute disclosure of key GEM inputs has frustrated stakeholders’ ability to assess either the reasonableness of GEM or any GEM-based standards, which again raises fundamental issues under the APA and the CAA. [EPA-HQ-OAR-2014-0827-1891-A1 p.3]
- The agencies have indicated that they are still assessing and modifying the duty cycles and weighting factors that will apply to the different categories of Heavy-Duty On-Highway (“HDOH”) vehicles. That continuing uncertainty regarding fundamental elements of the rulemaking package frustrates the ability to meaningfully assess the feasibility or reasonableness of the Proposed Phase 2 Standards. [EPA-HQ-OAR-2014-0827-1891-A1 p.3]
- The 30-day comment period for the NODA is not sufficient to conduct any fair evaluation of the revised GEM, especially when GEM is not yet suitable for use in any comprehensive assessment of vocational vehicles. [EPA-HQ-OAR-2014-0827-1891-A1 p.3]
- The assumption that manufacturers can reasonably assess the stringency and feasibility of the Proposed Phase 2 Vehicle Standards when GEM is still undergoing development, when the vocational vehicle subcategories and standards are still subject to ongoing baseline assessment and “normalization,” and when the aerodynamic and compliance test procedures are ill-defined, is fundamentally unreasonable and inconsistent with administrative due process. [EPA-HQ-OAR-2014-0827-1269-A1 p.72]

• The 30-day comment period for the NODA is not sufficient to conduct any fair evaluation of the revised GEM, especially when GEM is not yet suitable for use in any comprehensive assessment of vocational vehicles. [EPA-HQ-OAR-2014-0827-1891-A1 p.3]

Organization: Truck & Engine Manufacturers Association (EMA)

Conclusion
EMA appreciates the agencies’ publication of the NODA and its associated information. Nevertheless, basic information gaps still remain that go to the core of the feasibility and cost effectiveness of the Proposed Phase 2 Vehicle Standards. EMA urges the agencies to disclose that necessary information promptly to facilitate a fair and proper rulemaking process. [EPA-HQ-OAR-2014-0827-1891-A1 p.5]

**Organization:** Truck Trailer Manufacturers Association (TTMA)

TTMA values this opportunity to comment on the Proposal and appreciates that the EPA and NHTSA have been consulting with us while they were initially considering this proposal. Further, we appreciate that as the rule took shape, staffers from EPA and NHTSA took time to share with us the directions they thought the agencies would go with this rulemaking, such as they could. [EPA-HQ-OAR-2014-0827-0727-A1 p.1]

However, the details, which could not be shared ahead of publication, are critical to evaluating this proposal. This rulemaking is exceptionally involved for the truck trailer industry, which is both smaller in total and composed of many smaller entities catering to a much higher degree of specialization and customization than for the entities covered under Phase 1 of these regulations. The Proposal not only seeks to bring our entire industry under new regulation, but asks us to consider alternative phase-in periods. [EPA-HQ-OAR-2014-0827-0727-A1 p.1-2]

The EPA & NHTSA seem to have had dedicated teams working on crafting this rule for approximately 16 months. TTMA member companies have been given only 60 days (plus the short time the rule was released in its signed pre-publication form) to both read and comment on the proposal. While TTMA and its member companies have placed an exceptionally high priority on comprehending this proposal and have vigorously worked with EPA & NHTSA representatives to gain understanding, the time provided is simply too short for us to adequately review and comment on the multitude of claims and proposals in the docket as well as consider the full set of implications of being subject to regulation by an agency we have never worked with before. [EPA-HQ-OAR-2014-0827-0727-A1 p.2]

In light of this, TTMA would like to officially request a 90 day minimum, and ideally 6 month, extension of the September 11, 2015 deadline for comments. This extension will allow TTMA to respond properly to the regulations that EPA & NHTSA are proposing. [EPA-HQ-OAR-2014-0827-0727-A1 p.2]

As always, TTMA looks forward to working with both EPA & NHTSA to help craft the best and most appropriate regulations for the industry. Please contact TTMA with any concerns. [EPA-HQ-OAR-2014-0827-0727-A1 p.2]

The Truck Trailer Manufacturers Association (TTMA) has petitioned EPA to extend the comment period beyond September 11, 2015. Strick Trailers, LLC is a member of the TTMA. Strick Trailers, LLC is in full support of the petition to request a 90 day minimum, and ideally 6 months, extension of the September 11, 2015 deadline for comments. [EPA-HQ-OAR-2014-0827-0742 p.1]

We also had asked for a longer time to pursue a more detailed evaluation of the proposal. TTMA is an organization of trailer manufacturing companies and we rely on voluntary participation of our member companies. As the agencies admit, a large proportion of these member companies are small manufacturers and as such, lack the time and resources to detail to such a long and complicated proposal. We had asked for a 90 – 180 day extension to allow those small manufacturers to adequately be brought up to speed and provide specifics to our commentary, but were granted only a 14 day extension. We will continue to pursue a dialog with the agencies past the October 1st, 2015 deadline and
encourage the agencies to reach out to us as they have been doing so that we can work together to craft the best possible solutions. [EPA-HQ-OAR-2014-0827-1172-A1 p.2]

**Organization:** United Parcel Service (UPS)

While our company fully supports the objectives of increased fuel efficiency and reduced carbon emissions in our trucks, we also believe that this Phase II rulemaking is too important and too complex to shortchange the time for public comment. The subject is, simply put, too important to get wrong the first time. We have studied the thousands of pages involved in this rulemaking and conferred on the proposed regulations with other affected stakeholders in our industry. Frankly, we are dependent on our suppliers to understand the proposed regulations and prepare themselves to provide compliant trucks and equipment. Nevertheless, UPS will make every effort to file on time, but we would feel much more comfortable that we understand the issues raised in this docket, if we had more time. [EPA-HQ-OAR-2014-0827-1262-A1 p.1]

While a few select stakeholders have established teams to read and analyze the Proposed Rule and the thousands of pages of technical support documents and complex modelling formulations, few throughout the industry have been able to fully review and evaluate how Phase 2 will impact their operations and business plans. This especially holds true for most trucking fleets. ATA and other impacted stakeholders are currently dialoguing, conducting surveys, and gathering data to further assess and develop a sound and achievable regulation that will not result in market disruptions or unattainable goals. [EPA-HQ-OAR-2014-0827-1262-A1 p.2]

Given that fuel is one of the top operating expenses for trucking companies, ATA supports the aims of improving fuel efficiency and reducing the industry’s carbon footprint. However, ATA and its diverse membership seeks additional time to complete its reading to fully understanding this extremely complex and far-reaching rule which will directly impact and transform fleet operations for decades to come. Moving ahead, ATA looks forward to continued cooperative efforts with both EPA and NHTSA in crafting a rule that is both technologically and economically achievable. [EPA-HQ-OAR-2014-0827-1262-A1 p.2]

**Organization:** Volvo Group

We are, however, deeply concerned that the proposed rule is seriously flawed in both process and substance. First, we note that major parts of the proposal are incomplete, undecided, or subject to ongoing changes such that it is impossible to make any reasonable assessment of the true stringency of the proposal or the relative merits of various technology packages to meet the proposed targets. An adequate and firm proposal is lacking for vehicle duty cycles, aerodynamic testing, engine fuel mapping, vocational vehicle standards, vocational vehicle segmentation, powertrain testing, and the vehicle simulation software (GEM). Individually and collectively, this undermines the agencies’ responsibility to provide appropriate notice, allowing for informed and effective comments. EPA is required to provide, in its notice of a proposed rulemaking, information that is sufficient to allow the public a reasonable opportunity to participate in the rulemaking process. To participate meaningfully, interested parties must have a complete and settled picture of what the Agency is proposing. In light of the substantial elements of the proposal that remain either incomplete, unsettled or both, it simply
cannot be said that Volvo Group and other interested parties have had a reasonable opportunity to provide fully informed input into the rulemaking process. [EPA-HQ-OAR-2014-0827-1290-A1 p.10]

[Table, 'Protocol Impacts on Tractor Stringency', can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1290-A1]

While these issues all result in underestimating the rule’s true stringency, the proposed rule also overestimates the potential penetration levels of many efficiency technologies used to set the standards. The agencies have attempted to determine appropriate market acceptance rates (apparently without any market studies) for the various technologies deemed as feasible up through 2027 model year. In so doing, they have predicated the standards on some technologies that have not even been demonstrated as feasible such as stop/start for HHD engines, aerodynamic drag reduction levels, “deep integration,” and waste heat recovery; on penetration rates that are infeasible due to legal impediments such as 6x2 axles; or technologies that do not meet significant market requirements such as the low rolling resistance tire targets. [EPA-HQ-OAR-2014-0827-1290-A1 p.11]

Taken together, these substantial issues result in a proposed rule that is inadequately defined, incomplete, and technically infeasible. As noted, the proposal does not provide adequate notice to interested parties to allow for meaningful comment. Further, the agencies have not satisfied their obligation to identify support for and explain the factual basis for the proposal. These issues must be corrected and changes clearly communicated for additional review and comment before issuing a final rule. [EPA-HQ-OAR-2014-0827-1290-A1 p.11]

The Agencies’ Regulatory Proposal is Incomplete and Inadequate

The Volvo Group has spent many hours analyzing the content of the proposal, and worked with industry colleagues to identify issues, present feedback, and propose corrective measures to the agencies. Although we have undertaken considerable effort to study the NPRM, we remain concerned that, with a regulation of this size and complexity, there may remain many potential problems that we have not identified; some of which may only surface upon full implementation. Because of the strong financial impact of fuel efficiency on commercial fleet operations, the actual results of efficiency regulation will be closely measured and monitored by fleet owners. If the required technologies do not deliver expected fuel savings at affordable total cost, or result in excessive maintenance and down-time, fleets will not purchase vehicles. Instead, they will repair and rebuild their existing vehicles as they have increasingly done, due to costs and operational problems from recent emissions technologies. Thus, it is important that the regulation deliver the expected in-use performance. Given the complexity and potential for unintended consequences, it is essential that this rule is carefully considered and reviewed by industry and other experts, and that this detailed feedback be incorporated into the rulemaking. [EPA-HQ-OAR-2014-0827-1290-A1 p.12-13]

Although the agencies sought stakeholder inputs and provided some preliminary information prior to the issuance of the NPRM, these discussions have primarily focused on technology and efficiencies. Manufacturers have only gained visibility to many fundamental processes and test procedures, certification and audit protocols, and many more details since the release of the NPRM. Far too many of these details remain unclear, are still under development, or are even being reconsidered for totally new approaches barely mentioned in the NPRM. These include: the segmentation, duty cycles, and targets for vocational vehicles; duty cycle grades for tractors; method of engine efficiency mapping; the functionality of the GEM simulation model; the process for aerodynamic testing and analysis; and many more. With respect to these components of the rule, it is simply not possible for Volvo Group to conduct
the analysis necessary to provide meaningful input into the rulemaking process, which it is entitled to do. [EPA-HQ-OAR-2014-0827-1290-A1 p.13]

With major parts of the proposal still in flux and the overwhelming complexity of the rule itself, it is impossible to do a thorough evaluation, and likewise impossible to perform a thorough assessment of the underlying stringency. In addition, we assert that insufficient notice is provided when significant parts of the NPRM are modified through obscure and unclear memos to the docket (currently populated with more than 700 documents designated as “supportive,” many of which are not clearly delineated in the proposal). Given this, it is appropriate and necessary for the agencies to consider the comments submitted to the NPRM, improve the certification protocols accordingly, and by some formal mechanism, make the modified regulatory text, revised GEM simulation, and associated stringency proposals available for review by stakeholders. Stakeholders must be given opportunity to comment on these revisions. [EPA-HQ-OAR-2014-0827-1290-A1 p.13]

Volvo Group and its subsidiary companies in the U.S. appreciate the opportunity to comment on this Notice of Proposed Rulemaking for the Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles - Phase 2. Recognizing the need for sustainability of commercial transportation systems, we share a common goal to mitigate petroleum demand and reduce greenhouse gas emissions. We have been working proactively with EPA and NHTSA to develop these regulations, and we will continue to do so as the agencies work to finalize this important regulation. While we have attempted to conduct a thorough evaluation, the size and complexity of the proposal and supporting documentation virtually ensures that new issues will continue to surface. We will continue to work with the agencies to resolve the existing issues and any new issues. Given the cost and impact of this regulation, the agencies should take the time necessary to appropriately resolve these issues, rather than conform to an arbitrary time schedule. The Volvo Group remains committed to expend the resources necessary to ensure that the Phase 2 regulation drives significant real world efficiency gains and dramatic reductions in greenhouse gas emissions, in support of shared national goals to advance energy independence and stem the tide of climate change. It is our sincere hope to be able to support the final rule, but we can only do so if the significant issues that we have raised are addressed. [EPA-HQ-OAR-2014-0827-1290-A1 p.81]

2 See Motor Vehicle Manufacturers Ass’n v. State Farm Mutual Automobile Ins. Co. et al, 463 U.S.29, 43 (1983) (citation omitted). (Agencies are obligated to “examine the relevant data and articulate a satisfactory explanation for its action including a ‘rational connection between the facts found and the choice made.’”)

Given the broad scope of issues Volvo and other stakeholders raised in comments to the NPRM, we find the NoDA to be disappointingly limited in scope. The Agency action to issue a NoDA should have been used to rectify and clarify far more of the provisions set forth in the NPRM, so as to enable manufacturers to evaluate their ability to comply with the regulation. Without this needed clarity, manufacturers are still working with incomplete, unclear or undefined processes in many areas, and with unknown stringency targets. This is further complicated by not having a clear view of how the agencies will accommodate the additional stringency imposed by protocol and common certification and enforcement practices such as Selective Enforcement Audits that fundamentally force manufacturers to over-comply with the stated efficiency targets. (We recognize that a significant measure of this effect will be reduced by the modifications foreseen in the Final Rule). This continued uncertainty not only frustrates our ability to put into place the proper technology development and product planning to meet the requirements of the rule with any level of confidence, but more urgently precludes any opportunity to give timely feedback to the agencies as to our ability to comply, or any needed re-balancing of

Page 2017 of 2127
stringency demands among product segments before the rule is finalized. [EPA-HQ-OAR-2014-0827-1928-A1 p.2]

Since that time, we have understood that the agencies have worked to address many of the issues Volvo noted; however, there are several important issues that remain unresolved. More importantly, very few of the concerns raised by Volvo and other stakeholders were addressed within the NoDA release. The agencies should have used this opportunity to publically communicate many more significant revisions to the NPRM, so as to provide stakeholders the opportunity to review and submit comments, consistent with the requirements of the Administrative Procedures Act. Failing this, the following items from the Volvo Group’s NPRM comments are still of concern (listed by page number for the Volvo Group’s comments to the NPRM). We will continue submitting data, information, and recommendations to EPA and NHTSA, to the best of our ability, to support the goal that the agencies finalize a rule that meets the aforementioned prerequisites, providing real-world emissions reductions with substantive cost of ownership reductions for vehicle owners. [EPA-HQ-OAR-2014-0827-1928-A1 p.6]

**Organization:** Waste Management (WM)

Before discussing our views on particular aspects of the proposal, we want to commend the management and staff of the Office of Transportation and Air Quality (OTAQ) and the NHTSA Fuel Economy Division for the very collaborative process they used to develop this proposal.

**Organization:** Werner Enterprises

Werner respectfully requests the EPA and NHTSA to extend the comment period by providing an additional 60 days for public review and input. [EPA-HQ-OAR-2014-0827-1236-A1 p.1]

However, Werner respectfully requests the EPA and NHTSA to extend the comment period by providing an additional 60 days for public review and input, as we need more time to evaluate how Phase 2 will impact our operations and business plans. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

This rule will have a significant effect on Werner’s business operations, our employees, and our professional drivers, and must be evaluated carefully. Werner urges the agencies to extend the comment period, as it does not currently provide an adequate amount of time to review and respond to the complexity of the proposed rule. By extending the rulemaking process a minimum of 60 days it will allow Werner additional time to review the significant effect the rule will have on our company and evaluate the difficult decisions to be made to ensure compliance with the proposed rule. [EPA-HQ-OAR-2014-0827-1236-A1 p.3]

**Organization:** XL Specialized Trailers

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 202-203.]

XL Specialized Trailers is officially requesting a 90-day minimum, ideally six-month extension to the now September 17th, 2015 deadline for comments period. TTMA has petitioned EPA to extend the comment period beyond that original date of September 11th, 2015, and as a member, XL Specialized Trailers is in full support of this petition.
Response:

Many commenters thanked the agencies for their continued efforts to collaborate with and collect feedback from stakeholders and the public. We appreciate these comments, as the agencies have been committed to meaningful collaboration throughout the rulemaking process. During the development of this Phase 2 program, the agencies held over 400 meetings to gather input, data and views from heavy-duty vehicle and engine manufacturers, technology suppliers, trucking fleets, truck drivers, dealerships, environmental organizations, and state agencies (as documented in the extensive Stakeholder Meeting Log and in specific meeting memos found in the rulemaking dockets: EPA–HQ–OAR–2014–0827; NHTSA–2014–0132). The NPRM was posted on the agencies’ websites on June 19, 2015. Following publication of the NPRM in the Federal Register on July 13, 2015, the agencies held two public hearings, one in Chicago, IL on August 6, 2015 and one in Long Beach, CA on August 18, 2015. The comment period for the proposed rules was to end on September 17, 2015. The DEIS was published to a NHTSA Docket on June 19, 2015, and the comment period for that document was to end on August 31, 2015. In response to comments above calling for an extension of the public comment period, the agencies extended the original comment period for both the NPRM and the DEIS to October 1, 2015. Some commenters requested an additional extension of the comment period, citing reasons such as the length and complexity of the rule. However, we find that with the early notice of the Phase 2 proposal by posting it on the agencies’ websites upon signature, the two public hearings, the granted extension of the comment period, our considerable stakeholder outreach effort (documented in the Stakeholder Meeting Log and specific meeting memos, see above), and our consideration of late comments (see the Introduction to this RTC document), stakeholders and the public have indeed had notice and comment of all issues and have had adequate amount of time to review and provide meaningful comment on the proposal; further, the agencies have gone beyond the procedural steps required by law to promote transparency and public participation. Finally, in the spirit of our commitment to meaningful collaboration with stakeholders and the public, we are also addressing comments received after the comment periods were closed to the extent that they were received in time to include in this document.

With respect to the comments raising claims of inadequate notice, the agencies have met all legal notice and comment requirements through Federal Register notices for the NPRM and DEIS, a Notice of Data Availability (NODA) pointing to information in the public docket obtained after the proposal, and through specific outreach to affected stakeholders as documented in the Heavy-Duty Stakeholder Meeting Log and specific meeting memos in the rulemaking dockets (Dockets: EPA–HQ–OAR–2014–0827, NHTSA–2014–0132; examples of specific memos: “Record of Webinar on Vocational Custom Chassis” (EPA-HQ-OAR-2014-0827-1944), “Summary of Meetings and Conference Calls with the Truck and Engine Manufacturers Association to Discuss the Phase 2 Heavy-Duty GHG Rulemaking,” “Summary of Meetings and Conference Calls with Allison Transmission to Discuss the Phase 2 Heavy-Duty GHG Rulemaking”). We disagree with comments, such as those from Volvo, that suggest the proposed rules were incomplete and therefore inadequate. At the time of the proposal, the agencies clearly laid out a comprehensive program that allowed stakeholders and the public to provide meaningful comment. The agencies’ requests for comment on specific aspects of the program should not be confused with uncertainty about the program or about standard stringencies; rather, these requests were made to encourage stakeholder feedback (especially in areas where they had not communicated their concerns to us previously). The Heavy-Duty Stakeholder Meeting Log and memos recording specific stakeholder meetings (e.g., Record of Webinar on Vocational Custom Chassis” (EPA-HQ-OAR-2014-0827-1944), “Summary of Meetings and Conference Calls with the Truck and Engine Manufacturers Association to Discuss the Phase 2 Heavy-Duty GHG Rulemaking,” “Summary of Meetings and Conference Calls with Allison Transmission to Discuss the Phase 2 Heavy-Duty GHG Rulemaking”) demonstrate that the development of the Phase 2 was an iterative process, with the agencies considering stakeholder and public concerns well beyond the public comment period for the proposal, through meetings, phone calls, and an additional public comment period on information in the
public docket obtained after the proposal (the NODA). The meeting log and stakeholder meeting memos can be found in the rulemaking dockets (EPA–HQ–OAR–2014–0827; NHTSA–2014–0132). Where commenters have pointed to notice and comment issues about detailed aspects of the program or the GEM vehicle simulation model, we respond to those comments in earlier sections of this RTC (e.g., see Section 6.2.3 for comments on the custom chassis part of the vocational vehicle program, and Section 2 for comments on GEM), and as a whole below.

**Engines in GEM Changes**

Some commenters maintain that they did not receive sufficient notice to provide informed comment on the GEM. The agencies disagree. As described in the Section II.C of the Preamble, the agencies have provided numerous opportunities for comment on GEM, and its iterative development.

Shortly after the Phase 2 proposal’s publication in July 2015 (and before the end of the public comment period), the agencies received comments on GEM. Based on these early comments, the agencies made minor revisions to fix a few bugs in GEM software and in August 2015 released an updated version of GEM to the public for additional comment, which also included new information on GEM road grade profiles. The agencies also extended the public comment period on the proposal, which provided at least 30 days for public comment on this slightly updated version of GEM. Then, in response to comments submitted at the close of the comment period, in early January 2016 the agencies released a “debugging” version of GEM to a wide range of expert reviewers. The agencies provided one month for expert reviewers to provide informal feedback for debugging purposes. Because the changes for this debugging version mostly added new features to make GEM easier to use for certifying via optional test procedures, like the powertrain test, there were only minor changes to the way that GEM performed. In the March 2016 NODA, the agencies included another developmental version of GEM for public comment and provided 30 days for public comment. Based on the NREL report, which was also released as part of the NODA for public comment, the NODA version of GEM contained updated weighting factors of the duty cycles and idle cycles. Therefore, the outputs of GEM for a given vehicle configuration changed because these duty cycle weighting factors changed, but there were only minor updates to how the individual technologies were simulated in GEM. Based on comments received on the NODA, the agencies made minor changes to GEM and released another debugging version in May 2016 to manufacturers, NGOs, suppliers, and CARB staff. This change to GEM for the May 2016 version was that 0.5 miles of flat road was added to the beginning and end of the 55 mph and 65 mph drive cycles in response to concerns raised by manufacturers.

---

274 See EPA’s web site at http://www3.epa.gov/otaq/climate/gem.htm for the Phase 1 GEM revision dated May 2013, made to accommodate a revision to 49 CFR 535.6(b)(3).

275 See EPA’s web site at http://www3.epa.gov/otaq/climate/gem.htm for the Phase 1 GEM revision dated May 2013, made to accommodate a revision to 49 CFR 535.6(b)(3).

279 Memo to Docket, “Summary of Meetings and Conference Calls with the Truck and Engine Manufacturers Association to Discuss the Phase 2 Heavy-Duty GHG Rulemaking,” August 2016.
change did not change the way that GEM worked, but it did change GEM results because of the change in the duty cycles. This change was made to better align GEM simulation with real-world engine operation. The agencies provided the expert reviewers with at least a 3-week period in which to review GEM and provide feedback. Details on the history of the comments the agencies received and the history of the agencies responses leading to these multiple releases of GEM can be found in Section II.C.(1). The following list summarizes the changes in GEM in response to those comments and data submitted to the agencies in response to the Phase 2 proposal, NODA and other GEM releases:

- Revised road grade profiles for 55- and 65-mph cruise cycles, only minor changes since August 2015.
- Revised idle cycles for vocational vehicles with new vocational cycle weightings, weightings released for public comment in NODA.
- Made changes to the input file structures. Examples includes additions of columns for axle configuration (“6x2,” “6x4,” “6x4D,” “4x2”), and additions of a few more technology improvement inputs, such as “Neutral Idle,” “Start/Stop,” and “Automatic Engine Shutdown.” These were minor changes, all were in NODA version of GEM.
- Made changes to the output file structures. Examples include an option to allow the user to select an output of detailed results on average speed, average work at the input and output of the transmission, and the numbers of shifts for each cycle (e.g., 55 mph cycle, 65 mph cycle and the ARB Transient cycle). These were minor changes, all were in NODA version of GEM.
- Added an input file for optional axle power losses (function of axle output speed and torque) and replaced a single axle efficiency value with lookup table of power loss. These were minor changes to streamline the use of GEM, all were in NODA version of GEM.
- Modified engine torque response to be more realistic, with a fast response region scaled by engine displacement, and a slower torque response in the turbo-charger’s highly boosted region. These were minor changes, all were in NODA version of GEM.
- Added least-squares regression models to interpret cycle-average fuel maps for all cycles. These were minor changes to streamline the use of GEM, all were in NODA version of GEM.
- Added different fuel properties according to 40 CFR 1036.530. This was a fix to align GEM with regulations.
- Improved shift strategy based on testing data and comments received. These were minor changes, all were in NODA version of GEM.
- Added scaling factors for transmission loss and inertia, per regulatory subcategory. These were minor changes, all were in NODA version of GEM.
- Added optional input table for transmission power loss data. These were minor changes to streamline the use of GEM, all were in NODA version of GEM.
- Added minimum torque converter lock-up gear user input for automatic transmissions. This was a minor change to streamline the use of GEM, this change was in the NODA version of GEM.
- Revisited the default transmission power loss tables, based on test data. This was a minor change to streamline the use of GEM, this change was in the NODA version of GEM.
- Added neutral idle and start/stop effects idle portions of the ARB Transient cycle. These were minor changes, all were in NODA version of GEM
- Adjusted shift and torque converter lockup strategy. This was a minor change to streamline the use of GEM, this change was in the NODA version of GEM.

Notwithstanding these numerous opportunities for public comment (as well as many informal opportunities via individual meetings), some commenters maintained that they still had not received
sufficient notice to provide informed comment because each proposal represented too much of a “moving target.” The agencies disagree. Even at proposal, Phase 2 GEM provided nearly all of the essential features of the version we are promulgating in final form. These include: (1) the reconfiguration of the engine, transmission, and axle sub-models to reflect additional designs and to receive manufacturer inputs; and (2) the addition of road grade and idle cycles for vocational vehicles, along with revised weighting factors. Moreover, the changes the agencies have made to GEM in response to public comment indicates that those comments were highly informed by the proposal. The agencies thus do not accept the contention that commenters were not afforded sufficient information to provide meaningful comment on GEM.

Custom Chassis Vocational Vehicles

In their comments on the scope of the NODA, Volvo and Autocar specifically express concerns about the opportunity for notice and comment with respect to the vocational vehicle program. We disagree with these commenters that adequate notice and comment was not given. Besides the proposal and other notices published in the Federal Register, the agencies conducted timely outreach to affected stakeholders during the deliberative phase of this rulemaking, to share interim information about program revisions being considered in response to the initial round of public comments, conducting a web conference on March 22, 2016 for chassis manufacturers (EPA–HQ–OAR–2014–0827–1944) and many face-to-face meetings and telephone conferences as documented in the Heavy-Duty Stakeholder Meeting Log in the rulemaking dockets (EPA–HQ–OAR–2014–0827; NHTSA–2014–0132). Please see Section 6 of this RTC for further discussion of comments received expressing specific concerns with the custom chassis program (which, among other things, indicate the adequacy of notice provided, given the detailed and pertinent range of the comments in response).

Selective Enforcement Audits and Confirmatory Testing

As part of the NODA, EPA placed into the docket a memorandum providing additional discussion of SEAs and confirmatory testing with respect to aerodynamic testing for both tractors and trailers. This memorandum discussed key principles behind such testing and included draft regulatory text detailing a potential SEA structure for tractors. EPA made this available to the public in response to comments asking for more detail about how SEAs for aerodynamics would be conducted. NODA comments supported both the general principles and the specific regulatory text. EPA has finalized changes consistent with both this memorandum and these comments.

In response to comments from engine and vehicle manufacturers, EPA is also making changes to the regulations for SEAs and confirmatory testing with respect to engine fuel maps and other GEM inputs. These were discussed with manufacturers during meetings between EPA and the manufacturers to discuss compliance issues after the NPRM.

282 “Heavy-Duty Phase 2 Stakeholder Meeting Log,” August 2016.
284 Memo to Docket, “Summary of Meetings and Conference Calls with the Truck and Engine Manufacturers Association to Discuss the Phase 2 Heavy-Duty GHG Rulemaking,” August 2016.
We disagree with the EMA comment that it is “fundamentally unreasonable and inconsistent with administrative due process” to expect manufacturers to “reasonably assess the stringency and feasibility of the Proposed Phase 2 Vehicle Standards” when parts of the rule are still being revised. First, it is a legal commonplace that an agency may issue a final rule that does not coincide with a proposed rule as long as the final rule is a “logical outgrowth” of the proposed rule. Otherwise, a comment period would become a perpetual exercise, with every change occasioning a new comment period. See, e.g., Small Ref. Lead Phase-Down Task Force v. EPA, 705 F. 2d 506, 546-47 (D.C. Cir. 1983); Fertilizer Inst. v. EPA, 935 F. 2d 1303, 1311 (D.C. Cir. 1991); Conn. Light and Power Co. v. NRC, 673 F. 2d 535, 533 (D.C. Cir. 1982). Second, notice and comment obligations are fully satisfied when a commenter has actual notice. Small Ref. Lead-Phase Down, 705 F. 2d at 548, 549. Under section 307 (d) of the Clean Air Act (and section 553 (c) of the APA), the purpose of the public comment period is to give interested persons an opportunity to participate in the rule making through submission of written data, views, or arguments and to give affected parties an opportunity to develop evidence in the record to support their objections to a rule. See, e.g. Small Ref. Lead Phase-Down, 705 F. 2d at 547. All stakeholders had such an opportunity, and could reasonably anticipate not only the issues at stake, but also the contents of the final rule. See, e.g., Anne Arundel County v. EPA, 963 F. 2d 412, 418 (D.C. Cir. 1992); Am. Med. Ass’n v. United States, 887 F. 2d 760, 768 (7th Cir. 1989). Indeed, the agencies did not limit the manufacturers’ input to that provided within the two formal public comment periods. The agencies held numerous meetings and conference calls with the manufacturers until very late in the process. Clearly, throughout this rulemaking, manufacturers had ample opportunity to provide written data, views, and arguments on each area of the rulemaking.

We received comments from the motorcoach industry claiming that the agencies did not “engage with motorcoach manufacturers or the motorcoach industry, in any meaningful way.” This comment was made during the public comment period, when the agencies were in fact collecting feedback from all stakeholders. We note also that the list of stakeholder outreach we mention in the Preamble to the rulemaking is not meant to be comprehensive, but rather is as an example of all the types of stakeholders included. The complete list of stakeholders and our documented outreach can be found in the Stakeholder Meeting Log in the rulemaking dockets (EPA–HQ–OAR–2014–0827; NHTSA–2014–0132). Documented as part of the list are numerous meetings, phone calls, and conversations that the agencies have had with representatives of the motorcoach industry. As detailed in Section 6 of this RTC document, we have carefully considered the motorcoach industry’s comments and in response to their concerns we are adopting optional standards for seven applications of vocational vehicles, including motorcoaches, that we are calling custom chassis.

We received several comments with respect to the scope of the agencies’ release of a NODA, which called for public comment on information in the public docket obtained after the proposal. Some commenters felt that the scope was too limited. The purpose of a NODA is to provide an opportunity for stakeholders and the public to comment on new information being made available by the EPA and by NHTSA; it did not serve as means to make policy changes to the proposal. In fact, what the commenters are requesting by broadening the scope of the NODA would be a Supplemental Notice of Proposed Rulemaking, which is not needed because the agencies have provided ample notice and comment on all aspects of the rules and, after considering stakeholder feedback and public comments, have made changes that are logical outgrowths of the proposal and, in many instances, reflect determinations of which stakeholders had direct notice. We discuss how we have met our notice and comment obligations as part of this response above, and with respect to specific aspects of the program

285 Se emails with ABC Companies and CH Bus Sales/Temsa between September 2015 and April 2016; See also phone log for August 2015 call with MCI.
throughout this RTC. On the issue of the NODA, Autocar comments include a request for extension of the NODA comment period. We find the 30 days given as sufficient time for stakeholders and the public to review and provide meaningful comment, as we requested comment on only the following 10 items: powertrain data; additional aerodynamic test data; supplemental data relating to drive cycles for vocational vehicles; cycle average mapping data; certain revised test reports; a revised version of GEM; default gasoline engine fuel maps for GEM; a memorandum addressing potential requirements for selective enforcement audits and confirmatory testing related to greenhouse gas emissions; a memorandum addressing the applicability of emission standards and certification responsibilities for trailers, glider vehicles, and glider kits; and a late comment related to light-duty motor vehicles used for racing. Many other commenters provided detailed, exacting comments addressing these items. Moreover, the agencies further engaged with Autocar on the concerns expressed in their NODA comments, including multiple meetings and telephone calls as documented in the Stakeholder Meeting Log in the rulemaking docket, and the final program addresses their detailed issues as described further in Section 6 of this RTC.\textsuperscript{286}

In their comments, OOIDA encouraged the agencies to add a third public hearing at a location more focused on their representative segment of trucking, or to conduct a hearing to coincide with the Great American Trucking Show (GATS) in Dallas, Texas. The agencies accommodated this request by sending a representative to the GATS event to hear specifically from truck drivers and fleet owners; however, few of these stakeholders attended the meeting.

### 15.6 Mid-term Review

2024

**Organization:** American Iron and Steel Institute

An additional or alternative option would be for EPA and NHTSA to incorporate a 'mid-term evaluation' provision such as that incorporated in the MY 2017-2025 LDV rule. [EPA-HQ-OAR-2014-0827-1275-A1 p.19]

**Organization:** American Trucking Associations (ATA)

#### A Contingent Mid-Course Review Should be Incorporated into the Final Rule

Regulating heavy-duty vehicles is far more complex than that of light-duty vehicles. As such, it is imperative upon the agencies to ensure the multiple fuel efficiency milestones set out for trailers, engines, and vehicles under Phase 2 proceed in an achievable and orderly manner. ATA therefore strongly urges the agencies to undertake a mid-course review during the implementation process if warranted. [EPA-HQ-OAR-2014-0827-1243-A1 p.26]

Mid-course reviews are not unfamiliar to the agencies. EPA and NHTSA endorsed a mid-course review process under the Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards for MY 2017-2025. Such a review can determine whether the multiple standards remain appropriate in light of technological and other changes that may have occurred since the time of proposal. A mid-course evaluation, if necessary, would include consideration of the state of technology development, technology and fuel costs, market penetration rates, national harmonization of standards, the state of the national economy and the trucking industry, safety considerations, impacts of superseding regulatory or legislative activities, other factors considered by the agencies in setting the

\textsuperscript{286} See Emails between EPA and Autocar from August 2015 to June 2016.
standards, and the expected impact of those factors on the OEMs ability to comply. [EPA-HQ-OAR-2014-0827-1243-A1 p.26]

Of critical importance are the event or events that would trigger such a review. One such trigger would be finalizing any new state and/or federal NOx or PM emission standards for medium and heavy-duty engines and vehicles during the implementation period under Phase 2. Additional standards triggering an evaluation would include state-specific deviations from Phase 2; widespread OEM non-compliance due to impossibility (including agency miscalculations in technology market penetration rates, equipment cost estimates, economic factors, and other matters resulting in the agencies not achieving their respective GHG and fuel efficiency goals and objectives as set out under the final rule). [EPA-HQ-OAR-2014-0827-1243-A1 p.26-27]

If triggered, a mid-course review should be pursued as expeditiously as possible while ensuring any modifications to the standards enacted by the final rule are consistent with the lead time and stability requirements of the Clean Air Act (42 USC §7521(a)(3)(C)). Using the Light-Duty Rule as a guide, EPA and NHTSA should prepare and publish a draft Technical Assessment Report that should be peer-reviewed and made available for public comment. The agencies should also solicit comments on whether the standards and specific targets are being achieved. If the agencies conclude that the standards are not being achieved or likely will not be achieved due to some triggering effect, the agencies will initiate a rulemaking to revise the original standards, as appropriate under Section 202(a), and issue a joint rulemaking at least 18 months prior to the beginning of the next full model years of regulated equipment [EPA-HQ-OAR-2014-0827-1243-A1 p.27]

A mid-course review is more than just appropriate; it is a critical component of this rulemaking package if these standards are to be successful. Phase 2 will govern vehicle production 12 years from now and beyond, a particularly long time period when predicting the state of technology development, equipment costs and durability, maintenance issues, driver satisfaction, fuel pricing and consumption levels, consumer behaviors, the state of the economy and the trucking industry, other state and federal regulatory and legislative requirements, and future equipment build rates. As we are just beginning implementation under Phase 1, the trucking industry is now tasked with assessing potential impacts and feasibility under Phase 2, along with the real possibility of a Phase 2 conflict that will likely occur as a result of CARBs upcoming revisions to its truck GHG efforts. [EPA-HQ-OAR-2014-0827-1243-A1 p.27]

The Phase 2 effort and expense will further our country’s energy and environmental goals, but only if fleets choose to purchase these fuel-efficient, climate-friendly vehicle technologies. Any mid-course evaluation will allow the agencies to determine whether the standards are in fact achievable and make appropriate changes to ensure that progress in reducing GHGs and saving fuel will proceed based upon the multitude of factors that can impact the original targets established in 2016. [EPA-HQ-OAR-2014-0827-1243-A1 p.27]

Organization:  Great Dane

We believe that careful consideration and review of the impact of the proposed regulations and further interaction with stakeholders is necessary to properly weigh the effects on our industry and to reduce the probability of unintended consequences. Thus we feel that an arbitrary schedule to impose a regulation is inappropriate and that an aggressive schedule introduces additional risks. Thus we suggest that the agencies consider the potential benefits of incorporation of a review and adjustment process at the midpoint of the proposed regulatory period. [EPA-HQ-OAR-2014-0827-1219-A1 p.4-5]
Organization: National Automobile Dealers Association (NADA)

NADA/ATD specifically suggests that a mid-term “reality check” review be used to reassess the appropriateness, cost-effectiveness, and technologically feasibility of the Phase 2 program and whether changes are warranted. Ideally, the review should be conducted in calendar year 2021 and would cover key variables and assumptions applicable to MY 2024 and beyond. If a determination is made that the standards for those years require modification, they should be adjusted expeditiously. A “reality check” should not be used to strengthen the stringency or significantly revise the structure of the Phase II program, but rather only to account for new or previously unexpected information critical to program achievability. [EPA-HQ-OAR-2014-0827-1309-A1 p.11]

Organization: United Parcel Service (UPS)

Need for Mid-Course Progress Review

UPS believes that the time horizon for this rule is so distant and the technology availability and affordability is so uncertain, that a mid-course review is needed as a safeguard to ensure the program is viable. We believe that the decision on a review should come at a time when at least a year of data is in hand. We suggest that a midcourse review be triggered when a significant proportion of the engine or truck manufacturer capacity, as determined by the EPA Administrator and the Secretary of Transportation, is in danger of future non-compliance. [EPA-HQ-OAR-2014-0827-1262-A1 p.14]

Organization: Utility Trailer Manufacturing Company

Any Rule that the Agencies adopt should be reevaluated within a few years to account for uncertainties and changes, as well as availability of proven devices to comply with the Rule.

The Proposed Rule will establish regulations for the next dozen years and beyond. It is difficult, to say the least, to anticipate with any accuracy what the transportation, environmental, or regulatory landscape will look like at that time or what complying devices will be available. Rather than set guidelines now for those out years, Utility Trailer urges the agencies to limit its adoption to proposals for the first 6 years – through 2021, with the understanding that the agencies will revisit the topics as those deadlines approach to determine how the Regulations should be modified. [EPA-HQ-OAR-2014-0827-1183-A1 p.22]

For example, even if it used all the currently available existing efficiency-improving devices set forth in the EPA tables in 100% of trailer production (automatic tire inflation systems, level 2 low-rolling-resistance tires, combination of skirts and trailer tales and a roughly 950 pound weight reduction in refrigerated trailers), Utility Trailer would not be able to qualify its long-box dry-van trailer for the years 2024 and beyond, and it would not be able to qualify its long-box refrigerated trailer for the years 2027 and beyond. [EPA-HQ-OAR-2014-0827-1183-A1 p.22]

Organization: Walsh, Michael and Charlton, Stephen

3. If the agencies determine there is a need to manage risk associated with new technologies, they could consider a biennial review – as defined and implemented for the 2010 criteria pollutant program, Final Rule section III.H [19]. At each review, EPA collected and analyzed information from engine manufacturers, catalyst manufacturers, internal testing, and other sources as a mechanism for monitoring and evaluating technological progress. [NHTSA-2014-0132-0102-A1 p.10]
Response:

We believe that it is inappropriate to schedule a formal mid-term review within the Phase 2 program because the agencies have confidence that the Phase 2 standards are feasible and cost-effective; especially considering the long lead time and the variety of compliant technology paths we project to be available to manufacturers and users of heavy-duty vehicles and engines (see also our response in Section 1.5 of this document on lead time). While the agencies are not finalizing a formal process for such a review, we note that we expect to carefully monitor program as we work with the regulated industries to implement this program. In addition, manufacturers and other stakeholders retain the ability to formally petition us for a reconsideration of some or all of the Phase 2 program based on new information.

15.7 Comments Related to Competition Vehicles 2027

Organization:  Alliance of Automobile Manufacturers and Association of Global Automakers

The Alliance of Automobile Manufacturers (“Auto Alliance”) and the Association of Global Automakers (“Global Automakers”) respectfully submit these comments to the Environmental Protection Agency (“EPA” or “Agency”) in response to its Notice of Data Availability (NODA) to re-open the comment period for certain aspects of the Proposed Rule for comments on the impact the proposed language would have on off-road racing/competition vehicles [81 Fed. Reg. 10822, March 2, 2016].

INTRODUCTION

In the proposed rule Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2, 80 Fed. Reg. 40,138 (July 13, 2015) (Proposed Rule), in addition to proposing new greenhouse gas standards for medium- and heavy-duty vehicles, EPA included proposed language to insert in 40 C.F.R. § 86.1854-12 pertaining to new and in-use light-duty vehicles, that would make the modification of certified production or street vehicles for off-road racing/competition a prohibited act if such vehicles did not remain in their emissions-certified status.

While EPA staff have claimed that the proposal is merely a clarification of the Agency’s position with regard to competition vehicles, the proposed amendment to Part 86 represents a significant departure from EPA’s longstanding approach with respect to the emissions certification of these types of vehicles. The proposal also could create conflicts with the longstanding regulatory approach the California Air Resources Board (CARB) and EPA apply to aftermarket parts.

This issue was brought to our attention by the Specialty Equipment Market Association (SEMA), whose December 28, 2015 comments we support.

To the extent that EPA intends the proposed amendment to Part 86 to reduce tampering of certified vehicles driven on the U.S. roadways, we provide a recommendation that would accomplish this while
preserving the exclusion of off-road racing/competition vehicles from Clean Air Act (CAA) regulation
and preserving the aftermarket programs. [EPA-HQ-OAR-2014-0827-1884-A1 p.2]

We hereby submit these comments pursuant to the NODA. [EPA-HQ-OAR-2014-0827-1884-A1 p.2]

A. OVERVIEW OF EPA’S PROPOSAL

The Proposed Rule seeks to amend 40 C.F.R. § 86.1854-12, which is the section of EPA’s light-duty
vehicle regulations on prohibited acts, by adding the following subsection: [EPA-HQ-OAR-2014-0827-
1884-A1 p.2]

(a) (5) Certified motor vehicles and motor vehicle engines and their emission control devices must
remain in their certified configuration even if they are used solely for competition or if they become
nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for
any reason is subject to the tampering and defeat device prohibitions of paragraph (a)(3) of this section

80 Fed. Reg. at 40,565. This section of the federal regulations includes the general compliance
provisions for controlling air pollution emissions from new and in-use light-duty vehicles, light-duty
trucks, and heavy-duty trucks, and new and in-use engines. Thus, the Proposed Rule’s change for off-
road racing/competition vehicles would have a wide-reaching effect on a variety of vehicles. In essence,
this proposed amendment would prohibit the conversion of any production or “street” vehicles for off-
road racing/competition use by the installation of performance-enhancing parts or making other
alterations that take the vehicle out of its certified configuration. [EPA-HQ-OAR-2014-0827-1884-A1
p.3]

The proposed changes to Part 86 are accompanied by the following Preamble discussion:

The existing prohibitions and exemptions in 40 CFR part 1068 related to competition engines and
vehicles need to be amended to account for differing policies for nonroad and motor vehicle
applications. In particular, we generally consider nonroad engines and vehicles to be “used solely for
competition” based on usage characteristics. This allows EPA to set up an administrative process to
approve competition exemptions, and to create an exemption from the tampering prohibition for
products that are modified for competition purposes. There is no comparable allowance for motor
vehicles. A motor vehicle qualifies for a competition exclusion based on the physical characteristics
of the vehicle, not on its use. Also, if a motor vehicle is covered by a certificate of conformity at any point,
there is no exemption from the tampering and defeat-device prohibitions that would allow for
converting the engine or vehicle for competition use. There is no prohibition against actual use of
certified motor vehicles or motor vehicle engines for competition purposes; however, it is not
permissible to remove a motor vehicle or motor vehicle engine from its certified configuration
regardless of the purpose for doing so. [EPA-HQ-OAR-2014-0827-1884-A1 p.3]

80 Fed. Reg. at 40527. EPA appears to be signaling that it will no longer recognize an exclusion for
vehicles that have been modified to be used solely for competition purposes. As SEMA’s comments
explain, such action would be contrary to both the statutory text and the legislative history of the CAA. 3
[EPA-HQ-OAR-2014-0827-1884-A1 p.3]

EPA’S PRESS RELEASE ON PROPOSED RULE CHANGE TO PART 86
In response to SEMA’s comments and its public media efforts on this issue, EPA’s Deputy Press Secretary, Laura Allen, released the following public statements, which merely restate the Agency’s position on the prohibition against modifying certified vehicles for competition articulated in the Proposed Rule: [EPA-HQ-OAR-2014-0827-1884-A1 p.4]

People may use EPA-certified motor vehicles for competition, but to protect public health from air pollution, the Clean Air Act has – since its inception – specifically prohibited tampering with or defeating the emission control systems on those vehicles. The proposed regulation that SEMA has commented on does not change this long-standing law, or approach. Instead, the proposed language in the Heavy-Duty Greenhouse Gas rulemaking simply clarifies the distinction between motor vehicles and nonroad vehicles such as dirt bikes and snowmobiles. Unlike motor vehicles – which include cars, light trucks, and highway motorcycles – nonroad vehicles may, under certain circumstances, be modified for use in competitive events in ways that would otherwise be prohibited by the Clean Air Act. [EPA-HQ-OAR-2014-0827-1884-A1 p.4]

This clarification does not affect EPA’s enforcement authority. It is still illegal to tamper with or defeat the emission control systems of motor vehicles. In the course of selecting cases for enforcement, the EPA has and will continue to consider whether the tampered vehicle is used exclusively for competition. The EPA remains primarily concerned with cases where the tampered vehicle is used on public roads, and more specifically with aftermarket manufacturers who sell devices that defeat emission control systems on vehicles used on public roads. [EPA-HQ-OAR-2014-0827-1884-A1 p.4-5]

Both statements are a departure from what has been understood to be EPA’s approach to street vehicles used for off-road racing/competition. The second statement at least makes the distinction between modified vehicles used on the street or highway versus those used for competition and notes that EPA’s enforcement office focuses on former. However, in our view, the CAA’s definition of “motor vehicle” does not include vehicles that have been modified for use solely for competition purposes, or for use solely for off-roading purposes, and EPA therefore has no enforcement authority with respect to such vehicles in the first place. At the very least, it affords EPA with the discretion to categorically exempt such vehicles from its regulations concerning vehicle modifications—a position which we understand that EPA has long held. [EPA-HQ-OAR-2014-0827-1884-A1 p.5]

B. CAA PROVISIONS AND EPA REGULATIONS ADDRESSING MOTOR VEHICLES USED FOR OFF-ROAD RACING/COMPETITION

EPA’s proposed regulatory revision to Part 86 in the Proposed Rule would be a departure from how EPA has historically treated the conversion of street vehicles to off-road use, including for racing or competition. To date, the Agency has not attempted to regulate such conversions and thereby prohibit individual vehicle purchasers from engaging in lawful uses of their property. [EPA-HQ-OAR-2014-0827-1884-A1 p.5]

The CAA defines “motor vehicle” in Section 216(2) of the Clean Air Act (42 U.S.C. § 216(2)) as “any self-propelled vehicle designed for transporting persons or property on a street or highway.” Since off-road racing/competition vehicles ought not and generally are not driven on streets or highways, they have long been considered to fall outside of the CAA anti-tampering provisions. Additionally, 40 C.F.R. § 85.1703 provides the criteria for determining the applicability of § 216(2) of the CAA: [EPA-HQ-OAR-2014-0827-1884-A1 p.5]

(a) For the purpose of determining the applicability of section 216(2), a vehicle which is self-propelled and capable of transporting a person or persons or any material or any permanently or temporarily
affixed apparatus shall be deemed a motor vehicle, unless any one or more of the criteria set forth below are met, in which case the vehicle shall be deemed not a motor vehicle: [EPA-HQ-OAR-2014-0827-1884-A1 p.5]

(1) The vehicle cannot exceed a maximum speed of 25 miles per hour over level, paved surfaces; or [EPA-HQ-OAR-2014-0827-1884-A1 p.5-6]

(2) The vehicle lacks features customarily associated with safe and practical street or highway use, such features including, but not being limited to, a reverse gear (except in the case of motorcycles), a differential, or safety features required by state and/or federal law; or [EPA-HQ-OAR-2014-0827-1884-A1 p.6]

(3) The vehicle exhibits features which render its use on a street or highway unsafe, impractical, or highly unlikely, such features including, but not being limited to, tracked road contact means, an inordinate size, or features ordinarily associated with military combat or tactical vehicles such as armor and/or weaponry. [EPA-HQ-OAR-2014-0827-1884-A1 p.6]

Vehicles that have been modified for off-road racing/competition have traditionally been held to fall under the second criterion. Modified competition vehicles have features that are not associated with “safe and practical street or highway use” and indeed, are meant to be used on racetracks and closed circuits. Some competition vehicles may also fall under the third criterion, depending on how they are equipped. Similarly, modified off-roading vehicles virtually always fall under the second or third criterion, generally because components or features are added to the vehicle to enhance the off-roading experience, not that components are removed to enhance racing. [EPA-HQ-OAR-2014-0827-1884-A1 p.6]

Addressing solely competition vehicles, EPA has teamed up with the U.S. Department of Energy (DOE) since 2006 to develop and implement a Green Racing Program, which according to the agencies’ website, is an initiative to encourage “the racing industry to embrace innovation and enhance existing vehicle technologies to maximize efficiency.” The Green Racing program developed protocols that establish guidelines for motorsport competitors to utilize and develop technologies and fuels that support emissions reductions. If EPA meant to prohibit the modification of certified motor vehicles for racing/competition, establishing voluntary standards for those vehicles is contrary to EPA’s proposed “clarification” to Part 86. [EPA-HQ-OAR-2014-0827-1884-A1 p.6]

As noted above, it has been a long accepted understanding that the CAA does not prohibit the modification of certain vehicles and/or engines if those vehicles and/or engines are used “solely for competition” on race tracks and closed circuits, or used for exclusive use at off-road rally events. This understanding has been based, in large part on the CAA definition of “motor vehicle” and EPA’s regulations, as well as EPA’s practice in not pursuing enforcement actions against individuals and manufacturers who modify vehicles and/or engines for off-road racing/competition purposes. [EPA-HQ-OAR-2014-0827-1884-A1 p.6]

Finally, when considered in the broader context of permissible modifications to certified motor vehicles that occur in the aftermarket parts context, EPA’s proposed change to Part 86 to prohibit the modification of certified vehicles would conflict with California law which specifically exempts competition and racing vehicles that are not used on highways. See, California Health and Safety Code §§ 43001(a) and 39048. With regard to other aftermarket performance components that are used in on-highway vehicles, CARB has had a long standing program for approving aftermarket parts for certified vehicles through the Executive Order process. The proposed revision also conflicts with the Agency’s
own longstanding guidance with regard to aftermarket parts in EPA’s Enforcement Memorandum 1A (June 25, 1974), which recognizes express representation by a state agency that a reasonable basis exists that an aftermarket part (which would modify a certified vehicle) does not adversely affect emissions performance, and therefore, can be lawfully installed on a certified vehicle and is not considered tampering under the Act. EPA’s enforcement guidance also permits emissions testing to serve as a reasonable basis. EPA’s Proposed Rule could be interpreted as completely eliminating the ability to rely on this longstanding guidance for on-highway vehicles. [EPA-HQ-OAR-2014-0827-1884-A1 p.6-7]

C. REGULATORY TREATMENT OF OTHER COMPETITION VEHICLES

Attached is a matrix of the various regulatory provisions addressing competition vehicles in other vehicle segments as well as the general provision on prohibited acts and the exemption for equipment and engines used solely for competition. Included at the beginning of the matrix are the definitions and prohibited act provisions pertaining to light-duty “motor vehicles” for comparison purposes. [EPA-HQ-OAR-2014-0827-1884-A1 p.7][Attachment can be found in docket number EPA-HQ-OAR-2014-0827-1884-A2]

When reviewing the competition provisions for marine engines, recreational vehicles, and other types of nonroad engines and equipment, it is clear that manufacturers producing competition vehicles, in most cases, must affirmatively request an exemption from EPA, demonstrate that particular criteria are met, and must label the vehicle accordingly. See §§ 1042.620, 1045.620, 1048.630 (incorporating by reference § 1054.620), 1051.620, and 1054.620. [EPA-HQ-OAR-2014-0827-1884-A1 p.7]

With regard to modifying certified vehicles for competition, the general provisions in Part 1068 allow these vehicles to be modified without request so long as they are used solely for competition and the original emission labels are destroyed. Specifically, this provision states: [EPA-HQ-OAR-2014-0827-1884-A1 p.7]

(b) If you modify any nonroad engines/equipment after they have been placed into service in the United States so they will be used solely for competition, they are exempt without request. This exemption applies only to the prohibition in § 1068.101(b)(1) [tampering] and is valid only as long as the engine/equipment is used solely for competition. [EPA-HQ-OAR-2014-0827-1884-A1 p.7]

All the vehicle segments referenced above incorporate the general compliance provisions in Part 1068 by reference; thus, § 1068.235 applies to all the nonroad vehicle segments. In summary, there are two different pathways for vehicles in these other nonroad segments to become competition vehicles – they can be either manufactured specifically for that purpose and exempted through the specific provision in the relevant part applicable to those engines/vehicles, or they can be in-use vehicles/engines that are modified for that purpose according to Part 1068. Both pathways are lawful, provided that the regulations are followed and similar consideration should be applicable to light-duty vehicles. [EPA-HQ-OAR-2014-0827-1884-A1 p.7-8]

While the approaches outlined above are appropriate for nonroad vehicles, it is far easier to address light duty vehicles used for competition and off-roading. There are self-policing mechanisms that make it far easier to determine if a light-duty vehicle is used for competition purposes. These vehicles either will not be registered in a state or were formerly registered but modified and driven on non-highway terrain, insurance is typically unavailable, and in any instance, if the modifications are such the vehicle would fail state safety inspections if an owner attempted to drive this on public roads, that mechanism will serve as enforcement. For these reasons, a system such as contained in Part 1068 for nonroad vehicles need not be utilized for light duty vehicles. [EPA-HQ-OAR-2014-0827-1884-A1 p.8]
D. PROCEDURAL CONCERNS

SEMA’s comments raise a number of valid Administrative Procedure Act (APA) issues with regard to the lack of public notice, germaneness, and the arbitrary and capricious nature of the proposed revision to Part 86. Specifically, SEMA points to the fact that EPA’s statement regarding the prohibition against modification of certified motor vehicles even if used for competition is buried in the 629-page proposal for greenhouse gas standards for medium- and heavy-duty vehicles and that the Preamble discussion does not clearly identify the proposed regulatory revision to Part 86. While EPA has made it a practice over the years of including a number of different regulatory changes in a rule package, it was not clear, or even intuitive that the Proposed Rule for medium- and heavy-duty vehicles would include changes to the light-duty vehicle regulations. [EPA-HQ-OAR-2014-0827-1884-A1 p.8]

EPA has received 769 comments on the Proposed Rule. Of the organizations submitting comments that we were able to briefly review, those comments have not focused on the competition or off-roading issue discussed herein. Rather, they have focused mainly on fuel efficiency, the proposed emission standards, and greenhouse gas credits for medium- and heavy-duty vehicles and engines, the obvious and overtly intended purpose of the Proposed Rule itself. In addition to these comments, there were 49 anonymous comments filed since February 16 objecting to EPA’s proposed prohibition against modifying certified vehicles due to the negative effects on racing. It is very likely that these individuals commented as a result of SEMA’s press efforts on this issue. The lack of comments on the proposed Part 86 revision submitted during the comment period, followed by these late comments, demonstrates that EPA did not give adequate public notice of its proposal. [EPA-HQ-OAR-2014-0827-1884-A1 p.8]

E. POSITION OF ALLIANCE OF AUTOMOBILE MANUFACTURERS AND GLOBAL AUTOMAKERS

As discussed above, EPA’s proposal to prohibit the conversion of certified on-road vehicles to competition vehicles is a major departure from the Agency’s approach to this issue throughout the 40+-year history of the Clean Air Act. Moreover, the proposal would have the effect of depriving consumers of property rights by prohibiting legitimate uses of motor vehicles and depriving vehicle and engine manufactures, aftermarket component manufacturing and sellers, and dealers and retail establishments from their trade and commercial rights. [EPA-HQ-OAR-2014-0827-1884-A1 p.8]

We begin by acknowledging that EPA has the authority and the obligation, under the CAA, to prohibit tampering with certified motor vehicles. Individuals and entities who remove emissions control equipment from certified vehicles, or otherwise put such vehicles into an uncertified configuration, and then drive them on public roads, commit tampering under the Act. Likewise, outfits that sell “power chips” and other devices under false pretenses (often promising consumers that the devices do not affect their emissions or their warranty) tend to induce or encourage tampering, likely committing fraud or other violations of law in the process. We support EPA’s efforts to put an end to such practices. [EPA-HQ-OAR-2014-0827-1884-A1 p.8-9]

In cracking down on tampering, however, EPA must not go so far as to outlaw legitimate activities and businesses. If an individual purchases an emissions-certified production sports car, adds aftermarket components or removes production parts to convert it to a non-emissions-certified competition vehicle, and uses it only for competition, that individual has not engaged in tampering or otherwise violated the Clean Air Act. If an individual purchases an emissions-certified production sport utility vehicle, adds aftermarket components or removes production parts to convert it to a non-emissions-certified off-roading vehicle, and uses it only off-road, say, driving it over terrain an unmodified production vehicle could not, that individual similarly has not committed tampering or otherwise violated the Clean Air
Act. Thousands of vehicles sold annually are legitimately converted to competition or off-roading vehicles. EPA’s proposed rule would, with the stroke of a pen, prohibit these legitimate activities and suddenly deprive all vehicle owners of their right to convert an emissions-certified vehicle into a legitimate non-emissions-certified vehicle, and will suddenly deprive manufacturers and sellers the right to sell those owners the components they need for such vehicle uses. While such a broad-brush rule would undoubtedly make life easier for EPA, the deprivation of property rights inherent in the Proposed Rule it is neither consistent with, nor authorized by, the CAA. [EPA-HQ-OAR-2014-0827-1884-A1 p.9]

Like EPA, the Alliance and Global Automakers oppose vehicle tampering. We support more education and outreach to inform consumers about the CAA prohibition on tampering, and to explain the rules with respect to the conversion of emissions-certified vehicles to non-emissions-certified competition or off-roading vehicles. We also support government efforts to enforce the tampering prohibition against individuals and entities when warranted by the facts. We cannot, however, support an EPA initiative to enact a total ban on vehicle conversions, including legitimate activities that have been taking place since the inception of the CAA and before. Rather than “throwing the baby out with the bathwater” by banning legal activities as well as illegal ones, we recommend that EPA take a different approach as outlined below. [EPA-HQ-OAR-2014-0827-1884-A1 p.9].]

While the approaches outlined above are appropriate for nonroad vehicles, it is far easier to address light duty vehicles used for competition. There are self-policing mechanisms that make it far easier to determine if a light-duty vehicle is used for competition purposes. These vehicles will not be registered in a state, insurance is typically unavailable, and in any instance the modifications made make it almost certain that such a vehicle would fail state safety inspections if an owner attempted to drive this on public roads. For these reasons, a system such as contained in Part 1068 for nonroad vehicles need not be utilized for light duty vehicles. [EPA-HQ-OAR-2014-0827-1884-A1 p.9]

F. RECOMMENDED ACTIONS

In response to EPA’s NODA and request for comment on SEMA’s December 28, 2015 comments on how the proposal would impact off-road racing/competition, we recommend that EPA amend § 86.1854-12 as follows: [EPA-HQ-OAR-2014-0827-1884-A1 p.9]

(a)(5) Certified motor vehicles and motor vehicle engines that are designed to be operated on a street or highway and their emission control devices must remain in their emissions-certified configuration unless good engineering judgment or emissions testing provides a reasonable basis for knowing that a modification will not affect emissions performance. Anyone modifying such a certified motor vehicle or motor vehicle engine that renders such motor vehicle or motor vehicle engine non-compliant with its certificate of conformity and who drives such motor vehicle on a U.S. street or highway is subject to the tampering and defeat device prohibitions of paragraph (a)(3) of this section and 42 U.S.C. § 7522(a)(3). [EPA-HQ-OAR-2014-0827-1884-A1 p.10]

In conjunction with the change noted above, EPA also needs to include a new criterion excluding competition and off-roading vehicles from the definition of “motor vehicle” in § 85.1703. Specifically, EPA should add a new § 85.1703(a)(4) that would state: “The vehicle is used solely for competition or off-roping use.” This new criterion would reflect the concept in the statutory definition of “motor vehicle” in CAA § 216(2) that such vehicles are used for transporting persons or property on a street or highway and codify EPA’s longstanding treatment of these vehicles. This twofold approach would create a regulatory prohibition on modifying certified vehicles operated on U.S. roadways that would retain EPA’s, as well as CARB’s, regulatory programs for aftermarket parts and modifications, as well
as preserve the longstanding enforcement policy of EPA with regard to off-road racing/competition vehicles. [EPA-HQ-OAR-2014-0827-1884-A1 p.10]

2 In these comments, the term “off-road racing/competition” is intended to include exclusive off road use at rallies and similar events as long as the vehicle is not used on public roads or streets.

3 In addition to the proposed change to Part 86, the Agency is proposing to modify or add new regulatory definitions and provisions to several other sections of the C.F.R. that may impact vehicles modified for competition purposes. First, the Proposed Rule would amend the definition of “motor vehicle” in Part 85. Specifically, EPA is proposing to add a new § 85.1703(b) that would state:

Proposed Rule at 40,552.

As discussed in greater detail in the following section of these comments, the lack of safety features is one way that competition vehicles are distinguished from motor vehicles. While EPA explains that this regulatory language is intended to ensure that glider kits and glider vehicles are regulated as motor vehicles, the proposed language seems to narrow the kinds of competition vehicles that could be excluded from the definition of motor vehicle. When discussing this proposed change in the Preamble, EPA states that the Agency “is also considering whether to simply eliminate the clause ‘or safety features required by state and/or federal law’ from the regulatory definition.” 3 This is particularly troubling given that the lack of safety features is often relied on when distinguishing a competition vehicle from a motor vehicle used on streets and highways.

Second, the Proposed Rule would add new sections 40 C.F.R. §§ 1036.601(a)(2) and 1037.601(a)(3), which govern the control of emissions from new and in-use heavy-duty highway engines and heavy-duty motor vehicles. These proposed changes state that the §1068.235 exemption for vehicles used solely for competition does not apply to heavy-duty vehicles or heavy-duty engines. Third, the Proposed Rule would add a new definition to 40 C.F.R. §1068.30 – a section of EPA’s regulations that govern the general compliance provisions for highway, stationary, and nonroad programs. Finally, the Proposed Rule would add a new provision at 40 C.F.R. §1068.101(b)(4)(ii), which deals with prohibited acts under the Agency’s general compliance provisions for highway, stationary, and nonroad programs. This proposed provision reiterates the same language proposed for Part 86 that will require certified motor vehicles and engines to remain in their certified condition, regardless of whether they are used solely for competition.

4 42 U.S.C. § 7550(2).
5 42 U.S.C. § 7550(2) (emphasis added).
6 40 C.F.R. § 85.1703 (emphasis added).
8 40 C.F.R. §1068.235 (see attachment for entire provision).

EPA’s Clean Air Act Authority

Protecting Against Defeat Devices

Comments submitted in response to the Notice of Data Availability and raised in the media have expressed concern about EPA’s authority to regulate aftermarket modification of vehicles. Our organizations strongly support EPA’s long-standing authority to prevent tampering with emissions control systems, including the installation of defeat devices, on vehicles used on public roads. Many such technologies that alter or bypass emissions control systems are sold under the guise of competitive racing, but marketed for use on vehicles that are used on public roads. Such defeat devices lead to increased emissions of a range of pollutants which threaten public health. Going forward, EPA should continue to ensure that aftermarket defeat devices do not lead to increased emissions of health-threatening pollution from on-road vehicles. We note that EPA’s record of enforcement has focused on technologies that are being sold to defeat emission control devices in vehicles that are being used on public roads, not competitive racecars used off public roads. [EPA-HQ-OAR-2014-0827-1896-A1 p.7]

Organization: American Motorcyclist Association et al.

In support of the Specialty Equipment Market Association’s (SEMA) statement of December 28, 2015 to the EPA in opposition to that portion of the rule banning conversion of street vehicles into racecars and competition motorcycles, the following comments question the merits of the EPA’s proposal and the procedures taken by the EPA in pursuing it. [EPA-HQ-OAR-2014-0827-1929-A1 p.1]

The undersigned entities represent businesses encompassing all sectors of the racing industry. This includes companies that produce converted race vehicles, manufacturers of products for both converted and purpose-built race vehicles and race-sanctioning organizations. The issue has broad economic impact for millions of people employed in the racing sector in manufacturing, distribution, retailing, installation, marketing, publishing and entertainment, as well as millions of racing enthusiasts and spectators. [EPA-HQ-OAR-2014-0827-1929-A1 p.1]

In its July 13, 2015, proposed regulation the EPA included a provision to clarify that it has always been illegal to modify a motor vehicle into a race vehicle used solely for competition if the vehicle no longer remains in its certified configuration. The undersigned companies and organizations strongly disagree and respectfully request that the EPA withdraw its clarification. Congress did not intend for the EPA to regulate race vehicles, including production vehicles that have been converted into race vehicles and products used solely for racing. [EPA-HQ-OAR-2014-0827-1929-A1 p.1]

EPA’s Proposed Racing Vehicle Conversion Prohibition
On pages 429 and 584 of the 629-page proposed rule addressing greenhouse gases for trucks and buses, the EPA inserted the following proposed regulatory text on racecar and competition motorcycle conversions: [EPA-HQ-OAR-2014-0827-1929-A1 p.2]

PART 86--CONTROL OF EMISSIONS FROM NEW AND IN-USE HIGHWAY VEHICLES AND ENGINES

Subpart S--General Compliance Provisions for Control of Air Pollution From New and In-Use Light-Duty Vehicles, Light-Duty Trucks, and Heavy-Duty Vehicles

67. Section 86.1854-12 is amended by adding paragraph (b)(5) to read as follows:

§ 86.1854-12 Prohibited acts.

(b) * * *

(5) Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of paragraph (a)(3) of this section and 42 U.S.C. 7522(a)(3). [EPA-HQ-OAR-2014-0827-1929-A1 p.2]

Part 1068 - Subpart B—Prohibited Actions and Related Requirements

236. Section 1068.101 is amended by revising the introductory text and paragraphs (a)(1), (b), and (h) introductory text to read as follows: [EPA-HQ-OAR-2014-0827-1929-A1 p.2]

[40 CFR 1068.101(b)(4)(ii)]

Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of 40 CFR 1068.101(b) and 42 U.S.C. 7522(a)(3). [EPA-HQ-OAR-2014-0827-1929-A1 p.2]

The EPA’s proposed regulation would affect any racing vehicle that started its life as a street car or motorcycle. It would cover all motor vehicles produced since 1968 (1978 for motorcycles), the first year federal emissions standards took effect, which are used solely for racing and no longer remain in their certified configuration with respect to emissions-related equipment. The EPA provided little guidance on its goal beyond an intent to prohibit modifications affecting any emissions-related component. “Emissions-related” is broadly construed to include any change to a vehicle’s engine, engine control module, intake, exhaust system or other related part, even if the vehicle is converted into a dedicated track car and never again used on the streets. [EPA-HQ-OAR-2014-0827-1929-A1 p.2]

Clean Air Act Racing Vehicle Exclusion

Enacted more than 45 years ago, the Clean Air Act (CAA) prohibits the EPA from regulating “vehicles used solely for competition” (more commonly known as racecars and competition motorcycles). In the ensuing years, the regulated industry is unaware of a single instance in which the EPA previously took
the position that the CAA applies to vehicles converted for race-use-only purposes. At a March 15, 2016 hearing before the House Science, Space, and Technology’s Oversight Subcommittee, Brent Yacobucci with the Congressional Research Service (CRS) testified that the CRS was unable to identify any EPA document before this current rulemaking that stated motor vehicles converted for racing were ineligible for the CAA exclusion. [EPA-HQ-OAR-2014-0827-1929-A1 p.2-3]

Industry, the public and lawmakers have a clear understanding that these vehicles are excluded from the CAA. Today, there are more than 1,300 race tracks in the United States and the vast majority are not dedicated to purpose-built race vehicles. Tens of thousands of enthusiasts race converted street vehicles that are trailered to their local tracks. Most of these vehicles are sold through auto dealerships across the nation both as new and used vehicles to be converted into race cars. Furthermore, many dealerships, dealership organizations, and dealership employees are involved in sponsoring race teams, building out race cars, and even sitting behind the wheel on race day. [EPA-HQ-OAR-2014-0827-1929-A1 p.3]

**Legislative History**

The CAA prohibits modifications to motor vehicles used on public roads that would take the vehicle out of compliance. Under the law, the term “motor vehicle”[1] is limited to a vehicle designed for transport “on a street or highway.” When Congress authorized the EPA to regulate nonroad vehicles, it explicitly made clear that the term “nonroad vehicle”[2] did not include a “motor vehicle” or a “vehicle used solely for competition.” When enacting the CAA in 1970, Congress even confirmed in conference committee deliberations that the term “motor vehicle” does not extend to vehicles manufactured or modified for racing.[3][EPA-HQ-OAR-2014-0827-1929-A1 p.3]

**Flawed Regulatory Process**

Further, this proposed racing conversion prohibition raises significant fairness and due process concerns. The proposed prohibition was buried within a wholly unrelated 629-page greenhouse gas rule for trucks and buses. There was not even a subject heading alerting the public to its insertion. Rather, it was addressed along with other miscellaneous issues under the generic heading “XIV. Other Proposed Regulatory Provisions.” [EPA-HQ-OAR-2014-0827-1929-A1 p.3]

As a consequence, the EPA failed to comply with the Administrative Procedure Act and Clean Air Act requirements requiring that the public be notified and given an opportunity to comment on a proposed rule. Constitutional due process also demands agencies provide adequate notice to regulated individuals. [EPA-HQ-OAR-2014-0827-1929-A1 p.3-4]

Further, the EPA failed to conduct an economic analysis, regulatory-flexibility analysis or small business analysis on the race vehicle provisions, as required by law. [EPA-HQ-OAR-2014-0827-1929-A1 p.4]

When it published the March 2nd Notice of Data Availability, the EPA had an opportunity to acknowledge the inclusion of the unrelated prohibition of modified race vehicles and rescind that portion of its proposal. Instead, the EPA simply asked the public to comment on SEMA’s comments. The EPA did not defend its position and once again failed to provide an economic analysis, regulatory-flexibility analysis and small business analysis. [EPA-HQ-OAR-2014-0827-1929-A1 p.4]

**Conclusion**
The EPA has threatened to make illegal activities that have taken place for decades and accounted for billions of dollars of economic activity, and would account for billions more moving forward. This unannounced and unilateral action is being taken without regard to the decades-long understanding of the application of the law to street vehicles modified for exclusive use at the track or as much as a single economic analysis. [EPA-HQ-OAR-2014-0827-1929-A1 p.4]

The EPA’s proposed prohibition would be devastating to many types of racing, especially at the amateur level where the racers are not in a position to purchase purpose-built race vehicles. As previously noted, it would also threaten jobs and economic well-being for the entire racing industry, from companies that manufacture and market racing products to media outlets that cover amateur racing and communities that support the tracks. [EPA-HQ-OAR-2014-0827-1929-A1 p.4]

Despite the seeming clarity of the Clean Air Act statute and legislative history, the EPA is ignoring Congressional intent and previous application of the law, which has allowed street vehicles to be converted into racecars and competition motorcycles used solely for competition. The undersigned respectfully request that the EPA withdraw its clarification. Congress did not intend for the EPA to regulate racecars and competition motorcycles, including vehicles converted into race vehicles and products used solely for racing. [EPA-HQ-OAR-2014-0827-1929-A1 p.4]

[3] See House Consideration of the Report of the Conference Committee, Dec. 18, 1970 (reprinted in A legislative history of the Clean air amendments of 1970, together with a section-by-section index, U.S. LIBRARY OF CONGRESS, ENVIRONMENTAL POLICY DIVISION, Washington: U.S. Govt. Print. Off. Serial No. 93-18, 1974, p. 117) (Representative Nichols: “I would ask the distinguished chairman if I am correct in stating that the terms “vehicle’ and “vehicle engine” as used in the act do not include vehicles or vehicle engines manufactured for, modified for or utilized in organized motorized racing events which, of course, are held very infrequently but which utilize all types of vehicles and vehicle engines?”; Representative Staggers: “In response to the gentleman from Alabama, I would say to the gentleman they would not come under the provisions of this act, because the act deals only with automobiles used on our roads in everyday use. The act would not cover the types of racing vehicles to which the gentleman referred, and present law does not cover them either.”).

Organization: BorgWarner

As one of the top 30 automotive suppliers, employing over 6,900 people in the U.S., BorgWarner’s mission is to deliver innovative powertrain solutions that improve fuel economy, emissions and performance. We support regulations that help to create a clean, energy-efficient world. [EPA-HQ-OAR-2014-0827-1883-A1 p.1]

As a key industry stakeholder, BorgWarner offers the following comments in response to the Notice of Data Availability issued by the National Highway Traffic Safety Administration (NHTSA) and the U.S. Environmental Protection Agency (EPA) on the proposed Phase 2 Heavy-Duty National Program to reduce greenhouse gas emissions (GHG) and fuel consumption for new on-road heavy-duty vehicles and engines. We oppose the provision that emission control devices must remain in their certified
configuration, even if converting street vehicles into dedicated racecars. [EPA-HQ-OAR-2014-0827-1883-A1 p.1]

The Phase 2 provision on dedicated racecar conversions has the potential consequence of regulating the market and sport of competition racing out of existence. This provision will result in negative economic impact on jobs and revenue at our manufacturing facility in Asheville, North Carolina. [EPA-HQ-OAR-2014-0827-1883-A1 p.1]

Further, due to the competitive aspects of their business, motorsport customers are early adopters of advanced technologies. Their activities help companies, like BorgWarner, gather test data, performance data and determine manufacturing methods for volume production of advanced technologies. Product enhancements that improve fuel economy, emissions and performance can and do transition from competitive racing to production vehicle applications. An example of this technology transfer is BorgWarner’s Engineered for Racing (EFR) turbochargers, which include non-standard features such as Gamma-Ti turbine wheels, a dual-row ceramic ball bearing system and an all-aluminum water cooled bearing housing. These features, which are being considered for production applications, reduce the rotational inertia and weight resulting in better fuel economy and performance. [EPA-HQ-OAR-2014-0827-1883-A1 p.1-2]

Consequently, BorgWarner fully supports the comments of The Motor & Equipment Manufacturers Association (MEMA) and Specialty Equipment Market Association (SEMA) in their opposition to the EPA’s proposed provision on converting street vehicles into dedicated racecars: [EPA-HQ-OAR-2014-0827-1883-A1 p.2]

• This provision is not appropriate to be addressed in the Phase 2 proposed rule, as it is not related to medium- and heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1883-A1 p.2]

• Congress did not intend for dedicated racecars to be within the jurisdiction of the Clean Air Act (CAA). [EPA-HQ-OAR-2014-0827-1883-A1 p.2]

• The 1970 CAA Amendments included an exemption for anti-tampering provisions for the emission control devices of manufactured or modified racing vehicles, and the 1990 CAA Amendments clarified that EPA did not have authority to regulate “vehicles used solely for competition.” [EPA-HQ-OAR-2014-0827-1883-A1 p.2]

• The proposed racing conversion prohibition raises significant fairness and due process concerns. EPA’s process did not properly alert stakeholders of this significant policy change to an exemption that has been in place for decades. [EPA-HQ-OAR-2014-0827-1883-A1 p.2]

We strongly urge EPA and NHTSA to remove this provision from the Phase 2 proposed rule. We believe that policy change in this area should be studied further based on the economic and innovative impact of this market in the United States so that the complex issues raised by the key stakeholders may be carefully evaluated. The racecar conversion market plays an important role for BorgWarner in implementing advanced technologies for improving fuel economy, emissions and performance. [EPA-HQ-OAR-2014-0827-1883-A1 p.2]

Organization: Clean Air Task Force et al.
In this rulemaking, some organizations have questioned EPA’s authority to regulate aftermarket modifications of emission control systems on certified vehicles used for on-road use. We strongly support EPA’s authority to protect the health and welfare of all citizens by ensuring that the appropriate emission control devices are used on all vehicles driven on our nation’s roads. As we saw from the Volkswagen scandal, even a relatively small number of defeat devices can have an outsized impact on health-threatening pollution. [EPA-HQ-OAR-2014-0827-1925-A1 p.2]

Organization:  Diaz, Miguel

Regarding the light duty motor vehicles used for racing, I don’t think it should be a concern at this very moment. It would be counterproductive to address such topic in a world that can’t actually control the emissions of larger pollutants. Racing cars produce a relative small amount of emissions compared to the commercial trucks that are used every day. If you do a life cycle analysis of any aliment or product, you will notice that most of the time the most pollutant element is transportation by trailer. Besides, many of the racing cars are used sporadically while most of the trucks, trailers, buses and so are used daily. Addressing this topic should be the priority, while concerning whether the racing cars should be included or not, could create a great impact on the sport’s economy, a huge American tradition. This could cause many complaints from the people and loss of faith on the job EPA is currently doing. I’m not saying it shouldn’t be done, I’m just saying that is not the right moment to do it. You have to throw the big rock first before throwing the little ones and we are still struggling with the bigger emissions. We need to lower them down before trying to address every problem in the country. [EPA-HQ-OAR-2014-0827-1848-A1 p.2]

Organization:  Harley-Davidson Motor Company

Among other things, the EPA and NHTSA are soliciting feedback from interested parties on the Specialty Equipment Market Association’s (SEMA) additional comments on issues discussed in a late comment related to motor vehicles used for competition. We will also take this opportunity to comment on the July 13, 2015 EPA Proposed Rule itself because the agency failed to appropriately notify the public of the rule or solicit feedback from affected parties. [EPA-HQ-OAR-2014-0827-1893-A1 p.1]

Harley-Davidson, Inc. is the parent company of Harley-Davidson Motor Company and Harley-Davidson Financial Services. Since 1903, Harley-Davidson Motor Company has fulfilled dreams of personal freedom with custom, cruiser and touring motorcycles, riding experiences and events and a complete line of Harley-Davidson motorcycle parts, accessories, general merchandise, riding gear and apparel. Harley-Davidson maintains an active interest in continuing an earnest dialogue with the agency to address greenhouse gas emissions. The Company, however, does not condone the EPA’s actions in its Proposed Rule, which would unilaterally and without congressionally mandated authority materially change provisions within the Clean Air Act. [EPA-HQ-OAR-2014-0827-1893-A1 p.1]

On pages 429 and 584 of the 629 page rule addressing greenhouse gases for medium and heavy duty vehicles, the EPA inserted the following proposed regulatory text on race car and competition motorcycle conversions: [EPA-HQ-OAR-2014-0827-1893-A1 p.2]

PART 86--CONTROL OF EMISSIONS FROM NEW AND IN-USE HIGHWAY VEHICLES AND ENGINES

Subpart S--General Compliance Provisions for Control of Air Pollution From New and In-Use Light-Duty Vehicles, Light-Duty Trucks, and Heavy-Duty Vehicles
67. Section 86.1854-12 is amended by adding paragraph (b)(5) to read as follows:

§ 86.1854-12 Prohibited acts.

(b) * * *

(5) Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of paragraph (a)(3) of this section and 42 U.S.C. 7522(a)(3). [EPA-HQ-OAR-2014-0827-1893-A1 p.2]

Part 1068 - Subpart B—Prohibited Actions and Related Requirements

236. Section 1068.101 is amended by revising the introductory text and paragraphs (a)(1), (b), and (h) introductory text to read as follows: [EPA-HQ-OAR-2014-0827-1893-A1 p.2]

[40 CFR 1068.101(b)(4)(ii)]

Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of 40 CFR 1068.101(b) and 42 U.S.C. 7522(a)(3). [EPA-HQ-OAR-2014-0827-1893-A1 p.2]

Broadly, Harley-Davidson supports the comments submitted in the docket by SEMA on December 28, 2015. Explicitly, the Motor Company asserts that the agency’s proposal would make inappropriate and unnecessary changes to current law and practice, the agency does not have the authority to make the changes it proposes, adequate notice was not given for the proposed changes, and the agency did not follow government mandated protocols for evaluating economic impacts to small businesses and others according to the Administrative Procedure Act (APA), the Small Business Regulatory Enforcement Fairness Act (SBREFA), and the Regulatory Flexibility Act as they relate specifically to the race car and competition motorcycle conversion section above. [EPA-HQ-OAR-2014-0827-1893-A1 p.2]

Vehicles used solely for competition of all kinds, including racing vehicles created by converting certified vehicles into racing motorcycles, are not within the purview of the Clean Air Act. As drafted, the proposal would allow the EPA to broadly enforce this new provision against anyone making such changes including the owner, service provider, seller and manufacturer of competition vehicles and parts used for such conversions. Administrative rulemaking is not a process by which an agency is permitted to circumvent Congress. Only Congress is empowered to change the Clean Air Act. [EPA-HQ-OAR-2014-0827-1893-A1 p.2]

The EPA did not adequately notify the public in its original Notice of Proposed Rulemaking (NPRM) to encourage dialogue with affected parties. The EPA included the disputed language within a 629 page rulemaking entitled Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles Part 2. The agency did not call out motorcycles in the title, nor did it note the proposed change in the table of contents. However, the results of such a change would dramatically and negatively impact motorcycle competition, those who service those vehicles, and the supporting industry of vendors who make their livelihoods in the related industries of motorsports. The proposed
rule, if finalized, would effectively eviscerate an industry that has been around for decades. [EPA-HQ-OAR-2014-0827-1893-A1 p.3]

Currently, all motorcycles manufactured in or before 2005 are not required to meet EPA certification. The EPA allows certified motorcycles made from 2006 to be used exclusively for competition purposes if they meet certain criteria. According to an excerpt from the agency's own Frequently Asked Questions (FAQ) document issued in 2002 entitled “Emission Exemption for Racing Motorcycles and Other Competition Vehicles”, a motorcycle certified by the EPA is allowed to be used for competition under the following conditions: [EPA-HQ-OAR-2014-0827-1893-A1 p.3

[Table, 'Restrictions on Use and Maintenance', can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1893-A1]

SBREFA requires agencies to take steps to collect input from small entities on regulations and to determine whether a rule is expected to have a significant economic impact on a substantial number of small entities. No such analysis of the effects of the proposed prohibited acts appears to have been completed by the agency prior to the proposed rule being issued. Proposing such a significant and far-reaching change to the existing rule and practice will require additional due diligence by the agency to prove that there are no negative consequences to affected small businesses. [EPA-HQ-OAR-2014-0827-1893-A1 p.3-4]

The APA is intended to provide protections to the public to ensure that interested parties are given sufficient opportunity to comment on proposed rules. H-D contends that EPA did not provide sufficient opportunity to provide comment. [EPA-HQ-OAR-2014-0827-1893-A1 p.4]

We reject the EPA’s assertion that this is simply a clarification of the existing rules. The proposed prohibition of modifications to engines, exhaust, engine control modules and intakes of competition vehicles stands in stark contrast to 40 years of practice by the agency and directly contradicts the agency’s own guidance in the 2002 FAQ. This action would effectively kill the vast majority of motorsports that rely heavily on OEM vehicles as the primary source of competition vehicles. [EPA-HQ-OAR-2014-0827-1893-A1 p.4

A modification to a certified motor vehicle for purposes of competition does not constitute “tampering” if that vehicle is then used solely for competition purposes. Indeed, in response to the now public proposed rule changes, Congress acted swiftly to address the overreach by the agency, introducing bipartisan legislation in March in the House and Senate, HR 4715 (114th Cong. 2nd Session) and S 2659 (114th Cong. 2nd Session), to more expressly codify the existing practice of allowing competition vehicles to be used outside the Clean Air Act. [EPA-HQ-OAR-2014-0827-1893-A1 p.4]

In light of the fact that the EPA failed to adequately notice the public, attempted to hide the proposed changes in a non-germane rulemaking, did not conduct a Regflex assessment, SBREFA analysis, or small business economic impact analysis, and attempted to significantly alter a rule and practice that has been in effect for 40 years without the approval of Congress, we respectfully request that the EPA withdraw its “clarification.” [EPA-HQ-OAR-2014-0827-1893-A1 p.4]

Protection against defeat devices. Commenters in the rulemaking and NODA docket have raised a concern about the issue of modifying vehicles emission control equipment. It is important that EPA affirms its long-standing authority and continues to refine the specific regulatory language to prevent the proliferation of defeat devices for vehicles that are driven on public roads. Enforcement cases such as the one with Casper’s Electronics’ 44,000 defeat devices (see US EPA, 2015) highlight the importance of monitoring and enforcing which companies are developing the devices, and especially ensuring the devices are not being used on public roads. As such, we believe it is important that EPA continue to recognize that there is a legitimate concern about illegal aftermarket devices being used on public roads, and the EPA act to prevent their use (e.g., see US EPA, 2015). Such actions include ensuring that defeat devices are not sold under the guise of competitive race cars while being used on public roads. [EPA-HQ-OAR-2014-0827-1876-A1 p.2]

Organization:  Manufacturers of Emission Controls Association (MECA)

The Manufacturers of Emission Controls Association (MECA) is pleased to provide comments in response to the U.S. EPA’s request for public comments on their Notice of Data Availability covering the prohibition against tampering or disabling of emission controls on motor vehicles used for competition (Docket ID No. EPA-HQ-OAR-2014-0827-1469-A1). MECA supports the agencies position that the Clean Air Act expressly prohibits the tampering with the emission controls on certified motor vehicles that may be used for racing but may also find their way to occasional use on public roads. [EPA-HQ-OAR-2014-0827-1868-A1 p.1]

MECA is a non-profit association of the world’s leading manufacturers of emission control technology for motor vehicles. Our members have over 40 years of experience and a proven track record in developing and manufacturing emission control technology for the entire spectrum of internal combustion engines and mobile sources for gasoline, diesel, and alternative-fueled engines. A number of our members have extensive experience in the development, manufacture, and application of aftermarket emission control technologies for existing gasoline and heavy-duty engines to insure that emission controls originally certified on motor vehicles continue to operate beyond the vehicles emission warranty period. [EPA-HQ-OAR-2014-0827-1868-A1 p.1]

To protect public health, as intended by the Clean Air Act, it is imperative that the emission control systems that were originally certified on motor vehicles remain on these vehicles over their full operating life even once the OEM emissions warranty expires. Some MECA members develop and manufacture aftermarket converters that are legal to replace a damaged OEM converter on a vehicle outside of the OEM emissions warranty. Over the past 40 years, catalytic converter technology has advanced significantly to where the exhaust exiting the tailpipe is 99% cleaner than that coming out of the engine. [EPA-HQ-OAR-2014-0827-1868-A1 p.1]
Many states have implemented inspection and maintenance (I/M) programs to periodically inspect the emissions from passenger cars to insure that the emission controls continue to operate properly. There are many areas of the country that do not require I/M inspection and once a vehicle is sold, it may never be checked. The air quality is not confined to any particular area and pollution travels downwind to other parts of the country that may not benefit from up-wind clean air. Without I/M programs, emission controls may be tampered on a motor vehicle under the guise that the vehicle is used for racing. Such activity may be limited to weekends and the vehicle continues to operate on public roads during the week. Furthermore, there are manufacturers that offer exhaust modification kits for competition vehicles. Without an active I/M program there is no way to insure that these devices are not being misapplied to vehicles that may occasionally operate on public roads. Many of these purchases occur over the internet so there is no way to insure that the vehicle that is being tampered is used solely for the purpose of racing competition and never driven on public roads. The California Air Resources Board requires aftermarket parts manufacturers to inform the installer of the legal and proper installation of their parts and to retain records of the owner and vehicle where the parts have been installed. [EPA-HQ-OAR-2014-0827-1868-A1 p.1-2]

MECA members are avid car enthusiasts and many enjoy racing, however, our members believe that emission standards need to be enforced and emission controls should not be defeated. We support the EPA’s long standing policy against tampering or disabling emission control systems on roadworthy passenger cars from their originally certified configuration. We also believe that the sale of devices that defeat emission control systems should be banned on competition racing vehicles that may be periodically operated on public roads. Thank you for consideration of our comments. [EPA-HQ-OAR-2014-0827-1868-A1 p.2]

Organization:  Mass Comment Campaign sponsored by anonymous 2 (web) - (369)

I must speak up and protest the EPA’s proposed rule ‘Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles; Phase 2’, specifically the following sections: [EPA-HQ-OAR-2014-0827-1513 p.1]

I propose that these rules be struck out of the ‘Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium and Heavy-Duty Engines and Vehicles; Phase 2’ or that the entire Proposed Rule be eliminated altogether if these sections regarding converting on-highway vehicles to non-highway vehicles cannot be modified or eliminated from the Proposed Rule. [EPA-HQ-OAR-2014-0827-1513 p.2]

>>Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of 40 CFR 1068.101(b) and 42 U.S.C. 7522(a)(3). [EPA-HQ-OAR-2014-0827-1513 p.1]

This means that EPA is proposing that we as enthusiasts would potentially violate emissions equipment laws intended for vehicles to be used upon a highway for vehicles that have been declared to never to be used upon said highway. Even if a vehicle was once an on-highway vehicle, a non-highway vehicle is no longer legal to operate on-highway and no longer subject to on-highway vehicle emissions standards. These vehicles are driven less and are transported by trailer to and from closed courses, thus never polluting as an on-highway vehicle would. [EPA-HQ-OAR-2014-0827-1513 p.1-2]
Note that a new vehicle that will be used solely for competition may be excluded from the requirements of this part based on a determination that the vehicle is not a motor vehicle under 40 CFR 85.1703. [EPA-HQ-OAR-2014-0827-1513 p.2]

This means that only body-in-white vehicles would be the only form of legal racecar available to enthusiasts. A body-in-white car is a vehicle that has no VIN number and is intended as a non-highway vehicle. However, most enthusiasts are not able to afford such a vehicle as they can cost as low as $300,000 (US), a number most entry level enthusiasts cannot afford and is why we convert on-highway vehicles into non-highway vehicles for the sole purpose of racing on closed courses. [EPA-HQ-OAR-2014-0827-1513 p.2]

Organization: Mass Comment Campaign sponsored by anonymous 2 (web) - (369)

Competition engines/equipment. (i) For uncertified engines/equipment that are excluded or exempted as new engines/equipment from any requirements of this chapter because they are to be used solely for competition, you may not use any of them in a manner that is inconsistent with use solely for competition. Anyone violating this paragraph (b)(4)(i) is deemed to be a manufacturer in violation of paragraph (a)(1) of this section. We may assess a civil penalty up to $37,500 for each engine or piece of equipment in violation. [EPA-HQ-OAR-2014-0827-1513 p.2]

If these rules are enacted, the enthusiast who has converted their once on-highway vehicle to a non-highway vehicle will be subjected to a fine that is out of touch with reality in both the rule and the amount. These converted non-highway vehicles are transported by trailer, only started and ran on a closed course, never seeing an on-highway mile. Non-highway vehicles should not be subject to on-highway laws, no matter if they are originally non-highway vehicles or on-highway vehicles converted to non-highway use. [EPA-HQ-OAR-2014-0827-1513 p.2]

What you are doing is punishing thousands of United States Citizens and Taxpayers by creating a rule that limits them to buying a purpose built vehicle that is out of their reach. You are punishing enthusiasts who are doing the right thing and using their non-highway converted vehicles as they are intended; to be used off the highway. [EPA-HQ-OAR-2014-0827-1513 p.2]

Organization: Mazda North American Operations

In addition to proposing new greenhouse gas standards for medium- and heavy-duty vehicles, EPA included proposed language to insert in 40 C.F.R. § 86.1854-12 pertaining to new and in-use light-duty vehicles, that would make the modification of certified production or street vehicles for off-road racing/competition a prohibited act. [EPA-HQ-OAR-2014-0827-1924-A1 p.2]

MNAO is headquartered in Irvine, CA and oversees the sales, marketing, parts and customer service support of Mazda vehicles in the United States and Mexico through nearly 700 dealers. The EPA noted in its most recent Light Duty Fuel Economy Trends report that Mazda is the most fuel-efficient auto manufacturer in the U.S for the third year in a row. Mazda's unique SKYACTIV Technology has made this level of efficiency possible. SKYACTIV is a suite of component and engineering technologies intended to cut vehicle weight and improve engine efficiency for outstanding environmental and safety performance, without sacrificing the brand’s renowned driving pleasure. [EPA-HQ-OAR-2014-0827-1924-A1 p.2]
Mazda Motorsports is part of MNAO and provides a support program for anyone racing or building a Mazda car for racing. The Mazda Motorsports Competition Parts program serves 9,000 registered grassroots racers across the United States. These racers compete in up to 25,000 races and events each year across the country. Mazda has 58% market share in the Sports Car Club of America (SCCA) grassroots club racing program as of 2015 participation data. The cars that Mazda racers use in competition range from legally registered street going vehicles to full-on “race track only” vehicles. [EPA-HQ-OAR-2014-0827-1924-A1 p.2]

Mazda Motorsports members can purchase competition and stock parts directly from Mazda. This is a Membership only program and competition parts are not for sale to the general public. The parts available are all non-emissions affecting parts. Racers register with Mazda Motorsports through www.mazdamotorsports.com and provide proof images of the car they compete with. These racers have the opportunity to purchase racing or “competition only” parts, as well as, stock and production parts directly from Mazda through this motorsports program. The customer has to accept and acknowledge the terms and conditions agreement prior to purchasing parts. The disclaimer specifically states that the competition only parts being purchased are not for on-road use. [EPA-HQ-OAR-2014-0827-1924-A1 p.2]

The Mazda MX-5 Miata is the best-selling two seat sports car in the world, according to the Guinness Book of World Records. The car has also become the most road raced car in the world. Established in 2001, Spec Miata (as it is named), is “stock” car racing in the truest sense. The 2.0-liter four-cylinder engine is sealed to prevent any internal tampering/modifications and the race exhaust runs through a catalytic converter. This allows Mazda to make production changes to the road-going Miata when it uncovers issues on the track that may warrant changes to production components. Mazda has sold nearly 3,000 kits to turn a road-going Miata into a race car. Spec Miata also grew into the Mazda MX-5 Cup professional series which started in 2006. As of 2015, Mazda now sells a Global MX-5 Miata Cup car. This is a ready-to-race Miata based on the vehicle sold in dealerships nationwide. The U.S.-spec MX-5 Cup Car allows racers to bypass conversion kits for a conventional Miata and buy a pre-assembled racecar through a third-party supplier (Long Road Racing in Statesville, North Carolina). [EPA-HQ-OAR-2014-0827-1924-A1 p.2]

Through Mazda’s involvement in the American Le Mans series Prototype racing category (2005-2013), Mazda worked closely with the Green Racing Work Group, the EPA, the SAE, and the DOE to bring several alternative technologies and fuels to the race track. From 2005-2006, Mazda competed with a 3-rotor Mazda engine in the LMP2 category. This efficient engine technology is one of the cornerstones of the Mazda brand philosophy. From 2007-2013, Mazda competed with a 2.0L 4-cylinder single turbo engine. This engine was the smallest capacity/displacement engine in the series and competed with IMSA 100 fuel initially. In 2008, Mazda was given the opportunity to bring Isobutanol Fuel to the series to showcase this next generation fuel and Mazda earned the 2011 Michelin Green Racing Challenge Award after earning several race victories and the season long Championship. Finally, in 2013-2015, Mazda brought Clean Diesel technology and renewable synthetic diesel fuel to Grand-Am and the United Sports Car Championship. [EPA-HQ-OAR-2014-0827-1924-A1 p.2-3]

Mazda Motorsports also launched the Racing Accelerates Creative Education (R.A.C.E.) outreach program. RACE is a national touring program from Mazda Motorsports that uses the science, technology and math of auto racing to inspire students to consider the many career options in the STEM disciplines. The program has positively impacted more than 10,000 middle and high school students across the country. Our Motorsports program also supports Project Yellow Light, a national organization dedicated to eliminating distracted driving by high school and college age drivers. [EPA-HQ-OAR-2014-0827-1924-A1 p.3]
Mazda is a leading player in all aspects of sports car racing with an emphasis on endurance road racing. Mazda is the number-one brand for road-racers across North America among both club racers and professionals. Mazda Motorsports traces its origin to an independent racing team in 1967. Mazda remains the only Asian car company to score an overall win at the 24 Hours of Le Mans in 1991. Mazda is proud of our grass-roots racing heritage and view motorsports as an integral part of our brand identity. [EPA-HQ-OAR-2014-0827-1924-A1 p.3]

MNAO supports the position of the Alliance of Automobile Manufacturers and Association of Global Automakers on the EPA’s proposal to prohibit the conversion of certified on-road vehicles to competition vehicles. Individuals and entities who remove emissions control equipment from certified vehicles, or otherwise put such vehicles into an uncertified configuration, and then drive them on public roads, commit tampering under the Clean Air Act. MNAO opposes illegal tampering of road use vehicles. However, the EPA must not go so far as to outlaw legitimate activities and businesses. MNAO believes converting a certified on-road vehicle into an uncertified competition vehicle, and using that vehicle only for competition, does not constitute tampering or otherwise violate the Clean Air Act. [EPA-HQ-OAR-2014-0827-1924-A1 p.3]

Organization: Mead, Nathan

I am submitting comments below with respect to: ENVIRONMENTAL PROTECTION AGENCY [EPA-HQ-OAR-2014-0827-1864-A1 p.1]

40 CFR Parts 85, 86, 1036, 1037, 1065, 1066, and 1068

DEPARTMENT OF TRANSPORTATION

National Highway Traffic Safety Administration

49 CFR Parts 523, 534, and 535

RIN 2060–AS16; RIN 2127–AL52

In particular I find the following paragraphs troublesome: [EPA-HQ-OAR-2014-0827-1864-A1 p.1]

§ 86.1854-12 Prohibited acts.

(b) * * *

(5) Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of paragraph (a)(3) of this section and 42 U.S.C. 7522(a)(3). [EPA-HQ-OAR-2014-0827-1864-A1 p.1]

Here is my problem(s) with the above language.
So let's say a guy decided to starry racing his late model car he makes a few street legal modifications but eventually wants get more serious and use the vehicle for racing only and escalates his program incrementally. By my interpretation of the above language he will either have to find an older vehicle which of course there is a limited supply or step up to a built for racing only engine and chassis which for any is cost prohibitive. And all for what? To make sure that racers burn their negligible amount of fuel in exactly the way the manufacturer intended, Rules like this will have virtually no impact on improving the environment but a huge impact on individuals right to enjoy the sport of their choice and kill yet more domestic jobs held by those who manufacture and sell parts for modifying late model engines for off highway use. [EPA-HQ-OAR-2014-0827-1864-A1 p.1]

For sake of perspective I did a brief analysis: [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

Let's discount 10% that walked, biked or took public transportation although they all left a carbon footprint (we exhale more CO2 when exercising). [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

That brings us to 15.57M

If we take the following averages: 3 people per car and a round trip of 50 miles in a vehicles that gets 20 mpg we get 12,975,000 gallons of fuel consumed just to see pro football games. Although my numbers except for attendance are arbitrary I think any reasonable person would agree they are reasonable. At en.m.wikipedia.org it states that NASCAR consumes 216,000 gallons at the 36 cup points races combined. [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

It goes without saying there is much more fuel consumed by race cars in the aggregate, and of course a vastly larger amount by several orders of magnitude in fact consumed by fans traveling to pro and college and other amateur sporting events, cross country skiing, fishing, golfing and other sports that in and of themselves don't necessarily involve burning fuel, directly. [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

So what's next? No more attending live games or concerts the coverage is better on TV anyway with instant replay, and the album is generally as good or in many times better than a live concert? [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

Really if you want to take away our freedom to modify and race our cars. Then you should only allow people to travel within a certain radius to enjoy hiking or cross country skiing. [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

These rules have unpleasant consequences for everyone by infringing on individual freedom to pursue the hobby of choice by the precedent they set. All for a minuscule reduction in greenhouse gases. [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

These rules ring insincere to me and damage the credibility of the EPA. [EPA-HQ-OAR-2014-0827-1864-A1 p.2]

**Organization:** Motor & Equipment Manufacturers Association (MEMA)
MEMA supports comments submitted by the Specialty Equipment Market Association (SEMA) in opposition to the EPA’s proposed provision that emission control devices must remain in their certified configuration even if converting street vehicles into race vehicles.\(^2\) MEMA respectfully request that EPA withdraw this proposed provision. Our comments will address only this issue. [NHTSA-2014-0132-0229-A1 p.1]

In October 2015, MEMA submitted comments to the Phase 2 regulations that were generally supportive of the EPA’s endeavor while addressing some specific issue areas of concern to medium- and heavy-duty suppliers.\(^4\) MEMA and the motor vehicle supplier industry are committed to policies that enable the introduction of new technologies needed to support sustainable mobility. [NHTSA-2014-0132-0229-A1 p.1]

Within the 629-page Phase 2 proposed rule to establish regulations for GHG emissions and fuel consumption for medium- and heavy-duty vehicles, EPA included a policy revision that would make it illegal for certified motor vehicles to be converted into vehicles used solely for competition by reconfiguring emission control devices. MEMA supports the comments submitted by SEMA and objects to EPA’s tactic to revise current policy by including a provision in the context of the Phase 2 proposed rule on medium- and heavy-duty engines and vehicles. Furthermore, MEMA agrees with SEMA that Congress did not intend racecars to be within the jurisdiction of the Clean Air Act (CAA). [NHTSA-2014-0132-0229-A1 p.2]

MEMA shares SEMA’s concerns regarding EPA’s process. First, EPA did not alert impacted stakeholders that the agency was proposing a significant policy change. The current exemption, which is on vehicles used solely for competition, has been in place for decades. Second, the proposed provision on the modification of a certified vehicle for competition use is not germane to the Phase 2 proposed rulemaking on GHG emissions and fuel efficiency standards for medium- and heavy-duty vehicles and engines. Third, EPA failed to provide any economic analysis with this revision to a long-standing policy. EPA lifting this established CAA exemption on vehicles used solely for competition would impact the aftermarket industry’s performance sector and put an end to most forms of amateur racing and car shows, adversely impacting the sport with minimal gains on GHG emissions. [NHTSA-2014-0132-0229-A1 p.2]

Most importantly, according to statutory text and legislative history of the CAA, it is clear that vehicles used solely for competition are not within the jurisdiction of the CAA. The 1970 CAA Amendments included an exemption for anti-tampering provisions for the emission control devices of manufactured or modified racing vehicles, and the 1990 CAA Amendments clarified that EPA did not have authority to regulate “vehicles used solely for competition.” Further, at the March 15, 2016 House Science Oversight Subcommittee hearing, Brent Yacobucci with the Congressional Research Service (CRS) testified that the CRS could not identify any EPA document prior to the July 2015 proposed rule that stated converted racecars were ineligible for the CAA exclusion. [NHTSA-2014-0132-0229-A1 p.2]

For all these reasons, MEMA respectfully requests that EPA withdraw the proposed provision that would make it illegal for certified motor vehicles to be converted into vehicles used solely for competition by reconfiguring emission control devices. [NHTSA-2014-0132-0229-A1 p.2]

\(^4\) Docket No. EPA-HQ-OAR-2014-0827-1274
In its July 13, 2015 Notice of Proposed Rulemaking, EPA stated: 'The existing prohibitions and exemptions in 40 CFR part 1068 related to competition engines and vehicles need to be amended to account for differing policies for nonroad and motor vehicle applications.' This was proposed to be accomplished by adding a new subsection 40 CFR 86.1854-12(b)(5) stating that 'Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines'. Similar language appears in proposed section 40 CFR 1068.101(b)(4)(ii). In conjunction with a proposed section 40 CFR 1068.1(a)(3) subjecting highway motorcycles to part 1068, the language of 40 CFR 1068.101(b)(4)(ii) would extend the tampering prohibition to highway motorcycles used for competition. [NHTSA-2014-0132-0219-A1 p.1]

In comments dated December 28, 2015, the Specialty Equipment Market Association (SEMA) explained why it believes the proposed addition to 40 CFR 86.1854-12(b)(5) should be rescinded. The Motorcycle Industry Council agrees with SEMA's comments and also recommends that 40 CFR 1068.101(b)(4)(ii) be amended by striking the following text: [NHTSA-2014-0132-0219-A1 p.1]

Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of 40 CFR 1068.101(b) and 42 U.S.C. 7522(a)(3). [NHTSA-2014-0132-0219-A1 p.1]

In support, MIC submits the following comments.

A Tampering Prohibition for Racing Vehicles is Inappropriate

MIC acknowledges that highway motorcycles and other on-road motor vehicles are subject to the anti-tampering provisions of section 203 of the Clean Air Act. We also acknowledge that there is no exception in Sec. 203 for racing vehicles or racing conversions. If a literal, facial reading of Sec. 203 is controlling, any conversion that falls under its prohibitions (e.g., a conversion that removes or modifies a catalytic exhaust system or involves reprogramming of the fuel injection system) would not be legal, even if the conversion were done solely for racing purposes. [NHTSA-2014-0132-0219-A1 p.1-2]

However, we do not believe such a literal reading is controlling and that there is an alternative reading of the applicability of Sec. 203 to racing conversions that is more consistent with Congressional intent and established EPA policy with regard to modification of vehicles for racing. EPA has both the authority and the obligation to exempt vehicles being used for racing for a number of reasons: [NHTSA-2014-0132-0219-A1 p.2]

• Congressional Intent is Clear

Congress did not intend for the anti-tampering provisions of the Clean Air Act Amendments of 1970 to apply to vehicles converted to competition use. In the Conference Report, after Mr. Nichols asked for confirmation that vehicles affected ‘do not include vehicles or vehicle engines manufactured for, modified for or utilized in organized motorized racing events,’ Mr. Staggers (Chairman of the House Interstate and Foreign Commerce Committee and floor manager of the bill) confirmed that understanding’. [NHTSA-2014-0132-0219-A1 p.2]
Consistent with the Congressional intent, Section 202(b)(3)(B) of the 1970 Clean Air Act clearly gave EPA the authority to exempt subcategories of 'light duty vehicles' by stating that: 'The term 'light duty vehicles and engines' means new light duty motor vehicles and new light duty motor vehicle engines, as determined under regulations of the Administrator.' This language was not only broad enough to allow EPA to exempt vehicles used for competition, it allowed EPA to initially exempt motorcycles from emission standards altogether. [NHTSA-2014-0132-0219-A1 p.2]

• Avoiding Disparate Results

If the absence of an explicit exemption for racing conversions from the anti-tampering provisions is construed as an immutable statement that racing conversions are prohibited, the result would be an irrational and economically unfair non-uniform treatment of onroad motorcycles vis-à-vis nonroad motorcycles, where conversions are not allowed for the former but (as explained below) allowed for the latter. It is an established rule of construction that implying an intent to Congress that causes such disruptive, disparate results should be avoided. [NHTSA-2014-0132-0219-A1 p.2]

• EPA's Adoption Of An Anti-tampering Regulation For Nonroad Motorcycles

When Congress added current Sec. 213 to the CAA in 1990 requiring EPA to study and regulate nonroad vehicle and engine emissions, it did not extend the anti-tampering provisions in Sec. 203 to the nonroad sector. As noted above, Sec. 203 by its very terms is limited to vehicles used on a street or highway. But Congress did expressly exempt nonroad vehicles and engines used solely for competition from the definitions of nonroad vehicle and nonroad engine (CAA Sec. 216 subsecs. (10) and (11)). System or involves reprogramming of the fuel injection system) would not be legal, even if the conversion were done solely for racing purposes. [NHTSA-2014-0132-0219-A1 p.2]

So, with respect to nonroad motorcycles converted for racing, in 1990 EPA was faced with the obverse of the CAA treatment of onroad motorcycles converted for racing, i.e., no tampering prohibition and a racing exemption for the nonroad sector, and a tampering prohibition but no racing exemption for the onroad sector. [NHTSA-2014-0132-0219-A1 p.3]

Under those circumstances, EPA decided that it had the authority to fill the gap created by the Congressional silence on tampering for the nonroad sector by adopting a tampering prohibition in its nonroad regulations. Specifically, when EPA first adopted its general compliance regulations governing nonroad vehicles (67 FR 68242 et seq., Nov. 8, 2002), in its discretion it included anti-tampering provisions at 40 CFR 1068.101(b)(1)-(3). EPA did not explain why it took this action and its decision in this regard was not questioned or challenged during the regulatory adoption process (see 66 FR 51098 et seq., Oct. 5, 2001 (proposed rulemaking), and 67FR 68242 et seq., Nov. 8, 2002 (final rulemaking)). [NHTSA-2014-0132-0219-A1 p.3]

discretion to adopt, or otherwise enforce, a racing vehicle exemption from the anti-tampering provisions for onroad vehicles in Sec. 203. [NHTSA-2014-0132-0219-A1 p.3]

• Prior Recognition of a Racing Exemption by EPA

There are several indications in prior EPA regulatory and policy actions confirming that Congress's failure to mention a racing exception from the CAA anti-tampering provisions applicable to onroad vehicles, is merely a policy oversight or omission that can be addressed by EPA and is not an implied ban. [NHTSA-2014-0132-0219-A1 p.3]
For example, EPA has created a regulatory process for exclusion of racing vehicles from the restriction against the import of uncertified vehicles in Sec. 203(a)(1) of the CAA, even though Congress did not mention a racing exclusion or exemption in that section. (See 40 CFR Sec. 85.1511 establishing a racing exclusion and 40 CFR Sec. 85.1703 defining what constitutes a racing vehicle. Also See. 2.3.3 of EPA's 'Procedures for Importing Vehicles and Engines in the United States.') [NHTSA-2014-0132-0219-A1 p.3]

Likewise, in EPA's Document No. EPA420-R-03-016, dated December 2003, entitled 'Summary and Analysis of Comments: Control of Emissions from Highway Motorcycles', EPA states (at p.7) that while school buses and police vehicles must meet CAA emission standards, '...the Clean Air Act specifically exempts from emission regulation vehicles that are used solely for competition.' On p. 7, EPA goes on to state that NASCAR race vehicles, which were and are converted onroad vehicles, '... are not required to comply with emission regulations, and we do not have the authority to regulate them.' EPA states further (at p.107) in the specific context of discussing whether motorcycle customization and modification is allowed under the CAA anti-tampering prohibition, that 'Selling a 'competition only' version is allowed, but EPA expects aftermarket dealers and retailers to use reasonable prudence so that abuse of this provision does not result in an act of tampering by consumers.' [NHTSA-2014-0132-0219-A1 p.3]

Additional evidence of prior recognition of a racing exemption was noted in SEMA's comment: 'EPA personnel participated in a presentation at an industry trade show sponsored by SEMA on November 5, 2015 to speak to this very issue and made no mention of the pending rulemaking proceeding.' Indeed, EPA personnel routinely participated in SEMA trade shows at least as far back as the mid-1990s at which hundreds of products were on display that were designed for competition use only and not emissions compliant. EPA never informed SEMA that the sale of such products was inconsistent with EPA policy. [NHTSA-2014-0132-0219-A1 p.4]

For the reasons outlined above, EPA has both the authority and the obligation to exempt motor vehicles being used for competition without any statutory or regulatory changes. [NHTSA-2014-0132-0219-A1 p.4]

---

2 Personal communication with Edward Gardetto, former EPA employee.

**Organization:** National Association of Clean Air Agencies (NACAA)

3. December 28, 2015 comments from SEMA related to light-duty motor vehicles used for competition racing

NACAA is troubled by the December 28, 2015 comments submitted by SEMA to the Phase 2 docket, which we believe misconstrue EPA’s intent, existing rules and policy and the Clean Air Act. In its comments, SEMA takes issue with language in the proposed Phase 2 rule where EPA seeks to clarify that certain regulatory provisions related to nonroad vehicles do not, and cannot under the Clean Air Act, apply to onroad vehicles. Under the Clean Air Act, EPA has discretion to allow certified nonroad vehicles to be modified and used for competition. The statute does not provide EPA discretion for certified onroad vehicles. Certified onroad vehicles that are outfitted with aftermarket parts such as
those that defeat or delete emission controls are illegal under the Clean Air Act, even if the intention is to use such converted vehicles only for the purposes of competition. [EPA-HQ-OAR-2014-0827-1890-A1 p.2]

The proposed language in the Phase 2 rule is intended to clarify this distinction; it does not, in any way, change any existing rule or policy. In explaining this provision, EPA is clear that it does not apply to dedicated racecar vehicles – such as NASCAR and Indy vehicles – originally manufactured for the purpose of competition (and, therefore, never certified for onroad use). EPA has also been clear that the Clean Air Act plainly prohibits tampering and the agency has always had the authority to enforce against individual vehicles/owners that violate this law. EPA has never pursued an enforcement case against an individual, as SEMA implies the agency will in the future. Instead, EPA’s primary concern is the proliferation and increasing sales and installation of aftermarket parts that defeat or delete emission controls on cars and trucks used on the road in every state across the nation. These parts are readily available for sale online to anyone who wishes to purchase them for any purpose. (Though some of these conversions are intended for creating vehicles that will be used only for competition, many others are done on vehicles intended for continued use on the road. In either case, though, they are not allowed under the Clean Air Act). [EPA-HQ-OAR-2014-0827-1890-A1 p.3]

Organization: National Automobile Dealers Association (NADA)

II. LIGHT-DUTY RACE VEHICLES

In its October 1, comments, NADA/ATD did not address a proposal to regulate as tampering the conversion of light-duty “street” vehicle to dedicated race cars. At the time, NADA/ATD focused exclusively on the commercial truck standards set out in the proposal. A review of the NODA has caused NADA/ATD to take a position on the issue. [EPA-HQ-OAR-2014-0827-1932-A1 p.2]

Light-duty vehicle dealerships sell new and used vehicles that customers sometimes convert into race cars. Moreover and just as importantly, many dealerships and their employees are involved in sponsoring race teams, building out race cars, and driving or supporting cars and teams on race day. These time-honored activities have occurred throughout the 100 + years dealers have sold cars and are sometimes elegantly summarized by the phrase “race on Sunday, sell on Monday.” At the same time, dealers are aware of the Clean Air Act’s anti-tampering provisions, they recognize the importance of emissions tampering issues, and they endeavor to ensure that emissions systems are not tampered with when servicing or selling vehicles for road use. [EPA-HQ-OAR-2014-0827-1932-A1 p.2]

NADA concurs with positions taken by the Specialty Equipment Manufacturers Association (SEMA) on the race car tampering proposal. In fact, NADA has signed onto a set of joint industry comments on the issue. Note that by objecting to this provision, NADA is in no way arguing in support of clear-cut emissions tampering activities involving the improper modification of, or instillation of defeat devices into, vehicles used on public roads. Moreover, NADA fully supports EPA’s efforts to appropriately regulate companies that manufacture, import, market, or sell devices designed to “defeat” emissions performance under the guise of doing so only for the dedicated race vehicle marketplace to the extent that such is not the case. [EPA-HQ-OAR-2014-0827-1932-A1 p.2]

With respect to tampering, commercial truck dealerships have seen a surge in the number of tampered vehicles entering their service bays and used truck lots since at least 2007. Apparently, certain truck owners and operators have elected to tamper with emission systems as a means of avoiding the cost and burden of properly maintaining those systems or in an attempt to improve vehicle performance or reduce operating costs. In lieu of creating an unnecessary and inappropriate constraint on race vehicles,
NADA/ATD urges EPA to focus some of its limited but valuable tampering enforcement resources on this area of concern. [EPA-HQ-OAR-2014-0827-1932-A1 p.2]

2 40 CFR § 86.1854-12(b)(5) was proposed to be amended to include the following:

Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified motor vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions of paragraph (a)(3) of this section and 42 U.S.C. 7522(a)(3).

3 See e.g., http://www.successfuldealer.com/dealing-with-emission-tampering/

Organization:  Northeast States for Coordinated Air Use Management (NESCAUM)

The Northeast States for Coordinated Air Use Management (NESCAUM)\(^1\) submits these comments in response to the joint Notice of Data Availability (NODA) issued by the U. S. Environmental Protection Agency (EPA) and the U.S. Department of Transportation National Highway Traffic Safety Administration (NHTSA) on March 2, 2016 associated with the proposed rule – Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles – Phase 2 (81 Fed. Reg. 10822). NESCAUM’s comments are limited to issues raised in a December 28, 2015 comment on the Phase 2 rule from the Specialty Equipment Market Association (SEMA) related to the use of certified light-duty motor vehicles for competition racing. [EPA-HQ-OAR-2014-0827-1871-A1 p.1]

At issue is proposed new text in 40 C.F.R. §§ 86.1854-12\(^2\) intended by EPA to clarify the existing statutory and regulatory distinction between nonroad vehicles and certified motor vehicles as it relates to disabling or tampering with air pollution control devices: [EPA-HQ-OAR-2014-0827-1871-A1 p.1]

Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines; anyone modifying a certified vehicle or motor vehicle engine for any reason is subject to the tampering and defeat device prohibitions[.], 80 Fed. Reg. 40565 (July 13, 2015). [EPA-HQ-OAR-2014-0827-1871-A1 p.1-2]

In its comments, SEMA asserts that the proposed regulatory text represents a significant EPA policy change and, insofar as it would ban the conversion of motor vehicles originally designed and certified for onroad use into race cars, is contrary to congressional intent. [EPA-HQ-OAR-2014-0827-1871-A1 p.2]

NESCAUM supports the proposed amendments, which are consistent with the Clean Air Act and do not change any existing EPA requirements or enforcement policy. [EPA-HQ-OAR-2014-0827-1871-A1 p.2]

SEMA suggests that the proposed regulatory amendments will expose owners of modified motor vehicles converted solely for nonroad competition to enforcement actions and civil penalties. This suggestion is at odds with EPA’s track record. EPA can and has consistently exercised its enforcement
discretion by targeting manufacturers of defeat devices that sell their illegal products to vehicle owners who continue to drive their cars on public roads. The agency has not indicated any intention of expanding its enforcement effort to competition car owners or hobbyists. [EPA-HQ-OAR-2014-0827-1871-A1 p.2]

In areas of the Northeast, as well as elsewhere in the nation, air quality does not meet national health-based air quality standards. Sales of aftermarket parts that defeat emission controls to owners of certified motor vehicles still operating on public roads further degrade air quality. Under present circumstances, EPA’s enforcement approach to tampering with pollution control devices is a practical and straightforward application of the rule of law. [EPA-HQ-OAR-2014-0827-1871-A1 p.2]

Thank you for the opportunity to provide comments on the Notice of Data Availability. [EPA-HQ-OAR-2014-0827-1871-A1 p.2]

1 NESCAUM is an association of the state air quality agencies in the six New England States, New Jersey, and New York. This letter reflects the majority views of NESCAUM as a state membership organization. Individual NESCAUM member states may hold views different from the NESCAUM states’ majority consensus.

2 EPA has proposed a corresponding amendment applicable to certified heavy-duty engines and vehicles in 40 CFR § 1037.601(a)(3), 80 Fed. Reg. 40650.

Organization: Ohio Attorney General’s Office

I am writing to express my deep concerns about a conflict with the federal Clean Air Act buried within the provisions of the 629-page rule referenced above, which states: “Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines.” As written, this proposed addition attempts to expand the EPA’s statutory jurisdiction under the Clean Air Act to cover vehicles modified for racing or hobbyist competition. Such an approach would contravene the law and reverse decades of EPA practice.

I am writing to express my deep concerns about a conflict with the federal Clean Air Act buried within the provisions of the 629-page rule referenced above, which states: “Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines.” As written, this proposed addition attempts to expand the EPA’s statutory jurisdiction under the Clean Air Act to cover vehicles modified for racing or hobbyist competition. Such an approach would contravene the law and reverse decades of EPA practice. [EPA-HQ-OAR-2014-0827-1799-A1 p.1]
This unnecessary expansion conflicts with the expressed intent of Congress, and I urge you to remedy this problem in the final rule by deleting the provision quoted above. [EPA-HQ-OAR-2014-0827-1799-A1 p.1]

The specialty automotive industry is an important part of our economy. In 2014, consumers spent $36 billion on automotive specialty equipment parts and accessories. Ohio is home to Summit Racing Equipment and JEGS High Performance, America’s two largest retailers selling high performance automotive equipment. These companies, as well as many equipment manufacturers and racing venues in Ohio, employ thousands of Ohioans and are responsible for hundreds of millions of dollars in economic activity. This proposed rule would damage Ohio’s economy by making many of the products sold and installed by Ohio businesses illegal. [EPA-HQ-OAR-2014-0827-1799-A1 p.1]

While the federal Clean Air Act prohibits certain modifications to everyday motor vehicles used on public roads, statutory language and the EPA’s historic practice have made it clear that vehicles built or modified for racing purposes, and not used on public streets, are not regulated under the Clean Air Act. For example, 42 U.S.C. § 7550(2) limits the definition of a covered “motor vehicle” to a vehicle designed for transport “on a street or highway” as opposed to operation on a racetrack. Correspondingly, 42 U.S.C. § 7550(10) limits the term “nonroad engine” to an engine “that is not used in a motor vehicle or a vehicle used solely for competition,” while 42 U.S.C. § 7550(11) makes clear that the term “nonroad vehicle” also does not apply to “a motor vehicle or a vehicle used solely for competition.” [EPA-HQ-OAR-2014-0827-1799-A1 p.1]

Congress did not make these choices by happenstance. It intended to differentiate between a vehicle covered by this sort of rule and “a vehicle used solely for competition.” In fact, the U.S. House Committee on Foreign and Interstate Commerce identified and discussed this issue before passing the Clean Air Act in 1970: [EPA-HQ-OAR-2014-0827-1799-A1 p.1]

MR. NICHOLS. I would like to ask a question of the chairman, if I may. I am sure the distinguished chairman would recognize and agree with me, I hope, that many automobile improvements in the efficiency and safety of motor vehicles have resulted from experience gained in operating motor vehicles under demanding circumstances such as those circumstances encountered in motor racing. I refer to the tracks as Talladega in my own State, to Daytona and Indianapolis, competition. I would ask the distinguished chairman if I am correct in stating that the terms “vehicle” and “vehicle engine” as used in the act do not include vehicles or vehicle engines manufactured for, modified for or utilized in organized motorized racing events which, of course, are held very infrequently but which utilize all types of vehicles and vehicle engines? [EPA-HQ-OAR-2014-0827-1799-A1 p.1]

MR. STAGGERS. In response to the gentleman from Alabama, I would say to the gentleman they would not come under the provisions of this act, because the act deals only with automobiles used on our roads in everyday use. The act would not cover the types of racing vehicles to which the gentleman referred, and present law does not cover them either. [EPA-HQ-OAR-2014-0827-1799-A1 p.1]

Statutory language and legislative history clearly show that vehicles used solely for competition, including a race vehicle that has been converted from a certified highway vehicle, are not regulated under the Clean Air Act. The EPA is authorized to create regulations that interpret laws that Congress passes. However, the Agency cannot rewrite statutory definitions and -- as the U.S. Supreme Court has made clear -- “must always give effect to the unambiguously expressed intent of Congress.” [EPA-HQ-OAR-2014-0827-1799-A1 p.1]
I strongly urge the EPA to remove the language referencing vehicles “used solely for competition” from the final rule. Not only is this language inconsistent with the federal Clean Air Act, but any measurable benefit from this change would pale in comparison to the economic harm from lost jobs and reduced tax revenues in Ohio. [EPA-HQ-OAR-2014-0827-1799-A1 p.1]

Organization: Specialty Equipment Market Association (SEMA)

The EPA published a Notice of Proposed Rulemaking (NPRM) on July 13, 2015 for the primary purpose of proposing a second round of greenhouse gas emission standards for medium- and heavy-duty vehicles. Within the NPRM, the EPA included changes to existing regulations to put in place a policy that would prohibit any person from decertifying a motor vehicle to transform it into a vehicle to be used solely for competition (i.e., a racing vehicle). This new regulatory framework for racing vehicles represents a departure from previous EPA policy and was included in the NPRM without adequate notice or consideration of the impact on affected parties. Further, the changes are not in accord with the Clean Air Act, the statute under which they have been proposed. Lastly, the proposal is unnecessary and unreasonable in relation to the EPA’s stated purpose to enforce against the sale of illegal emissions defeat devices used on street vehicles. [EPA-HQ-OAR-2014-0827-1931-A1 p.1]

When the NPRM was originally released in the summer of 2015, industry stakeholders were unaware that changes to prohibit the conversion of mass-produced street vehicles into track-only racing vehicles had been included within the 629-page proposed rule on greenhouse gas standards for medium- and heavy-duty vehicles. SEMA did not discover the changes until late in 2015, after the comment period had closed, and submitted comments to the docket on December 28, 2015. 4 Prior to SEMA’s submission, not a single comment out of the thousands that were submitted to the docket made any mention of the racing vehicle issue. SEMA issued a press release to alert the public of the proposed changes on February 9, 2016. 5 Within 24 hours, a petition to the White House requesting the EPA withdraw the proposal had received more than 100,000 signatures. 6 When the NODA was published on March 2, 2016, SEMA was disappointed to find that the EPA had not provided any explanation or analysis on the proposal relative to racing, and instead requested comments on issues raised in SEMA’s comments. 7 While the rulemaking has been reopened for public comment, there is no supplemental information to fulfill EPA’s obligations to provide meaningful notice that would allow the public, small businesses, the Congress and the Government Accountability Office (GAO) to have a full understanding of the changes, the costs versus the benefits of the proposal, the impact it would have on small entities or the economic impact to the economy at large. [EPA-HQ-OAR-2014-0827-1931-A1 p.2]

New and Unreasonable Policy

The EPA’s proposal to prohibit racing vehicle conversions and the effective ban on use of parts in converted racing vehicles hinges on the EPA’s interpretation of the term “motor vehicle” in the Clean Air Act. A motor vehicle is defined in the Clean Air Act as “any self-propelled vehicle designed for
transporting persons or property on a street or highway” (emphasis added). In 1974, the EPA issued its first regulations interpreting the term “motor vehicle” in Part 85, Subpart R – “Exclusion and Exemption of Motor Vehicles and Motor Vehicle Engines.” The definition of “motor vehicle” that the agency ultimately adopted excludes vehicles based on certain characteristics, such as whether the vehicle “lacks features customarily associated with safe and practical street or highway use” or “exhibits features which render its use on a street or highway unsafe, impractical, or highly unlikely.” These criteria are used to assess whether a vehicle is used on-road, and is thus a “motor vehicle,” or has undergone significant modifications such that it will no longer be used on-road, which would naturally exclude vehicles substantially modified for racing or combat operations.

The EPA is now proposing a change to the definition of “motor vehicle” that could significantly limit the exclusion of racing vehicles. The change modifies the criteria used to determine whether a vehicle is excluded from the term “motor vehicle” by adding the following language as a new subparagraph (b):

Note that, in applying the criterion in paragraph (a)(2) of this section, vehicles that are clearly intended for operation on highways are motor vehicles. Absence of a particular safety feature is relevant only when absence of that feature would prevent operation on highways.

This limiting language is so severe that absence of a particular feature must prevent the vehicle from being operated on the highways in order to qualify for exclusion. This would present a stark departure from current regulatory guidance on the import of modified racing vehicles, which relies on the definition of “motor vehicle” to determine whether a modified racing vehicle qualifies for an exclusion. The agency has failed to explain how the change would affect the continued importation and conversion of racing vehicles.

In addition to overhauling the definition of motor vehicle that has been in place since 1974, language was inserted into various sections of the proposed rule to expressly prohibit the conversion of a motor vehicle into a nonroad vehicle or vehicle to be used solely for competition. The EPA claims in its explanation of the changes that it is changing the language to reflect longstanding policies, such as a policy that “if a motor vehicle is covered by a certificate of conformity at any point, there is no exemption from the tampering and defeat-device prohibitions that would allow for converting the engine or vehicle for competition use.” Essentially, the EPA is saying “once a motor vehicle, always a motor vehicle.” However, this contradicts long-standing agency policy, which has for decades recognized that vehicles that are used solely for competition are excluded from the EPA’s regulations under the Clean Air Act because they no longer meet the definition of “motor vehicle.” In spite of the EPA’s claims in comments to the media, the policy prohibiting street-to-race conversions is indeed a new one. In testifying before a March 15, 2016 congressional hearing on this issue, a Congressional Research Service (CRS) section manager confirmed that “CRS was unable to find a document from EPA from before 2015 that explicitly stated that conversions of motor vehicles for racing were not eligible for an exemption.”

Within the NPRM, significant changes have also been made to Part 1068 to make it generally applicable to all light-duty vehicles and highway motorcycles. The current Part 1068 expressly excludes light-duty vehicles and highway motorcycles, so this change is notable. The implications of the change are not adequately addressed in light of its significance. Along with applying Part 1068 to all light-duty vehicles and highway motorcycles, the EPA has amended the investigatory procedures under Part 1068 to remove provisions dealing with EPA investigators securing warrants or court orders before entering a
facility. In the current Part 1068, a facility owner may deny entry to investigators who do not present a warrant or court order. The EPA is deleting this provision such that a court order or warrant will no longer be required under the agency’s rules. These proposed changes may well serve the EPA’s enforcement strategy, but legitimate businesses in good standing in their communities deserve further guidance from the agency before investigators show up unannounced and without documentation.

Proposal Contradicts Other State and Federal Policies

The EPA’s proposal would subject the industry to two contradictory stances on competition use only products, since they would become illegal at the federal level but permitted by the State of California. Under section 43001 of the California Health and Safety Code, the vehicular air pollution control provisions contain the following exclusion:

The provisions of this part shall not apply to:

(a) Racing vehicles.

For purposes of this exclusion, ‘‘racing vehicle’’ means a competition vehicle not used on public highways.

The California Air Resources Board (CARB) routinely reinforces this exclusion in settlement agreements by requiring companies to appropriately label racing products with disclaimers to inform consumers that the part is legal only for racing and can never be used on a street or highway.

Regulations governing the import of racing vehicles also allow for street vehicles to be converted into racing vehicles in other countries and imported into the U.S. under the racing vehicle exclusion. To maintain this policy for imported racing vehicles that have been converted from street vehicles, but remove the ability to conduct the same activity in the U.S., would create an inconsistent and arbitrary policy. It could also lead to the absurd result of U.S. residents having to export a vehicle to be used in racing to another country to have it converted and brought back in as a racing vehicle under the EPA’s import guidance.

Incorrect Interpretation of Clean Air Act in Light of Legislative History

The EPA’s interpretation of the term “motor vehicle” and the anti-tampering provision is not supported by the language, congressional intent or legislative history of the Clean Air Act.

The seminal case on deference to an agency’s interpretations of statutory language is Chevron v. NRDC. Chevron instructs that when Congress has left a particular issue unresolved, an agency may interpret the statute through rulemaking and courts generally give the agency’s interpretations “controlling weight unless they are arbitrary, capricious, or manifestly contrary to the statute.” However, this deference is only available where a court is unable to determine Congress’ intent on a particular issue. Where congressional intent contradicts the agency’s interpretation, a court will not defer to the agency.

In contrast to the ambiguous term “source” in Chevron, Congress has spoken to the meaning of “motor vehicle” as it relates to racing vehicles. Congress first addressed this issue in the Motor Vehicle Air Pollution Control Act of 1965, when it defined “motor vehicle” as “any self-propelled vehicle designed for transporting persons or property on a street or highway.” When the Clean Air Act Amendments were enacted in 1970, Congress made clear in conference committee deliberations that the term “motor
“vehicle” does not extend to vehicles manufactured or modified for racing. In 1990, Congress provided the EPA with the authority to regulate nonroad vehicles/engines. Since the term “nonroad vehicle” could easily have been interpreted to include racing vehicles, Congress added language to unequivocally exclude vehicles used solely for competition from the definition of “nonroad vehicle.” [EPA-HQ-OAR-2014-0827-1931-A1 p.5-6]

Unnecessary to Accomplish EPA’s Stated Goals

Statements from the EPA suggest that the agency has proposed the changes relative to racing vehicles because it needs further enforcement authority to go after emissions defeat devices used on street vehicles. However, the EPA already has authority to enforce against anyone who offers, sells or installs products that knowingly take a regulated motor vehicle out of compliance with emissions standards. In fact, the EPA has successfully pursued these cases in the past. In 2007, the EPA successfully brought an enforcement action against Casper Electronics for selling defeat devices used in “‘on road’ or ‘on highway’ vehicles.” The EPA explained that the defeat devices were marketed for “off road” use, and explained that “there is no general ‘off road’ use exemption from the pollution control requirements of the Clean Air Act.” SEMA recognizes that there is no exemption for “off road” use because the EPA is authorized by the Clean Air Act amendments of 1990 to regulate emissions from nonroad vehicles. However, the agency is not authorized to regulate emissions from “vehicles used solely for competition.” The EPA again exercised its enforcement authority to regulate products for on-road use when it brought enforcement actions against Edge Products, LLC in 2013 and H&S Performance, LLC in 2015. It is unclear why the EPA believes it is no longer able to successfully pursue these cases. By making all non-certified emissions-related parts that could be used on mass-produced vehicles illegal, the EPA would indeed make it much easier for the agency to bring cases against sellers of these parts. However, such an overbroad approach is the equivalent of killing a fly with a howitzer: it is not only completely unnecessary, it causes a great deal of collateral damage to sellers of legitimate racing products. [EPA-HQ-OAR-2014-0827-1931-A1 p.6-7]

Failure to Engage in Reasoned Decision Making

Despite all of the significant changes contained within the NPRM, the regulated community was not provided adequate notice prior to the close of the initial comment period and the EPA has still not provided a detailed statement of basis and purpose for the changes, all of which are required under the Administrative Procedures Act and the Clean Air Act. The rationale behind the changes relative to racing vehicles was inexplicably absent from the NPRM and no explanation was included in the NODA, which merely requested the public comment on issues raised in SEMA’s comments. [EPA-HQ-OAR-2014-0827-1931-A1 p.7]

While the EPA does not disclose the specific statutory authority for the changes relative to racing vehicles, the Clean Air Act is cited as the overarching statutory authority. Certain rulemakings undertaken by the EPA under the Clean Air Act are subject to the procedures at section 307(d) of the Act. Section 307(d) states that proposed rules “shall be accompanied by a statement of its basis and purpose…” There are minimum requirements for the statement of basis and purpose, such as “the major legal interpretations and policy considerations underlying the proposed rule.” Adequate notice to interested parties is required under both the procedural provisions of the Clean Air Act and the Administrative Procedure Act, which governs rulemakings conducted by federal agencies more generally. Agencies “must provide sufficient factual detail and rationale for the rule to permit interested parties to comment meaningfully.” In reviewing the agency’s conduct, a court determines whether the agency’s process was conducted in an arbitrary and capricious manner, including looking to whether the “agency set forth the reasons for its actions.” Constitutional due process also demands

Page 2060 of 2127
“notice reasonably calculated, under all the circumstances, to apprise interested parties of the pendency of the action and afford them an opportunity to present their objections.” [EPA-HQ-OAR-2014-0827-1931-A1 p.7-8]

In attempting to regulate converted racing vehicles and parts used thereon, the EPA has failed to fulfill the basic procedural requirements found in the Clean Air Act and Administrative Procedure Act. The NPRM contains no basis for the changes or the EPA’s purpose in proposing them, only that “clarification” is needed – but clarification never comes. Instead of offering legal interpretations and policy considerations, the EPA flatly states that, unlike the exemptions available for nonroad vehicles used for competition, “[t]here is no comparable allowance for motor vehicles.” This bald statement does not equate to a useful explanation of the changes or the extensive impact they have on the regulated industry. In explaining its position to the public, the EPA issued statements muddying the issue further by stating that it is merely explaining the difference between “nonroad vehicles” and “motor vehicles” and indicating that it does not plan on pursuing enforcement against individual racers. The public’s confusion is indicative of a failure on the part of the agency to adequately explain the implications of the proposed changes. SEMA would also like to take this opportunity to note that the EPA’s frequent reference to nonroad vehicles used solely for competition is an oxymoron and confusing in itself, as the statutory definition of “nonroad vehicle” explicitly excludes any “vehicle used solely for competition.” When Congress sought to regulate nonroad vehicles, it added the exclusionary language for racing vehicles because it had not directed these vehicles to be regulated as “motor vehicles” and had no intention of having them regulated under the nonroad provisions either. [EPA-HQ-OAR-2014-0827-1931-A1 p.8]

Congress has put in place additional requirements to maintain the proper checks and balances on agency action, including the Regulatory-Flexibility Act (“Reg-Flex Act”), the Small Business Regulatory Enforcement Fairness Act and the Congressional Review Act. The Reg-Flex Act instructs federal agencies that they must “consider the impact of their regulatory proposals on small entities, [analyze] alternatives that minimize impacts on small entities, and [make] the agencies’ analyses available for public comment.” The Congressional Review Act requires an agency to submit reports explaining how it has complied with the Reg-Flex Act and any applicable Executive Orders, as well as any cost-benefit analyses, to Congress and the GAO. Rules that are considered “major” are subject to greater scrutiny, with a “major rule” defined as a rule that would “likely have an annual effect on the economy of $100 million or more… increase costs or prices for consumers, industries, or state and local governments… or have significant adverse effects on the economy.” Given the overwhelming impact that this proposal would have on the specialty equipment aftermarket, which generates approximately $36 billion a year and employs Americans across all 50 states, this rule certainly qualifies for enhanced scrutiny under the Congressional Review Act. [EPA-HQ-OAR-2014-0827-1931-A1 p.8-9]

The EPA has failed to conduct an analysis of how small businesses would be impacted or any cost-benefit analysis on the race vehicle provisions as required under the Reg-Flex Act and the Congressional Review Act. For example, the EPA’s rule would prohibit the sale of racing products for vehicles that started life as street vehicles but which have been converted into racing vehicles. If this change remains in the final rule, thousands of businesses selling products for use on converted racing vehicles would be considered to be operating outside the law overnight. Many of these businesses are small entities, and the EPA has made no attempt to explain how the benefits of the proposed changes outweigh the substantial costs and disruption to the economy. Racers that use converted street vehicles for their sport and the shops that undertake the modifications are also put out of business. Motorsports as an industry generates billions of dollars of economic activity across the nation. Many states see motorsports-related industry as a driving force of their economies, such as Indiana, which has an estimated 23,000 Indiana residents employed by motorsports companies with average salaries of...
In Ohio, Summit Motorsports Park sponsored by aftermarket parts supplier Summit Racing has a $99.5 million economic impact on the surrounding community. That translates into jobs lost as well as denying Americans the ability to enjoy the sport of racing, and an indirect hit to all the local businesses catering to the participants and spectators. The EPA has not made any attempt to explain the potential impact on motorsports, motorsport facilities, the industries that have developed around motorsports or the Americans whose livelihood depends on motorsports. Foreclosing this degree of economic activity without explaining the logic and rationale for the changes falls short of the procedural statutes and judicial precedent. [EPA-HQ-OAR-2014-0827-1931-A1 p.9-10]

Reliance Interests

Many individuals and businesses have also relied on previous EPA guidance issued in 2002 that provided for modifications for the purpose of converting certified vehicles into racing vehicles. The EPA’s 2002 guidance document presents the question: “May I modify a vehicle for competition?” The EPA answers the question by explaining that modifications to vehicles not subject to EPA standards are fine and followed with: “You may also modify EPA-certified vehicles if you will use them only for competition.” While the EPA may assert it meant this guidance solely for certified dirt bikes and snowmobiles, the language is certainly susceptible to the interpretation on which many in the industry have come to rely. [EPA-HQ-OAR-2014-0827-1931-A1 p.10]

For the forgoing reasons, SEMA respectfully requests the EPA withdraw the proposed regulations prohibiting the conversion of motor vehicles into vehicles to be used solely for competition. SEMA also requests the EPA more adequately explain the other proposed regulatory changes that will impact small businesses and give further guidance to businesses on compliance with existing policies [EPA-HQ-OAR-2014-0827-1931-A1 p.10]

Other Implications and Considerations

At least one other regulatory hurdle must be addressed if the EPA continues to pursue this new policy. Motor vehicles are regulated by both the EPA and NHTSA. Similar to the Clean Air Act’s tampering prohibition, under the Motor Vehicle Safety Act it is illegal for a manufacturer, distributor, dealer, or motor vehicle repair business to knowingly make inoperative any part of a device or element of design installed on or in a motor vehicle or motor vehicle equipment in compliance with an applicable motor vehicle safety standard. See 49 U.S.C. § 30122(b) (2015). The Motor Vehicle Safety Act’s “make inoperative” prohibition does not apply to a certified motor vehicle that has been modified into a vehicle used solely for competition, placing it in conflict with the EPA’s proposed interpretation of the Clean Air Act’s tampering prohibition. The EPA must explain how its proposed application of the Clean Air Act would harmonize with NHTSA’s application of the Motor Vehicle Safety Act. [EPA-HQ-OAR-2014-0827-1469-A1, p.8]

66 The EPA now contends this guidance is limited to “nonroad vehicles,” but has not taken steps over the years to correct the public’s misunderstanding.

Organization: State Attorneys General

As the chief legal officers of our states, we write to express our concerns about a conflict with the federal Clean Air Act found within the provisions of the 629-page rule referenced above, which states: “Certified motor vehicles and motor vehicle engines and their emission control devices must remain in their certified configuration even if they are used solely for competition or if they become nonroad vehicles or engines.” [EPA-HQ-OAR-2014-0827-1897-A1 p.1]
As proposed, this rule attempts to expand the USEPA’s statutory jurisdiction under the Clean Air Act to cover vehicles modified solely for racing or competition. This approach is contrary to the law and would reverse decades of practice by the USEPA. This unnecessary regulation conflicts with the expressed intent of Congress, and we urge you to remedy this problem in the final rule by deleting the provision quoted above. [EPA-HQ-OAR-2014-0827-1897-A1 p.1]

Throughout the United States, modifying and racing cars is one of our nation’s pastimes. It is also a large part of our country’s economy. In 2014, consumers spent $36 billion on automotive specialty equipment parts and accessories. All over the U.S., manufacturers, retailers, and technicians represent tens of thousands of jobs and billions of dollars. This proposed rule would purport to make many of the products made, sold, and installed by those businesses illegal, dealing a heavy blow to our economy. [EPA-HQ-OAR-2014-0827-1897-A1 p.1]

While the federal Clean Air Act prohibits certain modifications to everyday motor vehicles used on public roads, statutory language and the USEPA’s historic practice have made it clear that vehicles built or modified for racing purposes, and not used on public streets, are not regulated under the Clean Air Act. [EPA-HQ-OAR-2014-0827-1897-A1 p.1]

For example, 42 U.S.C. § 7550(2) limits the definition of a covered “motor vehicle” to a vehicle designed for transport “on a street or highway” as opposed to operation on a racetrack. Correspondingly, 42 U.S.C. § 7550(10) limits the term “nonroad engine” to an engine “that is not used in a motor vehicle or a vehicle used solely for competition,” while 42 U.S.C. § 7550(11) makes clear that the term “nonroad vehicle” also does not apply to “a motor vehicle or a vehicle used solely for competition.” [EPA-HQ-OAR-2014-0827-1897-A1 p.2]

Congress did not make these choices at random. It intended to differentiate between a vehicle covered by this sort of rule and “a vehicle used solely for competition.” In fact, the House Committee on Foreign and Interstate Commerce identified and discussed this issue before passing the Clean Air Act in 1970: [EPA-HQ-OAR-2014-0827-1897-A1 p.2]

MR. NICHOLS. I would like to ask a question of the chairman, if I may. [EPA-HQ-OAR-2014-0827-1897-A1 p.2]

I am sure the distinguished chairman would recognize and agree with me, I hope, that many automobile improvements in the efficiency and safety of motor vehicles have resulted from experience gained in operating motor vehicles under demanding circumstances such as those circumstances encountered in motor racing. I refer to the tracks as Talladega in my own State, to Daytona and Indianapolis, competition. I would ask the distinguished chairman if I am correct in stating that the terms “vehicle” and “vehicle engine” as used in the act do not include vehicles or vehicle engines manufactured for, modified for or utilized in organized motorized racing events which, of course, are held very infrequently but which utilize all types of vehicles and vehicle engines? [EPA-HQ-OAR-2014-0827-1897-A1 p.2]

MR. STAGGERS. In response to the gentleman from Alabama, I would say to the gentleman they would not come under the provisions of this act, because the act deals only with automobiles used on our roads in everyday use. The act would not cover the types of racing vehicles to which the gentleman referred, and present law does not cover them either. [EPA-HQ-OAR-2014-0827-1897-A1 p.2]

Statutory language and legislative history clearly show that vehicles used solely for competition, including a race vehicle that has been converted from a certified highway vehicle, are not regulated
under the Clean Air Act. While the USEPA is authorized to create regulations that interpret laws passed by Congress, the agency cannot rewrite statutory definitions and—as the United States Supreme Court has made clear—"must always give effect to the unambiguously expressed intent of Congress."2 [EPA-HQ-OAR-2014-0827-1897-A1 p.2]

On behalf of the undersigned states, we strongly urge the USEPA to remove the aforementioned language referencing vehicles “used solely for competition” from the final rule. Not only is this language inconsistent with the federal Clean Air Act, but any purported benefit from this change would pale in comparison to the economic damage caused by this regulation. [EPA-HQ-OAR-2014-0827-1897-A1 p.3]

Organization: Thomas Abbe of Englewood LLC

I may not know the full meaning of the new regulations proposed but I am in strong opposition to any conditions which intentionally of otherwise may stifle development and innovation of motor vehicles by anyone engaged in improving performance of motor vehicles. Racing and other related fields are a proving ground of inestimable value to the progress of technology. Be very careful about the consequences of the proposed rule as it affects our industry. [EPA-HQ-OAR-2014-0827-1735 p.1]

Organization: Specialty Equipment Market Association (SEMA)

Regulatory Flexibility Act

Reg-Flex Analysis: The proposed rule has the possibility of causing harm to a number of small businesses. Many companies, including small businesses, would be dramatically affected by this new rule. These companies sell hundreds of street vehicles for conversion to race vehicles, undertake the conversions, sell products for use on these vehicles and use the converted race vehicles to participate in the sport of automobile racing. The EPA has failed to conduct an analysis of how these companies would be potentially impacted, as required under the Regulatory Flexibility Act of 1980, as amended by the Small Business Regulatory Enforcement Fairness Act of 1996. See 5U.S.C. §§ 601-612 (2015). [EPA-HQ-OAR-2014-0827-1469-A1, p.4]

be transitioned into use in on-road vehicles. The EPA recognized that this transition would be possible because “[a]ll of the race cars have direct links to production vehicles,” with some cars in the series described as “more production-based but are highly modified for racing.” See Program Announcement: Green Racing Initiative, EPA420-F-10-058 (November 2010), http://www3.epa.gov/otaq/ld-hwy/420f10058.pdf (attached). [See Docket Number EPA-HQ-OAR-2014-0827-1469-A2 for document.] Given this understanding on the part of the EPA, it is unclear how and when the current conflicting position was formulated, and the rulemaking materials provide no clarification. [EPA-HQ-OAR-2014-0827-1469-A1, pp.4-5]

Other Implications and Considerations

Beyond statutory differences, the issue has significant economic and safety implications. Competition use vehicles are modified in shops across the nation and the vehicles are outfitted with safety equipment such as five-point seat belts, roll bars, cages and safety netting. These sales and services would cease as a result of the EPA’s proposed policy. The EPA’s unilateral action would threaten auto sector jobs and stifle the production of new and innovative safety equipment due to decreased product sales. Since many of the companies associated with these products and services are small businesses, the EPA’s Regulatory Flexibility Act analysis must take this issue into consideration. [EPA-HQ-OAR-2014-0827-1469-A1, p.8]

Response:
The language in the proposal regarding vehicles used for competition was intended to clarify how the Clean Air Act requirements apply for vehicles used on public roads. EPA’s focus is not (nor has it ever been) on vehicles built or used exclusively for racing, but on companies that violate the rules by making and selling products that disable pollution controls on motor vehicles used on public roads. These unlawful defeat devices lead to harmful pollution and adverse health effects. The proposed language was not intended to represent a change in the law or in EPA’s policies or practices towards dedicated competition vehicles. Since our attempt to clarify led to confusion, EPA has decided to eliminate the proposed language from the final rule.

With respect to the detailed comments we received on this issue, EPA will continue to consider them before making any additional attempts to clarify this issue. EPA will also continue to engage with the racing industry and others regarding the concerns raised in the comments, while maintaining the Agency’s focus where it has always been: reducing pollution from the cars and trucks that travel along America’s roadways and through our neighborhoods.

15.8 Comments Related to Criteria Pollutants
15.8.1 Comments on Engine Efficiency and NOx Tradeoff

Organization: Advanced Engine System Institute (AESI)

Our members have been working with the Department of Energy’s Super Truck program to demonstrate the magnitude of carbon dioxide reductions that engine and vehicle technologies can deliver while improving criteria pollution control systems. From this advanced research and development program as well as the independent investment our companies are making with EPA and the California Air Resources Board at the Southwest Research Institute, we are increasingly confident that there is a fuel economy/greenhouse gas optimization ‘bonus’ to be realized from integrating rapidly emerging and cost-effective NOx control strategies into heavy-duty manufacturers’ engines and powertrain designs. [EPA-HQ-OAR-2014-0827-1152-A1 p.2][This comment can also be found in section 3.3 of this comment]
There no longer needs to be the once evident tradeoff between engine efficiency and tailpipe NOx emissions. The presentation attached (attachment 1) illustrates many of the newest NOx and GHG reducing technologies and the continually declining NOx emissions rates of the more recent and more efficient engine certifications. Basically, as engine manufacturers have been, with the able assistance of AESI companies, certifying their engines to tighter criteria pollutant standards and simultaneously integrating carbon emissions reduction as a design priority, both categories of pollution have been dropping. However, without the appropriate policy signal, the newest and most promising NOx control technologies may not manifest on the right timescale to comport with the Phase 2 proposal and thus could leave significant fuel economy gains until a future time. [EPA-HQ-OAR-2014-0827-1152-A1 p.2][This comment can also be found in section 3.3 of this comment summary]

Because California, as well as other states, continues and will continue to have very serious ozone nonattainment problems due mainly to NOx pollution from vehicles, that state is seriously considering an additional 90% reduction in NOx emissions beyond the 2010 standards for medium and heavy duty vehicles. Should that state, states in the Ozone Transport Commission region or the Northeast, or EPA, choose to formally adopt that standard, AESI members will work very hard with our customers to ensure that that standard can be achieved and to realize the optimization 'bonus' that would make fuel economy/greenhouse gas targets easier to achieve. [EPA-HQ-OAR-2014-0827-1152-A1 p.2-3][This comment can also be found in section 3.3 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.291-292.]]

**Organization:** Caterpillar Inc., et al.

**The regulation must recognize trade-off of NOx and CO2 reduction targets**

There is a well-established inverse relationship between carbon dioxide (CO2) and oxides of nitrogen (NOx) emissions from an engine. If engine CO2 emissions and fuel consumption are to decrease, as is the intent of Phase 2 regulations, the engine-out NOx level must increase. This means that aftertreatment systems must be designed or redesigned to reduce the net tailpipe-out NOx emissions in order for the engine to remain compliant with the criteria pollutant regulation. EPA is encouraged to consider the relationship between CO2 and NOx emissions when issuing final GHG and fuel consumption standards. Based on testimony to the Agencies, the California Air Resources Board (CARB) believes they need to revise the California criteria pollutant regulation to implement an ultra-low NOx standard to mitigate ozone issues in some parts of the state. An extremely ambitious NOx reduction target in the timeframe of the Phase 2 rule, even if applicable only in some portions of the U.S., would make compliance with stringent GHG standards even more challenging. [EPA-HQ-OAR-2014-0827-1215-A1 p.8-9]

It is understood that the proposed Phase 2 regulations from EPA and NHTSA do not include a NOx reduction requirement. Nonetheless, the setting of the engine technology stringency for Phase 2 will influence the size of the effort and the ability to attain any future lower NOx standard. Therefore, it is important to consider the relationship between CO2 and NOx in the GHG and fuel consumption rulemaking process. It should be noted that in-use NOx emissions will be inherently reduced by technologies that reduce drag or decrease rolling resistance, thanks to reduced engine work demand. A Phase 2 rule that provides flexibility to deploy vehicle technologies over engine technologies allows manufacturers to maximize this effect. [EPA-HQ-OAR-2014-0827-1215-A1 p.9]
California Clean Diesel Adoption and Benefits

With one of the largest medium and heavy duty fleets in the country, California stands to benefit the most from these proposed Phase 2 rules. Already, model year 2010 and newer engines that are found in Class 3 – 8 vehicles in the state have eliminated 120,000 tons of NOx and 580,000 tons of carbon dioxide and saved 1.4 billion barrels of crude oil between 2010 and 2014, according to our most recent research. According to the Air Resources Board, the further adoption of new and newer diesel engines in heavy-duty applications in California is expected to reduce emissions of oxides of nitrogen by fifty percent between 2012 and 2020. [EPA-HQ-OAR-2014-0827-1171-A2 p.5][This comment can also be found in section 3.4 of this comment summary]

We believe these are also important considerations for EPA in developing a final Phase 2 rules, as follows: [EPA-HQ-OAR-2014-0827-1171-A2 p.5][This comment can also be found in section 3.4 of this comment summary]

The program must consider the longstanding trade-off between NOx and CO2. The rule should avoid driving technologies that realize gains in fuel efficiency at the expense of NOx, reversing the huge achievements of clean diesel technology in recent years and limiting the potential for further reductions in the future. As we have stated previously, technologies developed to meet the current emission standard established for model year 2010 maximize reductions in NOx and CO2. The maximization of this trade-off may become jeopardized if pushed too far. [EPA-HQ-OAR-2014-0827-1171-A2 p.6][This comment can also be found in section 3.4 of this comment summary]

The Relationship between NOx and CO2 Emissions from the Engine

The calibration of internal combustion engines is a delicate balance that has to deal with trade-offs to optimize performance and emissions. For example, there is an inverse relationship between PM and NOx emissions that engine manufacturers applied to meet emission standards up through the 2006 heavy-duty highway regulations. In 2007, the requirement to reduce both PM and NOx emissions caused OEMs to install particulate filters on diesel vehicles which allowed engine calibrators to optimize the combustion in the engine to meet lower NOx emissions while relying on the DPF to remediate the resulting higher PM emissions. This example of effective emission regulations provided a technology solution to overcome the traditional barriers of engine calibration. In 2010, another game changing technology was installed on most trucks in response to a further tightening of NOx limits. Selective catalytic reduction or SCR allowed calibrators to not only reduce the soot load on filters and soot regeneration as a way of improving fuel efficiency but also to take advantage of another well-known trade-off in combustion thermodynamics between fuel consumption, CO2 and NOx emissions out of the engine. [EPA-HQ-OAR-2014-0827-1210-A3 p.4]

Since 2010 the predominant technology to reduce NOx from diesel engines has been SCR and every generation of SCR systems has led to improvements in catalyst conversion efficiency (a detailed discussion of SCR technology is provided below). The SCR system is just one technology option that has allowed engine and vehicle manufacturers to meet the first phase of heavy-duty GHG standards while still achieving NOx reduction targets from the engine. The portfolio of technology options that are available to reduce greenhouse gas emissions from heavy-duty trucks and engines is continually
growing in response to tighter regulations set by U.S. EPA and the California Air Resources Board. In fact, a review of heavy-duty engine certifications from 2002 to 2015 shows that once emission and efficiency technologies were required on engines, the relationship between CO2 and NOx emissions at the tailpipe went from a trade-off to a benefit (see Figure 1 below). By setting stringent emission targets for both CO2 and NOx through realistic regulations and expanding the calibrator’s tool box from the engine to the powertrain allowed engineers to achieve both reduced NOx levels and engine efficiency improvements simultaneously. Figure 1 plots the certification level for NOx and CO2 from heavy-duty engines over the last 14 years and several generations of emissions technology. [EPA-HQ-OAR-2014-0827-1210-A3 p.4-5]

[Figure 1, 'Heavy-Duty Engine Certification Levels for NOx and CO2', can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1210-A3]

Selective Catalytic Reduction (SCR) Catalysts for Diesel Engines

Selective catalytic reduction (SCR), catalysts have been used to significantly reduce NOx emissions from lean combustion engines for decades. The SCR system uses a chemical reductant, usually a urea/water solution, or other ammonia sources (e.g., solid urea or metal chloride amines), to convert nitrogen oxides to molecular nitrogen and oxygen-rich exhaust streams across a suitable catalyst. Upon thermal hydrolysis and decomposition in the exhaust, urea forms CO2, water and ammonia which serves as the reductant for NOx over the catalyst. As exhaust and reductant pass over the SCR catalyst, chemical reactions occur that reduce NOx emissions to nitrogen and water. [EPA-HQ-OAR-2014-0827-1210-A3 p.5]

SCR catalyst can achieve over 98% NOx conversion in hot operation and over 70% during the cold-start portion of the heavy-duty transient test cycle. SCR catalysts are used on medium and heavy-duty engines around the world to achieve low NOx emission regulations. Applying SCR to diesel-powered engines provides simultaneous reductions of NOx, PM, and HC emissions. In addition to reductions in criteria pollutants, SCR applications on heavy-duty trucks allow engine manufacturers to further optimize and reduce fuel consumption of these engines through calibration optimization, in-turn providing important reductions in greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1210-A3 p.5-6]

SCR applications on new highway, heavy-duty trucks in both Europe and the U.S. have already been shown to allow engine manufacturers the possibilities of calibrating engines for lower fuel consumption (and lower greenhouse gas emissions), while still meeting applicable NOx emission standards. Engine manufacturers that employed SCR technologies on 2010-compliant heavy-duty, highway engines in the U.S. claimed up to 5% improvements in fuel efficiency vs. engines that did not employ SCR technology. These fuel efficiency improvements are most evident at highway speeds, however in the future, employing thermal management strategies can shorten the warm-up portion of the cold start and facilitate urea injection earlier in the test cycle and thus expand the calibration optimization window to further reduce CO2 emissions. The high NOx conversion efficiencies associated with SCR catalysts enable engines to be operated at conditions that yield lower fuel consumption. Engine manufacturers are expected to continue to further optimize engine fuel consumption characteristics and SCR system designs to assist in achieving the reductions proposed by EPA under this regulation. One example of future improvements in SCR catalyst system designs on heavy-duty engines is the direct application of SCR catalysts to diesel particulate filter substrates to provide a single catalyst module that provides reductions to all four criteria pollutants: hydrocarbons, CO, NOx, and PM. By deploying the SCR catalyst onto the filter moves the catalyst closer to the engine for faster warm-up, thus allowing earlier urea dosing. These SCR coated filters are already commercialized on several light-duty diesel passenger
car models and are expected on heavy-duty highway and off-road engines in the near future. Beyond 
SCR, a number of other technology advances will facilitate significant criteria emission reductions, 
efficiency gains and reductions of short lived climate pollutants. [EPA-HQ-OAR-2014-0827-1210-A3 
p.6] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.213-
214.]]

One such technology that has evolved specifically to address NOx emitted at low exhaust temperatures, 
includes a family of new materials referred to as passive NOx adsorbers (PNA). This catalyst 
technology is used upstream of the traditional exhaust control system, in combination with the DOC, to 
trap and store NOx at temperatures below 200°C before urea can be dosed into the hot exhaust. Once 
the exhaust temperature is sufficient for SCR catalysts to convert NOx to nitrogen, and to allow the urea 
dosing system to be activated, the NOx stored on the PNA begins to desorb so it can be converted by the 
ammonia reductant over the SCR catalyst. This emerging technology will be one of the strategies 
available to engine and vehicle manufacturers to achieve lower cold-start tailpipe NOx levels. [EPA-
HQ-OAR-2014-0827-1210-A3 p.6]

The Advanced Collaborative Emissions Study (ACES) Phase 2 report published in 2012 showed that 
modern heavy-duty engines are achieving PM and NOx levels well below the federal standards. 
Recognizing the capability of technologies to deliver complimentary reductions of NOx and GHGs, 
California has adopted voluntary low NOx standards to incentivize development of state-of-the-art 
engines and emission controls to achieve NOx levels as low as 0.02 g/bhp-hr which is equivalent to a 
90% reduction from EPA’s 2010 highway, heavy-duty engine standards. Certification of cleaner engines 
ahead of proposing mandatory standards opens up opportunities for the state to direct incentive funds 
toward the development of cleaner engines. To support their regulatory efforts, ARB is funding a 
technology demonstration test program at Southwest Research Institute to demonstrate the feasibility to 
further reduce NOx emissions from heavy-duty engines. Advanced emission technologies like SCR 
coated filters and passive NOx adsorbers are included in this demonstration test program. EPA is 
monitoring this important test program as a member of the program’s advisory committee. [EPA-HQ-
OAR-2014-0827-1210-A3 p.6-7] [[These comments can also be found in Docket Number EPA-HQ-
OAR-2014-0827-1420, p.214.]]

The engine certification levels for criteria pollutants and CO2 since 2010 demonstrate that these fuel-
efficient powertrain designs, combined with appropriate emission controls and efficiency technologies, 
can be optimized to improve overall CO2 emissions of the vehicle while also achieving ultra-low NOx 
and other criteria pollutant emissions. This optimization extends beyond carbon dioxide emissions to 
include other significant greenhouse gases such as methane and nitrous oxide. [EPA-HQ-OAR-2014-
0827-1210-A3 p.14]

**Organization:** National Association of Manufacturers (NAM)

The NAM also encourages the EPA and NHTSA to carefully examine the interaction between fuel 
efficiency and nitrogen oxides (NOx) reductions. This week, the EPA finalized new standards for 
ground-level ozone, for which compliance will require reductions in NOx across multiple sectors, 
including medium- and heavy-duty vehicles. NOx reducing technologies have typically reduced fuel 
efficiency. With new federal and perhaps even state NOx emissions standards on the immediate horizon, 
the EPA and NHTSA should carefully examine the interaction between reducing NOx from medium-

**Organization:** Navistar, Inc.
It is well known that a trade-off exists for heavy duty diesel engines between NOx and CO2. For example, certain technologies for NOx control involve lower in-cylinder temperature which controls NOx but can lower the efficiency of the engine. In addition, other technologies, such as SCR catalysts, require higher exhaust temperatures to reduce NOx and may use fuel to increase the catalyst temperature. In both cases, NOx is reduced while CO2 is increased due to either increased fuel use or decreased engine efficiency. In this regard, we fully agree with EMA. [EPA-HQ-OAR-2014-0827-1199-A1 p.10]

Navistar strongly believes that the feasibility of this Proposed Rule, assuming all other issues discussed are corrected, is very heavily dependent on NOx emissions levels for new engines remaining at their present levels. In addition, the costs of attempting to lower NOx while also lowering GHG emissions would be substantially higher than the costs of lowering GHG emissions alone while keeping NOx at its present levels. [EPA-HQ-OAR-2014-0827-1199-A1 p.10]

The agencies must consider the cumulative impacts of the Proposed Rule. We again have to stress that the feasibility of the Proposed Rule is dependent, among other things, on other emissions, particularly NOx, remaining at the same levels. Similarly, the adoption of the emission standards proposed would have a significant impact on the feasibility of future NOx regulation. Navistar strongly believes that this Proposed Rule and the technologies that will be necessary to meet it will impact the feasibility of any future regulation for NOx. [EPA-HQ-OAR-2014-0827-1199-A1 p.20-21]

A little background is appropriate here. The upcoming MY2017 standard from Phase 1 is technology-forcing for the tractor engine, as opposed to other elements of Phase 1. The second step of the Phase 1 regulations for the tractor engines is currently driving a significant improvement in engines and represents a 3.3% improvement from MY2014, a magnitude which was expected to and has proven to be technology forcing (primarily for air systems and fuel systems). As proposed, the Phase 2 standard for tractor represents yet another technology-forcing step in emissions in the 2024MY phase which requires a 3.5% improvement over the 2017MY engines (see Table 1 in the Attachment A). This appears at face value to include relatively long lead time. However, when the CO2 emission standard is considered with other portions of the proposed Phase 2 regulation the CO2 standard is actually more stringent and occurs earlier. This is due to the N2O proposal and the fuel map margins, which effectively add stringency earlier to the engine standard. [EPA-HQ-OAR-2014-0827-1199-A1 p.21]

These cumulative impacts, if they are not corrected, would render the CO2 standard infeasible if they are not corrected. Either the emission standard should be revised, or each of these issues must be corrected. Otherwise, the CO2 standard will not be achievable in the time frame allowed. [EPA-HQ-OAR-2014-0827-1199-A1 p.21]

The major concerns with the technology projections and penetrations for both vocational and tractor engine standards include: [EPA-HQ-OAR-2014-0827-1199-A1 p.21]

- For combustion improvements, the primary mechanism is increased injection pressure, a set of technologies that can put upward pressure on engine-out NOx

Organization: PACCAR, Inc.

Relationship between NOx and CO2 emissions

Complying with more stringent NOx standards would require significant investment in engine and aftertreatment technologies and would not be conducive to improving fuel consumption and lowering
CO2. As is documented and known, there is a trade-off between fuel consumption and engine-out NOx for a current certified Heavy Heavy-Duty (HHD) diesel engine. The negative impact on fuel consumption from reduced engine-out NOx levels is clearly understood. [EPA-HQ-OAR-2014-0827-1204-A1 p.5]

As part of an ongoing feasibility study of 0.02 g/bhp-hr NOx tailpipe compliance, Southwest Research Institute is exploring a variety of measures aimed at reducing engine-out NOx. The results from an August 20, 2015 report-out suggest a 12% fuel consumption penalty for a 6-fold reduction in engine-out NOx. The proposed tailpipe levels would likely require still more aggressive reductions in engine-out NOx. [EPA-HQ-OAR-2014-0827-1204-A1 p.5]

**Organization:** Truck & Engine Manufacturers Association (EMA)

Potential NOx and N2O Reductions

Several stakeholders are pressuring EPA to adopt lower NOx emission limits for heavy-duty vehicles. That pressure is likely to increase in light of the Agencies’ adoption of a lower NAAQS for ozone. Regardless, this rulemaking is not the regulatory vehicle for the consideration of any potential additional low-NOx standards. In fact, given the inherent emissions trade-off between GHG emissions and NOx emissions (which, unlike GHG emissions, favor lower combustion temperature regimes), any additional NOx reductions will require extremely careful and thorough analysis. [EPA-HQ-OAR-2014-0827-1269-A1 p.64]

**Organization:** Truck Renting and Leasing Association

However, TRALA has several concerns about the Proposed Standards, which we have set forth below:

(4) the trade-off between NOx emissions and engine efficiency could lead to impaired air quality [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

**The Trade Off Between NOx Emissions and Engine Efficiency Could Lead to Negative Air Quality Impacts**

The agencies have not fully taken into consideration the trade-off between NOx emissions and engine efficiency. Technology that reduces the engine work, such as improved aerodynamics or reduced rolling resistance, inherently results in a proportionate reduction in total NOx output. However, this is not the case with engine efficiency improvement, where there is a well-documented trade-off between NOx reduction and engine efficiency (and thus GHG emissions, as well). Excessive demands for stand-alone engine efficiency would limit the potential for NOx reduction, especially in urban duty cycles where NOx emissions reductions are most critical. [EPA-HQ-OAR-2014-0827-1140-A1 p.6]

**Organization:** Volvo Group

Fortunately, technologies aimed at reducing vehicle power demand, such as improving aerodynamics and reducing rolling resistance, result in less total work needed from the engine to complete the mission of moving cargo from point A to point B, and therefore proportionately less total NOx is emitted. This is not the case, however, when it comes to technologies focused on improving engine efficiency. Here, the NOx/efficiency trade-off typically results in precisely the opposite effect. The most logical thing EPA and NHTSA could do to avoid forcing this trade-off is to eliminate the separate engine standards in the proposal. At minimum, they should maintain the proposed engine stringency levels to mitigate undue
risk of unintended consequences. This would permit manufacturers to focus their development efforts on efficiency technologies that capitalize on synergistic GHG-NOx reduction opportunities, rather than those engine technologies that complicate and frustrate future NOx reductions. [EPA-HQ-OAR-2014-0827-1290-A1 p.60][This comment can also be found in section 3.3 of this comment summary]

That unique opportunity aside, EPA and NHTSA should give greater consideration to NOx implications of technologies when setting efficiency targets. EPA should calculate the NOx impact of individual engine technologies they propose. For example, hybrid technology can yield overall net increases in NOx if the engine aftertreatment temperature is compromised due to intermittent engine operation. Is the projected 23 to 25% efficiency gain of “strong hybrid” compromised by a more NOx-conscious control scheme? The stringency assessments that manufacturers are attempting to make in the review of the Phase 2 rule, especially in the extended timeframe of this rule, are meaningless if new NOx requirements are required in the same timeframe. [EPA-HQ-OAR-2014-0827-1290-A1 p.60]

The NOx reduction challenge to decrease ambient ozone levels will soon be upon us; the technical interplay with GHG emissions is far too great to ignore. It is appropriate and necessary that EPA and NHTSA structure a rule that allows manufacturers to achieve GHG-NOx synergies whenever possible, and that does not impede the ability to achieve further NOx reductions required in the future. [EPA-HQ-OAR-2014-0827-1290-A1 p.60]

Organization: Allison Transmission, Inc.

Onboard Diagnostic Requirements and NOx Testing of Hybrids Must Not Impede Adoption of Hybrid Technology

Higher NOx Emissions Are Not Attributable to Any Inherent Deficiency In Hybrid Technology

As part of the Phase 1 regulations, EPA adopted provisions to delay onboard diagnostics (“OBD”) requirements for heavy-duty powertrains. As the Agency properly determined, for multiple reasons, imposing full OBD requirements for hybrids in order to meet criteria pollution limits would create a substantial impediment for the adoption of such systems. Within this rulemaking, EPA and NHTSA are requesting comment on a letter received from the California Air Resources Board (“CARB”) requesting consideration of supplemental NOx testing of hybrids. [EPA-HQ-OAR-2014-0827-1284-A1 p.54]

Allison does not believe that higher NOx production is caused by any inherent deficiency in hybrid systems. Instead, Allison believes that this phenomenon has occurred because hybrid systems tend to run the diesel engine at lower engine speeds than the equivalent conventional non-hybrid powertrain. In the case of an Allison hybrid, the engine may run the majority of its time in the 1200-1500 rpm speed range. That same engine in a conventional powertrain may run the majority of its time in the 1800-2600 rpm speed range. Since selective catalytic reduction (“SCR”) systems are configured to be most efficient in the conventional powertrain speed range, different emission profiles can occur. [EPA-HQ-OAR-2014-0827-1284-A1 p.54]

If the engine were optimized for emissions in the hybrid speed range, Allison believes that NOx production would be on par with the conventional systems. This optimization would likely require sizing of the SCR catalyst for the lower exhaust gas flow rate experienced with the hybrid system. Additionally, however, test duty cycles for hybrids must create adequate opportunity for the SCR catalyst to reach proper operating temperatures that are necessary to effectively convert the NOx passing through the catalyst. [EPA-HQ-OAR-2014-0827-1284-A1 p.54]
Allison believes that testing to certify NOx levels should be performed on a cycle that would be representative of the speed ranges that the hybrid system will command. We believe that there is a risk that requiring special testing and potentially special after-treatment devices may result in dramatically increased costs for the engine supplier. This, in turn, could affect decisions by manufacturers whether to invest in this specialty vehicle segment. [EPA-HQ-OAR-2014-0827-1284-A1 p.54]

**Organization:** California Air Resources Board (CARB)

CARB previously submitted to U.S. EPA comments requesting a supplemental NOx check to safeguard against NOx increases from improperly designed heavy-duty hybrid systems; the current proposal does not address this issue or incorporate CARB’s recommendations. At a minimum, CARB recommends that the proposal specify the consequences for NOx emission increases identified during powertrain testing of hybrid systems, such as prohibiting manufacturers from counting high-NOx hybrid vehicles towards Phase 2 fleet averages. [EPA-HQ-OAR-2014-0827-1265-A1 p.4]

**Comment – Hybrid powertrain test/potential hybrid NOx increases**

The NPRM is proposing to allow a single powertrain test for hybrid vehicles. Instead of A to B testing as required for hybrids in Phase 1, manufacturers would be required to conduct powertrain testing solely on the hybrid system and the test results would be used as inputs for GEM for simulation. CARB staff has significant concerns on the possible NOx increases of improperly designed heavy-duty hybrid systems, especially in light of U.S. EPA and NHTSA’s current proposed provisions allowing the use of downsized engines and non-road engines in on-road heavy-duty hybrid vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.88]

The NPRM requests comment on CARB’s letter recommending that U.S. EPA consider including supplemental NOx testing of hybrids. The published version of the Phase 2 proposal does not contain the supplemental check for NOx emissions as recommended in the aforementioned CARB letter. Literature data point to possible increases in NOx emissions from heavy-duty hybrid vehicles if the hybrid system wasn’t properly designed and integrated and/or if the hybrid vehicles were placed in vocations with mismatched duty cycles. As an example, a recent NREL study of hybrid trucks (funded by CARB) shows the average NOx emissions level from a hybrid class 5 parcel delivery step van was 111 percent higher than the NOx emissions from a similar conventional step van when tested on a chassis dynamometer. CARB staff continues to believe that this is an important issue for heavy-duty hybrid vehicles and should not be ignored, and continues to support requiring supplemental NOx testing of hybrids. [EPA-HQ-OAR-2014-0827-1265-A1 p.88-89]

Although the Phase 2 proposal requires hybrid powertrain testing to record NOx emissions from the hybrid system, there are no provisions for addressing situations where the results show elevated NOx emissions levels. Since no penalties are specified for such a situation, manufacturers may have incentive to exploit a CO2/NOx trade-off and optimize the hybrid system for fuel economy at the detriment of NOx emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.89]

At a minimum, if the recommended supplemental check for NOx emissions is not required for every hybrid, CARB staff recommends that U.S. EPA and NHTSA specify in the Phase 2 standards the consequence for elevated NOx detected during the required hybrid powertrain testing. Possible consequences could include not allowing hybrid systems with elevated NOx to be certified under Phase 2 and/or requiring follow-up supplemental A to B testing if powertrain testing indicates elevated NOx emissions. CARB staff would be happy to work with U.S. EPA to develop the appropriate NOx
emissions thresholds for hybrid powertrain testing to identify elevated NOx emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.89]

If U.S. EPA and NHTSA ultimately decline to include the recommended supplemental check for NOx emissions (as described above) in the final Phase 2 rulemaking, CARB staff recommends an alternative approach. As an option, U.S. EPA and NHTSA could offer advanced technology credits to encourage manufacturers to perform the supplemental check for NOx emissions. Such credits could be offered to manufacturers who submit data showing hybrid NOx levels the same or lower than a conventional vehicle using supplemental A to B testing. CARB staff believes that these extra credits would provide incentives for hybrid manufacturers to produce hybrids without elevated NOx emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.89]

Organization: Daimler Trucks North America LLC

Hybrids and the ARB’s request to increase testing burden on hybrids by requiring NOx testing with GHG testing - The agencies note that the ARB has created an impediment to the adoption of hybrid systems in that hybrid OBD certification is very difficult. 80 FR 40298. The agencies note, however, that the ARB requests a further increase to certification burden through the additional requirement of NOx testing in certification of hybrid GHG benefits. We recommend against any increased certification burden. Hybrid certification costs (i.e., the cost of testing on a chassis dynamometer and of certifying hybrid OBD systems) are already so high and sales volumes so low that any increased certification burden just worsens hybrids’ cost-benefit position. We understand that ARB’s concern about hybrids' NOx emissions, but we think that the agencies cannot both seek to increase hybrid penetrations into the market and increase regulatory obstacles to their deployment. [EPA-HQ-OAR-2014-0827-1164-A1 p.95-96]

Response:

Commenters on this topic tended to fall into two groups: one group that believes there to be an inherent tradeoff between NOx and fuel consumption, and another group that believes the tradeoff no longer exists. However, both groups over-simplify this issue by neglecting differences in technologies. For some technologies, there is little or no tradeoff. For example, technologies that reduce brake-specific fuel consumption by increasing the amount of usable work from the engine (such as friction reduction or waste heat recovery) can also reduce brake-specific criteria pollutants. On the other hand, technologies that reduce fuel consumption by increasing peak cylinder pressure would generally increase engine-out NOx emissions. Interactions with SCR further complicates the potential tradeoffs.

EPA has considered these potential effects in developing the engine standards, and agrees they would also need to be considered in any effort to develop lower NOx standards. However, we also see viable pathways to reduce NOx emissions with aftertreatment improvements or better off-cycle controls.

With respect to NOx emissions from hybrids, EPA believes this would more appropriately be addressed in a separate rulemaking focused on NOx emissions.

15.8.2 Comments on Future HD NOx Standards

Organization: American Lung Association
The American Lung Association offers the following recommendations to strengthen the stringency and timing of the proposal and address several key elements of California’s commitment to protecting public health and air quality. [NHTSA-2014-0132-0087-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.143-144.]]

Second, the American Lung Association urges the US EPA to immediately begin a national rulemaking to set standards requiring lower emissions of nitrogen oxides (NOx) from these engines and vehicles. EPA should begin work on a concurrent low-NOx standard to ensure that all trucks working in California are held to the standards we need to protect our citizens from near-road exposures of NOx and from ozone pollution. California’s clean air progress must be protected against ongoing inter-state truck traffic with higher emissions. Under a stronger ozone standard, a national low-NOx standard of 0.02 grams per brake horsepower hour will help all regions with attainment, but this is especially true for Southern California. [NHTSA-2014-0132-0087-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.144-145.]]

Organization: American Trucking Associations (ATA)

Further Evaluation and Demonstration is Needed Before Committing to a Low-NOx Engine Standard

Having gone through three rounds of reducing tailpipe NOx emissions in 2004, 2007, and again in 2010, the lessons learned from these prior regulatory actions remain fresh in the minds of the industry. Fuel economy penalties, increases in greenhouse gas emissions, reliability issues, and vehicle pre-buys and low-buys were among the significant unintended consequences. Another major factor was the cost of compliance. The cumulative vehicle surcharge for all three rounds was in excess of $21,000, more than four times EPA’s projected cost of compliance. Given EPA expects fleets to pay an additional $14,000 for a new tractor-trailer combination meeting the Phase 2 standards, the agencies must be sensitive to the cost impacts additional regulatory pursuits will have on the trucking industry. [EPA-HQ-OAR-2014-0827-1243-A1 p.20]

Although CARB recently certified an 8.9 liter natural gas engine to an optional NOx standard of 0.02 g/bhp-hr, the ability to transfer this technology into the Class 8 truck sector remains unproven. The prospect of a commercially viable diesel engine meeting a NOx standard that is as much as 90% below the current standard should not be a foregone conclusion. [EPA-HQ-OAR-2014-0827-1243-A1 p.20]

If system designers push the NH3 to NOx ratio higher to try and achieve the maximum possible NOx reduction, it could increase N2O emissions. If EPA were to adopt a very low NOx standard (e.g., 0.02 g/bhp-hr) over existing test cycles, some reductions would be needed throughout the hot portion of the cycle (although most of the reductions would have to come from the cold start portion of the test cycle).... An increase in NH3 to NOx ratio could also further reduce NOx emissions; however this would also adversely affect NH3 slip and N2O formation. [EPA-HQ-OAR-2014-0827-1243-A1 p.21]

ATA is aware of the CARB-led research taking place at Southwest Research Institute to investigate the feasibility of achieving lower NOx emissions. While this evaluation is scheduled to be completed in late 2016, additional time will be needed to further develop and demonstrate any resulting technologies. In addition to the need to demonstrate the technical feasibility of meeting lower NOx emissions in the Class 8 sector, while at the same time achieving increasingly stringent GHG emission limits, the in-use performance of such an engine must be carefully evaluated to ensure it meets the reliability, performance and cost criteria of the purchaser. Otherwise, this pursuit will result in buyer avoidance and an increase in the overall age of the fleet. ATA recommends that EPA carefully evaluate the cost,
timing, and market readiness of emerging low-NOx technologies when considering requests for a low-NOx engine standard. [EPA-HQ-OAR-2014-0827-1243-A1 p.21]

Organization: California Air Resources Board (CARB)

5. Commit to future NOx control

California needs dramatic further reductions in NOX emissions beyond what our current programs will achieve by 2031 to attain health-based standards for ozone and fine particulate matter. Reaching these attainment levels in California's South Coast Air Basin will require an approximate 70 percent reduction in NOX from today's levels by 2023, and an overall 80 percent reduction in NOX by 2031. CARB expected the proposal to include a commitment from U.S. EPA to begin efforts to develop lower, mandatory NOX standards for heavy-duty engines and vehicles. Federal action is especially needed for the largest heavy-duty trucks that frequently cross state lines and therefore cannot be effectively regulated by California alone. CARB will begin development of lower, mandatory NOX engine standards in 2017, and will also petition U.S. EPA to establish lower, federal NOX engine standards. If U.S. EPA fails to initiate a timely rulemaking, CARB will continue with its efforts to establish a California-only standard. [EPA-HQ-OAR-2014-0827-1265-A1 p.4] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.25.]]

Comment – NOX reductions from heavy-duty vehicles are crucial to California’s air quality goals

In the NPRM, U.S. EPA and NHTSA rightly noted California’s unique challenge to attain the ozone and PM NAAQS in many regions of the state. In particular, California's South Coast Air Basin and San Joaquin Valley Air Basin, the nation’s only two “Extreme” ozone non-attainment areas, require significant reductions in NOX and volatile organic gases to reach state air quality goals. Since heavy-duty vehicles currently emit approximately one-third of the state’s NOX emissions, measures to reduce emissions from such vehicles are crucial for California. California needs dramatic further reductions in NOX emissions beyond what our current programs will achieve by 2031 to attain health-based standards for ozone and fine PM. Reaching these attainment levels in California’s South Coast Air Basin will require an approximate 70 percent reduction in NOX from today’s levels by 2023, and an overall 80 percent reduction in NOX by 2031. To make matters more challenging, U.S. EPA and NHTSA are revising the NAAQSs (due to be finalized by December, 2015). These new NAAQSs, which are more stringent than existing ones, will require even greater NOX emission reductions. This means that heavy-duty NOX emission reduction strategies must begin now and in parallel with GHG emission reduction strategies. [EPA-HQ-OAR-2014-0827-1265-A1 p.174]

California’s compelling need for emission reductions necessitates further actions now, despite the past significant achievements of U.S. EPA and CARB efforts to reduce heavy-duty vehicle emissions.
CARB’s Sustainable Freight Pathways to Zero and Near-Zero Discussion Document (Discussion Document) describes actions to identify and prioritize potential immediate and near-term measures and strategies to reduce criteria pollutants and GHG emissions from all vehicle/equipment sectors that move freight in California to assist in meeting both the State’s air quality attainment and climate needs. [EPA-HQ-OAR-2014-0827-1265-A1 p.174-175]

For the trucking sector, these strategies and measures include expanded enforcement efforts and financial incentive opportunities, reduced opacity limits for filter-equipped trucks, enhanced certification and warranty requirements to ensure low in-use emissions, increased flexibility for manufacturers in certifying advanced innovative truck engine and vehicle systems, and California Phase 2 GHG requirements, which may be more stringent than federal Phase 2 requirements, depending on the stringency of the final federal rule. The Discussion Document also calls for CARB to petition U.S. EPA to develop mandatory, NOx standards (which is discussed in more detail later in this comment). [EPA-HQ-OAR-2014-0827-1265-A1 p.175]

The CAA gives California independent authority to adopt its own heavy-duty vehicle and engine standards, which it has utilized on numerous occasions to achieve additional emission reductions as compared to the federal standards. However, the regulated industry has consistently preferred a single, national program, rather than a more stringent California-only standard. California recognizes this, and is committed to working with U.S. EPA and NHTSA to address heavy-duty truck NOx emissions. This is especially important for out of state trucks; of the one million heavy-duty vehicles that operate in California, approximately 60 percent of trucks operating in California were originally purchased in states outside of California. CARB is prepared to utilize its authority to develop California-only mandatory, lower NOx standards if U.S. EPA fails to take timely action in developing federal standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.17.5]

Although the NPRM claims some reductions in NOx emissions are expected due to the Phase 2 program (due to use of APU's instead of idling), CARB staff believes these emission reductions are overstated. Because nearly all of today’s engines already meet clean idle requirements which limit NOx at idle to 30 grams/hour, switching to APU use is not expected to appreciably reduce NOx emissions and hence Phase 2 is not expected to significantly reduce tailpipe NOx emissions. Instead, because the NPRM does not incorporate CARB’s recommendation for a supplemental NOx check for heavy-duty hybrids and proposes overly broad use of dirtier off-road engines in on-road vehicles, CARB staff instead is concerned that Phase 2 may result in overall NOx emissions to increase; recent work at NREL funded by CARB shows that heavy-duty hybrids can have NOx emissions more than three times those of comparable diesel vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.175-176]

As CARB staff has worked with U.S. EPA and NHTSA over the past several years on the Phase 2 program, we have repeatedly requested that U.S. EPA and NHTSA consider opportunities in the Phase 2 rulemaking to encourage further NOx emission reductions, prevent inadvertent NOx increases, and lay the groundwork for swift federal action to reduce NOx from heavy-duty trucks. However, these requests have not been addressed in the NPRM. [EPA-HQ-OAR-2014-0827-1265-A1 p.176]

CARB staff was anticipating the inclusion in the NPRM of a discussion on the need for federal action on future NOx control and a commitment from U.S. EPA and NHTSA to begin development on lower, mandatory NOx standards for heavy-duty engines and vehicles. Unfortunately, the proposal included no such commitment. [EPA-HQ-OAR-2014-0827-1265-A1 p.176]

In parallel with completion of the Phase 2 rulemaking, CARB staff recommends that U.S. EPA and NHTSA pursue a joint rulemaking effort to reduce the NOx emission standard for heavy-duty engine
The current emission standards for heavy-duty engines, the 2010 emission standards, were promulgated in 2001, which was 14 years ago. Since that time, engine manufacturers have made significant progress in improving the conversion efficiency of NOX aftertreatment technologies and in reducing emissions from engines. The next phase of NOX emission standards may be achieved with advanced engine controls and advanced aftertreatment technologies, leading to a significantly lower NOx emission standard than the 2010 standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.176]

CARB staff will begin development of lower, mandatory NOx engine standards in 2017, and also plans to petition U.S. EPA to establish lower, federal NOx engine standards. If U.S. EPA fails to initiate its rulemaking by 2017, CARB will continue with its efforts to establish a California-only standard. A lower NOx standard that reduces emissions from all trucks operating in California is critical to meeting 2031 air quality goals. [EPA-HQ-OAR-2014-0827-1265-A1 p.176]

CARB staff has already begun work to lay the technical foundation for a lower NOx emission standard for new heavy-duty engines. CARB has funded SwRI for a $1.6 million project to investigate advanced technologies to reduce NOx emissions by 90 percent from today's U.S. EPA and CARB heavy-duty engine standards. The engine technology package must continue to meet all applicable standards for hydrocarbons, carbon monoxide, and PM, including, and GHG emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.177]

In this research contract, SwRI is evaluating enhanced aftertreatment technology choices, aftertreatment configurations, catalyst optimizations, urea dosing strategies, engine tuning, and engine management practices for two heavy-duty engines: one natural gas engine with a three-way catalyst; and one diesel engine with a DPF and SCR. The target NOx emission rate for this project over the heavy-duty FTP is 0.02 g/bhp-hr. [EPA-HQ-OAR-2014-0827-1265-A1 p.177]

SwRI will characterize the emission performance of the two stock engines using procedures following Title 40, Code of Federal Regulations, Part 1065, determine stock engine characteristics for cold starts, hot starts, normal operation, and low-load-low-temperature operation, and will determine possible engine control strategies. Based on the engine performance and possible engine control strategies, SwRI will select candidate aftertreatment technologies and engine control strategies for screening. The candidate emission reduction strategies will be screened using low-cost exhaust emission sources and test benches. The best performing technology packages and strategies will be identified and their performance will be measured on engine dynamometer over the heavy-duty FTP, World Harmonized Transient Cycle, ramped mode cycle, extended Idle, and three low-load-low-temperature cycles derived from the Orange County Transit Authority bus cycle, New York bus cycle, and CARB Creep cycle. [EPA-HQ-OAR-2014-0827-1265-A1 p.177]

The screening process is currently progressing and it is showing promising results towards achieving the 0.02 g/bhp-hour NOx for both natural gas and diesel engines. [EPA-HQ-OAR-2014-0827-1265-A1 p.177] This research contract is expected to be completed by the end of 2016. [EPA-HQ-OAR-2014-0827-1265-A1 p.177]

To further reduce NOx emissions, CARB also adopted optional low-NOx standards in late 2013 that are 50 percent, 75 percent, and 90 percent lower than the current NOX standard of 0.20 g/bhp-hr. The optional low-NOX standards were developed to encourage engine manufacturers to develop new technologies and also to provide them have been updated to include incentives to encourage the development and certification of lower NOX heavy-duty engines. In response to these actions, Cummins Westport Inc. (CWI) announced in May 2015 that it achieved a 0.02 g/bhp-hr NOX emission level on its 8.9 liter ISL G spark-ignited natural gas engine, and was starting field testing in California. In September 2015, CARB issued Executive Orders for the 8.9 liter ISL engine certified to the 0.02
g/bhp-hr optional NOx standard for use in medium heavy-duty and urban bus applications. [EPA-HQ-OAR-2014-0827-1265-A1 P.177-178]

As discussed previously on California’s need for GHG reductions, another consideration for the adoption of lower NOx emission standards is its simultaneous implementation with the proposed Phase 2 GHG standards. The proposed Phase 2 Alternative 3 does not become fully implemented until the 2027 MY. A more stringent Alternative 4 would be fully implemented by the 2024 MY, which would allow earlier action on NOx, without the need for manufacturers to implement both rulemakings simultaneously. As a result, the need for timely NOx reductions lends additional support for U.S. EPA and NHTSA to choose Alternative 4 over Alternative 3. [EPA-HQ-OAR-2014-0827-1265-A1 P.178]

In light of California’s and certain other states’ pressing needs for NOX emission reductions to achieve the proposed more stringent NAAQS standards, CARB staff urges U.S. EPA and NHTSA to thoroughly describe the need for lower federal NOX emission standards for new heavy-duty engines in the Phase 2 rulemaking package and to initiate a parallel effort to adopt such standards as quickly as possible. [EPA-HQ-OAR-2014-0827-1265-A1 P.178]

70 Table VIII-20 in the Phase 2 Proposed Rule estimates 426,610 tons/yr downstream NOx reductions nationwide in 2050 due to Phase 2.

71 See <http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2014-0827-0036> for our comment regarding the need for a supplemental NOx check for hybrids.

**Organization:** California Interfaith Power and Light

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p.104.]
We also support other organizations, such as the South Coast Air Quality Management District, in their call for a tightening of the NOx standards.

Organization: Clean Energy

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 249-250.]

We understand that some stakeholders will be asking that the EPA and NHTSA consider establishing a low-NOx standard for engines within the final rulemaking, much like the one being proposed by the California Air Resources Board.

While Clean Energy does not currently have a formal position on this proposed addition to the rule, we are very proud of our industry's tradition in delivering optional low-NOx performance well in advance of competing combustion technologies. Specifically, Cummins Westport has recently announced its plans to deliver a nine-liter engine available to the market that meets a .02-gram per brake horsepower hour limit as early as quarter 1 of 2016. Further, Cummins Westport believes that it would deliver similar missions performance for its 12 and 6.7-liter product line as early as Q2 2017 if they receive onboard diagnostic flexibility from the Air Resources Board and additional R&D funding from local and state agencies.

Organization: Coalition for Clean Air/California Cleaner Freight Coalition

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 217-218.]

We cannot reach attainment of federal standards in Los Angeles region or the San Joaquin Valley without a .02 brake horsepower hour NOx heavy-duty standard.

And it should also initiate a separate rulemaking to lower the NOx standards.

Organization: Environmental Defense Fund (EDF)

EPA should commit to strengthen NOx standards for heavy-duty trucks

Ozone pollution continues to threaten the health of millions Americans – 4 in 10 people live in areas with unhealthy levels of ozone. Reducing emissions of nitrogen oxides (NOx) and volatile organic compound (VOC) – the precursors to ozone – is critical to providing cleaner air for communities and families across the nation. NOx emissions standards for heavy-duty vehicles were last issued in 2001 and implementation was completed in 2010. Those standards achieved significant reductions in NOx and particulate emissions through innovative technology and ingenuity by manufacturers. [EPA-HQ-OAR-2014-0827-1312-A1 p.53]

It has been nearly 15 years since the last standards were promulgated, and technology has continued to advance. It is also clear that additional reductions in ozone forming NOx are needed from the heavy-duty sector. In places like California – where much of the state is hard hit by ozone pollution – heavy-duty trucks still make up 33% of statewide NOx emissions. Developing technologies, together with the improvement of existing emissions controls can provide additional cost-effective, meaningful NOx reductions from the nation’s heavy-duty fleet. California has already begun research on the
technologies needed to reduce NOx by another 90 percent. EPA should collaborate with ARB to investigate the pathways to making NOx reductions. [EPA-HQ-OAR-2014-0827-1312-A1 p.53]

We urge EPA, in the final rulemaking, to commit to strengthen NOx standards for heavy-duty trucks as soon as possible. By initiating a NOx rulemaking immediately, manufacturers will be able to integrate the planning and the technology for CO2 and NOx reductions, helping to ensure that one benefit is not traded for the other. [EPA-HQ-OAR-2014-0827-1312-A1 p.53]

211 Preamble at 40332.

223 CARB, upcoming “Draft Technology Assessment: Lower NOx Heavy-Duty Diesel Engines.”

Organization: Manufacturers of Emission Controls Association (MECA)

The Advanced Collaborative Emissions Study (ACES) Phase 2 report published in 2012 showed that modern heavy-duty engines are achieving PM and NOx levels well below the federal standards. Recognizing the capability of technologies to deliver complimentary reductions of NOx and GHGs, California has adopted voluntary low NOx standards to incentivize development of state-of-the-art engines and emission controls to achieve NOx levels as low as 0.02 g/bhp-hr which is equivalent to a 90% reduction from EPA’s 2010 highway, heavy-duty engine standards. Certification of cleaner engines ahead of proposing mandatory standards opens up opportunities for the state to direct incentive funds toward the development of cleaner engines. To support their regulatory efforts, ARB is funding a technology demonstration test program at Southwest Research Institute to demonstrate the feasibility to further reduce NOx emissions from heavy-duty engines. Advanced emission technologies like SCR coated filters and passive NOx absorbers are included in this demonstration test program. EPA is monitoring this important test program as a member of the program’s advisory committee. [EPA-HQ-OAR-2014-0827-1210-A3 p.6-7] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1210-A3 p.214.]

To estimate the achievable level of NOx inventory reduction through the deployment of technologies capable of achieving a 90% NOx reduction below 2010 levels in the lower 47 states (excluding California), MECA funded an independent emission inventory forecast study, at ENVIRON. This analysis relied on EPA’s MOVES2014 emissions inventory model for on-road vehicle emissions to estimate the future NOx reduction potential of a 0.02 g/bhp-hr heavy-duty NOx standard under a federal program. By-model-year emissions were determined for on-road vehicles to develop emissions estimates with and without new potential future emission standards. The model was run to generate
emission inventories of NOx, VOC, CO and PM for on-road heavy-duty sources for calendar years 2025, 2030, 2040, and 2050. [EPA-HQ-OAR-2014-0827-1210-A3 p.7] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.214.]]

When fully implemented, the achievable reductions from tighter NOx regulations on the heavy-duty on-road sector are estimated to be 266,000 tons per year or 730 tons per day in 2050 across the 47 contiguous United States and D.C., excluding California. We believe that these heavy-duty control measures represent the largest opportunity for achieving NOx reductions from the mobile sector going forward. We estimated the incremental cost of the types of additional emission controls that would be necessary to achieve the target reductions from heavy-duty trucks, beyond the exhaust controls already being used to meet current 2010 heavy-duty on-road standards at approximately $500 per vehicle averaged over the medium and heavy-duty highway fleet. Based on the results of our analysis, we estimate that heavy-duty trucks can deliver NOx reductions at a cost of approximately $3,000-$4,000 per ton. The very cost-effective NOx reductions available from the heavy-duty highway sector reflect the continued evolution of diesel exhaust emission controls. It has been more than 15 years since EPA closely examined diesel emission technologies as part of finalizing their 2007-2010 heavy-duty highway engine standards. Manufacturers of these technologies have and continue to improve the base technologies used to control NOx and PM from diesel engines. Significant experience has been provided by commercial roll-out of heavy-duty engines equipped with DPFs and SCR catalyst systems in this sector since 2007. These evolutionary improvements provide the pathway to achieving additional significant, cost-effective NOx reductions from this sector. [EPA-HQ-OAR-2014-0827-1210-A3 p.7] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.214-215.]]

MECA believes that further reductions in NOx emissions from new heavy-duty on-road and off-road diesel engines beyond the 2010 on-road and Tier 4 off-road requirements will be possible through the combinations of more advanced diesel engines with advanced diesel exhaust emission control technologies. Much of the system development necessary to meet lower NOx emissions will be focused on the initial cold-start portion of the heavy-duty transient FTP test cycle representing approximately 70% of the total NOx emissions over the entire cycle. The types of future evolutionary technologies deployed, to achieve a future lower NOx standard, will likely include advanced substrates, improved SCR catalysts, more efficient SCR reductant delivery technologies and algorithms, and/or passive NOx adsorber catalysts. Substrate mounting matt materials have also evolved through newer technology generations including innovative, insulating intumescent canning materials that retain heat in the catalyst during periods of engine shutdown. The emission reduction benefits achieved through the deployment of cold start technologies such as advanced thermal management strategies, close-coupled catalysts, low thermal mass materials, improved ammonia dosing strategies among others will extend to increased conversion during low temperature duty-cycle operations. Already in several commercial light-duty diesel applications, higher porosity within the ceramic filter walls has allowed SCR catalyst to be deposited directly onto the DPF and thereby effectively moving the SCR closer to the turbocharger outlet in a more close-coupled position. Faster heat-up of the SCR catalyst has allowed earlier ammonia injection and NOx reduction. The sooner the SCR catalyst is activated in the test cycle, engine calibrators can optimize combustion for reduced CO2 emissions. Furthermore, these cold-start technologies will allow vehicle manufacturers to deploy hybrid systems, stop-start technologies and waste heat recovery to improve vehicle efficiency while still meeting tighter NOx limits. [EPA-HQ-OAR-2014-0827-1210-A3 p.7-8] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.213-214.]]

MECA believes the time is right for EPA to begin a rulemaking effort aimed at further significant reductions in NOx emissions from heavy-duty highway engines. Improved NOx reduction technologies are available today to deliver ultra-low NOx emissions from these engines. Existing and future ozone
non-attainment regions will need these cost-effective NOx reductions to support attainment plans. Engine manufacturers can combine these advanced NOx emission controls with other efficiency technologies to optimize future truck performance to deliver both lower NOx emissions and improved fuel efficiency. [EPA-HQ-OAR-2014-0827-1210-A3 p.8]

Ground level ozone also has a strong linkage to climate change. EPA needs to continue its efforts to review and adjust criteria pollutant programs for all mobile sources going forward to not only provide needed health benefits from technology-forcing emission standards but also the co-benefits these emission standards have on climate change. In particular for heavy-duty highway engines, MECA urges EPA to begin a rulemaking effort as soon as possible aimed at further NOx reductions from heavy-duty engines. [EPA-HQ-OAR-2014-0827-1210-A3 p.14] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.215.]

Organization: Moving Forward Network

EPA and NHSTA need an advanced NOx standard – Many of our communities live in areas with high levels of ozone pollution. It is vital that this regulation create requirements to reduce the amount of harmful NOx pollution coming from these trucks. [EPA-HQ-OAR-2014-0827-1130-A2 p.2]

Organization: National Association of Clean Air Agencies (NACAA)

Our March 18, 2015 letter also included a recommendation that EPA articulate in the proposal the need for significantly lower national heavy-duty NOx standards beyond the current 2010 onroad heavy-duty NOx exhaust emission standards and nonroad heavy-duty engine exhaust emission standards. We are very disappointed that EPA has not included such a discussion in this proposal. Although there is the potential for ancillary NOx reductions from the Phase 2 rule, the achievement of these reductions is not certain (we note that predicted ancillary benefits of Phase 1 did not occur). Moreover, even if ancillary NOx benefits do accrue under the Phase 2 rule, they will not be nearly sufficient given the challenges state and local agencies face in attaining and maintaining current and upcoming ozone and fine PM standards and protecting against visibility impairment and eutrophication of water bodies. [EPA-HQ-OAR-2014-0827-1157-A1 p.4] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.54.]

In addition to early climate benefits, federal action on our recommendation to adopt Alternative 4 (full implementation by 2024) would also provide manufacturers the ability to incorporate technologies to significantly reduce NOx emissions from heavy-duty vehicles in a more timely manner. While already crucial for a number of areas, NOx reductions from the heavy-duty sector will become increasingly important to additional areas under strengthened National Ambient Air Quality Standards for ozone, which are expected imminently. We urge that EPA include in the final Phase 2 rule a clear and comprehensive discussion of the need for very substantial additional NOx reductions from heavy-duty vehicles and engines and, even more critically, an explicit commitment to begin immediately a separate rulemaking initiative to capture those reductions. [EPA-HQ-OAR-2014-0827-1157-A1 p.4][This comment can also be found in section 1.5 of this comment summary] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.54.]

Organization: National Automobile Dealers Association (NADA)

NADA/ATD is categorically opposed to the imposition of any new NOx standards during the duration of the Phase 2 program. The prospect of significantly lower NOx standards is just now the subject of
cutting edge research and it will be many years before the technology sufficient to meet any such standards can be developed and demonstrated to the demanding performance, reliability, and cost requirements of new commercial vehicle customers. [EPA-HQ-OAR-2014-0827-1309-A1 p.10]

**Organization:** Navistar, Inc.

Navistar strongly believes that this Proposed Rule and the technologies that will be necessary to meet it will impact the feasibility of any future regulation for NOx. [EPA-HQ-OAR-2014-0827-1199-A1 p.20-21]

**Organization:** North American Repower

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 308.]

You have asked very specifically about .2 versus .02 grams per horsepower hour NOx. There are disclosures in place that I can't say exactly who we are working with. We have the technology. We have already shown it in the test cell, to our satisfaction. We can get to .02 NOx with natural gas engines with our technology. Do I push for that? No. Why? Because we have seen where we have pushed too quickly with new technologies and it has adversely affected the population.

**Organization:** Northeast States for Coordinated Air Use Management (NESCAUM)

In addition, our states remain concerned about emissions of nitrogen oxides (NOx) from this sector, and urge EPA to begin rulemaking to require further reductions in NOx from heavy-duty trucks at the earliest possible date. Below we discuss several specific areas in which the rule can and should be strengthened. [EPA-HQ-OAR-2014-0827-1221-A1 p.1-2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.136.]]

**EPA should address the potential for further NOx reductions at the earliest possible date.**

Heavy-duty trucks represent the second largest source of NOx emissions in the NESCAUM region, and our states remain very concerned about the need to further control NOx emissions from this sector. We thank the agencies for acknowledging the challenge that states continue to face in this regard, and we urge EPA to begin a rulemaking without delay to ensure that the next generation of trucks is not only more fuel efficient but also much less of a contributor to states’ air quality and public health problems. [EPA-HQ-OAR-2014-0827-1221-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.137-138.]]

The NESCAUM region, home to over 42 million people, is subject to episodes of poor air quality resulting from ground-level ozone and fine particle pollution. During severe events, the scale of the problem can extend beyond NESCAUM’s borders and include over 200,000 square miles across the eastern United States. Local and regional sources as well as air pollution transported hundreds of miles from distant sources outside the region contribute to elevated ozone and fine particle concentrations in the region. [EPA-HQ-OAR-2014-0827-1221-A1 p.3]

NOx emissions contribute to a number of adverse public health and environmental outcomes. NOx is the most important contributor to nitrogen dioxide and ground-level ozone pollution, and an important precursor to fine particulate matter formation. These pollutants are responsible for tens of thousands of
premature deaths, hospital admissions, and lost work and school days in the U.S. annually. NOx is also a key factor in a number of environmental problems that affect the Northeast. Table 1 summarizes the major adverse impacts of NOx emissions in the NESCAUM region. [EPA-HQ-OAR-2014-0827-1221-A1 p.4]

[Table 1 can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1221-A1]

Additional NOx reductions would benefit air quality and public health in the Northeast by: (1) lowering the “ozone reservoir” that forms in the eastern U.S., and (2) reducing the amount of low-level NOx emissions and pollutants derived from NOx that are transported into the Northeast/Mid-Atlantic region. [EPA-HQ-OAR-2014-0827-1221-A1 p.4]

**Ozone**

Ozone remains a persistent pollution problem in parts of the NESCAUM region during warm weather months. The evolution of severe ozone episodes often begins with the passage of a large high pressure area from the Midwest to the middle or southern Atlantic states. Three primary pollution transport pathways affect air quality in the region: long-range, mid-level, and near-surface. During severe ozone episodes associated with high-pressure systems, these pathways converge on the Mid-Atlantic area, where sea and bay breezes act as a barrier and funnel ozone and other air pollutants up the Northeast Corridor. [EPA-HQ-OAR-2014-0827-1221-A1 p.4-5]

Collectively, NOx emissions and ambient ozone concentrations in the region have dropped significantly since 1997, along with the frequency and magnitude of exceedances of the health-based ozone national ambient air quality standard (NAAQS). Despite this demonstrated progress, some of the most populous areas of the region continue to violate the 2008 0.075 ppm ozone NAAQS. Attaining the standard in these areas will require significant additional NOx reductions within the Northeast and in upwind areas. Looking toward the future, additional NOx reductions will be critical to ozone attainment in order to meet the recently revised 0.070 ppm ozone NAAQS, which EPA projects will continue to be exceeded in our region in 2025. [EPA-HQ-OAR-2014-0827-1221-A1 p.5]

**Particulate Matter**

Scientific evidence has established a solid link between cardiac and respiratory health risks and transient exposure to ambient fine particle pollution that is capable of penetrating deep into the lungs. Exceedances of the fine particle NAAQS can occur at any time of the year, with some of the highest levels often reached in the winter. There are important differences in the chemical species responsible for high fine particle levels during summer and winter in the Northeast. Regional fine particle formation in the eastern United States is primarily due to SO2, but NOx is also important because of its influence on the chemical equilibrium between sulfate and nitrate particles during winter when nitrates can be a relatively greater contributor to urban PM2.5 levels. [EPA-HQ-OAR-2014-0827-1221-A1 p.5]

The agencies, however, should strengthen certain provisions to maximize the benefits from this important program. In addition, EPA should ensure that emissions of other pollutants do not increase as a result of the rule, and should commence rulemaking to reduce NOx from heavy-duty vehicles at the earliest possible date. [EPA-HQ-OAR-2014-0827-1221-A1 p.7]
Air quality in our region does not meet the current ozone National Ambient Air Quality Standards (NAAQS) and is not expected to meet the proposed 2015 NAAQS without substantial not yet on the books decreases in Oxides of Nitrogen (NOx) emissions. Mobile sources, particularly heavy-duty vehicles, are a significant contributor of NOx emissions in the region. USEPA has the authority and responsibility to provide these remission reductions. The OTC calls on the USEPA to evaluate and deliver additional NOx reductions from medium- and heavy-duty vehicles in a time frame to assist the attainment of the 2008 and expected 2015 Ozone NAAQS. [EPA-HQ-OAR-2014-0827-1211-A2 p.1]

Background on Ozone

Ground-level ozone is a significant health threat. It is known to cause respiratory illnesses, exacerbate or trigger asthma related episodes, increase respiratory-related emergency room and hospital admissions, and compromise the immune system leading to increased incidents of other respiratory illnesses, including pneumonia and bronchitis, and to cause premature death. Ozone is formed when Volatile Organic Compounds (VOCs) and NOx mix and interact with sunlight. [EPA-HQ-OAR-2014-0827-1211-A2 p.1]

Research has shown that ozone formation in the OTR is predominately driven by regional NOx emissions from mobile sources. [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Importance of Diesel Trucks in Formation of Ground Level Ozone

Recent modeling and inventory analyses OTC completed to plan for meeting both the 2008 and expected 2015 Ozone NAAQS, has shown that diesel trucks are a large contributor of NOx emissions which lead to ground level ozone pollution. National runs of the USEPA MOVES model show that heavy-duty diesel trucks alone make up greater than 60% of the onroad mobile NOx emissions in the mid 2020's and when applied to our preliminary predictions of the anthropogenic NOx emissions inventory, make up 10% of the overall emissions. NOx emissions from diesel truck emissions need to be reduced substantially in order for the states in the OTR to meet the 2015 ozone NAAQS. [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Technologies and CARB

The California Air Resources Board (CARB) has a voluntary program for heavy-duty diesel manufacturers to certify that their vehicles meet lower NOx standards. Testing is also underway by CARB and members of industry to further demonstrate the technologies necessary to meet lower NOx standards for diesel vehicles. Some examples of the technologies available to meet lower NOx standards are: [EPA-HQ-OAR-2014-0827-1211-A2 p.2]
Thermal management [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Selective catalytic reduction (SCR) positioning improvements [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Advanced high porosity substrates [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Low temperature catalyst activity [EPA-HQ-OAR-2014-0827-1211-A2 p.2]

Passive NOx adsorber catalysts [EPA-HQ-OAR-2014-0827-1211-A2 p.3]

Improved urea dosing strategies [EPA-HQ-OAR-2014-0827-1211-A2 p.3]

These technologies allow diesel trucks to meet lower NOx standards and need to be implemented relatively quickly in order for the states in the OTR to attain the 2008 and expected 2015 Ozone NAAQS. Early action is needed given that the heavy-duty diesel fleet sector turnover is significantly slower than that seen in light-duty vehicle turnover. If standards began by 2020, OTC's analysis found that a 10% reduction in NOx could be achieved by the mid 2020s. [EPA-HQ-OAR-2014-0827-1211-A2 p.3]

Implications of a Lower 2015 Ozone NAAQS on the OTR

USEPA is under a court order to revise the Ozone NAAQS in October of 2015. USEPA has proposed a revision to the Ozone NAAQS in the range of 65 — 70 ppb and as low 60 ppb, whereas the current NAAQS is set to 75 ppb. Several states in the OTR do not meet the 75 ppb standard and if currently complete ambient air quality data is examined, all but two states in the OTR would be in at least marginal nonattainment for a 70 ppb NAAQS, and all but one state in the OTR would be in at least marginal nonattainment for a 65 ppb NAAQS. Furthermore, at the 65 ppb level, over half of the jurisdictions in the region are facing moderate nonattainment. The timeline legislated in the Clean Air Act would require states to begin achieving the ozone NAAQS in 2023. [EPA-HQ-OAR-2014-0827-1211-A2 p.3]

In the RIA, USEPA also found that 23% and 43% of the NOx controls needed in the OTR to meet the 70 ppb and 65 ppb NAAQS respectively were 'unknown.' These controls will need to come from mobile sources and need to be on the way by 2023 and is further evidence supporting the need for greater NOx reductions from heavy-duty diesel trucks. [EPA-HQ-OAR-2014-0827-1211-A2 p.3]

Implications of 2018 Regional Haze Planning

States are required to submit regional haze SIPs demonstrating improvement in regional haze by 2028. The latest science and analyses of emission trends show an increasing impact of nitrates and secondary organic aerosols on regional haze, both of which are impacted by NOx emissions. Reducing NOx emissions from heavy-duty diesel emissions through lower emission standards would assist states in meeting the Clean Air Act required regional haze goals. [EPA-HQ-OAR-2014-0827-1211-A2 p.3]

Work with Manufacturers

USEPA needs to send signals now to the manufacturers that additional NOx emission reductions will be required. Such an action would allow manufactures to holistically develop engine and emission control
This early signal to manufacturers could help reduce the costs of such systems and avoid the need for incremental designs, where manufacturers first implement technologies to meet the lower greenhouse gas standards and then, several years down to road, needing to address reduced NOx emission standards. USEPA needs to take a multi-pollutant approach with mobile source standards and finalize a rule that deals with all of the pollution that needs to be reduced from diesel trucks. Furthermore, if this does not occur, it is highly likely that additional NOx reductions needed from the sector will not occur in a timeframe necessary for the OTC states to meet their ozone nonattainment obligations and upwind states to meet their good neighbor contributions. [EPA-HQ-OAR-2014-0827-1211-A2 p.3-4]

**Organization:** PACCAR, Inc.

**EPA Should Not Adopt Significantly More Stringent NOx Requirements that Would Complicate Compliance with the GHG Standards, Nor Should EPA Approve any such California Requirements**

PACCAR also urges EPA to consider the relationship between carbon dioxide (CO2) and nitrogen oxide (NOx) emissions when issuing final standards. PACCAR is committed to working with EPA and the California Air Resources Board (ARB) to achieve significant NOx reductions over time. However, an accelerated and extremely ambitious NOx reduction target, even in only some portions of the U.S., would make compliance with more stringent GHG standards even more challenging. A patchwork regulatory scheme would undermine EPA’s GHG program, pose enormous compliance challenges, and could make the movement of goods more expensive. [EPA-HQ-OAR-2014-0827-1204-A1 p.5]

**Relationship between NOx and CO2 emissions**

Complying with more stringent NOx standards would require significant investment in engine and aftertreatment technologies and would not be conducive to improving fuel consumption and lowering CO2. As is documented and known, there is a trade-off between fuel consumption and engine-out NOx for a current certified Heavy Heavy-Duty (HHD) diesel engine. The negative impact on fuel consumption from reduced engine-out NOx levels is clearly understood. [EPA-HQ-OAR-2014-0827-1204-A1 p.5]

As part of an ongoing feasibility study of 0.02 g/bhp-hr NOx tailpipe compliance, Southwest Research Institute is exploring a variety of measures aimed at reducing engine-out NOx. The results from an August 20, 2015 report-out suggest a 12% fuel consumption penalty for a 6-fold reduction in engine-out NOx. The proposed tailpipe levels would likely require still more aggressive reductions in engine-out NOx. [EPA-HQ-OAR-2014-0827-1204-A1 p.5]

**Permitting California to Set More Stringent NOx Standards Would Adversely Affect the Movement of Goods Throughout the U.S.**

PACCAR strongly believes that a 50-state, nationwide regulation for Phase 2 is imperative to the success of this next step in GHG and fuel consumption reductions. GHG emission reduction is being driven by global climate change, not local impacts. As such, there is no benefit to an individual state to have a GHG reduction regulation that is not the same as that of EPA. [EPA-HQ-OAR-2014-0827-1204-A1 p.5]

The State of California has indicated that it will develop its own Phase 2 GHG emissions rule in late 2016 or 2017, after a final federal rule is promulgated. Under Section 209(b) of the Clean Air Act
(CAA), California has the unique authority to seek a waiver of CAA preemption to enforce its own vehicle and engine standards that are at least as protective as comparable federal rules. California was granted a 209(d) waiver for its own Phase 1 program in 2014 but ultimately harmonized these standards with the federal rule. While the state has been working with EPA and NHTSA in the development of the federal Phase 2 standards, ARB has recently indicated that the state may pursue more stringent Phase 2 GHG and NOx controls to ensure that California meets federal air quality targets and its long-term climate goals. [EPA-HQ-OAR-2014-0827-1204-A1 p.5-6]

The CAA permits states to adopt and enforce standards that are identical to California’s standards in lieu of the national standard. Five states—Maine, Massachusetts, New Jersey, Pennsylvania, and Georgia—have done so for heavy duty vehicles and engines. The remaining states require the sale of federally-certified vehicles. If California adopts separate standards and seeks and is granted a waiver for its own Phase 2 standards, other states with air quality problems may adopt identical requirements, undermining a single national standard for heavy duty trucks and raising cross-border regulatory issues not seen in Phase 1 of the rule. [EPA-HQ-OAR-2014-0827-1204-A1 p.6]

As EPA is aware, vehicles certified to federal standards may not be sold in states that require California-certified vehicles, and vehicles only certified for sale in California may not be sold in states that have not adopted California standards or are not contiguous to such states. However, “50-State Vehicles” conforming to U.S. EPA regulations and California regulations may be sold in any state, and EPA’s Cross-Border Sales Policy permits the sale of California-certified vehicles or engines in states bordering a state that has adopted the California standards. This complicated regulatory landscape will make it extremely difficult for Original Equipment Manufacturers (OEMs) to comply with both the national EPA standards and with more stringent California standards, or will require manufacturers to certify all vehicles and engines to the California program at a higher cost. [EPA-HQ-OAR-2014-0827-1204-A1 p.6]

PACCAR and other OEMs would be faced with the choice of not selling trucks and engines into California, which would dramatically affect our business and undermine our commitment to our dealers and shareholders. The other, also unappealing, option would be to certify the majority of our vehicles to the more stringent “50-State” standards to avoid the compliance issues associated with different standards in place in different states. This option would come with substantial costs and effort to develop, test, and certify products that meet more stringent standards. This would effectively turn the California standards into national standards, without the program undergoing evaluation and assessment by EPA, NHTSA, the Small Business Administration (SBA), regulated parties and customers for these engines and vehicles. EPA should not allow California to force the heavy-duty truck and engine industry to comply with that state’s more stringent requirements across the nation. [EPA-HQ-OAR-2014-0827-1204-A1 p.6]

Organization: South Coast Air Quality Management District (SCAQMD)

Given the challenges facing the South Coast Air Basin and other regions that are in nonattainment of the national ambient air quality standards for ozone and fine particulate matter, the proposed Phase 2 standards have the potential to not only further reduce greenhouse gas emissions from medium- and heavy-duty engines and vehicles, but more critically and urgently needed reduction in oxides of nitrogen (NOx) emissions that significantly contribute to the ozone and fine particulate air quality in the South Coast Air Basin. As you are aware, the South Coast Air Basin is designated as an “extreme” nonattainment area for the 1997 and 2008 federal 8-hour ozone ambient air quality standard and must attain the standards by 2024 and 2032. In order to meet these air quality standards, around 50 to 65 percent reduction in NOx emissions must be achieved by the applicable dates. As acknowledged in the
notice of proposed rulemaking. California has adopted tighter on-road heavy-duty engine emission standards to reduce NOx and greenhouse gas emissions (80FR40149). However, given the significant NOx emission reductions needed to attain federal ambient air quality standards (80FR40149), it is critical that every opportunity to reduce NOx emissions be afforded to the region. As such, we strongly urge U.S. EPA to adopt new on-road heavy-duty engine NOx emission standards that ultimately achieve a 90 percent cleaner emissions level compared to the current 2010 on-road heavy-duty engine standard. This action will enhance the production of such vehicles nationwide since a significant number of heavy-duty vehicles are purchased outside of the California market. [EPA-HQ-OAR-2014-0827-1181-A1 p.1-2]

Need for New National Low-NOx On-Road Heavy-Duty Engine Emissions Standard The South Coast Air Basin and many other areas that are in nonattainment of the federal ozone ambient air quality standards will face significant challenges in meeting the standards without assistance from the U.S. EPA. This will be especially true when U.S. EPA promulgates another more stringent ozone standard in the near future. While U.S. EPA believes that many of these areas will meet current and future ozone air quality standards within the applicable deadlines, many areas must assess the need to reduce emissions from stationary and industrial sources to meet these standards. In addition to meeting existing and future air quality standards, regions designated nonattainment for ozone air quality standards that have been revoked must continue to show progress in meeting those standards. Such is the case with the 1990 national ambient air quality standard for the 1-hour ozone, which the South Coast Air Basin must achieve by 2022. Clearly, without new federal regulations to establish tighter emissions standards from not only on-road heavy-duty engines, but also non-road engines including locomotives, marine vessels, and aircraft, mobile source emissions will increase due to increased activity and economic growth. Establishing new criteria pollutant exhaust emission standards will provide assurance that cleaner combustion engines will be commercially available to help meet not only existing federal ambient air quality standards, but also tighter future air quality standards. [EPA-HQ-OAR-2014-0827-1181-A1 p.3]

The South Coast Air Basin not only has to attain the national ambient air quality standard for ozone, but must also attain new fine particulate ambient air quality standards in the early 2020 timeframe. As the SCAQMD and CARB develop the 2016 State Implementation Plan (SIP) to meet the various national ambient air quality standards, we find that the predominant contributors to the ozone and fine particulate air quality are from on-road and non-road mobile sources as shown in Figure 1. Figure 1 shows the NOx emissions historically in 2012 and projected NOx emissions in 2023 and 2031 assuming full implementation of current regulations. The primary path to meeting both ozone and fine particulate air quality standards requires significant reductions in oxides of nitrogen (NOx) emissions. [EPA-HQ-OAR-2014-0827-1181-A1 p.3]

[Figure 1 can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1181-A1]

Figure 2 shows the top NOx emissions sources in the South Coast Air Basin for 2023 and 2031, the two years required to demonstrate attainment of the 1997 and 2008 ozone air quality standards. As shown in Figure 2, mobile sources are among the largest emission sources with on-road heavy-duty trucks as the number one contributor to the region’s air quality problem. As the SCAQMD continues to implement controls on stationary sources, the mobile source emission contributions are the largest contributors to the NOx emissions in the region. [EPA-HQ-OAR-2014-0827-1181-A1 p.4]

[Figure 2 can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1181-A1]

In preparing the 2016 SIP, the SCAQMD and CARB are projecting that the region must further reduce NOx emissions by around 50 and 65 percent to meet the federal 8-hour ozone air quality standards by
2024 and 2032, respectively. Figure 3 illustrates the NOx reductions needed to achieve the two air quality standards with the emission sources from Figure 2 rearranged by mobile and stationary sources. As shown in Figure 3, if there were no stationary sources contributing to the NOx emissions in 2023, mobile source emission contributions alone will result in ozone levels greater than the targeted 50 and 65 percent NOx reduction needed for attainment. Thus, it is vitally important that mobile sources reduce their NOx emissions as early as possible. Many of these sources are the primary responsibility of the U.S. EPA and/or international regulations. The region cannot attain mandated federal air quality standards without critical actions from the U.S. EPA and international organizations governing these sources. 

As such, we urge the U.S. EPA to begin immediate actions to adopt new low-NOx heavy-duty engine emissions standard at 0.02 g/bhp-hr. These actions do not necessarily need to be part of the current proposed greenhouse gas emissions rulemaking. However, a combined rulemaking would allow engine manufacturers to develop control technologies that will reduce both NOx and greenhouse gas emissions. Regardless, such rulemaking must begin immediately to help the region attain air quality standards. [EPA-HQ-OAR-2014-0827-1181-A1 p.6]

Relative to timing for the need for a new low-NOx emissions standard, CARB has conducted an analysis on the need for a national on-road heavy-duty engine NOx emissions standard compared to a California only standard. Figure 4 shows the difference in having a California only standard compared to a national standard. Since on-road trucks are mostly purchased out-of-state, there will be significantly more NOx emission reductions with a national standard. In addition, based on CARB’s analysis, it will take almost 15 years for fleets to turnover to the new low-NOx engines. The SCAQMD staff and CARB recognize the need to incentivize the accelerated deployment of such engines as early as possible. As such, immediate action by U.S. EPA will provide certainty for the commercialization of such engines and enable the region and the state to develop programs to accelerate the deployment of such engines. [EPA-HQ-OAR-2014-0827-1181-A1 p.7]

The SCAQMD and CARB have initiated efforts to conduct research and demonstration of on-road heavy-duty engines to meet NOx emissions levels at 0.02 g/bhp-hr as early as possible. Relative to the SCAQMD efforts, the SCAQMD along with the California Energy Commission, and the Southern California Gas Company, are co-sponsoring the development of on-road heavy-duty natural gas engines that are at 0.02 g/bhp-hr with the goal of having these engines commercially available within the next few years. Cummins Westport, Inc. is one of the manufacturers participating in this effort. Cummins Westport recently received a California certification of its 8.9 liter natural gas engine at the 0.02 g/bhp-hr level. The CARB Executive Order for this engine is provided in Attachment 2. As you are aware, this engine can be used in several classes of on-road heavy-duty vehicles, primarily in transit buses and solid waste collection vehicles. In addition, we are encouraging the use of biomethane as the primary source of fuel rather than fossil based natural gas to further reduce greenhouse gas emissions. Cummins Westport has indicated its intent to expand commercialization of two additional natural gas engines at the 0.02 g/bhp-hr level, the 11.9 liter and 6.7 liter engines. The 11.9 liter engine is a preference by many operators of over-the-road Class 7 and 8 trucks, while the 6.7 liter engines are used in medium-duty and light-heavy duty vehicles in the Class 4 through 7 range. We strongly believe that the initiative taken by Cummins Westport will spur other engine manufacturers to begin the development of the next generation of on-road heavy-duty engines meeting the 0.02 g/bhp-hr. However, commercialization of such engines requires setting a national emissions standard to provide a benchmark for all engine manufacturers to meet. [EPA-HQ-OAR-2014-0827-1181-A1 p.7-8]
More importantly, in order for the South Coast Air Basin and other areas in nonattainment of national ambient air quality standards, U.S. EPA must act immediately to adopt new, tighter engine exhaust standards to further reduce NOx and fine particulate emissions. As discussed above, such rulemaking need not be part of the proposed Phase 2 rulemaking. However, work must begin in parallel to finalizing the Phase 2 rulemaking with the goal of adopting the low-NOx engine emission standards by the end of 2017. [EPA-HQ-OAR-2014-0827-1181-A1 p.8]

Organization: Truck & Engine Manufacturers Association (EMA)

Potential NOx and N2O Reductions

Several stakeholders are pressuring EPA to adopt lower NOx emission limits for heavy-duty vehicles. That pressure is likely to increase in light of the Agencies’ adoption of a lower NAAQS for ozone. Regardless, this rulemaking is not the regulatory vehicle for the consideration of any potential additional low-NOx standards. In fact, given the inherent emissions trade-off between GHG emissions and NOx emissions (which, unlike GHG emissions, favor lower combustion temperature regimes), any additional NOx reductions will require extremely careful and thorough analysis. [EPA-HQ-OAR-2014-0827-1269-A1 p.64]

Organization: Truck Renting and Leasing Association

For example, we appreciate that the agencies have discussed the need for national uniformity of relevant standards with the California Air Resources Board (CARB). It will be imperative for the EPA in particular to work with CARB going forward to ensure that California regulators do not stray from this approach by, for example, targeting additional NOx reductions that would upset the careful balances struck in this rulemaking. [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

Organization: Union of Concerned Scientists (UCS)

FURTHER REDUCTIONS IN NOX EMISSIONS

Advances in criteria pollution emission controls, driven by tailpipe emissions standards set by EPA and California, have led to major reductions pollution from heavy-duty trucks and reduced health risks (Propper et al. 2015). However, contributions of nitrogen oxides (NOx) from heavy-duty trucks and other diesel sources continue to be a major source of air pollution and contribute to regional challenges in meet health-based federal air quality standards. Analysis by California air regulators shows a need to dramatically reduce levels of NOx emissions, on the order of 90 percent, to meet the existing 75 part per billion ozone standard by 2032 (CARB 2015). NOx emissions from heavy-duty trucks are also of a concern in states outside of CA, particularly in meeting lower ambient ozone standards necessary to protect public health and soon to be finalized by EPA (NESCAUM 2015). Moving forward with fuel economy and greenhouse gas emissions, as proposed in this rulemaking, and making further reductions in NOx emissions in a future rulemaking is critical for meeting air quality standards as well as meeting climate and oil savings goals. Improvements in emissions control technologies and engine combustion, application of vehicle technologies, and deployment of advanced technologies including plug-in and fuel cell technologies in the heavy-duty sector will allow continued advances in lowering both NOx and global warming emissions (Figure 3).
[Figure 3, 'Reducing criteria pollution and global warming emissions from diesel engines', can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

**Organization:** US Hybrid Corporation

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 304-306.]

I believe they missed the major goal of achieving a stringent NOx reduction required to meet our future environmental target. These rules will not drive the NOx level down low enough to improve the health of residents in nonattainment areas.

As has been published and as stated by engine manufacturers, the NOx reduction and fuel economy improvement contradicts the engine controller strategy.

**Organization:** Volvo Group

**Future NOx and CARB GHG Regulation**

The timeframe of this rule, as proposed, stretches 15 years into the future. EPA and NHTSA are thereby shaping the technology development and deployment plans of medium and heavy-duty manufacturers according to these aggressive efficiency standards for many years to come. In the meantime, there is considerable discussion in California and elsewhere concerning persistent elevated ozone levels in urban areas and the associated health risks. Many states include large cities that are not currently expected to meet federal ambient ozone limits according to their regulated deadlines, the most extreme example being broad areas of California, not only due to the many square miles of heavily populated urban areas, but also due to difficult geographical and topological circumstances. So challenging is the problem in California that the Air Resources Board is currently on a path to promulgating NOx emissions standards more stringent than the federal standards. [EPA-HQ-OAR-2014-0827-1290-A1 p.59]

On top of these challenges, EPA is expected to soon announce a reduction in the National Ambient Air Quality Standard for Ozone. This is expected to significantly increase the number of counties in non-attainment status, which will increase the pressure to impose tighter limits on NOx emissions sources **nationally**, including heavy-duty trucks. Signals are emerging that EPA will initiate a rulemaking to further reduce HD NOx emissions after the Phase 2 regulation is finalized. For various reasons, CARB would prefer to see new standards set at the **national level**, and is expected to petition EPA to
promulgate lower NOx standards. Nonetheless, whether considering GHG or NOx emissions, CARB has been quite clear that they are motivated to pass stricter standards than those set by EPA if they feel it’s necessary to meet the State of California’s goals. [EPA-HQ-OAR-2014-0827-1290-A1 p.59]

Despite this backdrop of growing pressure to further regulate NOx emissions from medium and heavy-duty vehicles, there has been little consideration given to this anticipated demand in the Phase 2 notice. This is a considerable oversight, given not only the well documented inverse relationship between NOx and CO2 emission for internal combustion engines\textsuperscript{10}, but also considering the impact to manufacturers’ resource demands if they must develop an even broader array of technologies to simultaneously reduce NOx. [EPA-HQ-OAR-2014-0827-1290-A1 p.59]

The development necessary to meet the proposed GHG standards should not be taken lightly. In many ways, we’re embarking into a new era. The development work to meet the NOx and PM reduction challenges required by EPA’s 2004/2007/2010 standards was based on widespread deployment of mostly singular technologies – first Exhaust Gas Recirculation, then Diesel Particulate Filters, and finally Selective Catalytic Reduction. In this Phase 2 GHG regulation, however, EPA and NHTSA are counting on manufacturers to develop a series of technologies, each targeting a subset of applications. Manufacturers lack the development capacity to meet the multiple, parallel development demands for Phase 2. Waste-heat recovery, stop-start, hybrids in widely different vocational applications, engine/transmission control integration, etc. – all of these are major engineering challenges. On top of this is the strong possibility that this will be complicated by, and supplemented with, additional development to address NOx reductions is not even considered in the NPRM. There are limitations to the capabilities of manufacturers to deliver on all fronts. Overstressed delivery demands lead to product launches with poor reliability and delayed purchases, which undermine all stakeholders’ goals. [EPA-HQ-OAR-2014-0827-1290-A1 p.59-60]

Response:

Because EPA did not propose to establish new NOx standards beyond the existing 2010 standards in this rulemaking, these comments are somewhat out of scope. Nevertheless, we understand why commenters supporting more stringent NOx standards included such comments. EPA has added a section to the FRM Preamble describing our current position with respect to future NO\textsubscript{X} standards for heavy-duty engines. Please see Preamble Section I.F.

15.9 Comments on the NHTSA DEIS

Organization: Michelin North America, Inc.

The DOT draft Environmental Impact Statement (EIS) states ‘... the literature review did not identify HD vehicle LCA studies that examined impacts from other stages of the tire life cycle, including manufacturing, retreading, and end-of-life management specific to LRR and WBS tires...’. [EPA-HQ-OAR-2014-0827-1286-A1 p.4]

In terms of a life cycle analysis (LCA), see the attached summary chart from the Quantis 2013 Truck Tires Life Cycle Analysis Project and attributes summary chart. [EPA-HQ-OAR-2014-0827-1286-A1 p.4]

[Graphs, 'Tire system comparison at endpoint' and 'NGWBS Summary of Attributes', can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1286-A1]
Response:

NHTSA received many written and oral comments to the NPRM and the DEIS. NHTSA reviewed, analyzed, and considered all relevant comments it received during the public comment period. The agency then updated and revised the DEIS to prepare the FEIS, which is being released concurrently with this final rule and ROD. For a more detailed discussion of the comments NHTSA received, including the agency’s responses to those comments, see Chapter 9 of the FEIS.

Organization: National Biodiesel Board

Although the agencies do not focus on lifecycle GHG emissions, NHTSA does address lifecycle emissions of biodiesel in the Phase 2 Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles Draft EIS (DEIS) (NHTSA-2014-0074-0034 at 6-15 to 6-16). NHTSA appropriately recognizes that “[w]hen used as a fuel in on-road vehicles, biodiesel offers significant GHG emission advantages over conventional petroleum diesel.” DEIS at 6-15. It also references a more recent study showing lifecycle emissions can be decreased by up to 52 percent when using biodiesel as a replacement for petroleum diesel, which is based on soybean oil. The DEIS also references, however, the potential for land use changes. NBB continues to dispute the inclusion of land use impacts in the analysis as there is still no real-world evidence that the increased production of biodiesel has resulted in significant land use changes and the modeling that has been used remains inappropriate for measuring actual emissions. Moreover, the U.S. remains a sink for GHG emissions regarding the land use sector. While NHTSA references an analysis by Searchinger, as NHTSA also recognizes, the Searchinger article was disputed by the Department of Energy and should not be considered as a valid scientific analysis. Indeed, there are numerous factors that influence decisions regarding land use, and it would be too speculative to attempt to identify what emissions can be attributed to biofuel production. Further, as noted above, the industry has increased use of waste feedstocks, which has greater GHG emissions reductions. In any event, even considering such impacts, EPA still found lifecycle GHG emission reductions compared to petroleum to be above 50 percent (and as high as 86 percent). [EPA-HQ-OAR-2014-0827-1240-A1 p.11-12]

NBB also requests that NHTSA make certain corrections to the discussion on use of biodiesel blends in diesel equipment in the DEIS at 6-15. NBB agrees that vehicles on the road today are compatible with higher blends of biodiesel. No detrimental effects have been seen with blends up to B20. NBB disagrees, however, with the notion that engines are only “warranted” (or not warranted) for certain fuels. OEMs generally identify the fuels they recommend for use in the owner’s manuals, but we believe this is unrelated to any warranties provided on the engines themselves. OEMs generally do not warranty fuel at all, no matter if that fuel is biodiesel, diesel, gasoline or otherwise. Rather, the OEMs only warrant the actual parts and workmanship of the vehicle or engine that they themselves produce, and they simply provide recommendations for the types of fuel, lubricants, etc. that are suggested for use in those vehicles.14 [EPA-HQ-OAR-2014-0827-1240-A1 p.12]

In addition, NHTSA states that “[b]iodiesel performance improves in cold temperatures as the blend is reduced.” DEIS at 6-15. But, additional measures taken by the industry such as cold-flow additives, blending with #1 diesel fuel, and heated tanks/lines have demonstrated the ability to use blends up to B20 even in the coldest months and regions of the country. [EPA-HQ-OAR-2014-0827-1240-A1 p.12]
Organization: Avista Oil AG et al.

As companies engaged in the collection, processing, refining and sale of used motor oil, we recommend allowing the manufacturers of MHDD vehicles to obtain credit for the significant greenhouse gas benefits associated with re-refined engine oil when it is supplied and used as initial factory fill in the engines of new vehicles subject to the rule and/or when re-refined oil is sold by these manufacturers to be used by vehicle owners in service or preventative maintenance fill. Both methods of use could be easily tracked and verified, and the GHG emission reduction benefits could be credited toward the proposed target reductions and OEMs. [EPA-HQ-OAR-2014-0827-1266-A2 p.1]

Overview: Re-refining used engine oil generates significant environmental and energy benefits, and has been deemed by federal agencies and national research laboratories as the highest and best use of this valuable commodity. Among these benefits is a significant overall life cycle reduction in greenhouse gas emissions when compared to incinerating used oil for energy and replacing it with lubricants made from virgin crude oil. Re-refined oil meets American Petroleum Institute performance classifications; has been deemed suitable for use by major manufactures of gas and diesel engines; and is used successfully by government, commercial and local transit fleets, among others. In addition, re-refined oil is comparably priced to oil made from virgin crude and widely available in the U.S., particularly for large fleets and OEMs. [EPA-HQ-OAR-2014-0827-1266-A2 p.1]

Premise: Allowing Greenhouse Gas Emission reduction credits as part of the Phase 2 Rule, when re-refined engine oil is utilized in medium- and heavy-duty engines, as opposed to engine oil made from virgin crude oil, will significantly reduce the amount of GHG emissions over the lifespan of the engines, while encouraging the expansion of used motor oil recycling in the United States. [EPA-HQ-OAR-2014-0827-1266-A2 p.2]

Key Metrics on the Management of Used Motor Oil in the United States: Used Motor Oil (UMO) can be redefined almost limitlessly into API-Certified Lubricant stocks, thereby reducing GHG emissions, compared to oil made from virgin crude. If OEMs are allowed to use re-refined oil to obtain GHG emissions credits, it would increase demand and production of this oil technology that reduces GHG emissions. The most recent EPA data (1995) indicates that the U.S. generates approximately 1.4 billion gallons per year (B usg/yr) of UMO. Of that, we “recycled” about 945M usg/yr. In this context, recycling included re-refining into base oil which is then manufactured into finished lubricants. In 1995, this was estimated to be 200M usg/yr, but is likely closer to 300M usg/yr. Today. Burning for energy recovery was and is treated by regulation as recycling and, in 1995, included about 745M usg/yr. While burning for energy recovery does reclaim the energy value, it results in destruction of a valuable resource which could otherwise be reused indefinitely. Also, within the category of used oil burned for energy recovery, an estimated 113M usg/yr was used oil burned in space heaters approved for use in garages, greenhouses and other locations. These heaters are often in small workplaces proximate to workers, and have no emission controls for the harmful pollutants in the used oil that can include arsenic, chromium, cadmium, lead, and even PCBs. Significantly, the data from 1995 indicated that the remaining 455M usg/yr was being indiscriminately disposed into the environment – either by discarding into landfills or, worse yet, simply draining into sewers and spilling on the ground. To put this into perspective, this volume of UMO being improperly discarded annually in 1995 was 39 times the quantity of oil spilled in the Exxon Valdez oil spill and about double the amount of crude oil spilled as a result of the Deepwater Horizon spill. [EPA-HQ-OAR-2014-0827-1266-A2 p.2]

Today, we estimate that more oil is being responsibly recycled than in 1995 but the amount of oil being responsibly reused is still far less than other developed and some developing countries. The 2006 DOE study (which relied on 1995 data) indicated that countries like France and Germany had much higher
collection rates (78% and 94%, respectively) and also that they favored re-refining over other reuse options, resulting in re-refining rates that are three to four times higher than the 1995 data indicated for the U.S. (12% in the U.S. versus 42% in France and 41% in Germany. The EU continues to favor re-refining over other uses and continues to promote re-refining using a variety of governmental policies. More current data for Germany suggests that re-refining rates have essentially doubled and that in 2012-2013, Germany re-refined 82% of the used oil available for re-refining. [EPA-HQ-OAR-2014-0827-1266-A2 p.2]

Existing Legislation and Executive Orders about Re-refined Oil: There are some policies in place at the Federal and state level that encourage recycling of used oil and also the use of re-refined oil by the Federal government. For example, section 2 of the Federal Used Oil Recycling Act of 1980 (P.L. 96-463) declares that it is “in the national interest to recycle used oil in a manner which does not constitute a threat to public health and environment and which conserves energy and materials.” This legislation is generally codified at 43 USC 3014 and requires that EPA set recycling and performance standards for used oil to protect public health and the environment. The Act authorizes the Administrator of the EPA to make grants to States with approved or proposed solid waste plans which: (1) encourages the use of recycled oil; (2) discourages use hazardous to the protection of the public health and environment; (3) calls for informing the public of the uses of recycled oil; and (4) establishes a program for the collection and disposal of oil in a safe manner. Also, the Act authorizes the Administrator to provide technical assistance to States in removing impediments to the recycling of used oil. [EPA-HQ-OAR-2014-0827-1266-A2 p.2-3]

Further, Executive Order (EO) 13101 approved by President Clinton on September 14, 1998, “Greening the Government through Waste Prevention, Recycling, and Federal Acquisition,” strengthened and expanded the Federal government’s commitment to recycling, waste prevention, and buying recycled content and environmentally preferable products and services, including lubricants made from re-refined oils. A key objective of this EO is to implement green procurement initiatives to foster development of markets for recovered materials through modifications to Federal purchasing rules, regulations and guidelines. As a result of EO 13101, the Department of Defense and other Federal agencies instituted new guidelines fostering use of re-refined engine oil in Federal vehicles including heavy equipment fleet such as HUMVEES used in battle. This program has proven to be highly successful and continues to provide the “Greening of the Government through Waste Prevention and Re-cycling” as the major market for re-refined lubricants. [EPA-HQ-OAR-2014-0827-1266-A2 p.3]

Environmental Cost-Benefit Analysis: Re-refined oil is comparable in cost to oil from virgin crude for initial factory fill or maintenance. Both are API certified and of comparable quality. According to peer reviewed life cycle analyses by the State of California and Safety-Kleen, re-refining used motor oil reduces up to 80% of GHGs, when end of life emissions are included, compared to manufacturing lubricants from virgin crude. This means that use of re-refined engine oil reduces GHG emissions by .003363 MT of CO2e for each gallon of re-refined oil used, based on a typical ratio of 85% re-refined base oil and 15% additives. While this GHG emissions reduction may appear small when compared to total fuel burned by the MHDD fleet, it is truly significant in the aggregate. Further, re-refined oil is available in adequate supply to cover demand, at a cost comparable to that for oil made from virgin crude. For example, the GHG savings from 50M gallons of re-refined oil is approximately 168,000 metric tons of CO2e. The GHGs reduced are equivalent to the emissions from 15M/usg of #2 fuel oil. These benefits are significant enough to warrant providing some incentive for the use of re-refined oil as part of the Phase 2 rulemaking. Allowing some GHG emissions offset credit will incentivize the re-use of a precious natural resource, while encouraging more collection and re-refining of used motor oil that escapes into the environment through mismanagement. [EPA-HQ-OAR-2014-0827-1266-A2 p.3]
More on Greenhouse Gas Emission Reductions: Attached is a summary of the methodology and results of the GHG benefits of re-refining provided by Environ International, Inc., one of the leading and most respected environmental consulting firms in the world. Their analysis, based on a comprehensive peer reviewed life cycle analysis done in 2009, but updated for these comments, indicate that production of re-refined engine oil generates approximately 70% fewer GHG emissions than production of oil from virgin stock, and up to 80%, when end of life emissions are considered. [EPA-HQ-OAR-2014-0827-1266-A2 p.3-4]

When GHG emissions tied only to production and transport are calculated and ancillary carbon impacts are included, the total GHG benefits are slightly reduced because of the higher transportation emissions associated with collection and transport to re-refining facilities. However, even with those ancillary benefits included, the total life cycle benefits show a total reduction of 56 percent over production from virgin crude for the production of lubricating oil of equal or better quality. [EPA-HQ-OAR-2014-0827-1266-A2 p.4]

Further, re-refining means the used oil is not released into the environment through illegal dumping or burned in unregulated incinerators without emission controls as a cheap, high carbon source of energy, thereby resulting in further GHG reductions even when a substitute energy source (natural gas) is factored in. While these additional carbon reduction benefits can be significant (as much as an 80 percent total reduction of GHG in some cases), they depend on the substitute fuel used; therefore, we are not including those benefits in this analysis. [EPA-HQ-OAR-2014-0827-1266-A2 p.4]

Suggested Addition to Phase 2 Standards that Will Further Reduce GHG Emissions: The proposed standard should be expanded to allow for an opportunity to encourage the use of re-refined oil as a way to reduce greenhouse gas emissions, while ensuring the use of methodologies and technologies that have a solid basis to reduce emissions and can be easily and accurately tracked and verified. Specifically, we recommend expanding the Phase 2 standards to allow OEMs of vehicles under the rules to obtain “Early Action Credits” beginning with Model Year (MY) 2017 and recurring GHG credits throughout the life of the Phase 2 rules, when OEMs use re-refined engine oil for factory or preventative maintenance service fills, instead of engine oil derived from virgin crude used. Re-refined engine oil should be defined as a gallon of engine oil that contains 100% base oil. That’s equal to about 85% of the blended gallon of engine oil, as about 15% of the volume is the additive package. The GHG emissions examples and calculations provided in this document are based on this same ratio. At this ratio, a gallon of re-refined engine oil reduces GHG emissions by .003363 MT of CO2e/usg of re-refined oil used. Every 3 gallons of re-refined oil used results in avoidance of the emissions equivalent of burning a gallon of diesel fuel. The projected GHG emissions reduced by using re-refined engine oil across the projected sales of Class2b-8 Phase 2 vehicles is estimated as follows, including estimates of gallon volumes and adoption rates in the chart and footnotes on the next page. [EPA-HQ-OAR-2014-0827-1266-A2 p.4]

These GHG emissions credits could be held by the OEMs, until EPA/NHSTA determines that it is practical to trade them under the ABT provisions of the Phase 2 standards. [EPA-HQ-OAR-2014-0827-1266-A2 p.5]

Initially, we recommend only providing GHG credits for the re-refined oil gallons used or sold by OEMs for factory or service fill, as it could be more complicated to track and verify use through other distribution channels and sources. However, if a reliable process to report and verify use by other sources could be devised, we hope the Agencies would be open to expanding the use of credits for
service fills performed by other vendors provided adequate documentation and verifications systems are in place. [EPA-HQ-OAR-2014-0827-1266-A2 p.5]

It would be rather simple and reliable to track and verify use of re-refined oil for initial factory fill or preventative maintenance service fills as follows: [EPA-HQ-OAR-2014-0827-1266-A2 p.5]

[Chart can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1266-A2]

Vehicle and engine OEMs that wish to obtain GHG credits for use of re-refined engine oil would submit information on gallons used and the agreed upon calculation for GHG reduction (CO2e/usg). The rule would indicate how the Agencies require OEMs to stipulate projected and actual usage, along with documents needed to verify amount of use. It could be validated using copies of invoices and documentation from the re-refined oil manufacture that stipulates the amount of re-refined oil content. [EPA-HQ-OAR-2014-0827-1266-A2 p.5]

In our discussions with OEMs, we have come to believe that they are interested in this tool and have said they could easily implement it if given some “credit” by EPA. In the beginning of a model year, the OEM could submit a projection of the gallons of engine oil to be used for initial factory and service fill, along with value of GHG emissions reduction at .003363 MT of CO2e/usg of re-refined oil multiplied by the anticipated gallons used. The OEM could later submit the actual gallons used or sold in their end of year report to the agencies and adjust the credits received. [EPA-HQ-OAR-2014-0827-1266-A2 p.6]

Allowing GHG emissions credit for use of re-refined motor oil will increase demand and production of re-refined engine oil. It will not just be a shifting of re-refined oil gallons that would otherwise be sold in other channels. This can be verified by the growth in total production capacity and sales of refined oil. This would be incremental volume sold to these OEMs. Thus, it would increase demand for and use of re-refined oil and reduce total emissions of GHGs. [EPA-HQ-OAR-2014-0827-1266-A2 p.6]

It will also provide these other benefits: [EPA-HQ-OAR-2014-0827-1266-A2 p.6]

- continue to foster environmental stewardship;
- reinforce congressional and Executive Office mandates to recycle used motor oil into its highest and best use;
- allow engine lubricants to be continuously recovered and re-refined becoming a truly “renewable” and sustainable resource; and,
- reduce GHG emissions, at no additional cost to the regulated community. [EPA-HQ-OAR-2014-0827-1266-A2 p.6]

Other Considerations to Further Reduce GHG Emissions: While not relevant to these Phase 2 standards for MHDD vehicles, we want to point out that re-refined engine oil and industrial lubricants can be used to reduce GHG emissions in the following additional applications. We believe that the EPA’S objective to reduce GHG emissions from multiple sources would be significantly furthered by a discussion of expanded use of re-refined oil in other policies and standards. [EPA-HQ-OAR-2014-0827-1266-A2 p.6]

- Railroad Diesel Engine Oil (RREO) – A re-refined product can be produced that could reduce GHGs. Already a re-refined product is available and used by some railroads because the quality and cost is comparable to oil made from virgin crude. However, the lack of policies or standards does not encourage railroads to prefer it. The railroad industry consumes over 15M usg/yr of
RREO in the U.S. If 15M usg/yr were converted to re-refined RREO it would reduce GHG emission by 50,452MT (CO2e) per year. [EPA-HQ-OAR-2014-0827-1266-A2 p.6]

- **Passenger Car Lubricants** – According to some estimates, OEMs buy over 125M usg/yr for factory and service fill under their brands. If 125M usg/yr were converted to re-refined oil, it could reduce GHG emission by 420,431MT (C02e) per year. [EPA-HQ-OAR-2014-0827-1266-A2 p.6]

- **Industrial Lubricants** – Similarly, re-refined oils are available for the broad array of products in manufacturing that include hydraulic oil, way oil, spindle oil and other industrial lubricant that can be made from re-refined oil. Over 200M usg/yr is consumed in the U.S. If 200M usg/yr were converted to re-refined products, it could reduce GHG emission by more than 672,690MT C02e per year. The re-refining industry would need to increase blending capacity to make this much industrial oil, instead of selling it as just base oil. But, it would also drive toward consuming some of the 600M+ usg/yr that is burned or indiscriminately disposed into the environment. Already re-refined industrial lubricants are available and used by many manufacturers, including the big three automakers in their plants in the U.S., but, more could be done, if policies and standards were created to encourage usage. [EPA-HQ-OAR-2014-0827-1266-A2 p.6-7]

In summation, for all the reasons enumerated above, we further believe that the EPA’s consideration of this proposal is consistent with a more global strategic approach to dealing with the interconnected components of internal combustion engines that contribute to the emission of GHGs. This is an opportunity to treat that engine system holistically without the need, cost and complication of adding a new gadget, and thereby achieve a coherent and cohesive regulatory regimen that synergistically produces even greater environmental and energy benefits. [EPA-HQ-OAR-2014-0827-1266-A2 p.7]

**Response:**

We find this comment to be outside the scope of this rulemaking, but we thank you for the information on re-refined engine oil.

**Organization:** CALSTART

Development and Demonstration Funding Tied to Goals

While we realize it is outside the scope and provision of this rule making, we strongly encourage the Agencies’ to actively work with other segments in the federal government, including other agencies in
the Department of Transportation, the Department of Energy, the Department of Defense, the
Department of Commerce, and others, to align federal development, incentive and deployment funds
around supporting and commercializing technologies to achieve Phase 2 and later success. The
breakthroughs highlighted from the Supertruck program make clear what the value can be of a
consistent, long-term and aligned public funding program linked with private industry investment. The
heavy-duty industry can achieve the fuel economy and carbon goals of the program, but a joint effort
with the public sector around common goals will better leverage and focus industry capabilities and
resources, and better prime the pump for the additional solutions needed beyond this rule timeline. We
have seen the growing success of this strategy in California, which is directing significant funding from
cap and trade revenues back into low carbon transportation development with industry. We would
encourage a comparable funding target at the federal level. [EPA-HQ-OAR-2014-0827-1190-A1 p.9]

Response:

We agree that this comment is outside the scope of this rulemaking, but we thank you for the
suggestion.

Organization:  Climate 911

In addition, because diesel trucks last for up to 30 years, fleet turnover will be slow. It is important that,
in addition to setting standards for new vehicles, EPA mandate retrofits of existing ones. [EPA-HQ-

Response:

We find this comment to be outside the scope of this rulemaking.

Organization:  Innovus Enterprise LLC

Additionally, it does not go unnoticed that whenever CARB comes forward with a new waiver request,
as was the case when they were issued a waiver for OBD, EPA treats these waivers as so-called ‘waiver
decisions’ and not ‘rules’ thereby avoiding review by the Office of Management and Budget; avoiding
the Regulatory Flexibility Act mandates; and avoiding the Small Business Regulatory Enforcement
Fairness Act. Let it be known; we are emphatically opposed to how the EPA sees this as an honest
administrative procedure with the public at large. We ask the EPA to review this waiver process and
reaffirm to the public how they truly feel they are meeting the spirit and intent of these Congressional
Acts, especially for making ‘decisions’ which do in fact have major impact on large numbers of small
businesses. [EPA-HQ-OAR-2014-0827-1116-A1 p.8]

Response:

We find this comment to be outside the scope of this rulemaking. As a general matter, EPA evaluates
waiver requests consistent with Clean Air Act section 209.

Organization:  PACCAR, Inc.

Likewise, PACCAR requests EPA’s support to limit any actions by ARB regarding new onboard
diagnostic (OBD) requirements, which will allow manufacturers to focus on the technology
development and implementation of these GHG and fuel consumption reducing technologies. The
imposition of additional OBD requirements while manufacturers are focusing on Phase 2 implementation will stretch PACCAR’s and other OEM’s engineering and development resources and significantly risk Phase 2 compliance achievement. [EPA-HQ-OAR-2014-0827-1204-A1 p.6-7]

Response:

We find this comment to be outside the scope of this rulemaking.

15.10.2 Comments on Other Means of Reducing GHGs

Organization: Center for Neighborhood Technology

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 125-128.]

One reason is the fact that heavy duty trucks are now the leading -- the most rapidly growing source of mobile emissions in the country. We’ve seen a pattern since the recession in which car driving automobile VMT has been declining. It’s flattened out in the last few years. It’s now going into a slight decline. At the same time, truck use has been increasing more or less in proportion to the rise in GNP. So as this pattern continues, what we can expect to see is a greater need to regulate the amount of emissions that's being generated by heavy trucks.

The other reason that we think is significant is for lowering the emissions of heavy trucks is the impact that it has on other forms of economic development, particularly mode shift to rail, and the development of businesses, industrial and logistics businesses, distribution businesses, around intermodal freight terminals. If we had the best possible methods of reducing emissions from trucks, we would still find it desirable to have a major mode shift in freight movement between -- from truck to rail. We're all familiar with the data for that, which indicates that depending on three to seven times more efficient per ton mile movement of freight when moving the freight by rail.

And intermodal freight had made significant gains in reducing and generating savings through mode shift. The amount of volume of containers that's moving by intermodal has risen from a little than six million to over 13 million just over the last 20-year period. And as this has happened, intermodal terminals have been built in 64 different regions and created thousands of jobs that have the basic advantage of lowering transportation costs for the manufacturing and distribution companies that are locating there.

Today new technologies are making it possible to reduce the pollution that occurs from terminal operations and from rail operations. And we can talk about potential for zero emission ports, zero emission intermodal terminals despite the fact that the railroads still have a long way to go to improve their operations.

But the major impediment to the development -- further development of businesses co-located with intermodal freight terminals is the amount of truck traffic that's associated with those kinds of facilities. Because of the environmental risk involved in having several hundred, several thousand trucks a day coming to one location, this is serious impediment to locating these kinds of facilities in place where there's already an existing industrial base, places where workers can get to.
And consequently, these facilities are often relocated in exurban locations, which creates a whole
cascade of other problems, long interregional truck trays, problems with people getting to work, longer
commutes for workers.

**Organization:** Diesel Technology Forum

**Expand Efficiency Consideration Beyond New Engine and Vehicle Standards:**

There are also significant opportunities for efficiency improvements through adoption of other policies
that impact vehicle operations and in turn fuel use and emissions, and these should be an increasing part
of policy consideration. For example, heavy-duty trucks and passenger vehicles are estimated to have
wasted 2.9 billion gallons of fuel due to traffic congestion. Efforts to better maintain and modernize
freight-related transportation infrastructure will also contribute to fuel savings alongside the latest truck
technologies. [EPA-HQ-OAR-2014-0827-1171-A2 p.4-5]

**Organization:** FedEx Corporation

Adopt Complimentary Policies: Other governmental policies must promote research, development and
deployment of efficient technologies in the heavy duty and vocational vehicle space. Financial and other
incentives – including investment tax credits; accelerated depreciation of new capital investment;
increased highway infrastructure spending – can accelerate the deployment of new, more fuel efficient
trucks and assist in rapid fleet turnover. [EPA-HQ-OAR-2014-0827-1302-A1 p.3]

**Organization:** Green Transportation Solutions

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August

So beyond the costly vehicle upgrades and modifications that are being discussed here today, it is rather
difficult for some of these drivers to purchase some of these things. We usually actually recommend
three simple and inexpensive ways to reduce petroleum consumption, and, thus, greenhouse gas
emissions with our clients.

So the second is to promote and enforce an idle reduction policy.

It does get zero miles per gallon, such as the hybrid vehicles. They're somewhat more expensive, and
they do have payback, but you can reduce your idle time without a hybrid through management. So that
would just come down to enforcing really because there is an idling law in Illinois already, and if you
walk around the city it's not necessarily followed all the time or enforced for a variety of reasons. So if
there could be stronger enforcement near communities, particularly schools and parks, as the parts per
million for particulate matter go way up for young children with smaller lungs.

**Organization:** Midwest Truckers Association

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August
May we suggest, though, also that other measures should be considered in the big picture, especially here in the Chicago area. There are other ways to make transportation more efficient for trucks, and thereby reduce congestion, unnecessary emissions due to idling and traffic jams, and what have you. Here in the Chicago area, we're working with transportation specialists at the University of Illinois-Chicago to encourage off peak delivery schedules for trucks. In these types of situations, trucks could run more efficiently and reduce traffic on the highways right now if we would encourage more nighttime and weekend deliveries.

This would require the cooperation of shippers, trucker, and government bodies that would encourage off peak deliveries and maybe encourage a reduction in tolls on the tollway, maybe a change in the hours of service regulations to encourage truckers to operate at night. And also it would improve truck access.

**Organization:** PepsiCo

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 43-44.]

As in the past, PepsiCo believes that it is important to complement these standards with financial incentives to help organizations implement new technologies and alternate fuel strategies.

For example, previous incentives help our Frito Lay North America division build one of the largest private electric fleets in the United States. We believe that additional financial incentives will spur future opportunities and increase implementation and innovation of fuel-saving technologies.

**Organization:** Volvo Group

Environmental care is one of Volvo Group’s core values, together with product safety and quality. We share a strong concern about the effects of greenhouse gas (GHG) emissions on the global climate and the unsustainability of continued reliance by commercial transportation on petroleum-based fuel. While continued vehicle efficiency improvements are critical to addressing these concerns, we also note that there are many cost-effective opportunities for improving freight efficiency that are beyond the reach of individual vehicle technology, including: platooning, routing, and trip planning enabled by vehicle to vehicle communications; congestion mitigation; smart highway systems; permitting longer and heavier combination vehicles; improved shipping logistics; and packaging. Such infrastructure improvements and market incentives to enhance shipping efficiency should be considered in addition to vehicle regulations. [EPA-HQ-OAR-2014-0827-1290-A1 p.2]

**Response:**

The agencies agree that today’s standards are but one part of a broader effort to address fuel consumption and greenhouse gas emissions. We are supportive of a wide range of complementary measures to further these goals. The SmartWay Transportation program and the Diesel Emission Reduction Act (DERA) programs are but two examples of incentive programs that complement the standards we are adopting today. We appreciate the commenters’ concerns and suggestions with respect to infrastructure improvements, intermodal freight transport, and other policies that could lead to GHG reductions. However, we find these comments to be outside of the regulatory framework of this HD Phase 2 program. The agencies thank the commenters for the information provided.
However, we find these comments to be beyond the scope of this rulemaking.

15.10.3 Fuel-Related Comments

Organization: Diesel Technology Forum

Advanced renewable biofuels offer significant reductions in greenhouse gas emissions

While this proposed rule focuses on vehicle and engine standards, in the context of efficiency and reducing greenhouse gas emissions, we believe that it is important to also note the benefits from changes to fuels. The diesel platform is most unique in its ability to operate on a wide range of renewable low-carbon biofuels. Today, most heavy-duty diesel engines are approved to operate on blends of biodiesel up to twenty percent. Renewable diesel fuels made from renewable bio-feedstocks are now also commercially available. These “drop-in” replacement fuels couple even greater carbon reduction with further emission reduction. Studies by the California Air Resources Board indicate that such fuels can reduce by 70 percent the greenhouse gas emissions over conventional diesel fuel. [EPA-HQ-OAR-2014-0827-1171-A2 p.4] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.112.]

Recently, the City of San Francisco announced that renewable diesel fuel will power all city owned diesel vehicles and equipment by years’ end. Still yet, UPS, the world’s largest package delivery service, recently announced that it plans to consume 46 million gallons of renewable diesel fuel over the next three years. [EPA-HQ-OAR-2014-0827-1171-A2 p.4]

Organization: Green Transportation Solutions

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 234-236.]

So beyond the costly vehicle upgrades and modifications that are being discussed here today, it is rather difficult for some of these drivers to purchase some of these things. We usually actually recommend three simple and inexpensive ways to reduce petroleum consumption, and, thus, greenhouse gas emissions with our clients.

The first is to increase the use and availability of biodiesel fuels in trucks. Most trucks only use a blend of five percent when they’re capable of using upwards towards 20 percent. So that comes down to the availability and their choice at the pump. Often enough they don’t have that choice, and if they did more often they would choose it.

As most people know, increasing biodiesel blends will automatically reduce petroleum consumption because you’re using five percent, 10 percent, or 20 percent less petroleum, and also providing rural economic benefits domestically, plus a significant reduction in greenhouse gases by -- at the molecular structure having an oxygen piece component to that.

Organization: National Biodiesel Board

The National Biodiesel Board (NBB) is the trade association for the U.S. biodiesel industry. Made from a diverse mix of resources such as recycled cooking oil, soybean oil and animal fats, biodiesel is a renewable, clean-burning diesel replacement, and is the first and only commercial-scale fuel produced
across the United States to meet EPA’s definition of an Advanced Biofuel. We appreciate the opportunity to provide these comments on the proposed rule entitled “Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2.” The proposed rule seeks to reduce greenhouse gas (GHG) emissions from medium- and heavy-duty engines and vehicles. Also important, however, is the goal of promoting this country’s energy security—a key purpose of the Administration’s Climate Action Plan—by reducing this country’s reliance on foreign oil and by diversifying the mix of energy sources. We believe biodiesel is a viable part of the solution, and its use must be promoted to meet these goals. NBB submits these comments, because it does not believe that the proposal provides any real incentives to ensure increased use of biodiesel in diesel engines and vehicles. [EPA-HQ-OAR-2014-0827-1240-A1 p.1-2]

NBB believes the proposal should encourage use of fuels from renewable sources, not just continue down the path of using alternative forms of fossil fuels. The following comments propose an option to include credits under the new Phase 2 GHG emissions reduction and fuel economy standards for those Original Equipment Manufacturers (OEMs) who have chosen to support and employ the use of B20 or higher biodiesel blends in their diesel vehicles and engines as one of the technological pathways they are pursuing to meet these standards and improve their environmental profile. We believe increased use of biodiesel presents a cost effective means for achieving emissions reductions from the transportation sector, particularly as the use of diesel fuel is estimated to continue to increase to meet the demands of the medium- and heavy-duty vehicle industry. [EPA-HQ-OAR-2014-0827-1240-A1 p.2]

1) Increasing Biodiesel Use is Key to Meeting the Administration’s Climate Change Objectives. [EPA-HQ-OAR-2014-0827-1240-A1 p.2]

The Obama Administration has made climate change a top priority, outlining a Climate Action Plan to address U.S. GHG emissions. See White House, Climate Change and President Obama’s Action Plan, https://www.whitehouse.gov/climatechange (last visited Oct. 1, 2015). The transportation sector is estimated to be the second largest contributor (28 percent) to U.S. GHG emissions behind electricity (32 percent). Id. As part of the Action Plan, the Administration committed to “support the Renewable Fuel Standard and invest in research and development to help bring next generation biofuels on line.” Id. “Heavy-duty vehicles (commercial trucks, vans, and buses) are currently the second largest source of greenhouse gas pollution within the transportation sector.” Id. The Phase 2 program for medium- and heavy duty engines and vehicles is intended to be in response to the Action Plan, seeking to reduce fuel consumption and GHG emissions. See EPA Fact Sheet, Cutting Carbon Pollution, Improving Fuel Efficiency, Saving Money, and Supporting Innovation for Trucks, EPA-420-F-15-900 (June 2015), available at www.epa.gov/otaq/climate/documents/420f15900.pdf. [EPA-HQ-OAR-2014-0827-1240-A1 p.2]

The United States has seen substantial growth in the availability of diesel vehicle options, which can also operate on biodiesel blends. With 47 new clean diesel car, truck and SUV models available in the 2015 model year, automotive industry experts have predicted that consumers will have more than 62 diesel vehicle models to choose from in North America by 2017. Add to that the more than 27 other automotive brands supplying numerous diesel engines and over 115 different diesel models for the medium- and heavy-duty truck, bus and RV markets, and there is tremendous potential for biodiesel blends to make a positive impact in reducing GHG emissions on the roadways. Industry experts predict that diesel vehicles will make up to 10 to 15 percent of the U.S. market by the year 2025, up from just over 3 percent in 2014. Because diesel-fueled vehicles deliver up to 40 percent better real-world fuel economy than their gasoline counterparts do, more and more automakers have turned to diesel vehicle platforms to help them meet the aggressive new U.S. Corporate Average Fuel Economy (CAFE) standards, which mandate a fleet average of 54.5 MPG by 2025. [EPA-HQ-OAR-2014-0827-1240-A1 p.3]

While providing improved efficiency compared to gasoline, diesel fuel also has greater carbon emissions. The EIA estimates that diesel fuel and heating oil emit 22.4 pounds of carbon dioxide (CO2) per gallon compared to 19.6 pounds for gasoline. EIA, Carbon Dioxide Emissions Coefficients, (Feb. 14, 2013), http://www.eia.gov/environment/emissions/co2_vol_mass.cfm. EIA also has reported increasing CO2 emissions from energy consumption associated with distillate fuel oil since 2012. EIA, Table 12.5 Carbon Dioxide Emissions from Energy Consumption: Transportation Sector (Sept. 2015), available at www.eia.gov/totalenergy/ data/monthly/pdf/sec12_8.pdf. Moreover, upstream GHG emissions from diesel are increasing as more diesel is refined from heavier crude oils or marginal sources, such as tar sands. [EPA-HQ-OAR-2014-0827-1240-A1 p.3]

In addition to the GHG benefits, biodiesel is “nontoxic and contains no hazardous materials.” NHTSA Safety Study at 35. Biodiesel has lower carbon content than petroleum diesel and higher oxygen content, which allows it to burn more completely. Most volumes of biodiesel also have lower sulfur content than even ultra-low sulfur diesel (ULSD). As such, use of biodiesel also provides for reduced
non-GHG emissions, including hydrocarbons (HC), particulate matter (PM), carbon monoxide (CO), and air toxics. See id. at 34. These “reductions increase as the amount of biodiesel blended into diesel fuel increases.” Id. A recent study of bus fleets found that use of B20 reduces PM emissions from buses by 17 percent compared to ULSD. See Mineta National Transit Research Consortium, Combustion Chemistry of Biodiesel for Use in Urban Transport Buses: Experiment and Modeling (Oct. 2014), available at http://transweb.sjsu.edu/PDFs/research/1146-biodiesel-bus-fuel-combustion-chemistry.pdf. This study also confirmed that lower emissions of CO and CO2 are related to lower ratios of carbon to oxygen in biodiesel fuels compared to ULSD. Id. at 53. The improved lubricity with using biodiesel may also mean less wear on engine parts and less maintenance. Moreover, the substantial emissions reductions and other benefits associated with increased use of biodiesel are achieved cost-effectively. The overall total cost of ownership for operating a diesel vehicle on biodiesel blends is less than promoting new vehicles and fueling infrastructure to accommodate other alternative fuels such as natural gas—a fossil fuel—and electric power—largely generated by fossil fuels. [EPA-HQ-OAR-2014-0827-1240-A1 p.4-5]

Through EISA, therefore, Congress sought to promote the use of biodiesel, including increasing the amount present in blends to at least B20. The RFS program indicates that Congress intended these amounts to be even higher. [EPA-HQ-OAR-2014-0827-1240-A1 p.5]

In fact, the biodiesel industry has epitomized the benefits envisioned by Congress in seeking to promote use of biodiesel under these various programs. The growth and expansion of the U.S. biodiesel industry in recent years represents a tremendous success story for fleets and individual consumers all across the United States. Today, nearly 2 billion gallons of biodiesel and renewable diesel displace an equivalent amount of petroleum diesel, helping to protect our domestic energy security while creating millions of dollars in economic impact here in the United States. Biodiesel is produced in nearly every state in the country and is supporting more than 62,000 American jobs. Using EPA’s own estimates regarding GHG emissions, biodiesel has cut carbon pollution by 75.5 million metric tons with nearly 8.2 billion gallons used from 2005 to 2014—the same impact as removing more than 15.9 million passenger vehicles from America’s roadways. [EPA-HQ-OAR-2014-0827-1240-A1 p.5]

In the Phase 1 rule for medium- and heavy-duty vehicles, which the agencies propose to continue under the Phase 2 program, 80 Fed. Reg. at 40,158, the agencies purport to have implemented a uniform approach to fuels, despite recognizing that “this uniform approach to fuels may not take advantage of potential additional energy and national security benefits of increasing fleet percentages of alternative-fueled vehicles.” 77 Fed. Reg. 51,499, 51,502 (Aug. 24, 2012). “More alternative-fueled vehicles on the road would arguably displace petroleum-fueled vehicles, and thereby increase both U.S. energy and national security by reducing the nation’s dependence on foreign oil.” Id.; see also 76 Fed. Reg. 57,106, 57,124-57,125 (Sept. 15, 2011). While treating fuel consumption and GHG emissions on a one-to-one basis, the agencies also noted that they would consider proposing standards that would more fully consider the reduction in use of petroleum-based fuels. 76 Fed. Reg. at 57,125. Indeed, EPA’s credits appear to incentivize continued fossil fuel use over renewable resources, focusing on natural gas and electricity, which may be from coal-based power plants. Assuming a uniform approach may have made sense for Phase 1, it no longer continues to make sense. [EPA-HQ-OAR-2014-0827-1240-A1 p.6]

a) Biodiesel is a drop-in alternative fuel from renewable sources, and is technically and economically feasible to use to reduce GHG emissions and increase energy security. [EPA-HQ-OAR-2014-0827-1240-A1 p.6]

Biodiesel is essentially a drop-in fuel to current technologies for diesel fuel. Blends up to B5 are considered fungible with diesel fuel and do not require additional labeling. NHTSA has noted that “[b]lends up to B20 can be used in existing equipment without modification.” NHTSA Safety Study at 33. NHTSA further noted that “most engines made after 1994 have been constructed with gaskets and seals that are generally biodiesel resistant.” Id. at 36. NHTSA concluded: [EPA-HQ-OAR-2014-0827-1240-A1 p.6]

Biodiesel is a drop-in alternative fuel that can support MD/HDV progress toward GHG and criteria pollutant reductions without major capital investment or infrastructure barriers. There is a minor decrease in fuel efficiency due to the 8 percent lower energy density of biodiesel versus petroleum diesel, but the magnitude of the emissions decrease is substantially larger. [EPA-HQ-OAR-2014-0827-1240-A1 p.6]

As for any bi-fueled vehicles, the potential for refueling with petroleum diesel reduces potential safety risks associated with vehicle stranding due to fuel supply shortage or refueling infrastructure limitations. [EPA-HQ-OAR-2014-0827-1240-A1 p.6]

In conclusion, the literature reviewed and DOE/AFDC resources indicate that biodiesel, as a viable drop-in alternative fuel, has both safety and environmental benefits. [EPA-HQ-OAR-2014-0827-1240-A1 p.7]

Id. at 36 (emphasis added). While EPA and NHTSA contend that the medium- and heavy-duty vehicle and engine program provides sufficient incentive to use alternative fuels, it does not adequately explain how the proposal promotes biodiesel use, which, as noted above, was contemplated by EISA and provides feasible and economic GHG emission reductions. [EPA-HQ-OAR-2014-0827-1240-A1 p.7]

In 2011, the agencies contended that the fuel consumption measurements under the medium- and heavy-duty vehicle and engine rule provide incentives for alternative fuels. 76 Fed. Reg. at 57,124. The agencies assert this method shows a benefit of approximately 1 to 3 percent for biodiesel and ethanol blends. Id.; see also EPA, Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles: EPA Response to Comments Document for Joint Rulemaking, EPA-420-R-11-004, at 16-148 (Aug. 2011) (EPA-HQ-OAR-2010-0162-3635)
(“Furthermore, the agencies believe that the fuel consumption benefits that FFVs will obtain in engine test cycles accurately reflects their energy benefits and thus provides sufficient incentives for these vehicles.”). While NBB agrees that biodiesel use provides greater GHG emissions reductions from the tailpipe, this ignores the distinction between CO2 emissions from renewable resources compared to fossil fuels. [EPA-HQ-OAR-2014-0827-1240-A1 p.7]

The regulations also appear to focus on natural gas, electricity, and E85 as alternative fuels, not vehicles that are approved to use B20 or higher blends. Cf. 40 C.F.R. §§ 1036.801 (defining “alcohol-fueled engine”), 1037.801 (defining “alcohol-fueled vehicle”). EPA’s regulations also note that “[t]here can be multiple grades within a single fuel type,” referencing gasoline and E10. 40 C.F.R. § 1036.801; see also 40 C.F.R. § 1037.801. EPA recognizes that “[o]nly where the vehicle or engine technology inherently demands a certain type of fuel do the standards account for that fuel use, by specifying the calculation procedure used to determine tailpipe emissions.” 77 Fed. Reg. at 51,705. Moreover, unlike the light-duty rule, EPA does not require that the fuel actually be used, limiting the usefulness of the incentives purportedly provided under the rule. [EPA-HQ-OAR-2014-0827-1240-A1 p.7]

The agencies also indicated that they would not provide additional incentives similar to the light-duty rule because “the HD sector does not have the incentives mandated in EISA for light-duty FFVs, and so has not relied on the existence of such credits in devising compliance strategies for the early model years of this program.” 76 Fed. Reg. at 57,123. Again, the agencies focused on E85 and natural gas in this discussion. Id. But, the agencies have ignored the reliance the biodiesel industry has made on Congress’ and this Administration’s promises. The U.S. biodiesel industry has worked to address fuel quality concerns, and has moved to increase production and diversify feedstocks. They continue to innovate by reducing their energy consumption, while expanding their production capacity. [EPA-HQ-OAR-2014-0827-1240-A1 p.7-8]

In addition, the vast majority of OEMs of medium- and heavy-duty engines have found that blends up to B20 are compatible with their engines. Nearly 80 percent of U.S. manufacturers support B20 or higher blends in at least some of their equipment, and nearly 90 percent of medium-duty and heavy-duty truck models support B20. See NBB, Biodiesel Industry Overview & Technical Update, Slide 34 (Sept. 2015), available at http://biodiesel.org/docs/default-source/ffs-basics/biodiesel-industry-and-technical-overview.pdf?sfvrsn=14; see also NBB, OEM Support (Jan. 2015), available at http://biodiesel.org/docs/default-source/ffs-engine_manufacturers/oem-support-summary.pdf?sfvrsn=16. But, without adequate incentives, these OEMs may limit the vehicles that are approved for B20, despite the clear benefits as noted above. Moreover, there is little incentive to ensure their future vehicles and engines will continue to be compatible with higher biodiesel blends. Indeed, certain OEMs have been reluctant to list B20 as an approved fuel for use or have declined to consider higher biodiesel blends as part of their engine and vehicle designs. [EPA-HQ-OAR-2014-0827-1240-A1 p.8]

EISA defined B20 as an alternative fuel eligible for flexible fuel vehicle credits under the CAFE program. Vehicles approved to utilize B20 should receive credit, incentivizing the entire new fleet to be approved for at least B20. Approval for higher biodiesel blends above B20 can receive increased credits. Indeed, EISA requires that NHTSA establish a program “designed to achieve the maximum feasible improvement.” 49 U.S.C. § 32902(k). Diesel engines also are increasingly being used in the light-duty sector, and the agencies should consider similar means to further incentivize alternative fuel use in passenger vehicles. To ensure the benefits of using biodiesel are realized, the agencies also can include a requirement that biodiesel actually be used in the U.S. marketplace, as indicated by annual U.S. biodiesel consumption figures. [EPA-HQ-OAR-2014-0827-1240-A1 p.8]
b) Credits could include a multiplier that reflects the biodiesel blend content approved for use by the OEM. [EPA-HQ-OAR-2014-0827-1240-A1 p.9]

We propose that credits for OEMs supporting the use of B20 or higher biodiesel blends should apply to four of the five regulatory categories being guided by the proposed standards, namely: [EPA-HQ-OAR-2014-0827-1240-A1 p.9]

1. Combination Tractors;

2. Heavy-Duty Pickup Trucks and Vans;

3. Vocational Vehicles which include all other heavy-duty vehicles such as buses, refuse trucks, and concrete mixers; and

There is no perceived involvement for biodiesel credits in regards to the fifth category of regulated vehicles under the proposed Phase 2 rule—Trailers Pulled by Combination Tractors. [EPA-HQ-OAR-2014-0827-1240-A1 p.9]

Biodiesel is defined as meeting the ASTM International Standard D6751. Biodiesel blends up to B5 are essentially ubiquitous with diesel fuel in the market today. B20 is an optimal level for biodiesel blend acceptance by OEMs today as it provides a balance between vehicle performance, maintenance and emissions reductions, and proven industry specifications. Providing additional credits for higher biodiesel blends recognizes current use in niche market applications as well as helping to promote future technological developments. [EPA-HQ-OAR-2014-0827-1240-A1 p.9]

These credits could be provided to OEMs which support the use of B20 or higher biodiesel blends as publicly stated in their Owners Manuals or other official documentation. A multiplier such as the MY2012-2015 light-duty incentive for dedicated alternative fueled vehicles and dual-fueled vehicles could be applied, but based on the level of biodiesel blend approved for use.\(^9\) For example, for vehicles that the OEM has indicated can be run on B20, one gallon of fuel would be treated as 0.80 gallon to account for the 20 percent biodiesel.\(^10\) [EPA-HQ-OAR-2014-0827-1240-A1 p.9]

c) EPA cannot rely on the RFS program to contend no additional incentives are necessary. [EPA-HQ-OAR-2014-0827-1240-A1 p.10]

Although the agencies previously declined to provide certain credits for alternative fuels, they should reassess this position. EPA limited the incentives for alternative fuels in the light-duty rule stating “[t]he RFS is a standalone program designed to increase the use of renewable fuels and to achieve GHG emission reductions primarily through upstream emission reductions.” 77 Fed. Reg. at 62,823. In the Phase 1 medium- and heavy-duty rule, EPA stated that “[f]or the fuels covered by the Renewable Fuels Standard additional incentives are not needed in this regulation given the large volume increases required under the Renewable Fuel Standard.” 76 Fed. Reg. at 57,124. Since then, however, EPA has proposed to reduce the statutory volumes and, moreover, to limit its proposed increases for biomass-based diesel. See generally Renewable Fuel Standard Program: Standards for 2014, 2015, and 2016 and Biomass-Based Diesel Volume for 2017, 80 Fed. Reg. 33,100 (June 10, 2015). In short, EPA is not fully implementing the RFS program. NBB has opposed this proposal and requested EPA reassess the advanced biofuel and biomass-based diesel volumes.\(^11\) Even if EPA revises these volumes, however,
these programs can and should work in conjunction with one another. [EPA-HQ-OAR-2014-0827-1240-A1 p.10]

Rather, EPA has cited to limitations on getting the fuel to consumers as rationale for reducing the statutory volumes under the RFS program. See generally 80 Fed. Reg. at 33,101. EPA’s proposal focused on the so-called “E10 blendwall,” noting that there were insufficient numbers of FFVs and “an even smaller number of FFVs that have ready access to an E85 retail outlet.” Id. at 33,114. Unlike ethanol, any blend of biodiesel is authorized for use in motor vehicles. Nonetheless, EPA also references B2/B5 blends in its RFS proposal, noting the “efforts” underway to continue to expand product offerings. Id. at 33,116. To avoid similar purported “constraints” or “limitations” in the future, EPA should reward those in the industry that are moving forward with respect to higher biodiesel blends as intended by Congress, rather than resort to its limited authority under the RFS waiver provisions as it is attempting to do with ethanol today. [EPA-HQ-OAR-2014-0827-1240-A1 p.10]

Although the CAFE program had a special provision for light-duty vehicles, the agencies have indicated that this does not limit their authority. See, e.g., 77 Fed. Reg. at 62,831. NBB agrees. Thus, EPA and NHTSA should consider additional means of supporting those OEMs that have approved B20 and providing incentives for use of higher blends. As noted above, one possible alternative is to give OEMs approving B20 or higher blends some credit for the benefits associated with the reduced GHG emissions and greater energy security benefits. To the extent EPA continues to believe, notwithstanding its current proposal for the 2014-2016 RFS and 2017 biomass-based diesel volume, the RFS provides adequate incentives, EPA can include requirements to establish that the fuel is being used (similar to its approach for MY2016 and later light-duty vehicles) and adjust the required volumes (and thereby available credits) to apply only to those above the minimum amounts required by the RFS. [EPA-HQ-OAR-2014-0827-1240-A1 p.10-11]

NBB appreciates the opportunity to submit these comments. We believe that EISA and this Administration’s policy requires promotion of increased use of biodiesel to help meet the goals of the GHG and Fuel Efficiency Standards, and we look forward to working with both EPA and NHTSA on this important issue. [EPA-HQ-OAR-2014-0827-1240-A1 p.12]

Organization: Plant Oil Powered Diesel Fuel Systems

Although the two agencies have approved POP Diesel's retrofitting of select diesel engines to run on 100 percent jatropha plant oil based on POP Diesel's evidence that such engines and renewable fuel do not produce higher criteria emissions than baseline petroleum diesel, the Truck Rule 2 automatically disqualifies a new diesel engine that is equipped to run on 100 percent plant oil from ever winning certification compliance running on such fuel, a requisite for sale of such a new engine to the U.S. market. The reason is two-fold. First, the two agencies measure both fuel consumption (as an incorrect proxy for fuel efficiency) and GHG emissions by tailpipe carbon emissions. Second, the presence of oxygen atoms in the plant hydrocarbon molecule, as depicted in the vegetable oil molecule in Exhibit 2 [exhibit 2 can be found on p.18 of docket number EPA-HQ-OAR-2014-0827-1125-A1], that are absent from petroleum hydrocarbon oil give plant oil lower energy content than petroleum diesel and therefore cause a compression ignition (diesel) engine running on ordinary plant oil to consume more of this fuel by mass or volume and produce more carbon emissions from the tailpipe than if the engine were running on baseline petroleum diesel fuel. However, as set forth in the attached declaration of Dr. Paul T. Henderson, a diesel engine will consume the same amount of energy per unit of work performed, whether running on 100 percent plant oil or petroleum diesel fuel. Exhibit 3 [exhibit 3 can be found on p.20 of docket number EPA-HQ-OAR-2014-0827-1125-A1]. [EPA-HQ-OAR-2014-0827-1125-A1 p.5]
In addition, plant oil fuel running in such an engine has net, life cycle greenhouse gas emissions that are far lower than baseline petroleum and such alternative fuels processed from plant oil as biodiesel and so-called ‘renewable diesel’ (hydro-processed esters and fatty acids, or HEFA’s). [EPA-HQ-OAR-2014-0827-1125-A1 p.5]

In the alternative that the agencies do not adopt the remedy proposed in section 3 above, POP Diesel seeks a waiver or 15 percent variance from the measurements of fuel consumption and tailpipe GHG emissions under the proposed Standards for a new, plant oil-enabled compression ignition engine for the time period of any test protocol under which the engine is operating on plant oil fuel. [EPA-HQ-OAR-2014-0827-1125-A1 p.5-6]

D. A Waiver or 15% Variance Is Required If Plant Oil Powered Truck Engines Are to Win Certification, If the Proposed Truck Rule 2 Remains Unchanged

If the two agencies do not revamp the Truck Rule 2 according to the foregoing comments, then POP Diesel appeals to them to adopt a waiver from emissions testing for an engine equipped with a dual tank fuel system and running on 100% jatropha plant oil, or a permissible variance of 15% for the portion of any certification test protocol on which an engine equipped with a dual tank fuel system operates on 100% jatropha plant oil. [EPA-HQ-OAR-2014-0827-1125-A1 p.13]

There is sufficient evidence submitted with these comments, based on the arguments presented herein, for the two agencies to issue a rule granting a simple waiver from the GHG Emissions and Fuel Efficiency Standards for an engine specially equipped to run on 100% jatropha plant oil to run on such fuel. The engine would still have to pass these Standards and be certified to run on No. 2 petroleum-based diesel fuel. [EPA-HQ-OAR-2014-0827-1125-A1 p.13]

In the alternative, a variance of 15% from the fuel consumption emissions levels permitted under the GHG Emissions and Fuel Efficiency Standards is warranted for that time portion of a certification test protocol that a new engine specially equipped to run on 100% jatropha plant oil runs on such fuel. A variance of 15% is justified on the following grounds. [EPA-HQ-OAR-2014-0827-1125-A1 p.13]

As is set forth in Exhibit 11 [exhibit 11 can be found on p.106 of docket number EPA-HQ-OAR-2014-0827-1125-A1], which is a Final Report from West Virginia University's Center for Alternative Fuels, Engines & Emissions comparing stationary point dynamometer emissions testing of a diesel engine running on 100% No. 2 diesel and 100% jatropha plant oil, the overall conclusion, reported in the Final Report in Table 22 on page 395, was that across five of six modes of engine operation, as measured by the Tailpipe Rule, fuel consumption of 100 percent plant oil was a total of around 18 percent more than of petroleum diesel while the engine was performing the same amount of work. Similarly, as reported in the Draft Final Report, Exhibit 12 [exhibit 12 can be found on p.108 of docket number EPA-HQ-OAR-2014-0827-1125-A1], the comparison of carbon dioxide (CO2) readings from baseline testing on petroleum diesel, appearing on page 294 of the Draft Final Report, are significantly lower than the CO2 results for the same engine with POP Diesel’s Fuel System activated and running on 100 percent jatropha plant oil, appearing on the very next page, page 295 of the Draft Final Report, for each and every of the six engine modes of operation (engine speed and torque settings) tested. [EPA-HQ-OAR-2014-0827-1125-A1 p.13-14]

POP Diesel believes that, if the two agencies adopt a variance for its engines as proposed above, the variance should be on the order of 15%. As stated above, stationary point testing showed that fuel consumption was around 18% higher for the engine running on 100% jatropha plant oil as when it was running on No. 2 diesel. Jatropha plant hydrocarbon oil requires an engine to consume more fuel per
unit of work performed because it has 10% lower energy content than petroleum diesel (due, as stated above, to the presence of oxygen atoms that are absent from petroleum hydrocarbon). Evidence for this 10% difference in energy content appears on the face of the very last page of the Final Emissions Report, Exhibit 11, stating that the BTU content for 100% jatropha plant oil is 116,613 BTU’s per gallon. This compares with energy content of petroleum diesel, on average, of 10% more, 129,240 BTU’s per gallon (the point at which most diesel engines equipped to run on No. 2 petroleum-based diesel are calibrated), as stated in course materials from ASTM International's Petroleum Products Committee, which are Exhibit 13 [exhibit 13 can be found on p.14 of docket number EPA-HQ-OAR-2014-0827-1125-A1]. The presence ion jatropha plant oil of oxygen atoms lending lower energy content, compelling the diesel engine to command more fuel consumption, and producing greater tailpipe carbon emissions will produce variable results in fuel consumed and carbon emitted from the tailpipe, according to engine load and torque and other operating conditions. Therefore, since POP Diesel is proposing that this variance only apply to the portion of the test protocol on which the engine is supplied by 100% jatropha plant oil, some leeway is required. POP Diesel proposes that a 15% variance should be sufficient. [EPA-HQ-OAR-2014-0827-1125-A1 p.14]

I write on behalf of the above-named corporation, which goes by the short name POP Diesel, to make one correction and amplify one point for your consideration in addition to the comments submitted on September 11, 2015 (“Comments”). These supplemental and amended comments give details on and concern matters that your two agencies have not heretofore considered. Because of the novelty and profundity of its Comments, POP Diesel had been unable to formulate these details by the deadline of its September 11 submission. Therefore, I respectfully request that the agencies give this statement full consideration at this time. [EPA-HQ-OAR-2014-0827-1467-A1 p.1]

The correction is to the amount stated in Part III, Section (D) of the Comments as the variance that POP Diesel requests as an alternative solution to your two agencies’ either (i) revising the Standards to accord fully with measuring fuel efficiency by the amount of energy input to the engine per unit of work performed and greenhouse gas emissions by net life cycle emissions or (ii) adopting a waiver from these Standards for truck engines equipped to run on 100 percent jatropha plant oil while they are running on this fuel. The Comments, at page 13, suggested that a variance from the Standards “on the order of” 15 percent would suffice. However, POP Diesel’s call for a 15 percent variance was in error. POP Diesel hereby amends its Comments to request a 20 percent variance, for the following reason. [EPA-HQ-OAR-2014-0827-1467-A2 p.1-2]

The data submitted in Exhibits 11 and 12 to the Comments are that a diesel engine running on 100 percent jatropha plant oil generates approximately 18 percent more fuel consumption and tailpipe carbon emissions, versus when the engine operates on petroleum diesel fuel. Other than POP Diesel’s mistaken request for a 15 percent variance, there is no reason for the two agencies to hold a POP Diesel-equipped engine to a variance of 15 percent that, from the start, establishes odds against this engine’s being certified, which is the only conclusion that can be drawn from the evidence submitted. [EPA-HQ-OAR-2014-0827-1467-A2 p.2]

Therefore, POP Diesel requests a variance, if the agencies’ consideration of its Comments lead them to adopt a variance, of at least 20 percent. The 18 percent variation evident in Exhibits 11 and 12 is an approximate average. Tailpipe plant oil carbon emissions results involving some models of diesel engine may be much higher than the 18 percent average. Therefore, a 20 percent variance is reasonable, and anything less than 18 percent is unreasonable. [EPA-HQ-OAR-2014-0827-1467-A2 p.2]
A POP Diesel-equipped engine starts and shuts down on No. 2 petroleum-based diesel fuel, but runs on 100% jatropha plant oil in the interim. The portion of a test protocol on which the engine operates on No. 2 petroleum-diesel versus 100% jatropha plant oil will depend on the test protocol and the fuel mapping programmed into the engine's power control module.

**Organization:** Volvo Group

**No Provision for Lower Carbon Fuels**

Although EPA is charged with administering the federal Renewable Fuels Program, this NPRM makes no provision to provide credits for vehicles that are developed to run on lower carbon alternative fuels. While it is not clear what fuels may become available during the next 15 years, it is clear that the proposal creates a disincentive to develop vehicles to utilize such fuels unless they provide lower tailpipe GHG emissions, regardless of the well-to-wheel life cycle emissions. [EPA-HQ-OAR-2014-0827-1290-A1 p.32]

**Response:**

We provide credit for renewable fuels under the Renewable Fuels Standard (RFS) program. We thank the commenters for the information provided on the use of renewable biofuels in heavy-duty vehicles; however, these comments are germane to the Renewable Fuels Standard (RFS) program, which appropriately addresses renewable fuels. Biofuels that are demonstrated to meet specified GHG emission reductions on a lifecycle basis, and which meet all other requirements including the definition of renewable biomass, have an opportunity to generate RINs under the RFS program after approval by EPA. With respect to comments from POP Diesel, manufacturers can request certification of an alternative fuel vehicle running on POP Diesel under 40 CFR 1065.701(c).

**15.10.4 Comments Related to the 2007/2010 Criteria Pollutant Standards**

**Organization:** Corwin, Michael

I currently work for a small trucking company that has 26 trucks running the US & Canada. We currently have 3 of our trucks down due to major DPF issues, and this has been pretty constant for the last 1.5 – 2 yrs, so what worries me is we are contemplating more regulations before we even figure out what is wrong with the currently mandated technology. [EPA-HQ-OAR-2014-0827-0730-A1 p.1]

**Organization:** Competitive Enterprise Institute et al.

Small and midsize trucking companies are finding they are ill-equipped to adapt [to the new regulations]. Hundreds of these firms, with an average fleet size of about a dozen vehicles, have gone out of business in the past two years, according to Avondale Partners LLC. Others have sold out to larger competitors, which are more likely to have cash reserves or access to financing to weather changes in the industry. [EPA-HQ-OAR-2014-0827-1251-A2 p.3]

A chart from the article shows how the cost of new trucks has increased since 2009: [EPA-HQ-OAR-2014-0827-1251-A2 p.3]

[Chart can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1251-A2]
A study prepared for American Truck Dealers (a division of the National Automobile Dealers Association) finds that EPA emission standards adopted in 1997, 2000, and 2001, which phased in between 2004 and 2010, increased the inflation-adjusted cost of new semis by more than $21,000. For each phase of the regulations, the study compares the actual costs with the costs projected in EPA’s regulatory impact analyses. Cumulative actual costs were more than four times bigger than EPA’s estimate.³ [EPA-HQ-OAR-2014-0827-1251-A2 p.4]

[Figure 7, ‘Cumulative Surcharges for Heavy Heavy-Duty Trucks’, can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1251-A2]

From January 2000 to January 2015, the CPI increased by roughly 38% while small owner-operator net income increased by 11%. The typical independent owner-operator incurred a loss of $11,260 in purchasing power.⁶ Thus, small truckers have been losing ground under existing regulatory burdens. [EPA-HQ-OAR-2014-0827-1251-A2 p.4]

We urge the agencies to proceed with special consideration for the rule’s impacts on small trucking companies. The agencies claim the rule’s fuel savings will more than offset the higher cost of compliant vehicles. However, even if realized, the projected fuel savings will be of no benefit to firms that go out of business because they can’t afford to buy compliant trucks. [EPA-HQ-OAR-2014-0827-1251-A2 p.4]

The agencies also show no awareness of the comparatively greater risks small truckers incur from regulation-induced maintenance problems. A large firm with hundreds of vehicles will not lose business when a mandated new technology malfunctions and one or more trucks must be sent to the shop for repairs. But in small firms, such unanticipated downtime can cut weekly income and damage reputations. Consider the experience of owner-operator Tilden Curl, who testified at an EPA/NHTSA listening session in Olympia, Washington: [EPA-HQ-OAR-2014-0827-1251-A2 p.4-5]

Curl detailed his truck ownership and fuel economy starting with a 1995 Peterbilt he bought for $65,000. After 10 years with the truck, Curl had invested just less than $95,000 in maintenance and repairs, including a rebuild and transmission. The last year he owned the truck he averaged 6.58 mpg. [EPA-HQ-OAR-2014-0827-1251-A2 p.5]

In October 2008, Curl purchased a new aerodynamic, emission-compliant 2009 Kenworth for $140,000. In seven years of ownership, Curl drove the truck more than 752,000 miles and had $105,000 in maintenance and repairs. He suffered significant downtime that hurt his income and reputation as a reliable carrier, he told the panel. And, in the end, the truck was only able to achieve 6.15 mpg. [EPA-HQ-OAR-2014-0827-1251-A2 p.5]

Finally giving up on the ’09 truck, Curl bit the bullet and bought a 2016 Kenworth earlier this year for $167,000. He had originally planned to pay off the 2009 Kenworth and sock away what was the truck payment toward his retirement, he told the panel. [EPA-HQ-OAR-2014-0827-1251-A2 p.5]

“As I see it, these regulations, and a rush to push technology beyond tested capabilities, have cost me my retirement. There is no mechanism in place to compensate small-business truckers for the costs of these mandates,” he said. “We cannot afford for this to happen again.” [EPA-HQ-OAR-2014-0827-1251-A2 p.5]

Nowhere in the proposal do the agencies acknowledge EPA’s penchant for low-balling regulatory costs, the precarious economics of small-business trucking, and the existential risks small truckers face when technology mandates impair vehicle reliability. We have been told that EPA consulted OOIDA to
address small trucker concerns. However, to all appearances, the rule is a bull in a china shop. [EPA-HQ-OAR-2014-0827-1251-A2 p.5]

The proposed rule is silent about the potential impacts of new GHG and fuel economy standards on small trucking firms. History suggests the standards will increase equipment costs, operating expenses, and engine malfunctions by more than the agencies anticipate. The rule evinces no awareness that small firms already struggle to cope with existing regulations, and that additional regulatory burdens may drive many small owner-operators out of business. [EPA-HQ-OAR-2014-0827-1251-A2 p.24]

6 Personal communication from OOIDA regulatory affairs director Scott Grenerth to Marlo Lewis, September 28, 2015

Organization: Curl, Tilden

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 186.]

Small business truckers that purchase this equipment to start up will be challenged to exist if this regulation proceeds without a reality check. The agencies are seemingly using facts they prefer, with little regard for the actual burdens it places on small business operations.

Organization: Schneider National Inc.

In the past, the costs of compliance have been underestimated and the benefits overstated. By way of illustration, since 2002, tractor cost increases directly attributed to emission regulations have increased the cost of a semi-tractor by 30% while increasing fuel consumption by 5% from 2003-2010. EPA estimates did not recognize the fuel consumption increase and the cost estimates were a small fraction of the actual costs incurred. [EPA-HQ-OAR-2014-0827-1201-A1 p.3]

Response:

These comments appear to be with respect to EPA’s 2004/2007/2010 criteria pollutant standards and therefore are not germane to this rulemaking. We strongly disagree with claims that the rule does not consider the potential impacts of new GHG and fuel economy standards on small business, and we refer the commenter to Chapter 12 of the RIA which includes the agencies’ analysis of the impacts of the standards on small entities and to Section 15.4 of this RTC.

The agencies have also devoted considerable attention to the issue of technology reliability. See, e.g. RIA chapter 2.3.9. Indeed, this is a primary reason the agencies are not adopting standards reflecting
Alternative 4. For each standard, the agencies have explained why there is adequate lead time not only to develop and deploy control technology, but also to assure its reliability.

15.10.5 **Trailer Clearance/Identification Lamps 2123**

**Organization:** STEMCO

- STEMCO requests a written confirmation from NHTSA allowing the placement of rear identification and clearance lamps on the lower frame rail of long van trailers. This facilitates an additional 0.14 delta C\textsubscript{D,A} aerodynamic improvement from boat tails at no additional cost or complexity. [EPA-HQ-OAR-2014-0827-1259-A1 p.2]

NHTSA written support of optimized boat tails in relation to “49 CFR 393.11 Lamps and reflective devices”

As part of the final regulation, STEMCO requests that NHTSA include a clear written guidance confirming that trailer manufacturers may locate both the rear identification and clearance lamps on the lower frame rail for all box trailers, such that the entire rear lighting package may be located at the lower regulatory location (see Figure 1 in the Appendix for illustration). These lower clearance and identification lamp locations will pave the way for both higher-efficiency boat tails for swing door box trailers and the 2016 commercial launch of boat tails for roll door box trailers. [EPA-HQ-OAR-2014-0827-1259-A1 p.3]

To date, STEMCO has sold TrailerTails\textsuperscript{®} into both the new trailer and retrofit markets without requiring that any modifications be made to the trailer design itself. This has forced the top panels of TrailerTails\textsuperscript{®} to be inset 2-3” below the roof of the trailer (Figure 2) to satisfy the DOT visibility requirements of the rear identification and clearance lamps installed along the rear header of the trailer [23 CFR 658.16(b) (4)]. This inset creates an un-aerodynamic gap as airflow transitions from the trailer roof onto the TrailerTail\textsuperscript{®} panels and has prevented TrailerTails\textsuperscript{®} from delivering maximum environmental benefit. Wind tunnel flow visualization\textsuperscript{1} highlights the contrast in airflow between flush and inset panels and our own internal testing estimates an additional 0.14 delta CDA (measured drag area) gain\textsuperscript{2} can be achieved simply by installing a TrailerTail\textsuperscript{®} flush with the trailer roof. [EPA-HQ-OAR-2014-0827-1259-A1 p.4]

We believe that no modification is needed to 49 CFR 393.11 because these lower mounting locations for rear identification and clearance lamps already satisfy the “as high as practicable” definition. Additionally, flat bed and container chassis trailers currently use these lower mounting locations as their standard (see Figures 3 and 4 in the Appendix). However, a written confirmation letter from NHTSA to all trailer manufacturers would eliminate any confusion due to the subjective “as high as practicable” verbiage. This NHTSA confirmation letter would also eliminate uncertainty for highway patrol officers during trailer inspections in the same way that FHWA’s 2008 letter to ATDynamics (now STEMCO) regarding the TrailerTail’s\textsuperscript{®} length exclusion was used by early adopting TrailerTail\textsuperscript{®} fleets as a valuable education tool at weigh stations. [EPA-HQ-OAR-2014-0827-1259-A1 p.4]

---

Page 2123 of 2127
2 Assumptions & Calculations:

1) Current TrailerTail® (with top panel inset) is verified as 5% fuel savings device by EPA SmartWay

2) Table IV-9 correlates 5% fuel savings to 0.7 delta CDA

3) Internal STEMCO aerodynamic testing has shown that a TrailerTail® mounted flush to the trailer roof achieves 20% higher aerodynamic gains than a TrailerTail® that is inset below the identification and clearance lamps on the rear header

4) 0.7 delta CDA X 20% = 0.14 delta CDA additional gain when a TrailerTail® is mounted flush to the trailer roof

Response:

This comment is out of the scope of this rulemaking. However, this commenter and others who are interested in reading or seeking interpretations of NHTSA regulations are encouraged to visit http://isearch.nhtsa.gov/. On that website, users will find instructions on how to search for interpretations, how to use letters of interpretation, and how to submit requests for interpretation.

15.10.6 Nonroad Engine Credits

Organization: California Air Resources Board (CARB)

On a separate but related topic, CARB staff recommends that U.S. EPA and NHTSA adopt provisions to set a reasonable timeframe for the compulsory expiration of Tier 4 non-road compression ignition emission credits, and codify the terms for expiration in 40 CFR 1039.740. California is a participant in the federal ABT program and is therefore dependent on U.S. EPA and NHTSA for action regarding this request. Our concern is the delay in the full implementation of engines in California equipped with advanced exhaust aftertreatment controls for both PM and NOx. More manufacturers than anticipated are certifying off-road compression ignition engine families in California to Tier 4 final standards without simultaneously employing both PM and NOx aftertreatment devices, and this is due in part, we believe, to manufacturers’ use of banked emission credits. We recognize that other factors may contribute to this situation as well, but addressing the expiration of emission credits would help California to more quickly achieve its much needed PM and NOx emission reduction goals. [EPA-HQ-OAR-2014-0827-1265-A1 p.128]

Response:

EPA did not propose such restrictions and considers them to be outside of the scope of this rulemaking. However, we are willing to work with CARB and other interested stakeholders in this area.

15.10.7 Black Carbon Emissions

Organization: Advanced Engine System Institute (AESI)

Finally, though the agencies’ proposal does not seek to place limits on black carbon emissions from medium- or heavy-duty vehicles or engines, it is worth noting that the global warming potential of this pollutant is very significant, particularly in the short term. According to EPA's 2012 report to Congress
on black carbon, the pollutant's 20-year global warming potential could be around 4,470 times that of carbon dioxide. While existing EPA vehicle regulations are on track over the next two decades to gradually reduce particulate matter pollution, a sizable fraction of which is black carbon, EPA could shrink heavy-duty vehicles' and engines' carbon footprint almost immediately and very cost effectively by application of high-efficiency diesel particulate filters that eliminate 99.9% of black carbon emissions. The Agency may want to consider incentives in the final rule for the rapid installation of such filters on vehicles/engines not already required to have them. [EPA-HQ-OAR-2014-0827-1152-A1 p.3]

**Organization:** Manufacturers of Emission Controls Association (MECA)

**Control of Black Carbon with Particulate Filters**

Black carbon is a major component of particulate matter emissions from mobile sources and is believed to have a significant net atmospheric warming effect by enhancing the absorption of sunlight. Black carbon is a mix of elemental and organic carbon, in the form of soot, emitted by fossil fuel combustion, bio-mass burning, and bio-fuel cooking. Black carbon is a dominant absorber of visible solar radiation in the atmosphere. Anthropogenic sources of black carbon are transported over long distances and are most concentrated in the tropics where solar irradiance is highest. Because of the combination of high absorption, a regional distribution roughly aligned with solar irradiance, and the capacity to form widespread atmospheric brown clouds in a mixture with other aerosols, emissions of black carbon are thought to be the second strongest contribution to current climate change, after CO2 emissions. The glacier retreat has accelerated since the 1970s and several scientists have speculated that solar heating by soot in atmospheric brown clouds and deposition of dark soot over bright snow surfaces may be an important contributing factor for the acceleration of glacier retreat. A study published in a 2009 issue of Nature Geoscience (vol. 2, 2009) by researchers from the NASA Goddard Institute and Columbia University found that black carbon is responsible for 50% of the total Arctic warming observed from 1890 to 2007 (most of the observed Arctic warming over this timeframe occurred from 1976 to 2007). [EPA-HQ-OAR-2014-0827-1210-A3 p.10]

It is estimated that 70% of the black carbon emissions from mobile sources are from diesel-fueled vehicles, with the assumption that 40% of gasoline PM is black carbon and 60% of diesel PM is black carbon. The black carbon concentration and its global heating will decrease almost immediately after reduction of its emission. Black carbon from diesel vehicles can be significantly reduced through emission control technology that has been required on every U.S. heavy-duty diesel truck manufactured since 2007. The basis for the design of wall-flow particulate filters is a ceramic honeycomb structure with alternate channels plugged at opposite ends. As the gases pass into the open end of a channel, the plug at the opposite end forces the gases through the porous wall of the honeycomb channel and out through the neighboring channel. The porous wall and the filter cake of particulate matter that forms within and on the surface of the wall serve as the filter media for particulates. Since the filter can fill up over time by developing a layer of retained particles on the inside surface of the porous wall, the accumulated particles must be burned off or removed to regenerate the filter. This regeneration process can be accomplished with a variety of methods including both active strategies that rely on generating external sources of heat (e.g., fuel burners, fuel dosing strategies that utilize fuel combustion over a catalyst, electrical elements, intake air throttling) and passive strategies that utilize catalysts that are displayed directly on the filter element or upstream of the filter. During the regeneration of DPFs, captured carbon is oxidized to CO2 but this filter regeneration still results in a net climate change benefit since the global warming potential of black carbon has been estimated to be as high as 2,200 times higher than that of CO2 on a per gram of emission basis. It is estimated that the installation of DPFs has reduced PM emissions from U.S. heavy-duty diesel vehicles by 110,000 tons per year. The
ACES Phase 2 study that evaluated the PM emissions from 2010 technology heavy-duty engines showed that DPF equipped engines emit PM at one to two orders of magnitude below the current standard of 0.01 g/bhp-hr and deliver over 99% PM capture efficiency over their lifetime. MECA encourages EPA to develop policies and/or incentives that reward vehicle and engine manufacturers for employing technologies such as particulate filters that provide significant reductions in mobile source black carbon emissions. [EPA-HQ-OAR-2014-0827-1210-A3 p.10-11]

Diesel particulate filters are extremely effective at removing black carbon emissions from diesel engines. Effective climate change policies should include programs and incentives aimed at reducing black carbon emissions from unfiltered new off-road engines and existing diesel engines through effective retrofit programs that implement filters on the full range of in-use diesel engines operating in the U.S. [EPA-HQ-OAR-2014-0827-1210-A3 p.14]

Response:
In this rulemaking, the agencies are addressing reduction of GHG emissions from new heavy-duty vehicles starting in the MY 2021 time frame. These vehicles utilize engines that are already regulated to very low particulate matter levels, of which black carbon is a component. The agencies appreciate the comment on retrofit initiatives to further reduce black carbon and particulate matter from the existing (pre-2007) fleet, however we do not intend to address retrofitting of diesel particulate filters to these engines in this rulemaking, as fleet changeover already has, and will continue to remove non-DPF equipped vehicles from the in-use fleet.

The agencies appreciate the comment on reduction of black carbon and particulate matter from nonroad fleet by further reducing standards to a level that would force the use of diesel particulate filters, however we are not addressing GHG, black carbon, or particulate matter emissions from these nonroad engines in this rulemaking action. It is worth noting, however, that we are finalizing provisions that will achieve reductions in PM emissions from tractor APUs and from glider vehicles.

15.10.8 Defeat Devices

Organization: Center for Biological Diversity

The Center requests that the EPA address the potential for “defeat devices” to be used during engine testing, such as those recently discovered connection with several models of Volkswagen passenger vehicles.31 Software algorithms appear to have been used to engage certain NOx controls only during testing conditions, not during normal driving. The Center requests that EPA delineate what preventative measures will be implemented to strengthen its testing protocol and detect any defeat devices. [EPA-HQ-OAR-2014-0827-1460-A1 p.8]

Organization: Houston-Galveston Area Council (H-GAC)

The final rule should stress the importance of operator compliance and deter the disabling of vehicle pollution controls. [EPA-HQ-OAR-2014-0827-1142-A2 p.1]
Response:

EPA is requiring that NOx emission be measured for all testing to measure GHG emissions to verify that NOx and GHGs are both being controlled. In addition, we plan to continue our efforts to find appropriate ways to enhance our compliance program and will likely consider such enhancements in any future NOx rules.

Organization:  FedEx Corporation

In addition to the provisions of the proposal referenced above, FedEx is also advocating for new efficiencies in Less-than-Truckload (LTL) freight movement by extending the length of twin 28-foot trailers to 33 feet. This would enable approximately 18 percent more freight to be hauled on the same trip, improving road safety and reducing emissions by significantly reducing the number of trucks on the road. Just five more feet in for these twin trailers would: [EPA-HQ-OAR-2014-0827-1302-A1 p.4]

- Reduce congestion by 6.6 million truck trips per year [EPA-HQ-OAR-2014-0827-1302-A1 p.5]
- Reduce truck traffic by 1.3 billion miles per year [EPA-HQ-OAR-2014-0827-1302-A1 p.5]
- Reduce carbon emissions by 4.4 billion pounds per year [EPA-HQ-OAR-2014-0827-1302-A1 p.5]

Response:

This issue is not within the scope of this rulemaking.
