has collected similar data sets from its trucks in the field, and that Autocar’s data and resulting analysis differs significantly from what is reflected in the report. Thus, Autocar requests that the agencies provide the underlying refuse truck drive cycle data for review, and also take the opportunity to receive and review Autocar’s data and analysis, to determine whether the agencies are using appropriate data and analysis as the basis for its rulemaking. Autocar plans to submit its readily available data in response to the NREL report later this week. Additional time will allow Autocar to provide other drive cycle data sets developed during the testing and development of hybrid drives for refuse trucks, which will be important in assessing the validity of the NREL data and the analysis of those data. [EPA-HQ-OAR-2014-0827-1869-A1 p.2-3]

**Autocar's Data Contradicts the Limited Data Set Presented by the NREL Report.**

1.1 Autocar Has Identified Two Sources of Data on Refuse Truck Drive Cycles. As set forth in Autocar's request for an extension of time to review and comment on the Vocational Custom Chassis Memorandum (the 'Memorandum') and the Notice of Data Availability (the 'NODA') (see Section 4 of these comments, below), Autocar has data which contradicts the drive cycle data presented in the National Renewable Energy Laboratory report (the 'NREL Report'). Further, Autocar believes that the manufacturer of its hybrid-drive powertrain may be a source of additional data which accurately represents the drive cycle of refuse trucks. [EPA-HQ-OAR-2014-0827-1885-A1 p.4]

1.2 The Data in the NREL Report on Refuse Vehicle's Operational Duty Cycles Are Not Representative of Refuse Trucks. In Tables 3 and 4 of the NREL Report, the number of Mean Stops noted for refuse trucks indicates that the data were collected on urban and commercial, high-density routes, which does not reflect the diversity of refuse chassis' operation (city and suburban residential collection in particular). Additionally, while the NREL Report noted high average RPM relative to low speed, there is no mention of stational PTO operation, a staple of virtually every refuse truck and a drive cycle factor that renders workday idle-reduction technologies useless. Finally, the performance of work trucks such as refuse trucks is measured in hours, not miles, and thus none of the 'per mile' metrics are relevant or informative. Autocar recognizes the difficulty of accurately plotting the drive cycle in heavy-duty refuse trucks but believes that ignoring these particular factors has led to an impossible proposed compliance requirement for refuse. In the limited time available for review and reaction to the NREL Report, Autocar assembled its own test data on drive cycle and offers the informative and analysis set forth in Appendix 1. [Appendix 1 can be found in docket number EPA-HQ-OAR-2014-0827-1885-A2] Autocar believes that this more representative data demonstrates that the drive cycles of refuse trucks in particular are so unique that they cannot be held to the same standards and compliance structure as other vocational and heavy-duty trucks. As set forth in the request for extension of the comment period on the NODA, Autocar welcomes the opportunity to review its data and analysis with the agencies, in an effort to ensure appropriate data is used as a basis for the regulations. [EPA-HQ-OAR-2014-0827-1885-A1 p.4]

Autocar footnotes: 2 Vocational Vehicle Technology Packages for Custom Chasses Memorandum, From Lauren Steele, EPA Environmental Engineer, OTAQ/ASD (Feb. 12, 2016), No. EPA-HQ-OAR-2014-0827-1719.

5 ‘PTO,’ or power take-off, refers to drawing power from the engine to run auxiliary systems or functions such as compacting trash, dumping carts, loading and unloading roll-off containers or mixing or pumping concrete. The engine may operate at high RPMs during the PTO operation.

**Organization:** Navistar, Inc.

The agencies request comment on a National Renewable Energy Laboratory ("NREL") study of vocational vehicle segmentation by drive cycle and weight.\(^5\) A drive cycle is a data set that shows the speed versus time of a vehicle during its route, including stops. It is important here because the assumed drive cycles in GEM directly impact a vehicle’s GEM score. Apparently the agencies intend to use this data analysis to support “ongoing refinement” of the proposed rule and GEM, the sole means to determine a vehicle’s emission level. It does not appear that NREL collected new data for this study, but analyzed existing data. [EPA-HQ-OAR-2014-0827-1919-A2 p.3]

Navistar’s initial issue is whether the data used to generate the NREL study is representative. The NREL study is based on data from its Fleet DNA database, which appears to be based on voluntary submissions of data for the drive cycles for particular vehicles that happen to have been submitted to NREL by fleets and others. A primary concern is sample size. For example, in the NREL study the refuse truck population in Class 6/7 was a mere 2 trucks and only 55 in Class 8. The total refuse truck population has been estimated by EPA to be approximately 176,000.\(^6\) For aggregated drive cycles to be minimally representative, they should at least reflect urban, suburban and rural conditions and flat, hilly and mountainous terrain and combinations of the foregoing. It is impossible for the agencies to have a truly representative sample from only two Class 6/7 refuse trucks driving their individual routes. Without accurate drive cycle data, the ultimate GEM-derived emission level could be wildly inaccurate based simply on differences between the way a vehicle is driven on real world routes and the assumptions built into GEM. [EPA-HQ-OAR-2014-0827-1919-A2 p.3-4]

It also appears that this data comes largely if not entirely from voluntary submissions from various fleets. This means that it is largely self-selected, coming from fleets and others that choose to provide information and do so accurately. Moreover, it seems likely that much of this data comes from multiple vehicles in one fleet. A fleet may very well operate in a limited geographical area and have similar drive cycles, which means that the representative nature of this data with respect to the national fleet may be highly suspect and could be skewed by only a few fleets that have chosen to contribute data. [EPA-HQ-OAR-2014-0827-1919-A2 p.4]

The agencies, nonetheless, propose significant changes from the original NPRM based on the data. EPA concluded from the NREL vehicle study that “[t]wo distinct clusters were identified: one with fewer stops and higher avg speeds, other with more stops and lower avg speeds. A third exhibits characteristics of each: multimodal vehicles.” Observations such as this from the NREL limited vehicle dataset have led the agencies to propose a very different weighting scheme for the vocational drive cycles. The major changes are significantly more idle time and a shift in the split for each category regarding % miles for 65, 55 and transient.\(^7\) The new GEM on the docket provides results that are no longer comparable to anything included in the NPRM for vocational as the technology benefits are significantly revised. These changes are significant and require additional clarification with respect to the segmentation and standards in order to assess the impact. [EPA-HQ-OAR-2014-0827-1919-A2 p.4]

Unfortunately, the NREL study does not clarify the uncertainties with regard to the vocational portion of the proposed rule. We remain very concerned that the agencies do not have sufficient data to revise the rule in a manner that is not wholly arbitrary. Beyond that, as we discussed above related to the Memorandum, we know very little about how the agencies intend to use this data. As such, we reiterate
our request that the agencies postpone finalization of the vocational rule until they have an appropriate amount of real-world data. [EPA-HQ-OAR-2014-0827-1919-A2 p.4]

2 NPRM Comments at 31.

5 EPA-HQ-OAR-2014-0827-1621.

6 Environmental Protection Agency, Population and Activity of On-road Vehicles in MOVES2014, EPA-420-R-16003a (March 2016). The MOVES2014 report does not break out vehicle class from the total 176,000. However, the total population in the NREL study was a sample of 57 to represent 176,000 vehicles, only .0003% of the actual population.

7 Included with the docket entry referenced in the immediately preceding footnote was a document entitled “Vocational Strawman” in the form of a powerpoint presentation. It appears that this may be a rough outline of revisions to the proposed rule.

Organization: California Air Resources Board (CARB)

Comment – Proposed composite test cycle weightings (in percent) for vocational vehicles

The Composite Test Cycle is weighted based on the CARB transient cycle, 55 mph cruise with road grade cycle, and 65 mph cruise with road grade cycle. The idling portion is already included in those three cycles. But in the NPRM’s Table V-2, it appears that idling is additional to the three cycles. And if the percentages in each row in Table V-2 are added up, they sum to higher than 100 percent. For example, under urban conditions, the table indicates 94 percent CARB transient, 6 percent 55 mph cruise, and 20 percent idle. CARB staff recommends clarification on how these percentages will be used. [EPA-HQ-OAR-2014-0827-1265-A1 p.121-122]

Allison Transmission:

The agencies have requested comment regarding “the nature of vocational workday idle operation, including how much of it is in traffic and how much is while the vehicle is parked.” [EPA-HQ-OAR-2014-0827-1284-A1 p.42]

Allison is the largest supplier of transmissions for vocational vehicles in North America. We routinely capture and analyze actual work day duty cycles for numerous different vocations. In support of the Phase 2 GHG initiative, we randomly selected 240 North American duty cycles covering vocations such as Airport Refueler; Bus (Transit, Commuter, Shuttle, Tour Coach, School), City Delivery (Armored Car, Beverage, Van, Walk-In Van), Construction (Concrete Mixer, Dump, Snow Plow, Equipment Hauler), Farm, Straddle Carrier, Line Haul, Log Hauler, Oil Field (Draw Works, Pumping), Refuse (Landfill, No Landfill, Recycling, Transfer), Utility (Municipal Maintenance, Public Utility, Street Sweeper), Wrecker, and Dock Spotter. These duty cycles averaged 7.6 hours in length and generally represented a full workday of operation. The stop time data for a representative sample of the data are summarized below: [EPA-HQ-OAR-2014-0827-1284-A1 p.42]

[Tables of stop time data can be found on p.43 of docket number EPA-HQ-OAR-2014-0827-1284-A1]
This data does not differentiate between stopped in traffic and parked. Knowing the ARB Transient cycle has 16% time at a stop and there is an idle cycle of various percentages, the agencies have proposed that the vocational weightings result in the following equivalent stop time percentage: [EPA-HQ-OAR-2014-0827-1284-A1 p.43]

With the exception of the concrete mixer vocation, the stop time percentages from the current EPA weightings appear reasonable and reflect Allison’s own analysis of percentage stopped time for the cross section of the wide variety of vocational vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.43]

**Organization:** New Flyer of America Inc.

As an example of differences in the vocational driving cycles, the FTA requires transit bus manufactures to complete fuel economy testing. This test program is prescribed under the Safe, Accountable, Flexible, and Efficient Transportation Equity Act (SAFETEA-LU) under the Bus Test Program. [EPA-HQ-OAR-2014-0827-1306-A1 p.1]

There are three test phases to replicate the operating conditions of a transit bus: [EPA-HQ-OAR-2014-0827-1306-A1 p.2]

1. A central business district (CBD) phase of 2 miles with 7 stops per mile and a top speed of 20 mph.
2. An arterial phase of 2 miles with 2 stops per mile and a top speed of 40 mph
3. A commuter phase of 4 miles with 1 stop and a maximum speed of 40 mph.

Transit bus manufacturers optimize fuel economy performance to the FTA standard test procedures. These test results are commonly used by transit authorities during bus procurements for product performance comparisons. While it’s quantitatively unknown the magnitude of GHG and fuel consumptions differences between the FTA driving cycle and the proposed vocational and fuel economy drive cycle, New Flyer is concerned the categorization of transit buses into the larger segment of vocational trucks may yield a further economic burden to bus manufacturers and transit agencies. [EPA-HQ-OAR-2014-0827-1306-A1 p.2]

**Organization:** Odyne Systems LLC

Odyne has found that our customers drive an average of 25 miles a day (1.5 hrs). Outside of the benefits that hybrids provide to the driving portion (MPG improvements), reductions in idling can be significant. Idle time is currently broken into two categories: traffic and parked. Odyne believes that the parked idle should also be broken down to normal and work (jobsite) idle. Normal idle occurs around 750RPM and work idle is typically much higher and can range from 800 to 2000RPM, which has a greater impact on fuel consumption and emissions. It is also important to account for the amount and type of work being done since that relates to work being done on the IC engine or replaced by the hybrid system. We have found that the typical duty cycle of the total time in work mode (PTO mode, work load) relative to the actual time running the application is around 20%. Based on our customers’ workday we see an average of 1.6 hours just parked (non-PTO) and an additional 2.8 hours parked in the work mode (PTO, e-PTO). Fuel consumption during parked and work idle is also dramatically different. We have found that parked idle can consume up to 1 gals/hr, whereas work idle can consume as much as 2 gals/hr during high RPMs and load. [EPA-HQ-OAR-2014-0827-1239-A1 p.22-23]
This information comes from the fleet data we collected using our telematics. Based on this information Odyne feels that the percentage of idle time that is being proposed for the vocational drive cycles (Regional, Multi-purpose, Urban) is not high enough and is not weighted properly. The Urban drive cycle – proposed at 20% – would be used for our application, and our data shows that the percent idle time can be significantly higher. Using our daily averages we found a typical workday to be 6 hours (this doesn’t account for other things like startup, shutdown and lunch). In general, we’ve found that driving is only 25% of the workday and time at the parked/jobsite accounts for the remaining 75%. Then when looking at idle time over the workday and breaking it down into each component, we’ve found the full workday to represent 3% idle while driving (11 min., transmission in drive, brake pedal applied, vehicle at 0 MPH), 26% idle while parked (1.6 hrs., parking brake on, in neutral, no PTO) and 46% idle (2.8 hrs., parking brake on, in neutral, and PTO engaged) while parked in work mode (e-PTO). [EPA-HQ-OAR-2014-0827-1920-A2 p.11-12]

Odyne strongly believes that it is important to account for the full workday vocational vehicle duty cycle: including driving, idling, and stationary operation of truck-mounted equipment through a Power Take-off (PTO). Then relative to idle it is very important to break it down into the three categories mentioned above and properly weight them. We believe that the worksite idle is the most important aspect of idle reduction and has the most benefit for vocational work truck applications. Since most of the vocational vehicles monitored were observed to spend most of their time at the jobsite in the work mode it should be weighted more heavily. For additional details you can reference our testimony at the public hearing in August at Chicago and our comments submitted for the main proposal under Docket ID No. EPA–HQ–OAR–2014-0827 in October. [EPA-HQ-OAR-2014-0827-1920-A2 p.16-17]

Organization: Odyne Systems LLC

Comments on docket EPA-HQ-OAR-2014-0827-1621: The draft report entitled “The Development of Vocational Vehicle Drive Cycles and Segmentation” helps to advance the understanding of vocational vehicle duty cycles, an important aspect in developing appropriate Greenhouse Gas Emissions and Fuel Efficiency Standards for medium- and heavy-duty engines and vehicles. The report has helped to identify and characterize various vocational vehicle segments and the typical drive cycles for those segments. Odyne agrees it is very important to use appropriate drive cycles when evaluating vehicle performance, since there is such a wide range of applications for vocational medium and heavy duty vehicles. [EPA-HQ-OAR-2014-0827-1920-A2 p.4]

Based upon Odyne’s work with the U.S. Department of Energy, the Electric Power Research Institute (EPRI) and various state agencies within California (SCAQMD, CEC and CARB), please see report: http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000003002006566, the company recommends that the entire duty cycle, not just the vehicle drive cycle, should be incorporated into future regulations and testing, especially for medium and heavy duty vocational vehicles. [EPA-HQ-OAR-2014-0827-1920-A2 p.4]

Odyne considers the “drive cycle” of a medium or heavy duty vehicle as the portion of vehicle operation that occurs when the vehicle utilizes propulsion to drive from location to location. The “drive cycle” includes the operation of the vehicle when it is moving and when it is stationary along the route, such as at a stop sign, stop light or in stop and go traffic. [EPA-HQ-OAR-2014-0827-1920-A2 p.4-5]

Odyne considers the entire duty cycle to include both the “drive cycle” and operation of the vehicle when it provides power during stationary activities (such as operation of the engine to power HVAC during delivery of goods or to power equipment often mounted to a vocational vehicle at a work site). The entire vehicle duty cycle may be composed of several modes of operation that create GHG emissions. Those modes include driving, engine idle while in drive (such as when at a stop sign or when in stop and go
traffic), engine idle while in neutral (such as when a vocation vehicle is stationary and operating engine powered HVAC and/or has continuing low voltage loads, such as warning lights that are on at a work site), and engine idle while using Power Take-off (PTO) (such as when operating the prime mover to power truck mounted hydraulic equipment). In some circumstances an additional vehicle mounted engine might also be consuming fuel, such as an independent engine powered electrical generator or engine powered a welder. The various types of engine idle in aggregate can compose a very significant percent of overall GHG emissions for vocational vehicles. [EPA-HQ-OAR-2014-0827-1920-A2 p.5]

Based upon testing performed at SwRI and CE-CERT, fuel consumption at idle can vary significantly depending on the operation of the stationary vehicle. Engine idle in neutral may consume less than one gallon of diesel fuel per hour, or the same engine may consume over 2 gallons per hour in a high idle mode when providing power to equipment through a PTO. Due to the significant variation in fuel consumption at idle, the large number of hours in idle per year and the large number of vehicles that idle, Odyne encourages the EPA to characterize non-propulsion operation of the engine carefully. [EPA-HQ-OAR-2014-0827-1920-A2 p.5-6]

Inaccurate test results may be produced if the testing was performed the same way for significantly different applications due to differences in duty cycles and fuel consumption. The NREL study helps to reinforce this point, especially in terms of drive cycles, but it was not clear that differences between driving and stationary (work / job site) impacts were adequately measured and segmented. Odyne recommends that testing be developed to accurately reflect the fuel consumption of vocational vehicles that occurs over the entire day, especially if vehicles typically operate engines for extended periods of time to power equipment at work sites. [EPA-HQ-OAR-2014-0827-1920-A2 p.6]

As an example, referring to Figure 1, page 8 of the report entitled “Vocational Strawman,” while Odyne supports the increase in the percent of time at zero mph (24%, 52% and 47%) for the possible composite test cycle revisions, because the higher percentages generally are supported by Odyne’s own 1 Hz telematics measurements of over 100 vocational vehicles in the field that show a high percent of stationary engine operation, Odyne has concerns about the type of idle that is incurred and what type of test will be used to assess various efficiency solutions. It is not clear to Odyne whether the increased idle time percentages in the possible composite test cycle revisions were incurred when the vehicle was in drive (such as when an engine is typically spinning a torque converter on an automatic transmission but the vehicle brakes keep the vehicle stationary at a stop light), or whether a significant amount of time was spent with very little load on the idling engine (such as during delivery of goods with the transmission in neutral and the parking brake applied) or whether the engine was under high load in idle with the PTO engaged. Odyne requests that the EPA specify if the idle time would be tested with the transmission in drive (which might favor an engine stop/start system or electrically powered de-fueling solution such as that described in U.S. patent 9,061,680), or if it would be tested with the transmission in neutral with the parking braking applied (which might favor an idle reduction system focused on HVAC and 12 volt power), or if it would be tested with the transmission in neutral with the parking brake applied and a significant load on the Power Take-off (PTO) (which might favor a hybrid, PHEV or ePTO solution that can power the PTO with the engine off). [EPA-HQ-OAR-2014-0827-1920-A2 p.6-7] [Figure 1 can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1920-A2]

The population of vocational trucks that have a power take-off is very significant and often appears to be treated as a small minority of overall sales for testing and regulatory purposes. Odyne recommends making it easier for efficiency solutions that provide power to the PTO to gain credit for GHG reductions. Based upon work performed with input from the National Truck Equipment Association (NTEA), Odyne estimates that over 145,000 Power Take-off units (PTOs) are typically installed on medium and heavy duty trucks annually (please see the original Odyne submission for details and / or contact NTEA’s Director of market data and research, Steve Latin-Kasper at 248-489-8193 or via email at stevelk@ntea.com). Based upon the estimated number of class 4 – 8 straight truck chassis sales (box-off)
sold in 2015, which closely represents total medium and heavy duty vocation truck sales, PTO’s may be installed on approximately 50% of vehicles within that range. [EPA-HQ-OAR-2014-0827-1920-A2 p.8-9]

Odyne encourages the EPA to include accurate PTO modeling in GEM and encourages the further characterization of entire duty cycles (both driving and stationary operation) for vocational vehicles. The modeling of hybrid and ePTO solutions should include a variety of factors in addition to inputs affecting propulsion efficiency already in the model, including: [EPA-HQ-OAR-2014-0827-1920-A2 p.9]

- Increase or decrease in fuel efficiency during driving due to work site efficiency solution
- Odyne has demonstrated increases in driving efficiency of over 40% during high charge deplete operation of plug-in hybrid systems that interface through the PTO with unmodified fully automatic transmissions (please see EPRI report: http://www.epri.com/abstracts/Pages/ProductAbstract.aspx?ProductId=000000003002006566 for details). Those inputs should be recognized, but should also factor into worksite efficiency modeling. [EPA-HQ-OAR-2014-0827-1920-A2 p.9]
- Certain ePTO systems that are designed to only provide electric power for equipment when the vehicle is stationary, actually reduce driving fuel efficiency. ePTO systems add weight to the vehicle without providing a propulsion benefit, decreasing driving efficiency, and may charge the ePTO battery system when the vehicle is in motion, further reducing driving efficiency. [EPA-HQ-OAR-2014-0827-1920-A2 p.9]
- Loads (power and energy) to be supplied during stationary operation of the vehicle by hybrid, ePTO or export power systems
  - Odyne recommends better characterization of the loads typically requiring power during stationary work site operations. Those loads may include power to operate electrical HVAC for the cab, low voltage loads including lights or small inverters for electronics, mechanical loads due to the operation of hydraulic pumps and air compressors, and electrical loads to provide 120V/240V power for tools or equipment. Overall power and energy should be characterized so that various efficiency solutions can be accurately tested. [EPA-HQ-OAR-2014-0827-1920-A2 p.10]
  - Capabilities of the hybrid, ePTO or other work site solution in terms of its ability to provide power and energy with the engine off. Battery size of various systems can differ, a smaller battery may result in greater engine operation at the work site. [EPA-HQ-OAR-2014-0827-1920-A2 p.10]

Testing and Verification

Testing truck emissions requires a concise understanding of the full workday for all classes of trucks and vocation. For vocational vehicles, with their myriad of applications, this can be a difficult task. However, Odyne has been tracking full day duty cycles for Utility work trucks covering Aerial / Compressor / Digger / Underground applications for the past 5 years, alongside leading organizations including EPRI, DOE, CEC, and SCAQMD. Odyne appreciates the EPA’s focus on the importance of accurate modeling here. We have also done testing at facilities like SWRI and CE-CERT to verify fuel economy and emission benefits. The EPA has done well in identifying the importance of the full workday (real world usage) and separating it into driving (traffic) and stationary (parked). Our system impacts both categories and needs to be accounted for appropriately since we are not just an idle reduction technology. Our understanding is that the EPA has chosen the HDT drive cycle for the transient portion of testing, and CARB has chosen the UDDS drive cycle; both drive cycles represent how our customers drive their vehicles. Odyne would highly suggest having a common drive cycle used by CARB and EPA (preferably the HDT cycle) to be used across all testing and it is important to evaluate this over a realistic period of time or distance instead of just the single drive cycle. [EPA-HQ-OAR-2014-0827-1239-A1 p.21-22]
Current regulations are focused on engine certification and some consideration for vehicle or powertrain testing under specific drive cycles. In Odyne’s work truck applications, driving does occur, though this is a small portion of activity compared to the time spent at the jobsite idling at higher speeds and loads (in addition to normal idle when they are not working). So we feel it is very important to evaluate fuel consumption and emissions based on a full workday instead of only driving. Just as it is important to test driving conditions with the appropriate type of drive cycle it is also important to test the stationary with the appropriate cycle. The workday test cycle needs to account for the appropriate type of driving and stationary to have a better correlation to real world usage and impacts. [EPA-HQ-OAR-2014-0827-1239-A1 p.22]

Response:

The agencies are relying on work conducted by the U.S. Department of Energy at the National Renewable Energy Laboratory (NREL), as well as the duty cycle information provided in these public comments, in establishing the weighting factors for the test cycles to be used in the certification of heavy-duty vocational vehicles to the final Phase 2 standards. We disagree that we have not provided adequate notice of these cycles. At proposal we included analysis in the docket on the possible impact of an increased weighting of the idle cycle on vehicle emissions as represented in GEM. Further, the NREL report released with the NODA was not a surprise, as we had signaled intent to rely on that work at the time of the proposal (80 FR 40288), and some manufacturers voluntarily shared data with NREL as part of this process. In any case, the NODA afforded opportunity to comment on the data, an opportunity of which commenters vigorously availed themselves.

Based on available fleet data, NREL identified three general clusters of vehicle behavior: one cluster of vehicles most often driving with slower speeds and frequent stops; one with higher average speeds and fewer stops; and one multi-modal cluster with vehicles that may operate similarly to either of the other clusters on any given day. In response to concerns expressed by some commenters that the vehicles from which NREL collected data for the cycle may not be representative of the overall vocational vehicle fleet, we are confident any discrepancies are sufficiently small to allow us to use the NREL work to establish weighting factors for three general driving patterns. NREL’s Fleet DNA database contains millions of miles of historical real world drive cycle data captured from medium- and heavy vehicles operating across the United States. The database encompasses data from existing DOE activities as well as contributions from valued industry stakeholder participants. The agencies consequently do not accept the criticism in comments that this database is arbitrarily self-selected. For the vocational vehicle project, NREL examined data drawn from the Fleet DNA database representing 913 unique vehicles comprising 16,250 days of operation. The Fleet DNA data used as a source for the NREL analysis has been collected from a total of 30 unique fleets/data providers operating across 22 unique geographic locations spread across the United States. This includes locations with topology ranging from the foothills of Denver, Colorado to the flats of Miami, Florida. The range of fleets, geographic locations, and total number of vehicles analyzed ensures results which include the influence of these factors. While no analysis will be perfect without unlimited resources and data, it is the researchers’ understanding that the Fleet DNA database is the largest and most thorough publicly accessible vocational vehicle usage database currently in operation. Further, the NREL cluster analysis was performed on the data and the NREL staff examined the results along vocational and weight class parameters. As the analysis was focused on characterizing driving behavior independent of vehicle configuration, the results of the analysis and aggregation of the weight classes is representative of the vehicles demonstrating similar driving behavior regardless of weight.

174 See http://www.nrel.gov/transportation/fleettest_fleet_dna.html
NREL performed additional analysis attempting to subdivide the results into a greater number of clusters (see Chapter 2.3 of the NREL drive cycle report) and provided no superior findings.

Although the agencies have attempted to develop these factors to accurately represent average vehicle behavior, failure to do so would not necessarily make the cycles invalid. Just as the in-use effectiveness of engine technologies can be reasonably evaluated using testing that is limited to 68-86°F, the effectiveness of vehicle technologies could be reasonably evaluated using duty cycles that reflect operation different than the average vehicles. We believe the more relevant question is whether or not the final duty cycles exercise the technologies over enough of the range of in-use operation to effect in-use reductions. In this context, the weighting factors and duty-cycles are fully adequate as we now go on to discuss.

Public comments as well as the NREL work supported stronger weighting of idle in the test cycles. At proposal and even at the time of the NODA we had not yet received analysis from NREL on how to distinguish parked idle from driving idle operation. We have since conducted extensive outreach to affected stakeholders including interim releases of GEM, to provide opportunity for comment on the regulatory impacts of distinguishing parked idle from driving idle. Statistical summaries of vehicles in the three NREL clusters demonstrated that on average, vehicles in all three clusters operated between 22 and 28 percent of a work day in a parked idle state. As explained in Section 1.5 of the NREL report, one of the drive cycle metrics that was analyzed was percentage of operating time at zero speed. That statistical metric was identified for each cluster initially, which essentially represented a combination of both parked idle and drive idle conditions. NREL found that vehicles in the Multipurpose and Urban clusters statistically experience an engine-on zero-speed condition between 47 and 52 percent of a work day. Effenco’s comments are corroborative of these data, where their comment suggested the range of total zero speed time might be between 35 and 55 percent. The further work to distinguish different types of zero speed operation (parked vs drive) is described in Section 5.5 of the NREL report. In response to compelling comments from Allison, time at zero speed during the ARB transient cycle is now accounted for when assigning weights to the drive idle cycle. By using these statistical targets along with the histograms of distance accumulated while operating within 2-mph speed bins, the agencies assigned weighting factors for each composite test cycle. We incorporated information from Volvo regarding percent of distance accumulated at speeds above 55 mph into the composite weighting factors for Multipurpose and Urban class 8 vocational vehicles. See discussion in the RIA Chapter 3.4.3.1. The Volvo information does show that the vehicles they produce with low cab forward configurations do accumulate more miles above 55 mph than those in NREL’s dataset, and the vehicles they identify as VHD/GU designed for construction applications do accumulate more miles above 65 mph than those in NREL’s dataset. Although both NREL and Volvo data showed vehicles whose behavior would logically be classified as Urban, accumulating some miles (from one to seven percent) in the 65 mph range, the agencies are applying a zero weighting factor to the 65 mph cycle for all Urban vehicles for certification purposes. The accumulated miles above 65 mph have instead been applied to the composite weighting of the 55 mph test cycle. This is because we believe it is important to have a test cycle available in the primary program for vehicles that may regularly drive on urban or local highways, but are not expected (or designed) to drive on rural highways. The final weighting factors of the composite test cycles are shown in Table 6-1.

The agencies do not agree with the comment that refuse vehicles are underrepresented in the NREL database. Indeed, because the full NREL database also contains over five percent refuse trucks and our MOVES model estimates that refuse trucks comprise only three percent of newly manufactured vocational vehicles each year, we directed NREL to remove excess refuse trucks from their final analysis, to avoid skewing the data by over-representing refuse trucks. We expect that manufacturers seeking to certify refuse trucks (in the primary program) that will have greater highway use than is represented by the Urban test cycle may certify in the Multipurpose subcategory. For refuse trucks certified to the
optional custom chassis standards, GEM will apply the Urban cycle weightings. Custom chassis manufacturers wishing to be recognized for applying cycle-dependent technologies such as driveline improvements may certify to the primary standards and select the most appropriate test cycle.

When vocational vehicles are tested over the parked idle cycle, their emissions and fuel consumption will be measured while in a low idle state, without torque applied from an automatic transmission in gear, for example. During the drive idle test cycle, the transmission torque will be applied unless the transmission is a manual, AMT, or an automatic with a neutral idle feature activated. The parked idle cycle does not include high-idle PTO operation. Although we agree with the commenter from Odyne that this is a mode during which significant GHG emissions and fuel consumption can occur for some vocational vehicles, we do not agree that the standard test procedure needs to include this mode for all vocational vehicles. Our reasons for reaching this conclusion are outlined in the Preamble at Section V.C.1.c.iii. In our partnership with NREL, we have characterized the operation of utility vehicles with PTO, and the results are somewhat similar to those described by Odyne. Of over 1,500 work days analyzed for over 80 trucks, NREL observed the average fraction of a work day spent driving is 34 percent, with average 36 percent in PTO mode, and average 30 percent in low (parked) idle. The fraction of low parked idle is consistent with the fraction observed for other vocational vehicles and is consistent with the test cycle weightings in Table 6-1. Below in Section 6.3.6.3 we address comments requesting the agencies to recognize technologies that can reduce emissions during high-idle PTO mode operation. This is also addressed in the Preamble at Section V.C.1.c.iii.

The agencies have determined that it is impractical, from a regulatory perspective, to establish separate, unique test cycles for other vehicles such as transit buses, coach buses, or refuse trucks (although the optional custom chassis standards provide flexibilities consistent with these vehicles’ duty cycles). In considering the challenges of such an undertaking, as well as the market structure of manufacturers who produce such vehicles, the agencies are instead adopting separate standards for transit buses and refuse trucks as part of the final Phase 2 program for custom vocational chassis, as described in Section 6.2.3. Further discussion of comments related to creation of separate regulatory subcategories for some vehicles is found below in Section 6.1.5.

In the final weeks before promulgation of the Phase 2 rules, the agencies received significant new comments from vehicle manufacturers, which suggest there is some uncertainty with respect to the three drive cycle structure being adopted. The agencies will continue to analyze this new information and any other new information we receive, and we will continue to actively engage with manufacturers and other stakeholders to determine if future revisions to the vocational vehicle program structure are warranted. In Chapter 2.2 of the NREL report, an alternate bi-modal clustering analysis is also presented, where instead of having a distinct middle cluster, vehicles with highly variable driving patterns are grouped as either
high speed or low speed. A preliminary update provided by NREL includes cycle weightings that correspond with this two cluster depiction of vehicle behavior.\textsuperscript{175} Based on the NREL report and other information, the agencies believe it is appropriate to finalize a regulatory subcategory structure that includes a drive cycle appropriate for mixed use vehicles (a middle cluster); especially considering that the ultimate application of incomplete chassis is largely unknown at the time of certification. In other words, we are adopting a program structure that follows NREL’s three cluster depiction of vehicle behavior, although the record shows that a two cluster structure could have been chosen for one or more vehicle weight classes. It is possible that further analysis of new data could lead us to consider proposing amendments to adopt the two cluster approach for one or more vehicle weight classes, or to consider amending the regulatory constraints limiting the choice of drive cycle subcategory that we are adopting to prevent potential adverse impacts of vehicle misclassification (See Section 6.5.1 below). However, at this time the final program structure will remain in place unless and until the agencies determine that revisions to the vocational vehicle program structure are warranted. See Section V.b.1.a of the Preamble for further discussion of this issue.

6.1.5 Framework: Regulatory Subcategories

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Further vocational vehicle segments and more realistic test cycles. The more extensive segmentation of vocational vehicles and the accompanying cycle re-weightings will better reflect these vehicles’ operating characteristics. Test cycles will match vehicles’ real-world duty cycles much better than they do in the Phase 1 program, especially with the addition of an idle cycle. Inclusion of road grade on the 55- and 65-mph steady-state cycles in Phase 2 will better reflect real-world driving. [EPA-HQ-OAR-2014-0827-1280-A1 p.5] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.55-56.]]

Organization: BYD Motors

The agencies have made significant improvements compared to the MY2014-2018 standards, particularly in providing additional market segmentation options that reflect a larger share of transient operation as well as the addition of an idle-only cycle. These changes to the regulatory test cycles better reflect the diversity of the vocational fleet and the duty cycles of our customers and will help identify the appropriate technology solutions for reducing fuel use from this sector. [EPA-HQ-OAR-2014-0827-1182-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.227.]]

Organization: ABC Bus Companies, Inc.

Comments on proposed method of assigning vocational chassis to regulatory subcategories. A category for Passenger Carrier Vehicle, (PCV) could be defined. The GEM User Guide overview mentions Intercity Motorcoach operation should be classified under the Regional Duty Cycle. Given the nature of motorcoach designs as outlined in above comments, Fuel mapping, idling, ADA lift operations, etc. standards of these vehicles should have its own categories. The NREL should consider the PCV operation as described above to help define this vocational vehicle test cycle. [EPA-HQ-OAR-2014-0827-1430-A2 p.3-4]

Organization: PACCAR, Inc.

\textsuperscript{175} See memorandum dated July 2016 titled, “NREL Bi-Modal Vocational Vehicle Cluster Information.”
PACCAR has evaluated and is still evaluating the Phase 2 vocational vehicle segmentation scheme that is in the NPRM. The early results of this analysis questions the value of the normalization approach that is used. Although it is included by the agencies to mitigate purposeful attempts by OEMs or customers to switch between segments, the normalization may not be needed to accomplish that task. [EPA-HQ-OAR-2014-0827-1204-A1 p.22]

The spec changes to move a vehicle from the middle of the Multi-purpose segment to Urban, for example, require significant changes to the rear axle ratio to the point that the vehicle will be rendered incapable of efficient operation in the intended application. [EPA-HQ-OAR-2014-0827-1204-A1 p.22]

PACCAR recommends that the agencies consider returning to a Phase 1-style program for vocational categories since emissions reduction opportunities are smaller than on tractors and the segmentation approach does not seem to be rendering the value that was expected. In addition, it seems that the segmentation may not provide substantial benefit, so one vocational category for each major weight class grouping may be sufficient. [EPA-HQ-OAR-2014-0827-1204-A1 p.22]

**Organization:** School Bus Manufacturers Technical Council

The School Bus Manufacturers Technical Council (SBMTC) applauds the joint efforts of NHTSA and the EPA to develop a Phase 2 Heavy-Duty (HD) National Program that will reduce greenhouse gas (GHG) emissions and fuel consumption for new on-road heavy-duty vehicles. We would also like to use the opportunity to comment on this regulation and point out how school buses are very different and unique from all other types of motor vehicles and how some of the proposed regulations may create significant challenges. [EPA-HQ-OAR-2014-0827-1287-A1 p.1]

**Organization:** National Automobile Dealers Association (NADA)

The duty cycles of vocational vehicles range from significant over-the-road operation, to periodic over-the-road operation, to stop and start low speed operation, to limited over-the-road and significant “at rest” operation, to off-road-operations, and to every combination thereof. The complexity of vocational truck design, production, and use makes it a challenge to set out categorical fuel use and GHG reduction strategies. [EPA-HQ-OAR-2014-0827-1309-A1 p.9]

**Organization:** New Flyer of America Inc.

With our sustained commitment towards GHG and fuel consumption reduction, New Flyer is respectfully requesting the EPA and NHTSA to reconsider the classification of transit buses as Vocational Vehicles with the proposed standards. Transit buses are currently grouped into a broad category of purpose built vocational trucks which includes delivery trucks, utility trucks, refuse haulers and cement and dump trucks. [EPA-HQ-OAR-2014-0827-1306-A1 p.1]

The applicable technologies and design requirements for transit buses differs significantly from the aforementioned commercial vehicles. Unlike the larger volume commercial truck market (where OEMs have a high percentage of proprietary engines and drivetrains, and dedicated organizations and resources equipped to support ongoing emissions and fuel economy testing), transit bus manufactures in North America assemble purchased drivetrain components, purchase diesel and gas engines from one industry supplier (Cummins Inc.), and have access to a limited number of commercially available transmissions and powertrain systems certified for the transit bus market segment. [EPA-HQ-OAR-2014-0827-1306-A1 p.2]
In our discussions with other transit bus manufacturers (including Gillig LLC) and the American Public Transit Association (APTA), we share aligned concerns on other aspects of the program which are related to vocational classification, including air conditioning leakage (transit buses have significantly larger and more complex air conditioning systems than trucks), and payload. New Flyer believes the differences in vehicle systems and the operating characteristics warrant distinctive classification. [EPA-HQ-OAR-2014-0827-1306-A1 p.2]

Similar to the standalone categorization proposed by the EPA and NHTSA for emergency type vehicles, New Flyer encourages the EPA/NHTSA to consider separate GHG and fuel consumption reduction requirements for transit buses by creating a separate categorization with simpler testing and compliance standards. [EPA-HQ-OAR-2014-0827-1306-A1 p.2]

New Flyer encourages further dialog between the EPA/NHTSA and APTA members (including OEMs, powertrain suppliers, and end-user transit agencies) to finalize the GHG and fuel consumption reduction standards that support the shared clean air and more fuel-efficient objectives for the transit bus vehicle segment. New Flyer is committed to participating and supporting these discussions and proving additional information to the EPA and NHTSA as needed. [EPA-HQ-OAR-2014-0827-1306-A1 p.2]

Organization: Allison Transmission, Inc.

EPA and NHTSA Should Adopt Subcategorization of Vocational Vehicles With Changes to Address Several Types of Vehicles

The Proposed Rule contains nine different subcategories for vocational vehicles. These categories are intended to allow for the assignment of vehicles into categories based on use patterns; the proposed rule would utilize final drive ratios of vocational vehicles for this purpose. Subcategorization using the multi-purpose duty cycle would be presumed unless “some criteria were met that indicated either the Regional or Urban cycle could be more appropriate.” EPA and NHTSA have requested comment on the method for assigning vocational chassis to these regulatory subcategories. [EPA-HQ-OAR-2014-0827-1284-A1 p.39]

In general, Allison believes that EPA and NHTSA are proposing a reasonable approach to subcategorize vocational vehicles. We agree with the agencies that most vehicles should be classified as being Multi-Purpose and our analysis of the proposal indicates that this is likely to occur. As detailed below, however, we do have several issues concerning how the Proposed Rule would operate with respect to certain vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.39]

Allison Transmission

Our comments are based on a memorandum placed into the docket in connection with this NODA. 1 In this regard, Allison first commends EPA and NHTSA for the consideration of the small, custom chassis manufacturers in the Phase 2 rulemaking and generally supports the approach described in the memorandum.

Table 1 Custom Chassis Types

Allison recommends that EPA and NHTSA acknowledge that the custom chassis distinguishable features are not all-inclusive for each custom chassis listed and that the custom chassis definition is not limited to the narrow definition provided in Table 1. Instead, Allison would recommend that EPA and NHTSA provide additional vehicle uses as well as operational requirements for the vehicle classifications as noted in the attached table. For example, depending on the price range and whether they are built for comfort or
utility, everything from coach to RV to school bus chassis is used as the basis for an upfitted specialty vehicle, including entertainment travel, bookmobile, bloodmobile, mobile command station, etc. Yet the current Table 1 makes no mention of such vehicles. We would therefore suggest that a final Table 1 be supplemented and expanded as below: [EPA-HQ-OAR-2014-0827-1892-A1 p.3]

[Table 1 can be found on p.4 of docket number EPA-HQ-OAR-2014-0827-1892-A1]

**Organization:** Allison Transmission, Inc.

**EPA and NHTSA Should Create Subcategory for Transit Buses**

Finally, EPA and NHTSA should address transit buses in the final rule apart from the presumptive classification based on gear ratio. That is, under the Proposed Rule, a typical transit bus configuration will result in a Multi-Purpose subcategorization, instead of Urban subcategorization. But changing the transmission from a 6 speed to a 4 speed would change this result and produce a classification of the transit bus as an Urban vehicle. Doing so, however, carries with it the downside of reducing fuel efficiency and increasing CO2 emissions. Therefore, in the final rule, EPA and NHTSA should avoid this “incentive” and instead treat all transit buses as Urban. This alternation is both rational – given the vehicle’s intended use and low prospects that it will be converted to other uses – and would avoid the unintended consequence of reduced transmission speeds to change the regulatory sub-classification. [EPA-HQ-OAR-2014-0827-1284-A1 p.41]

EPA and NHTSA should also consider a sub-category for transit buses. Transit buses operate in urban areas and have a duty cycle of frequent starts and stops, with no 65 mph operation and very limited 55 mph operation so the current vocational test cycle does not represent how they operate. Transit buses are manufactured by few companies and are purchased with public funds, typically through a bidding process. They do not have a secondary use for anything other than a transit bus. Transit buses have unique construction from other vocational vehicles and incorporate specialized accessories which result in different losses and efficiencies. They are also good candidates for future hybridization and electrification. Allison believes that these reasons warrant a separate sub-category in Phase 2. [EPA-HQ-OAR-2014-0827-1284-A1 p.41]

**Organization:** Allison Transmission, Inc.

**EPA and NHTSA Should Incorporate Different Standards for Motor Homes**

Motor Homes (“MHs”) present different usage patterns than many other types of MD/HD vehicles primarily due to the fact that such vehicles are normally consumer-owned and not a vehicle that does vocational work. Therefore, EPA’s assumptions that underlie its estimation of the emissions output of such vehicles are incorrect since usage is intermittent. MHs are seldom driven over the course of a year; they tend to be stored over the winter, and then driven to various locations during the spring and summer months. MHs may also be parked for long periods of time and interstate driving, as a function of their overall use, is relatively small. MHs have a low number of idling events given their design elements to connect to the electric grid at campgrounds and other locations. Therefore, EPA and NHTSA should consider simplified compliance methods to MHs similar to those that may be applied to emergency vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.49]

**Organization:** Allison Transmission, Inc.
EPA and NHTSA should recognize that torque converter based ATs can launch with lower numerical axles than transmissions with clutch based launching systems. The lower numerical axles in conjunction with significant overdrives allow these vehicles to run lower engine speeds at the 65 and 55 mph cruise cycles – resulting in lower fuel consumption. The downside of the Proposed Rule subcategorization for vocational vehicles is that these configurations may be classified as Regional when the majority of their duty cycle is Multi-Purpose. Again, reducing the breakpoint from 75 to 70 would help to mitigate such concerns. [EPA-HQ-OAR-2014-0827-1284-A1 p.40]

Organization:  CALSTART

That said, there may be some categories still worthy of customized approaches. Refuse may be one because of its extreme duty cycle and sufficient volumes to justify monitoring. The other is transit bus. The transit bus segment has traditionally been the launch point of advanced technologies for air quality and efficiency, including natural gas, hybrid, electric and now fuel cell systems. There are myriad reasons for this leadership, including the higher visibility of transit buses in urban centers, the federal funding process which underwrites 80 percent of the capital costs of new buses, and the operational profiles which have been conducive to controlled introduction and use of new fuels and technology. As a result, the segment could serve as a leader for the rest of the heavy-duty industry in terms of higher GHG reduction potential. It can also serve as a laboratory for credit structures supporting the introduction of low carbon technology. While we have no specific proposal to offer, we would request additional exploration of how to leverage the leadership of the transit segment in considerations of flexibility. Transit bus makers able to sell their credits to other HD OEMs for advanced bus over-compliance can be useful in paying for their investments, if stringency levels help create the need for such credits. [EPA-HQ-OAR-2014-0827-1190-A1 p.4]

Organization:  GILLIG LLC

We have tried to address below two main areas of concern we have with the new rule. First, areas where we see a significant number of the underpinning assumptions for vocational vehicles in both the proposed GEM model and the Standards as not applicable to transit buses. Second, the business impacts associated with the certification process, limited compliance flexibility, burden of compliance, and the stockpiling rule. It is our belief that transit vehicles are designed, built and operated very differently from other vocational vehicles, and that the compliance process/burden has potentially devastating impacts for our business, employees and customers. GILLIG is very interested in pursuing a simplified compliance procedure and less stringent Phase 2 standards specific for transit buses and asks that the agencies consider establishing a separate subcategory for transit buses. [EPA-HQ-OAR-2014-0827-1156-A1 p.1-2]

GILLIG produces approximately 1800 MHD and HHD transit buses each year. These buses are configured with diesel, CNG and diesel/hybrid powertrains. Transit buses are purpose built, uniquely configured to each end users specific needs. Typical duty cycles are run in urban areas, and characterized by a significant number of stops and starts, high idle times, very low average speeds, limited operation above 55 mph, and a high percentage of the time run significantly under the fully loaded condition. The vast majority of these transit buses are sold to municipalities through a bidding process and are funded by federal (FTA), state and local governments with public tax dollars. We believe that significant differences between transit buses and the other vehicles in the vocational vehicle category necessitate a need for the agencies to consider establishing a separate subcategory for transit buses. [EPA-HQ-OAR-2014-0827-1156-A1 p.1]

GILLIG only produces HD transit buses. Annual volumes are approximately 1600 HHD transit buses and 200 MHD transit buses. The same engine models, hp, and fuel options (diesel, CNG, and diesel/hybrid)
are available in both weight classes. Our product line is so narrow that averaging does not provide much compliance flexibility. We request the agencies consider a separate subcategory for transit buses to address this. [EPA-HQ-OAR-2014-0827-1156-A1 p.4-5]

Organization: National Waste & Recycle Association

The National Waste & Recycling Association (NWRA) is the trade association representing private sector waste services companies. Our members collect municipal solid waste; own and operate waste transfer stations and landfills; collect and process recyclables; and collect and compost organic waste in cities and counties throughout the United States. We play an essential part in protecting America’s public health and environment. [NHTSA-2014-0132-0071-A1 p.1]

Our industry has a vital stake in ensuring that the Phase 2 rules will result in trucks that allow us to continue to protect America’s public health and environment as efficiently as possible. To manage America’s solid waste stream, our industry has a fleet of more than 100,000 refuse, recycling and compost collection trucks. We are constantly looking for ways to lower fuel consumption. In fact, our desire to conserve energy and lower emissions has lead us to be the leading heavy-duty truck user of non-diesel, alternative fuel vehicles. [NHTSA-2014-0132-0071-A1 p.1]

We are disappointed that the two agencies continue to lump all the many kinds of vocational vehicles together instead of creating standards for each kind of vehicle. As we note in subsequent comments, refuse trucks are vastly different from other vocational vehicles, yet the agencies persist in treating all vocational vehicles as if they are the same. This unfortunate one-kind-fits-all approach will fail to achieve the results that uniquely-tailored standards would achieve. [NHTSA-2014-0132-0071-A1 p.1-2]

The solid waste industry truck fleet: overview

In order to manage America’s solid waste, we are not just a public health industry. We also are a trucking industry with a large and highly diverse fleet of trucks that serve unique purposes and are different from each other in design and operation. The fleet includes, but is by no means limited to, garbage and recycling collection trucks, roll-off trucks, container delivery trucks and grapple trucks. These trucks are primarily Class 8 heavy-duty vocational vehicles. The industry also uses tractor trailers to haul solid waste from transfer stations to disposal facilities and pickups and similar lighter duty vehicles used by the industry. All of these trucks require off-road capability at some point. They are different in design and use, however, from the strictly off-road trucks used to manage waste at landfills. Most of the tractor trailers are owned and operated by contractors. [NHTSA-2014-0132-0071-A1 p.2]

The solid waste industry fleet: garbage and recycling collection trucks

The garbage and recycling collection trucks that stop at virtually every American house and business every week are the most recognized part of the solid waste fleet. Most Americans know a garbage truck when they see one. These are unique, highly specialized vehicles, almost all of which are classified in this regulatory proposal as heavy-duty vocational vehicles. They are totally unlike the other trucks in this subcategory in terms of their design, operation and function. Because garbage and recycling trucks are virtually identical in most respects, the generic term “refuse truck” will be used for both vehicles. Yard waste can be collected by either type of truck. [NHTSA-2014-0132-0071-A1 p.2]

Fuel consumption is determined by a variety of factors including the truck’s total weight, the use of compaction equipment, structural needs, route distance, the extraordinarily high number of stops and starts a truck makes in a day (and a week and a month and a year) and the extensive use of power take-off
units while the truck is stopped, but is still working. Virtually all refuse trucks use an automatic transmission. [NHTSA-2014-0132-0071-A1 p.2-3]

**Loading and compaction:** A refuse truck can be loaded manually or automatically in its front, rear or side, depending on the truck. Automatic loading can be accomplished by the use of an automated arm on side loaders, a cart tipper at the rear or side of a truck or a set of automated forks on its front. In the latter case, the forks go into sleeves on the sides of a container and then lift the container up and over the truck and deposit its contents into the truck’s hopper. Fuel is used to power the loading equipment. At some point, the material is compacted by a moving blade that presses against the wall of the hopper. Compaction is used because it allows the truck to compress garbage and thus, collect more. This lowers the numbers of trucks on the road. The truck is stopped while the material is being loaded. Compaction can occur while the truck is stopped or moving. [NHTSA-2014-0132-0071-A1 p.3]

The solid waste industry fleet: roll-off container and other trucks

A roll-off container truck is a heavy heavy-duty vocational vehicle designed to take empty “detachable containers” to waste generator sites. When those containers are full, they will be replaced with an empty container. The full container will be taken to a disposal facility, unloaded, and returned to the fleet yard to be cleaned and placed at another generator’s site. These are large containers, usually ranging in size from 10 to 40 cubic yards, primarily used at factories, construction and demolition sites and large commercial accounts such as shopping malls. They can hold a variety of materials, ranging from lightweight pallets generated at a factory to concrete generated at a construction or demolition site. [NHTSA-2014-0132-0071-A1 p.4]

The truck will raise its hydraulically operated bed allowing the empty container to roll off the bed and be lowered by means of a cable or hook lift. When the container is full, the process is reversed and the container is placed back on the truck. These trucks are subject to the same weight limits as are refuse trucks. When the truck is stopped and moving a container on or off its bed, the truck is still consuming fuel. These trucks often drive down alleys and go off-road, especially at construction sites. [NHTSA-2014-0132-0071-A1 p.4]

The solid waste industry also has other specialized equipment such as grapple trucks and container delivery trucks. Grapple trucks use specially mounted grapples to lift bulky waste such as logs, yard waste or debris and place them into a container on the truck. Container delivery trucks are used to deliver small containers to a commercial customer such as a gas station or restaurant, when a container needs to be repaired or when service is terminated. These vehicles are subject to the constraints of truck weight laws. [NHTSA-2014-0132-0071-A1 p.4]

The trucks used by our industry are in the “vocational vehicle” category in both the Phase 1 rule and the Phase 2 proposal. As they did with the Phase 1 proposal, EPA and NHTSA continue to ignore the advice of the National Academies of Science (NAS). In its study, “Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-duty Vehicles” (2010), NAS highlighted the wide differences between different types of vocational vehicles. In the press release accompanying the release of the study, NAS pointed out that “NHTSA will need to establish standards tied to the task associated with a particular type of vehicle; garbage trucks might be held to a different standard than transit buses, for example.” The failure of the agencies to heed that advice and to instead lump all vocational vehicles together with only minimal differences in regulatory approach, results in a proposal that fails to recognize their differences and that will accomplish far less than an approach tailored to each different kind of vocational vehicle. [NHTSA-2014-0132-0071-A1 p.6]
Phase 2, nonetheless, is a slight improvement over Phase 1 because it divides groups of vocational vehicle chassis into subcategories based on vehicle use patterns in which CO2 emissions and fuel efficiency standards vary. We appreciate that the agencies recognize this distinction. However we are concerned that the very example supplied in the discussion of the test cycles for these proposed subcategories (see page 40288, second column, first paragraph) does not understand the operational realities affecting “a neighborhood collection refuse truck” and a “roll-off straight/dump truck that makes daily highway trips to a landfill.” The agencies discussion implies that these are significant differences between the two types of trucks. In reality many “neighborhood collection refuse trucks” make daily trips on highways to either transfer stations or landfills. Many roll-off and dump trucks never go directly to a landfill. Yet the agencies are proposing to require manufacturers to classify the intended test cycles without knowing where or how the purchasers of their trucks will use those vehicles. As a result, we suspect those manufacturers will opt for the “multi-purpose” cycle as a compromise between “urban” and “regional.”

The agencies have chosen to cover all medium- and heavy-duty trucks in this regulatory proposal. We understand their reasoning as applied to most pickup and tractor trailers. We do not, however, understand this logic as applied to the tremendous diversity among vocational vehicles. Unlike pickup trucks and tractor trailers, vocational vehicles come in an extraordinary array of design, sizes, functions, configurations, weights, and duties. Instead of recognizing this diversity and crafting regulations that distinguish among, for instance, refuse trucks, fire trucks, septic tank trucks and motor coaches, EPA and NHTSA continue to support a procrustean, “one size fits all” approach for vocational vehicles. In effect, the agencies are proposing rules for a truck that does not exist. If that truck existed, it would not resemble any truck used by the waste services industry. [NHTSA-2014-0132-0071-A1 p.6]

We look forward to working closely with EPA and NHTSA as they proceed with this rulemaking and with further regulatory actions in this area. As we stated in the beginning of our comments, our industry is constantly looking for ways to lower fuel consumption. We are a public health industry. We support lowering greenhouse gas emissions. We also believe that the public is best served by regulations that will reduce fuel consumption and greenhouse gases in the real world, not in a computer simulation that ignores the real world realities created by Federal and state truck weight limits [NHTSA-2014-0132-0071-A1 p.7-8]

Organization: Oshkosh Corporation

Vocational Vehicle Duty Cycles Vary Dramatically - Vocational vehicle duty cycles vary considerably, both between vocations, and within the same vocation. The most important factor to consider is that most vocational vehicles do not perform the majority of their work by transporting cargo, rather they perform work at a job sight, an emergency scene, or on the roadway. Consider the following examples: [EPA-HQ-OAR-2014-0827-1162-A2 p.2]

Utility Bucket Trucks - The cargo carried by a utility truck is typically limited to lineman’s tools. Once on site, the bucket truck will idle just to run the hydraulics that operate the bucket while the lineman performs his/her work on the overhead lines. Mechanics Trucks Mechanics trucks carry tools, spare parts, and lubricants for repairing equipment in the field. The truck may idle to keep it warm during cold weather. [EPA-HQ-OAR-2014-0827-1162-A2 p.2]

Recovery Vehicle - Recovery vehicles, or “wreckers” will spend some amount of time on the road towing disabled vehicles, and some time operating the recovery equipment (winches, cranes, and towing devices). [EPA-HQ-OAR-2014-0827-1162-A2 p.2]
Concrete Placement - Ready mix concrete trucks spend approximately half their time driving to the delivery site, and half their time dispensing the load. Part of this time will be spent waiting for the crew to be ready for the pour, and the other portion of time is spent pouring concrete. If the pour is a remote site, the concrete may be moved from the truck to the site via wheelbarrows or other means. In this case the wait time will be considerable. [EPA-HQ-OAR-2014-0827-1162-A2 p.2]

We do not envision Table V-17 through V-19 representing an attainable regulation for vocations such as Ready-Mix Concrete trucks. As evident from the following comparison, even assuming that tire improvements are possible and practical, the actual improvements are limited to not much more than whatever can be accomplished with engine improvements alone. [EPA-HQ-OAR-2014-0827-1162-A2 p.5] [Table can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1162-A2]

Refuse Truck - Refuse trucks come in a variety of configurations. Roll-on-Roll-off vehicles will pick up a single container and haul it to the landfill. Type T container haulers will pick up loads from many containers. A large type T container can take 10 minutes to empty with the truck at high idle most of the time. Residential trucks will have aggressive stop-drive cycles while loading, and then some period of mixed urban and country driving to reach the landfill. [EPA-HQ-OAR-2014-0827-1162-A2 p.2]

Snow Plows - The snow plow may carry a load of sand or salt while plowing at the same time. Some of the engine power goes into hauling the load, but a significant amount of power is consumed pushing the snow. [EPA-HQ-OAR-2014-0827-1162-A2 p.3]

Communications Vehicles - Electronic news gathering and incident command vehicles carry communications transmission equipment as well as audio and video processing capability. These vehicles become on-site production or emergency response offices that idle for long periods of time to provide power and climate control for the occupants. [EPA-HQ-OAR-2014-0827-1162-A2 p.3]

Tree Trimming - Similarly to utility trucks, the tree-trimming industry uses bucket trucks to obtain overhead access to their work. Tree trucks will spend most of the day logging no road miles, but running the truck engine for hydraulic power to operate the bucket. [EPA-HQ-OAR-2014-0827-1162-A2 p.3]

Fire Apparatus - Fire apparatus typically drive a short distance and then run at the scene to pump water, generate power, or operate aerial devices. [EPA-HQ-OAR-2014-0827-1162-A2 p.3]

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 166]

Heavy vocational trucks are characterized by niche applications, low volumes, and special purpose designs. Example segments include dump, plows, utility, refuse, fire, and concrete delivery. Within each segment, there are often widely varying vehicle types. There are, for instance, seven unique types of refuse collection vehicles as one example. This extreme variability and complexity renders a design prescriptive regulation untenable.

**Response:**

We are keeping the phase 1 subcategory boundaries of vehicle weight class, with three groups in ranges of GVWR. Applying the three general duty cycles described above in Section 6.1.4 to these three weight class groups, we have created nine vehicle subcategories in the primary program. We believe that this additional level of segmentation with different duty cycles is necessary to recognize the vehicle technologies that are duty cycle dependent, especially transmission technologies and idle reduction.
This structure enables the technologies that perform best at highway speeds and those that perform best in urban driving to each be fairly recognized over appropriate test cycles, while avoiding the unintended consequence of forcing vocational vehicles that are designed to serve in different applications to be measured against a single baseline. The agencies believe these three duty cycle groups balance the competing pressures to recognize the varying performance of technologies, serve the varying needs of customers, and maintain reasonable regulatory simplicity.

We recognize that by adopting a few meaningful duty cycles that “bound” how vocational vehicles are generally used, we cannot perfectly match how every vocational vehicle is actually used. We agree with commenters that there are some vehicle applications for which these general cycles are likely to be poorly representative, and for which unique chassis characteristics are unlike those in the reference GEM vehicles used to establish the subcategory baselines. The agencies have determined that it is impractical, from a regulatory perspective, to establish separate, unique test cycles for all the vocational vehicle applications for which commenters requested separate treatment. In order to determine an appropriate path, we spoke with stakeholders and obtained information about many businesses that produce the chassis mentioned in the comments as well as other purpose-built chassis produced in low sales volumes.

In considering whether to create additional subcategories, the agencies have taken into account the fact that many manufacturers of chassis for which special consideration has been requested do not have diversified products. For manufacturers offering a narrow range of products, averaging is not of practical value as a compliance flexibility, and there are not large sales volumes over which to distribute technology development costs. Based on the comments received and extensive stakeholder outreach, the agencies have identified over a dozen chassis manufacturers serving the U.S. vocational market who produce a narrow spectrum of vehicles for which many technologies underlying the primary standards will either be less effective than projected, or are infeasible. We do not believe it is warranted to force any of these specialized manufacturers to certify their narrow product line of vehicles to the primary standards, where stringency is premised on performance of some technologies unsuited for their specialized type of vehicle. Thus, the agencies have developed optional standards derived using separate subcategories tailored for seven chassis types we are describing as custom chassis. Further discussion of the optional program for custom vocational chassis can be found below in Section 6.2.3.

6.2 Vocational Vehicle Standards for CO2 and Fuel Consumption
6.2.1 Baselines

Organization:  Isuzu Motors Limited

Isuzu has several issues with the proposed rulemaking, specifically with vocational vehicles which is the primary vehicle segment Isuzu participates in North America. These potential issues could affect our future product offerings and potentially limit the applications that we could certify. While Isuzu believes the GEM model is capable of accurately representing our vehicles, we note that it has several technically significant limitations and inaccuracies due to the fact that the user-defined parameters are limited. [EPA-HQ-OAR-2014-0827-1263-A1 p.2]

Organization:  GILLIG LLC

The standard engine for GILLIG MHD and HHD transit buses is an 8.9L 280 hp diesel engine. A diesel-electric hybrid is the only configuration, MHD or HHD, where a 6.7L 280 hp diesel engine is used. We are concerned that differences in the fuel maps between these transit specific engines and the urban duty cycle engines used to establish the baseline vocational vehicles used to create the standards may make it
appreciably more difficult for transit buses to meet the Phase 2 standards. We feel the best way to address this is with a unique subcategory for transit buses. [EPA-HQ-OAR-2014-0827-1156-A1 p.3]

In the GEM HHD and MHD predefined modeling parameters, the payload figures are high relative to what a typical Class 7 or 8 transit bus normally carry. A typical 40’ Class 8 transit bus total passenger capacity is around 73 people, and a typical 30’ Class 7 transit bus passenger capacity is around 48 people. Feedback from some end users have placed the operating time at full capacity at less than 5%. Transit bus payload is very transient throughout the service day and much different than other vocational vehicles. [EPA-HQ-OAR-2014-0827-1156-A1 p.2]

In the GEM predefined modeling parameters for all vocational vehicles electrical power draw is modeled at 300W. In comparison, the vast majority of our transit buses are capable of producing 14kW to power lights, air conditioning fans, information systems, electric engine cooling fans, etc. Additionally, mechanical losses are modeled in GEM at 1000W, but on transit buses refrigerant compressors can pull 18kW and on buses with hydraulic engine cooling fan systems the pump can pull 37kW. Transit buses have significantly different system losses compared to other vocational vehicles. [EPA-HQ-OAR-2014-0827-1156-A1 p.2]

Organization: Daimler Trucks North America LLC

Simulating Axles for Vehicle Certification - Whether this pre-specified efficiency is reasonable. (Fixed axle ratio energy efficiency of 95.5 %). The proposed fixed axle ratio is reasonable at the baseline with the option of the truck manufacturer to input its own value if superior to the baseline. 80 FR 40185. [EPA-HQ-OAR-2014-0827-1164-A1 p.62]

Organization: Navistar, Inc

Navistar feels the following are key areas the agencies must address: The vocational vehicle standards must start from the actual MY17 standards as the baseline and must be simplified and revised throughout. [NHTSA-2014-0132-0094-A1 p.2]

Organization: Allison Transmission, Inc.

For vocational vehicles, the 1.3kW constant power accessory load is unrealistically low and unrealistically constant. Further, to use this accessory load for engines of all sizes is an oversimplification. The Allison best practice for estimating engine accessory loads is the following: [EPA-HQ-OAR-2014-0827-1284-A1 p.28]

- Fan power is 6.5% of peak engine power at peak engine power speed and varies cubically with engine speed. [EPA-HQ-OAR-2014-0827-1284-A1 p.28]

- Air compressor power is 0.5% of peak engine power and is constant. [EPA-HQ-OAR-2014-0827-1284-A1 p.28]

- Alternator/generator power is 1.0% of peak engine power at peak engine power speed and varies proportionally with engine speed. [EPA-HQ-OAR-2014-0827-1284-A1 p.28]

- Steering pump power is 1.0% of peak engine power at peak engine power speed and varies proportionally with engine speed. [EPA-HQ-OAR-2014-0827-1284-A1 p.28]
Although Allison includes a few vocationally specific exceptions, this is the general characterization used to estimate engine accessories. The figure below shows the Allison estimated accessory loads for the EPA sample engines, in contrast with the EPA estimated accessory loads. [EPA-HQ-OAR-2014-0827-1284-A1 p.28]

[Charts, plotting speed against power for Allison estimated accessory loads versus EPA estimated accessory loads, can be found on p.28 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

Revising the load upwards would be more consistent with EPA and NHTSA’s generally conservative approach to estimation of the GHG and fuel efficiency benefits of this rulemaking. Such a revision, coupled with the corresponding stringency adjustments, would better characterize accessory losses and more accurately demonstrate the impact of engine downspeeding. Therefore, Allison recommends GEM utilize a higher and variable power accessory load which is scaled to each engine in the manner described above. [EPA-HQ-OAR-2014-0827-1284-A1 p.29]

Allison recognizes the need to simplify the quantity of pre-defined modeling parameter sets; however, there are some discrepancies in the typical configurations EPA has defined in Table 8. Specifically: [EPA-HQ-OAR-2014-0827-1892-A1 p.5]

- In the case of Coach Bus: HHD Regional, the transmission forward gear ratios shown are “wide” ratio, and a bus would have a “close” ratio set. A better definition would be 3.51, 1.91, 1.43, 1.00, 0.74, 0.64. [EPA-HQ-OAR-2014-0827-1892-A1 p.5]

- In the case of Transit, Refuse, Mixer, Emergency: HHD Urban, the ratios shown are “wide” ratio which would not be used for a transit bus. The “close” ratios used in a bus would be 3.51, 1.91, 1.43, 1.00, 0.74. It should also be noted that this collection of vehicle types would not all be 5-speeds. [EPA-HQ-OAR-2014-0827-1892-A1 p.5]

Organization: Autocar, LLC

The agencies’ proposed baselines and standards are not suitable for Low-speed/Frequent-stop Vehicles. Autocar does not have the ability to comment on the agencies’ proposed baselines and GHG and fuel consumption standards, but the Company believes a fundamental disconnect exists with respect to the baselines and standards applied to Low-speed/Frequent-stop Vehicles: The agencies propose to measure CO2 emissions in grams per ton-mile and fuel consumption in gallons per ton-mile for these trucks, and yet recognize these types of trucks generally are low-mileage vehicles (80 Fed. Reg. 40286). The refuse and sweeper industries appropriately track fuel consumption in gallons per hour. The extreme variation in payload that refuse vehicles carry throughout a day (from zero load to full, one or more cycles per day), and the relatively low number of miles per unit of work for these vehicles, makes any ton-mile metric inappropriate for trying to measure fuel efficiency and GHG emissions per unit of work. Refuse vehicles can travel as little as 50 miles in an entire day on a collection route, and such vehicles expend fuel even while stationary to power compaction and loading mechanisms that run on engine power from a PTO. Thus, gallons per hour is the only logical and appropriate measure of fuel efficiency, and the current proposed standards – measured in grams per ton-mile and gallons per ton-mile – are not appropriate for Low-speed/Frequent-stop Vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.8-9]

Organization: Volvo Group

When setting stringencies the agencies have made errors in their assumptions regarding transmission applicability and penetrations, most egregiously in assuming the baseline vocational vehicles in all but the
HHD Regional subcategories are equipped with automatic transmissions (AT) and that there is no penetration of other transmission types (reference Preamble Section V.C.2.a). Chapters 2 and 4 of the RIA and Section V of the Preamble make no mention of why these subcategories utilized an AT as the baseline with an assumed 100% penetration. The results of this assumption are over-inflated baselines and stringencies. [EPA-HQ-OAR-2014-0827-1290-A1 p.25]

Volvo Group finds this error to be large and the assumption unsubstantiated. For Volvo Group N.A. production for the years 2013 and 2014 (the first two full years of production for Phase 1) the Volvo Group built more than 20,000 units of the Mack Granite, Titan, and TerraPro and Volvo VHD HHD vocational models. These truck models are designed and optimized solely as vocational vehicles for either on/off-road or refuse operation. Of these trucks, just over 60% were equipped with ATs, while just under 40% were equipped with manual transmissions (MT). This does not include volumes of AT and MT in other highway optimized models that are sold into vocational applications where the volumes of AT are very low in favor of MT or automated manual transmissions (AMT). [EPA-HQ-OAR-2014-0827-1290-A1 p.25]

Additionally, ATs increase heat rejection requirements on HHD vocational vehicles. In many cases it is necessary to restrict AT offerings on vehicles with specific packaging constraints or with high torque engines due to the inability to package additional cooling capacity. These constraints would primarily impact vehicles performing more shifts and/or operating at a higher percentage of time at heavier load, such as an increased percentage of transient operation. Thus, the assumption of 100% penetration of automatic transmissions in the agencies’ proposed Urban and Multipurpose subcategories is not justified. [EPA-HQ-OAR-2014-0827-1290-A1 p.25-26]

Response:

In response to comments on the chassis specifications for the baseline GEM configurations, the agencies have revised many vehicle characteristics since the NPRM. In response to comments from manufacturers of LHD vocational chassis including Isuzu, the agencies have revised downward the default aerodynamic drag area for all LHD vocational vehicles. In response to comments from transmission suppliers and engine manufacturers noting that unloaded idle speeds were too low, we have revised upward the default mechanical and electrical accessory loads for vocational vehicles in all subcategories. Other changes made in response to comment include the gears of the transmissions on coach buses and transit buses and the axle ratios and tire revs/mi of LHD and MHD vehicles. The most significant changes to the HHD baselines are in establishing blended baselines for HHD Regional and Multipurpose vehicles. These blended baselines have been created in response to information received during meetings with EMA using a weighted average of the GEM performance of two very different vehicles: one with a 10-speed manual transmission and one with a 6-speed automatic transmission. See RIA Chapter 2.9.2. We believe that these changes enable the final Phase 2 program to better measure the improvements in fleet performance beyond that being achieved by today’s vehicles.

In response to comments that the metric of the standard, grams per ton-mile and gallons per ton-mile, is inappropriate for some vehicles, we have determined that the simplification of a single metric for all vehicles is warranted. In Phase 1 the agencies considered other metrics, in view of the fact that not all

---

176 See memorandum dated July 2016 titled, “Summary of Comments on Vocational Vehicle Baselines.”
177 See Memo to Docket, “Summary of Meetings and Conference Calls with the Truck and Engine Manufacturers Association to Discuss the Phase 2 Heavy-Duty GHG Rulemaking,” August 2016.
vehicles have a primary purpose to haul freight. Some vehicles carry passengers and others conduct work while in stationary mode sometimes operating a device through use of a PTO. Nonetheless, we are adopting Phase 2 standards using the same metrics we adopted in Phase 1. Based on NAS’s recommendation and feedback from the heavy-duty truck industry, NHTSA and EPA are adopting standards for vocational vehicles that are expressed in terms of moving a ton of payload over one mile. Thus, NHTSA’s final fuel consumption standards for these trucks are represented as gallons of fuel used to move one ton of payload one thousand miles, or gal/1,000 ton-mile. EPA’s final CO2 vehicle standards are represented as grams of CO2 per ton-mile. The agencies note that the commenter claims that a payload-based metric is not appropriate for all types of vocational vehicles, specifically buses and waste haulers. The agencies recognize that a payload-based approach may not be the most representative of an individual vocational application; however, it best represents the broad vocational category, and is appropriate for this phase of standards. Furthermore, by creating two new idle cycles with emissions and fuel consumption measured per hour over those cycles, we are in essence incorporating an alternate metric as part of the standard-setting process. Furthermore, a more differentiated metric would not affect the technology choices for vocational vehicles. Thus, the agencies are adopting the proposed metric, but will revisit the issue of metrics in any future action, if required, depending on the breadth of each standard.

6.2.2 Comments on the Standard-Setting Process

Organization: Truck & Engine Manufacturers Association (EMA)

In developing their multi-subcategory approach, the agencies apparently became concerned that the differing proposed standards for the different vehicle subcategories might incentivize vehicle manufacturers to certify their vehicles in certain categories over others. For example, if the relative stringency and cost of the proposed standards for the heavy-duty Urban subcategory are deemed more onerous than for the Regional and Multi-Purpose subcategories (given the differing underlying assumptions, including those regarding hybrid penetration rates and other factors), there is a perceived risk that manufacturers might try to avoid having to certify vehicles within that subcategory. This prospect for potential “gaming” of the proposed regulatory scheme – in itself, an unrealistic concern – has led the agencies to introduce a “normalization” process that is overly-complex and fundamentally problematic – in effect, resulting in an unreasonable “solution” to an unlikely problem. [EPA-HQ-OAR-2014-0827-1269-A1 p.29-30]

In their “normalization” process – ostensibly designed to help ensure that all of the proposed vocational standards reflect the same relative stringency – the agencies have assumed that a certain percentage of vehicles in each weight category will fall into each of the three cycle-based subcategories. For example, the agencies have assumed that the medium heavy-duty category is comprised of 25% Regional vehicles, 50% Multi-Purpose vehicles, and 25% Urban vehicles. The agencies then used that assumed mix of cycle-based categories to derive GHG/FE targets for where the Proposed Phase 2 Standards should be set, again premised on assumptions regarding available technologies and forecasted penetration rates. However, the agencies’ multistage layering of multiple assumptions has created significant risks of error at each stage of the assumption-building process. [EPA-HQ-OAR-2014-0827-1269-A1 p.30]

Beyond the likelihood of incorrect baseline assumptions about the nine vehicle subcategories, the numeric output of the agencies’ “normalization” process – which according to the agencies’ own admissions is

178 Responses to comments on the metric of the Phase 1 standard may be found beginning on page 230 of the Phase 1 response to comments document, available at https://www3.epa.gov/otaq/climate/documents/420r11004.pdf
still subject to substantial revision – is fundamentally incorrect as well. For example, the GEM-based output for determining where the Phase 2 Standard should be set for the heavy heavy-duty Urban vehicle subcategory is 219 g CO2/ton-mile. That is the result obtained if the full GHG technology mix as predicted by the agencies is fully deployed for heavy heavy-duty Urban vocational vehicles. However, the “normalized” output for determining the Phase 2 Standards for that same type of vehicle is 209 g CO2/ton-mile, a result that is more stringent than the GEM-based approach, and thus, on its face inherently infeasible. A manufacturer cannot be expected to achieve a Phase 2 GHG/FE result that is better than the fully optimized GEM-based result. Consequently, a “normalization” process that makes achieving the Urban-cycle-based Phase 2 standards even less feasible will not reduce manufacturers’ incentives to avoid the Urban category; it will increase them. [EPA-HQ-OAR-2014-0827-1269-A1 p.30]

It is fundamentally insufficient and unreasonable for the agencies to try to rely on potential future averaging, banking and trading (“AB&T”) credits in support of infeasible vocational vehicle standards. In that regard, the agencies state as follows at page 40308 of the NPRM: [EPA-HQ-OAR-2014-0827-1269-A1 p.30]

“We are aware that in this approach, some of the projected technology packages would not provide a direct path to compliance for manufacturers, such as in the example of the MHD Regional vehicle. Using the technologies adopted at projected rates, it would still fall short of the standard by 1.5 percent. The agencies believe that the Phase 2 program has enough regulatory flexibility (averaging, banking and trading provisions in particular) to enable such a vehicle to be certified.” (80 FR at 40308). [EPA-HQ-OAR-2014-0827-1269-A1 p.30]

That rationale cannot sustain an infeasible rulemaking. AB&T provisions are not a substitute for the logical and transparent development of well-reasoned and feasible standards. Moreover, AB&T credits are inherently dependent upon achieving product mixes and over-compliance capabilities that may not occur. Consequently, while the agencies may “believe” that their Phase 2 vocational vehicle standards are feasible, that belief, divorced from the necessary real-world demonstration, cannot sustain a federal rulemaking. [EPA-HQ-OAR-2014-0827-1269-A1 p.31]

**Organization:** Truck & Engine Manufacturers Association (EMA)

As noted, one fundamental problem with the NRPM is that the Proposed Phase 2 Standards for vocational vehicles are still subject to ongoing revision as the agencies are continuing to modify the “normalization” process that they are using to try to “align” the relative stringency of the proposed standards, as assessed under the proposed Urban, Multi-Purpose and Regional test cycles. Apparently, the agencies are endeavoring to “normalize” the results obtained from GEM, and thus the relative stringency of the proposed standards, under each of the Urban, Multi-Purpose and Regional cycles, so manufacturers are not incentivized to classify their vocational vehicles as one type over another. For example, if it is perceived to be harder for a vocational vehicle tested under the Urban test cycle to meet its targeted standards than it is for a vehicle tested under the Multi-Purpose cycle, manufacturers may skew their vocational vehicle subcategories accordingly. [EPA-HQ-OAR-2014-0827-1269-A1 p.40]

The problem is that the agencies’ “normalization” process is not complete. Nor is it transparent or logical. In fact, it seems that the agencies are still trying to figure out how best to “balance” the different results obtained from the different vocational test cycles. Consequently, manufacturers are being forced to comment on the stringency of standards that remain subject to change as a result of “normalization.” That is neither fair nor in accordance with requisite rulemaking procedure. If the Proposed Phase 2 Standards for vocational vehicles were still subject to further internal review and modification by the agencies, promulgation of the NPRM as it pertains to those vehicles should have awaited completion of the pending
“normalization” process. Simply stated, manufacturers should not be required to assess and comment on moving regulatory targets. [EPA-HQ-OAR-2014-0827-1269-A1 p.40]

It is not a sufficient answer for the agencies to claim that changes to the GEM-based determination of “normalized” GHG/FE standards would not amount to changes to the stringency of the proposed standards. They would, and they are. Manufacturers must have the ability to assess compliance with fixed numeric standards in order to determine whether their available and projected technology packages, along with their unique product mixes within the proposed subcategories of vocational vehicles, can meet those fixed numeric standards. Otherwise, any feasibility assessment becomes a theoretical exercise divorced from the certainty required under a proper notice-and-comment rulemaking process. In sum, in the absence of fully fixed vocational vehicle standards, manufacturers cannot properly assess the potential infeasibility of those standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.40]

Moreover, the agencies’ assumptions regarding the percentages of vocational vehicles that would fall into each category are dramatically different from the percentages based on manufacturers’ experience, which indicates additional fundamental errors in the agencies’ “normalization” process. On top of that, the applicable vocational duty cycles are not yet settled. Those cycles are integral to determining the potential GHG/FE impacts of available technologies and the appropriate stringency of the Phase 2 Standards.

Organization: Daimler Trucks North America LLC

Normalization and Equalization Must Be Eliminated - The agencies discuss additional vocational vehicle categories and the manner for baselining then request comment on whether the proposed configurations adequately represent a reasonable range of vocational chassis configurations likely to be manufactured in the implementation years of the Phase 2 program. 80 FR 40308. We comment elsewhere on the additional categories. As we have discussed in meetings with the agencies, we think that the baselines and the normalization/equalization processes are inappropriate. In particular, with the baselines, we find that the agencies’ technology packages do not meet the emission standards and FE requirements because of these normalization and equalization processes. In other words, the processes make otherwise feasible technologies incapable of meeting the standards. That is not appropriate. The agencies should choose categories of vehicles correctly and should eliminated normalization and equalization. [EPA-HQ-OAR-2014-0827-1164-A1 p.74-75]

Further, we are unable to provide any meaningful input to the agencies on the vocational vehicle portion of the program, even at this late stage in the rulemaking. The agencies have not yet clarified (for example) how vehicles will be categorized and how problems like normalization and equalization will be eliminated. We understand from discussions with the agencies that the NPRM’s proposal for a “deep integration” benefit, which (as we explained in our response to the NPRM) was unclear and (as far as we can tell) not related to an actual facet of vehicle engineering, and which would have required onerous powertrain testing, has been eliminated from the proposal—a correct choice. And we understand that the agencies’ analysis of drive cycles for vocational vehicles shows a much greater value of idle-reduction technologies, which seems consistent with real-world data we have seen. Beyond this, we are unable to actually model our vocational vehicles in GEM to provide any meaningful comments to the agencies on their proposed regulations. With regard to the agencies’ investigation of the benefit of hybrid technology we like to point out that there is a difference between the energy that could potentially recuperated and the energy that can actually be recuperated. Once actual conversion efficiencies and other system limitations (i.e. how fast can the battery absorb and discharge energy) come into play, hybrids should be expected to perform significantly worse than the agencies expected. That is why we strongly urge the agencies to incorporate these considerations into any projection of potential hybrid savings. Otherwise this will lead
to an inaccurate assessment of hybrid benefits and unrealistic expectations of CO2 reductions that cannot be met in the real world. [EPA-HQ-OAR-2014-0827-1918-A2 p.2]

**Organization:** Navistar, Inc.

As briefly noted above, the NPRM contains a proposal for vocational vehicles that has been developed with a “normalization” process utilized to adjust the MY2017 standard baseline and thus adjust the current standards accordingly. [EPA-HQ-OAR-2014-0827-1199-A1 p.31]

The NPRM contains only a reference to the RIA, which contains only one paragraph and a table that explains this process. The process sets out a set of assumptions that the agencies applied to “normalize” across vocational vehicle categories to adjust the baseline. [EPA-HQ-OAR-2014-0827-1199-A1 p.31]

The process uses assumed populations for various classifications, including urban, regional and multipurpose, to which apparently arbitrary population percentages are then applied. The resulting proportions are then applied to the 2017 emission baseline (the 2017 standard), resulting in modified beginning points. As a result, the starting point is not where it should be, the MY2017 vehicle emission standards, but instead reflects some adjusted standard. No significant explanation is given as to why certain numbers were chosen, including the percentage of vehicles assigned to various cycles. [EPA-HQ-OAR-2014-0827-1199-A1 p.31]

It is difficult if not impossible to adequately comment on this portion of the proposal. From what we can tell, the proposal uses arbitrary populations and adjustments and cites no actual data in support of its percentages. It also appears that this proposal seriously misrepresents the actual classification of vehicles. This results in a seriously skewed starting point, since the assumptions that an emission limit can be met are based on assumptions about penetration rates for new technologies in various vehicle classifications. If those assumptions are wrong, the bases for the emission standards are wrong and, therefore, the standards themselves are wrong. [EPA-HQ-OAR-2014-0827-1199-A1 p.31]

In particular, we think the normalization incorrectly stated the populations. Currently, we think that the percentages are off as much as 20% in some categories. This will inappropriately penalize some manufacturers and benefit others, based on their particular mix. Some manufacturers, because of this mix, may adopt all of the technologies assumed in the RIA yet still not reach compliant levels because of the arbitrary normalization, which skews the actual emissions goals based on incorrect assumptions of the current product mix for the industry. [EPA-HQ-OAR-2014-0827-1199-A1 p.31-32]

Normalization or equalization could benefit one manufacturer over another based on their mix. It is likely that the unknown elements of the regulation could translate into a rule that drives customers to the incorrect specification for their application or to avoid upgrading their vehicles entirely. This normalization should be eliminated from the rule. [EPA-HQ-OAR-2014-0827-1199-A1 p.32]

**Organization:** Volvo Group

In setting stringencies for the Phase 2 regulation the agencies have included technologies, penetration rates and processes such as “normalization” that, by their own admission (see below), result in targets that are not attainable even using the proposed technology packages and penetration rates. Volvo Group agrees that the Averaging, Banking and Trading (AB&T) flexibility provision is necessary to help meet individual customer needs and to offset any one OEM’s product mix and market share in each segment. However, we also believe that stringencies for any one market segment must not be based on the
This is best illustrated within the vocational vehicle subcategories, where the agencies have set stringencies that cannot be attained with their own technology packages, let alone after accounting for realistic penetration rates. One example of this is the normalization process that the agencies used, supposedly to avoid an incentive to certify vocational vehicles in a less stringent subcategory. The agencies state in Section V.C.2.b of the Preamble that they “are aware that in this approach, some of the projected technology packages would not provide a direct path to compliance for manufacturers...Using the technologies adopted at projected rates, it would fall short of the standard.” but that the “Agencies believe that the Phase 2 program has enough regulatory flexibility (averaging, banking, and trading provisions in particular) to enable such a vehicle to be certified.”[EPA-HQ-OAR-2014-0827-1290-A1 p.30-31]

Indeed, any vehicle can be certified regardless of its performance when compared to the standard. However, it is completely unacceptable that the Agencies promulgate a regulation where an entire class (regulatory subcategory) of vehicles is known and intentionally targeted beforehand to be incapable of meeting the standard for that subcategory when utilizing the full technology package and the expected penetration rates used to set the standard. [EPA-HQ-OAR-2014-0827-1290-A1 p.31]

Another example of this is found in the very first paragraph of the aforementioned section of the Preamble where the Agencies state “the proposed standard stringency does reflect, to some extent, the ability of manufacturers to utilize credits. For example, we project that hybrid vehicles would generally be certified in the urban subcategory and would generate emission credits that would most likely be used in the other subcategories within the weight class group.” This is compounded by the Agencies’ inclusion of the same 18% penetration rate of hybrids in the vocational Multi-purpose subcategory as they have assumed in the urban subcategory, even with the aforementioned statement around their projection of most hybrids being certified in the urban subcategory. [EPA-HQ-OAR-2014-0827-1290-A1 p.31]

The Agencies’ position leaves OEMs susceptible to non-compliance if they cannot offset a negative balance of credits within three years. This will, given the Agencies’ position, put OEMs at the mercy of their product mix and market strength across the vehicle subcategories. Per the Agencies’ example in the referenced section if an OEM is dominant in the MHD Regional subcategory in MY2021 and had little participation in the other MHD vocational subcategories then that OEM would have no way to accrue an average positive credit. The only way an OEM can meet the normalized standards given the Agencies technology packages and penetration rates is to match the 25%-50%-25% vocational product mix in the Regional, Multipurpose, and Urban subcategories respectively, or to over-comply, which few, if any, OEMs will be able to do. Volvo Group’s sales do not match this assumed mix, nor have the Agencies provided any data to support their assertion that the general market matches this mix. [EPA-HQ-OAR-2014-0827-1290-A1 p.31]

As requested elsewhere in this document and within the EMA comments, we request that the standards set for each regulatory subcategory be set based on the ability to meet the standard for that regulatory subcategory with a reasonable penetration of technically and commercially feasible technologies for that subcategory, and that subcategory alone, in the timeframe of the regulation and its’ individual stringency steps. [EPA-HQ-OAR-2014-0827-1290-A1 p.31]

**Organization:** California Air Resources Board (CARB)
CARB staff recommends that U.S. EPA and NHTSA re-examine the weighting procedure used to set equivalent standards for the three subcategories of vocational vehicles in the NPRM. CARB staff agrees it is important to set the standards so manufacturers do not have an incentive to purposely “misclassify” their vehicles. However, CARB staff is concerned that the method described on page 40308 of the NPRM may inadvertently present just such an incentive. [EPA-HQ-OAR-2014-0827-1265-A1 p.52]

In the example on page 40308, the NPRM explains that for one technology that would provide a 5 percent benefit for regional vehicles, 7 percent for multipurpose vehicles, and 8 percent for urban vehicles, when setting the proposed standards, they weighted the reductions and assumed 6.6 percent benefit for all three subcategories. CARB staff is concerned that a manufacturer using such a technology would have an incentive to classify their vehicle as urban (to show an 8 percent benefit) even if their vehicle actually would fit more appropriately in the regional or multipurpose subcategories (where the device would show only a 5 to 7 percent benefit). CARB staff encourages U.S. EPA and NHTSA to re-examine whether it may be more appropriate to set differing standards for the differing vocational vehicle subcategories, to remove this potential incentive for misclassification. [EPA-HQ-OAR-2014-0827-1265-A1 p.52-53]

Response:

At proposal our standard-setting process included a process described as ‘normalizing’, where the GEM-derived baseline values were adjusted prior to applying improvements, as well as an equalization process where subcategory-specific technology-based improvements were averaged before applying reductions to the adjusted baselines. The agencies have carefully considered all comments and we have reconsidered our standard-setting process. Now that we have revised our baselines in response to comment (as described above in section 6.2.1), we are more confident that we are reasonably representing the MY 2018 vocational vehicle fleet without needing to “normalize” the baseline GEM values. We also have revised our standard setting process to no longer include equalization. The stringency of the final standard for each of the subcategories is derived directly from the final technology package found to be feasible in each subcategory, without any fleet mix assumptions (i.e. equalizing assumptions) baked into the equation. We agree with comments noting that the equalization approach at proposal could have inappropriately benefitted one manufacturer over another based on their product mix. We also note that the equalization process as proposed would have made the standards for the Regional vehicles unattainable using the technology pathway identified by the agencies, thus motivating manufacturers to select less appropriate test cycles for vehicles that are designed for Regional service.

In comparing our relative stringencies in each subcategory with each respective baseline, the Regional vehicles are generally able to achieve the smallest percent improvement from the lowest (cleanest) baseline. By contrast, the Urban vehicles are generally able to achieve the greatest percent improvement from the highest (dirtiest) baseline.

The proposed normalization/equalization approach was motivated in part by a legitimate desire to avoid inappropriate subcategorization. In the final process to establish numerical standards, we conclude we have found a way to prevent enabling reasonably efficient vehicles in today’s fleet from avoiding installing any technology simply by certifying in an inappropriate subcategory. We do so by specifying certain equipment-related constraints – if a vocational vehicle is equipped with certain equipment then it cannot certify in a specified subcategory. The constraints we are adopting on selection of subcategory at the time of certification are discussed below in Section 6.5.1. Preamble Section V.C also discusses recent information relating to program structure and constraints on choice of duty-cycle and the agencies’ intention to continue discussions on these issues.

6.2.3 General Comments on Custom Chassis Standards
Custom Chassis Manufacturer Issues

Beginning on page 40294 of the NPRM, EPA recognizes the dilemma caused by smaller manufacturers who produce vehicles on their own chassis. The flexibility inherent in the Phase II regulations are not available to small volume manufactures as they do not have other categories of vehicles to average over. EPA suggests setting less stringent targets, or providing additional time to meet the targets, would be a way of addressing this dilemma. They also suggest limiting the volume over which this relief would be provided. [EPA-HQ-OAR-2014-0827-1162-A2 p.6]

The dilemma here is caused, not by the size or method of manufacturing, but by the almost certain fact that vocational vehicles cannot be designed to practically comply with the proposed regulations. If a large manufacture can produce a compliant truck for a specific vocation, then a small manufacturer can do the same. In anticipating the problem custom chassis manufacturers will have in meeting the Phase II criteria, EPA is essentially admitting that the criteria is unlikely to be attainable without the averaging component of the regulation. Large manufactures will not make compliant vocational vehicles, they will simply rely on credits from their high production models make up the difference. [EPA-HQ-OAR-2014-0827-1162-A2 p.7]

We suggest that the Phase II regulations must limit mandates to realistic and practical improvements that can be met for each vocation, and then applied equally to all manufacturers. The NRPM has two suggested solutions: [EPA-HQ-OAR-2014-0827-1162-A2 p.7]

1) Provide relief through less stringent regulation of low volume vocational vehicles, but place a limit on the sales volume. [EPA-HQ-OAR-2014-0827-1162-A2 p.7]

2) Provide extra time to meet the more stringent regulations. [EPA-HQ-OAR-2014-0827-1162-A2 p.7]

We believe that both of these approaches are flawed. If more stringent regulations are impractical and cannot be met, then less stringent regulations on a limited production volume stifles a custom chassis manufacturers’ opportunity to grow their business. Providing extra time to meet an impossible target simply delays the inevitable. [EPA-HQ-OAR-2014-0827-1162-A2 p.7]

It is an inherent fact that most efficiency related innovations in heavy vehicle components come first on high volume applications. This is natural because the large fleets who purchase high volume trucks are most sensitive to fuel economy improvements, and component suppliers have a greater incentive to invest in new product development when the potential sales volume is greater. Vocational vehicle manufactures are therefore not in a position to influence components such as engines, transmissions, axles, tires, wheels, drivelines, etc... where the EPA is presuming the majority of efficiency improvements will come from. [EPA-HQ-OAR-2014-0827-1162-A2 p.7]

While not part of the NODA, an agency memorandum on alternative approaches to certifying specialty vocational vehicles, or custom chassis, has recently been added to the docket. The two approaches are a simplified model of GEM similar to Phase 1 and a minimum applied technology package. The vehicles that these could be applied to are motor homes, intercity coaches, school buses, transit buses, refuse trucks, cement mixers, and emergency vehicles. These vehicles together represent around 20 percent of
vocational vehicle sales, with motor homes being the largest contingent. [EPA-HQ-OAR-2014-0827-1896-A1 p.5]

The standard for these vehicles proposed in the memorandum is significantly weaker than the proposal for every single class of vehicle, by an average of between 5 and 7 percent. This means that if manufacturers take advantage of this approach for the 20 percent of the fleet that is eligible, the vocational vehicle standard would need to be strengthened by more than 1 percent, on average, to offset the application of these standards and maintain the environmental benefits of the proposal. [EPA-HQ-OAR-2014-0827-1896-A1 p.6]

If manufacturers are able to identify these specialized classes of vehicle as would be required to take advantage of this proposal, then they should also then be able to take advantage of the most appropriate fuel-saving technologies for that unique duty cycle (e.g., aerodynamic improvements for motorcoaches that spend extensive time at high speed cruise). The ability for manufacturers to identify these applications should therefore result in a more stringent vocational vehicle target for these custom chassis, not less. [EPA-HQ-OAR-2014-0827-1896-A1 p.6]

Furthermore, the simplified compliance pathway eliminates incentives for technologies directly applicable to these vehicles, including transmission improvements and hybridization. This is especially concerning for intercity buses, school buses, and refuse trucks, all of which are ideal applications for powertrain improvements that would not be captured or incentivized under this approach. This could significantly undermine the vocational vehicle target and erode benefits of the rule. [EPA-HQ-OAR-2014-0827-1896-A1 p.6]

Simulating the technology packages identified in the memo with GEM P2v1.1 resulted in a shortfall for the vehicles ranging from 3 to 17 percent, which yielded an approximate sales-weighted average of 7 percent. Accounting for the reweighted drive cycles would reduce this average to 5 percent, with only motor homes having a standard that is as strong as the proposed vocational vehicle target for its class.

Organization: Autocar, LLC

EPA’s Memorandum Proposes an Ineffective and Costly Compliance Scheme.

Simplified GEM Misses the Mark. Autocar disagrees with EPA’s conclusions and compliance suggestions in the Memorandum and is seeking an opportunity to provide formal comments to this substantive rule proposal that appears to be largely based on the data in the NODA. Although Autocar appreciates EPA’s attempt to provide a more manageable compliance construct for vocational custom chassis manufacturers, the diversity of the applications, and the unique characteristics of refuse drive cycles and payload needs in particular, render the data and the proposed technologies unusable, as set forth in this section. [EPA-HQ-OAR-2014-0827-1885-A1 p.5]

If Adopted, EPA’s Proposal Will Require Autocar to Certify Some of its Vocational Chassis to the Full Greenhouse Gas Emissions Model (‘GEM’), while Refuse Chassis Will Have only Limited Variables to Certify to in Simplified GEM. Autocar acknowledges that EPA is attempting to address certain of Autocar’s concerns set forth in its October 1, 2015 Comments, incorporated herein, in proposing an alternative compliance scheme to full GEM certification. In particular, Autocar appreciates EPA’s willingness to develop separate standards for vocational vehicles manufactured as custom chassis, and EPA’s recognition in the Memorandum that certain manufacturers in these vocational segments will not be able to avail themselves of banking and averaging credits to comply with the Proposed Regulations. However, Autocar respectfully notes that some of the suggestions in the Memorandum, while well-

EPA's Proposal for Simplified GEM as a Compliance Path Does Not Include Conventional Refuse Trucks, Street Sweepers, Concrete Pumpers or Other Vocational Custom Chassis. If Simplified GEM is available only for Autocar's refuse chassis, and not for its chassis that are final-stage manufactured into street sweepers, asphalt patchers, striper and blasters, concrete pumpers and conveyors, aircraft deicers, refuelers and stockers and sewage suction trucks, then Autocar will still be burdened with full GEM compliance obligations, for these highly customized and low-volume chassis applications. Assuming this bifurcated compliance structure was not intended, the agencies have no basis to exclude these applications as vehicle types covered by the Memorandum because these other vocational applications have operating characteristics that are similar to some of the vehicle types covered by the Memorandum (i.e., low-speed/frequent-stop PTO usage). Had the NREL Report mapped these applications' drive cycles, it would have provided an adequate basis for crafting standards and determining compliance technologies for these vehicle types (see Section 1.2 for further discussion of this issue). [EPA-HQ-OAR-2014-0827-1885-A1 p.5-6] /8/ All of these applications together constitute less than 130 annual chassis sales for Autocar.

EPA's Proposal for Simplified GEM Allows Refuse Trucks Merely Seven Input Variables, Only Two of Which May Be Useful in the Refuse Segment. Tables 4-6 of the Memorandum indicate that refuse custom chassis will have to comply with Phase 2 through certification in Simplified GEM and specific adoption rates of five technology packages. Table 3 of the Memorandum suggests GEM inputs for Simplified GEM, and allows refuse chassis only seven technology package inputs, while the most significant fuel-efficient and emission-reducing technologies - certified engines and transmissions - are made a default (requirement), with no credit toward GEM compliance. Of the technology packages listed, only two are arguably useful in refuse truck applications: Low Rolling Resistance (LRR) Tires, and Tire Pressure Monitoring.

As noted in Figure 1, whether LRR tires can successfully reduce fuel consumption, and whether weight reduction can be achieved, are largely dependent upon the truck owner and the body builder, respectively, neither of whom are subject to the regulations. Other than engine and transmission producers, body builders may have the greatest potential for reducing GHG emissions by improving or changing PTO performance (PTOs are generally specified, procured and installed by body builders) and reducing weight, but there is no allowance for that possibility in the instant proposal. And with respect to vocational customers, who are likely to enjoy much less fuel-cost savings with these proposed technology packages than their long-haul tractor-trailer colleagues gain with their compliance requirements, they will not likely voluntarily seek these features. This puts Autocar in the position of having to market any components the agencies may compel, and that reduces its ability to comply because it cannot average, bank and trade credits. The agencies should consider the need to communicate the requirements for the proposed technologies to customers and additionally take measures to prohibit their removal or disabling after purchase. [Figure 1 can be found on p.7 of docket number EPA-HQ-OAR-2014-0827-1885-A1]

2.2.5 Compliance Efforts for Refuse Trucks May Be Futile. Using the information in the Memorandum and additional guidance provided by its author, Lauren Steele, but without the benefit of reviewing an actual Simplified GEM file (see Appendix 2 for Autocar's request for extension), Autocar attempted a refuse truck GEM simulation, using the defaults provided in Table 8 and the proposed technologies listed in Tables 4-6 of the Memorandum. [Appendix 2 can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1885-A2] TPMS and ATIS were not available in the model. 'Neutral at Idle' provided only a 2.8% improvement in emissions and consumption. 'Low Rolling Resistance Tires' provided only a
1.4% improvement in emissions and consumption. Even with the addition of either (but not both) TPMS or ATIS, the only remaining technologies available, it appears that any attempt to reach the required fuel savings and tailpipe GHG emissions reductions under the proposed compliance scheme is futile.11 [EPA-HQ-OAR-2014-0827-1885-A1 p.8] /9/ This additional guidance was provided in the form of a sample input file for use with the Phase 2 GEM, where certain rows indicated the types of vehicle configurations the agencies anticipate using to set the baseline 2018 performance levels for regular vocational vehicles using the full GEM program, and other rows indicated the types of vehicle configurations the agencies anticipate using to set the baseline 2018 performance levels for custom vocational vehicles using Simplified GEM. /10/ Although notably, the default engine in Table 8 is not available for Autocar's refuse trucks. /11/ The apparent impossibility of compliance under the Simplified GEM with the available proposed technologies may result from the non-representative drive cycle data and inappropriate defaults. Autocar believes it is similarly impossible to have default engines, transmissions, weight and payload for such diverse vocational vehicles.

2.3 With the Instant Proposal, Autocar Has Little Control Of Its Destiny. Regulations requiring the integration of certain technologies make Autocar entirely dependent on third party suppliers for compliance. This is a particularly precarious position for a small, low-volume business, subjecting it to the mercy of the suppliers with regard to lead time and pricing. Autocar is not vertically integrated and only installs suppliers' components; thus, Autocar does not enjoy the real flexibility EPA likely intended with technology-based packages. Also, refuse truck customers almost always specify desired components and may resist purchasing them at the adoption rates EPA suggested in Tables 4-6 of the Memorandum. In fact, specifying adoption rates less than 50% for certain technologies virtually assures the failure of this compliance scheme, as Autocar will be forced to market and sell to some customers more expensive and payload-displacing components, in order to obtain the required averages. Larger, more diversified chassis manufacturers could achieve these levels using credits from other vehicles, creating a lopsided market incentive. Unless all custom chassis makers are required to install the mandated technology packages on all vocational trucks, the agencies will have created a commercial imbalance in which a certain number of Autocar refuse customers, for example, will have to choose between buying a more expensive and component-laden Autocar chassis, or a non-compliant, but cheaper and lighter, competitive brand. [EPA-HQ-OAR-2014-0827-1885-A1 p.8-9]

3.5 Some Small Businesses Received Greater Flexibilities. In the Memorandum, EPA exempted manufacturers of emergency vehicles and cement mixers from compliance with Phase 2, requiring only that they install LRR tires on their vehicles. Manufacturers of recreational vehicles also have a lesser compliance burden than other vocational vehicle types. Neither the Memorandum nor the documents included in the NODA explain why emergency vehicles, cement mixers and recreational vehicles should be exempt, but not refuse vehicles. Moreover, Autocar and other small volume manufacturers assemble custom chassis in other heavy-duty vocational applications that are not addressed in the Memorandum, such as conventional (non-cab-over-engine) refuse trucks, concrete pumpers, street sweepers, tank trunks and sewer cleaners. Without explanation, these similar applications have been excluded from the proposed Simplified compliance scheme, and presumably require full GEM certification. This bifurcated approach will further unnecessarily burden small businesses. [EPA-HQ-OAR-2014-0827-1885-A1 p.12]

3.6 If EPA's Proposal is Used, It Must Not Allow Any Refuse Trucks to be Sold Without the Proposed Technologies. Given the questionable effectiveness of the proposed technologies to provide fuel savings to refuse truck owners (see Section 2.2.2 above), if the final regulations reflect the compliance scheme described in the Memorandum, then it is imperative that every vehicle of the same vehicle type be required to be sold with the same proposed technologies; meaning, the adoption rate of the proposed technologies must be 100%. If a customer knows it can purchase a vocational vehicle without ATIS, for example, it will find a manufacturer who will sell the truck without ATIS. That means that larger
manufacturers will have an advantage over small manufacturers, who cannot average, bank or trade credits, and that must be prevented. [EPA-HQ-OAR-2014-0827-1885-A1 p.12]

**Organization:** Daimler Trucks North America LLC

We are unable to provide meaningful input to the agencies on the proposal to allow a stripped-down GEM or to allow certification without use of GEM at all for certain types of vocational vehicles classified as “custom chassis.” The reduced procedural requirements may be beneficial to certain small or unsophisticated custom chassis manufacturers. But the primary issues are 1) whether all manufacturers, small or large, sophisticated or not, get to use the procedures and 2) what the substance of the program is, specifically, the actual emission standards. Regarding the first issue, we recommend that the agencies not create inequity in custom chassis markets by allowing some manufacturers of a type of vehicle to use a simplified procedure or meet a relaxed standard, while requiring other manufacturers of the same type of vehicle to play by other rules. Rather, it should be the type of vehicle, and not the type of manufacturer, that determines the rules that apply. Regarding the second issue, in proposing the reduced procedural burdens (e.g., at a webinar on March 22), the agencies described example standards a manufacturer might have to meet if it opted for the reduced procedural burdens (e.g., a set tire rolling resistance, Crr). It was not clear whether those standards are meant only as examples or as the actual standards, nor was it clear whether those standards are achievable by the various types of custom chassis. For example, the Crr’s were considerably lower than those on vocational vehicles built today, and it is not clear that new tire technology is being developed that will allow vocational operation while meeting the agencies’ proposed Crr’s. [EPA-HQ-OAR-2014-0827-1918-A2 p.3]

**Organization:** Navistar, Inc.

In a memorandum posted to the docket in February 2016, but not included in the NODA, 3 (“Vocational Memorandum”) EPA is proposing a regulatory scheme that is completely new and appears to carve out a less stringent rule for some vehicles based on the identity of the manufacturer. Even so, the proposal is only very roughly sketched out, and inadequate for meaningful comment. The NODA was an opportunity for EPA to share additional information on this portion of the rule, but the baseline, segmentation, structure, standards, and other key elements are still unknown. Although the GEM includes the technologies, it is uncertain what EPA’s stringency will be for any category, as GEM and the duty cycle weightings have changed so substantially since the NPRM. The Vocational rule covers an extremely diverse group of vehicles with hundreds of downstream equipment manufacturers. It is important that this portion of the regulation be structured correctly to ensure no adverse consequences. The custom program with a simplified GEM could provide an unlevel playing field for manufacturers.

Another key element is missing, as there is virtually no additional examination of costs as a result of this major potential change to the original proposal. The entire examination of costs is one sentence, in which EPA concludes that the average cost for custom vehicles would be less than the average for the rest of the vocational sector (presumably regulated by the proposal in the NPRM) under the scheme set out in the Vocational Memorandum. No explanation is given as to why this is the case or how this analysis was conducted. More distressingly, no explanation is given as to why this should be the case. No basis is given for dividing vocational vehicles into sectors with resultant differing manufacturing costs. As near as we can tell, the difference appears to be based on whether a company is diversified or not, although no meaningful explanation is given as to the basis for that division or any justification for the division. It appears to be a completely arbitrary distinction, between different vehicles presumably based on certain undefined aspects of the company that manufactured them, rather than the vehicles themselves. Navistar objects to such an arbitrary reclassification. This clearly has the potential to cause significant disruption in
Navistar is also concerned with that the NODA did not call attention to these potentially major changes. The Memorandum, dated February 12, 2016, discussing the custom chassis was not listed in the NODA as something for which the agencies are seeking comment. It appeared in the docket on February 25, 2016, which likely means there was sufficient time for it to be listed for additional comment in the NODA. As such, it appears that the agencies are contemplating a wholesale restructuring of the vocational program, and yet not seeking comment on the key document. While the NODA did seek comment on vocational segmentation in one document, this statement by EPA itself was not highlighted. [EPA-HQ-OAR-2014-0827-1919-A2 p.3]

3 Memorandum, Vocational Vehicle Technology Packages for Custom Chassis, February 12, 2016. EPA-HQ-OAR-2014-1719. We would also note that some level of customization is extremely common among all manufacturers, diverse or not.

Organization: Truck & Engine Manufacturers Association (EMA)

The agencies’ proposal to create separate Phase 2 Standards for seven categories of custom-chassis vehicles could result in an unlevel regulatory playing field for larger integrated manufacturers that provide non-custom chassis for the targeted vehicle applications (e.g., school buses). The agencies need to provide more details regarding this proposal to enable meaningful public comment. [EPA-HQ-OAR-2014-0827-1891-A1 p.4]

Organization: Volvo Group

Technology Packages for Custom Chassis – EPA-HQ-OAR-2014-827-1719

Volvo’s Opposition To The Custom Chassis Optional Standard

Based on the limited information available at present about the vocational vehicle program, the Volvo Group does not believe that an optional standard is warranted for small manufacturers, even if it is extended to larger OEMs. To the contrary, Volvo believes that the base vocational vehicle standards should be set such that all manufacturers can comply. This approach would also limit compliance burden, as well as provide for a level playing field. [EPA-HQ-OAR-2014-0827-1928-A1 p.12]

Under “Industry Characterization” on page 2 of the Custom Chassis document the agencies note that “it would be likely that the single-type (non-diversified) manufacturers would be able to certify their products as custom vocational vehicles, while only some of the multiple-type manufacturers (diversified) would have sufficient knowledge about, or control over, the intended use of their products to certify one or more types as custom vocational vehicles.” [EPA-HQ-OAR-2014-0827-1928-A1 p.12]

This explicitly states the agencies’ belief that most large OEMs would not be able to certify their vehicles to the simplified and less stringent standard, thus creating an un-level playing field that would give smaller manufacturers the ability to produce less technically complex, more reliable, and less expensive options for end-users. For this reason, the Volvo Group finds this provision completely unacceptable in its current form. [EPA-HQ-OAR-2014-0827-1928-A1 p.12]

A Manufacturer’s Ability To Comply Is Subject To Its Supplier’s Offering
The agencies' purpose for the custom chassis flexibility is to allow small manufacturers who cannot average over a larger mix of vehicle types the ability to meet the requirements of the Phase II GHG regulation without the need for credit averaging, banking and trading. This approach allows these manufacturers the ability to meet a simplified set of requirements, according to the agencies; however, it is not entirely clear whether this will actually be the case, as none of the targeted manufacturers produce their own components and, therefore, their ability to comply is subject to the product offering provided by their supplier base. As noted in the following section, this may result in an inability to provide a reliable and durable stop-start engine offering. [EPA-HQ-OAR-2014-0827-1928-A1 p.12]

Response:

At proposal the only type of vocational vehicle for which we proposed any less stringent standard was emergency vehicles. Although we asked for comments that could lead us to adopt separate standards for other vehicle types (80 FR 40294), the proposal on its face would have held all non-emergency and non-exempt vocational vehicles to the proposed standards that were predicated in part on significant adoption of a large menu of technologies that, on average, could improve the fuel efficiency of the U.S. vocational vehicle fleet by 12 to 16 percent. Thus, at proposal, we gave notice that we could finalize standards with that level of stringency and those associated costs for nearly all vehicles. If we had done so, any business that could not reasonably have applied a set of cost-effective technologies at adoption rates leading to compliance for any reason would have either had to purchase credits from a competitor or accrue a credit deficit.

During the course of the comment period and subsequent months of stakeholder outreach, we became aware that this outcome could be realized for some non-diversified manufacturers and we began to develop options with intent to prevent this. Upon careful consideration of all the comments related to vocational vehicle chassis manufacturers who produce non-diversified products, we are adopting optional standards for seven applications of vocational vehicles that we are calling custom chassis.

Although we had received informed comment regarding which technologies would not be cost-effective for each of these custom chassis in response to notice of what could be thought of as a worst-case scenario (higher costs and stronger technology packages than we intended to finalize), we decided to provide actual notice to manufacturers who build and certify chassis for these vocational applications, in the form of a memorandum to the docket along with a public web conference. By doing so, we offered another opportunity for affected manufacturers to weigh in on the reasonableness of the direction we were moving as we responded to previous comments. Commenters are correct that the memorandum provided only draft technology packages with adoption rates, without technology-specific effectiveness values or costs. The technology effectiveness and cost values were the same as those used in the proposed rules. Using this available information, preliminary package costs and stringencies for custom chassis could have been easily estimated by stakeholders. We thus disagree with Navistar that the memorandum was inadequate for meaningful comment. In fact, as evidenced by the detailed comments from UCS and other stakeholders found in the administrative record, we received ample comment and have been able to further refine the program in response.

We agree with the commenter that if manufacturers are able to identify that a chassis will be finished as one of the vehicle applications that are eligible to certify under the custom chassis program, then they

should also be able to take advantage of the most appropriate fuel-saving technologies for that unique
duty cycle. The optional standards for custom chassis are predicated on that exact premise.

Although the memorandum indicated that we were exploring adoption of three levels of standards with
the same implementation years as the primary program (MYs 2021, 2024, 2027), we are not adopting any
MY 2024 custom chassis standards in the final rules. Our reasons for this are related to regulatory
stability and incremental technology improvements. First, for those small businesses that may begin in
MY 2022, having a new standard in MY 2024 would only provide two years of stability between sets of
standards. Second, as presented in the Preamble Section V.B.2.b.ii, there are relatively small incremental
changes between MY 2021 and MY 2027 standards in terms of technologies that are within the control of
the vehicle manufacturer. We appreciate the comments from OshKosh and Volvo emphasizing the point
that the ability of a custom chassis manufacturer to comply is subject to the product offering provided by
its supplier base. Considering that the custom chassis user inputs exclude engine data, we have
established the numerical standards for both model years using default engines that meet the MY 2027
engine standard. This promotes better transparency because the incremental difference between the MY
2021 and MY 2027 numerical standard for each custom chassis subcategory is due solely to vehicle-level
technologies. By comparing the values in Preamble Tables V-12 or V-13, manufacturers choosing to
certify emergency vehicles, concrete mixers, motor homes, or coach buses under this optional path will
see that the incremental difference in stringency between MY 2021 and MY 2027 is two percent or less,
excluding the engine. Manufacturers choosing to certify transit buses or refuse trucks under this optional
path will see that the incremental difference in stringency between MY 2021 and MY 2027 is five percent
or less, excluding the engine. Manufacturers choosing to certify school buses under this optional path
will see that the incremental difference in stringency between MY 2021 and MY 2027 is less than seven
percent, excluding the engine.

Given that the GEM-based numerical standard is a target for manufacturers to meet on average, it thus
does not appear worth the extra programmatic complexity to set an intermediate target with a very small
incremental improvement. Even for school buses, where the incremental improvement is the largest, it
does not appear to be worth the extra programmatic complexity to have one custom chassis subcategory
with a MY 2024 standard where others do not.

As requested by commenters, we have estimated ranges of package costs for each of the custom chassis,
and simplified cost summaries are presented in Table 7 in the Executive Summary of the RIA. The
values shown below in Table 6-2 are taken from those tables. The ranges represent variations in cost that
are relative to different vehicle and engine weight classes.

Note:

a Diesel engine costs are included in average vehicle costs. These costs are based on our projected market adoption rates of various technologies and these costs include indirect costs via markups along with learning impacts. For a description of the markups and learning impacts considered in this analysis and how it impacts technology costs for other years, refer to Chapter 2 of the RIA (see RIA 2.11).

In response to the comment about whether the technology packages for custom chassis are feasible, we note that this comment is from Daimler, which provided sufficient information in its MY 2014 production report for the agencies to identify different vocational applications including motor homes. We have determined from these reports that of the nearly 6,000 class 6-8 motor homes certified by Daimler in 2014, they have an average drive and steer tire CRR of 6.1 kg/ton. Thus, it is reasonable that we predicate the MY 2021 Phase 2 motor home standards on adoption of LRR tires with CRR of 6.1 kg/ton and MY 2027 standards that are based on CRR improvements even slightly beyond that level.

In response to Volvo’s comment against offering an optional standard for a selection of vocational applications even if it is extended to larger OEMs, and setting a standard “such that all manufacturers can comply,” we interpret this comment to mean that the mandatory standards for all vocational vehicles should have a stringency on the order of the proposed Alternative 2. In that alternative, no transmission-related technologies would have been considered, instead the standards would have been predicated on adoption of lower rolling resistance tires, neutral idle, and axle lubricants. See Section 8.4 for responses to comments on consideration of less stringent alternatives.

In the final Phase 2 program, simplified GEM means that for some subcategories the full Phase 2 GEM is run with some input fields populated with agency defaults instead of user inputs. These defaults include the engine maps, transmission, drive axle ratio, tire revs/mile, and aerodynamic drag area improvement. In response to comments from Autocar and others, the available inputs for custom chassis have been expanded since release of the docket memo and the accompanying stakeholder outreach. In particular, manufacturers certifying vehicles to the optional custom chassis standards may now enter inputs in GEM for vehicle speed limiters, improvements over the separate hybrid PTO test, and electrified accessories, in addition to automatic engine shutdown that has since become available to all manufacturers. The simplified GEM has far more user inputs than the Phase 1 GEM, and allows for fair and reasonable
recognition of many feasible vehicle technologies with a lower certification burden than with use of full Phase 2 GEM.

We disagree with Autocar that the custom chassis standards are not achievable. With the standards being predicated on use of a different set of technologies than the standards of the primary program, the stringency is adjusted accordingly. For example, the refuse truck stringency in MY 2027 is 12 percent below the 2017 baseline, which includes a certified engine plus about six percent reductions attributable to vehicle technologies beyond the engine improvements. With the final drive cycle weightings in GEM and the characteristics of refuse truck baselines, applying neutral idle would result in reduced emissions in GEM of about 5 percent. If TPMS were added with a defined improvement of 0.9 percent, this could easily represent a path to compliance for a custom chassis refuse truck. Autocar is mistaken that the final rule mandates use of any particular technologies for custom chassis (or, indeed, any vocational vehicle), and we are not inclined to agree with their comment requesting that we mandate specific technologies on vehicles. The agencies have been promulgating performance-based standards for decades, and have found that this offers many benefits over a design-based approach, especially with respect to product variability and opportunity for manufacturer innovation. Even with excellent input from manufacturers and suppliers, we are not equipped to mandate specific technologies to be installed on any subcategory of vocational vehicles for the next decade or more. There are multiple feasible pathways for custom chassis manufacturers to attain the performance standards, even with a default driveline in GEM.

Furthermore, we disagree with Autocar that having a default driveline creates any sort of disadvantage. On the contrary, with a default driveline, vocational vehicles within a subcategory may be compared solely on the basis of the allowed user inputs, which facilitates a level playing field where some applications necessarily have features needed for vehicle utility that do not improve fuel efficiency in GEM. For example, the driveline gearing on a refuse truck may be such that its emissions over the Urban cycle could be higher than that of a typical urban work truck (See comments from Allison at EPA-HQ-OAR-2014-0827-1284-A1 p.45), putting it at a disadvantage in terms of the amount of additional technology needed to comply. In this case, having an optional standard where refuse trucks are compared on the basis of tire rolling resistance, workday idle reduction, and tire pressure systems (excluding engine, axle and transmission) minimizes any disadvantage associated with the driveline. If a manufacturer decides that the most cost-effective pathway to complying with Phase 2 is by certifying to the primary program where engine and driveline technologies may be recognized, that is an option for any refuse vehicle family in any year, for any manufacturer. Finally, the entire Phase 1 program is structured with default engines, transmissions, weight and payload where each subcategory of vocational vehicles is compared solely on the basis of tire rolling resistance. The use of defaults does not mean that vehicles are actually built similarly; rather, it provides freedom to build widely varying products without affecting regulatory status.

Use of simplified GEM as an optional certification tool is most easily justified in cases where either the typical duty cycle of the vocational application is poorly represented by any of the three final test cycles, or where we find that the default GEM vehicle characteristics are so different from real world characteristics (for example engine power to vehicle weight ratio) that use of full GEM with active simulation of actual driveline parameters would not reasonably test the effectiveness of applied technologies. Furthermore, use of a simplified GEM as an optional certification tool can also be justified where the certifying manufacturer produces small volumes of vocational chassis using a non-integrated business model where driveline optimization is not feasible and other transmission improvements would either be ineffective or not cost-effective. See Section 6.4.1 for responses to specific comments related to this issue.

In response to the comment requesting clarification on our reasons for adopting a non-GEM design standard option for motor homes, cement mixers, and emergency vehicle chassis, this is because we have
determined these vehicles have the least number of feasible technologies that can be applied in Phase 2. Emergency vehicles and concrete mixers have been determined by the agencies to essentially need only to apply low rolling resistance tires in addition to certified engines and low leakage air conditioning (i.e. stringency of the custom chassis standard for these vehicles is predicated on use of only these technologies). Motor homes have been determined to apply these technologies as well as tire pressure systems. Where a manufacturer of these vehicles is able to apply the same technology on all of its production without averaging, we offer the non-GEM option as a compliance flexibility to avoid the certification burden associated with running GEM. We were unable to identify other custom chassis technology packages that we believed could be applied at a 100 percent adoption rate; thus, averaging (and use of GEM) was deemed necessary for other vehicles.

We disagree with commenters that we need to explicitly include a large list of miscellaneous vocational vehicles in the custom chassis program. First, we have crafted definitions in the regulations that allow vehicles of similar characteristics to be reasonably certified to the custom chassis standards. For example, we would allow a bookmobile built on a motor home chassis to be certified as a motor home. Further, we believe that many of the low speed/off-road vehicles described in the above comments would likely be eligible for exclusion from vehicle-level GHG requirements pursuant to 40 CFR 1037.631. However, we agree with commenters that some of the vehicles described in the comments may legitimately have a need to travel at highway speeds or may need to conduct work that does not require an affixed component designed for doing off-road work. In response, the agencies have adopted additional flexibility whereby a vehicle partly meeting the criteria may optionally certify to the custom chassis standard established for concrete mixers.¹⁸⁰ This approach does not allow such vehicles to be excluded from applying any vehicle-level technologies, but does not require use of the full GEM certification path for vehicles where the full suite of technologies is not feasible. See Section 6.4.2 for further responses to comments on issues related to low speed/off road vehicles. Please see Section 6.4.1 below for more detailed responses to comments related to small volume manufacturers and small businesses.

In response to comments expressing concerns about the Phase 2 creating an unlevel playing field, we believe that forcing non-diversified manufacturers to certify to the primary standards that are predicated in part on use of technologies that are not universally feasible would create a disruptively unlevel playing field and potentially infeasible standards. By providing an optional path to compliance for those types of vocational vehicles that are either poorly represented by our regulatory baselines or for which reasonable technology options are severely limited, the agencies have created a regime allowing these specialized vehicles to certify based on standards most likely to result in real world benefits by setting appropriate standards. In addition, by creating this type of potential compliance path for the non-diversified manufacturers and permitting diversified manufacturers to choose this option where the end use of the vehicle is known at the time of certification, we believe we have structured Phase 2 to minimize the potential market disruptions due to this program.

Technology-Specific Comments

We believe that some custom chassis manufacturers are better positioned than others to adopt transmission technology to improve fuel efficiency. Most have little or no in-house research capacity, and purchase off-the-shelf transmissions. We agree with commenters that businesses that purchase components such as transmissions in the hundreds instead of thousands have less leveraging power and tend to pay higher prices. Some, such as Gillig and Autocar, have partnered with suppliers to successfully implement hybrids on their vehicles. Some bus chassis manufacturers are exploring the benefits of applying transmissions with additional gears. In real world driving, vehicles with a lot of transient

¹⁸⁰ Vehicles must meet either 40 CFR 1037.631(a)(1) or 1037.631(a)(2) but need not meet both.
operation including custom chassis with urban driving patterns, can see real fuel savings from adoption of improved transmissions, including those with more efficient gears and advanced shift strategies. We expect that suppliers will continue to develop improved transmissions for vocational vehicles including some custom chassis, and that manufacturers will continue to select transmissions that deliver reliable products to fuel-conscious customers. Specifically, we believe that bus manufacturers will continue to have choices of competing products that offer performance characteristics that improve over time. However, we believe that a final Phase 2 program that is impartial to these transmission-based improvements for custom chassis will avoid adverse unintended consequences for reasons similar to those given in response to Allison’s refuse example above.

Because we agree with commenters that motorcoach buses and school buses can reasonably apply transmissions with a higher number of gears (with wider spread of gear ratios), we have revised the regulations applicable to manufacturers opting to use simplified GEM to permit recognition of this technology in a simplified manner. Below in Section 6.3.3 we explain how we have addressed comments specifically related to adoption and effectiveness of transmission technologies on custom chassis.

We disagree with commenters that locking out the driveline inhibits adoption of hybrids for custom chassis. In fact, we believe it may offer an incentive in some cases. In the final Phase 2 program, all hybrid systems certified with full GEM must undergo the complete set of tests for engine mapping (including powertrain testing as applicable) and must meet OBD requirements as well. However, manufacturers certifying hybrid vehicles with simplified GEM need not undergo such testing, and where the certified configuration does not rely on functioning of the hybrid system to comply, it need not meet the hybrid OBD requirements of 40 CFR 86.010-18(q). Further, where the hybrid system includes a stop-start function, the manufacturer may select “Yes” as a GEM input for this feature and obtain reduction emissions in GEM as determined by the default engine. As a result, custom chassis manufacturers have a pathway to sell vehicles with hybrids that is similar in many ways to current practice under Phase 1, with opportunity for stop-start emissions credit without an unduly high certification burden.

We disagree with commenters that there is no allowance for weight reduction at the body builder level. The intended path to credit weight reduction is the table of lookup values for chassis components using preapproved values. However, the off-cycle approach is available for manufacturers who are able to demonstrate a lightweighting improvement over a baseline value, either on a component-specific basis or a system basis as approved. If the lightweighting for which certification credit is sought will be completed by a downstream manufacturer, the delegated assembly provisions may apply. See Section 6.3.9 for discussion of other comments on weight reduction, and Section 1.4.4 for discussion of comments on delegated assembly.

We disagree with commenters that the simplified GEM must recognize aerodynamic improvements for custom chassis. Although motorcoach buses do operate frequently at speeds where aerodynamic drag forces are strong, those vehicle bodies are so different from typical freight trucks that to improve the aerodynamics from buses, a very different set of technologies would need to be considered than the bolt-on fairings reviewed by the agencies in these rules. We imagine that some improvements could possibly be made through streamlining mirrors and redesigning frontal areas, however we have no information on the availability, cost or effectiveness of any such technologies. Thus, we have not identified any technologies likely to provide in-use benefit to coach buses, even in the primary program with full GEM. The types of aerodynamic technologies listed by the agencies as available for non-custom vocational vehicles are bolt-on fairings for which an improvement value may be entered in GEM to reduce the default drag area. Further, the default drag area in our baselines may not be reasonably similar to the drag area of a coach bus. If a coach bus or motor home chassis manufacturer were to conduct A to B testing pursuant to the test procedures of 40 CFR 1037.527, it may obtain an improvement value under the
primary program. Below in Section 6.3.10 we explain how we have addressed comments specifically related to adoption and effectiveness of aerodynamic technologies on vocational vehicles.

We disagree with claims made by commenters expressing concerns with respect to a shortfall or gap in emissions reductions between the primary vocational vehicle program and the custom chassis program. Some commenters have attempted to quantify a difference in stringency by comparing select technology packages for custom chassis described in a February 2016 memorandum with the proposed technology packages for comparable subcategories. Because most of the baseline configurations for the custom chassis are tailored for each vocational vehicle, the only vehicle types where this comparison is straightforward is school buses and motor homes. In comparing the MY 2027 stringency of the medium heavy-duty Urban subcategory with the optional MY 2027 standard for school buses, for example, it can be seen that diesel vehicles in the primary program are projected to achieve 22 percent improvement on average, while school buses are expected to achieve 18 percent improvement on average. This is nowhere near the gap posited by the commenter. The differences are due to the documented different projections of technology feasibility, which are discussed in more detail in the Preamble Section V and below in Section 6.3.

This comparison is not straightforward for motorcoaches and other custom chassis types, however, because the baselines are different and the vehicle attributes are not similar. For example, our baseline configuration for coach buses includes a 350 hp 11-liter engine with a 6-speed automatic transmission. However, the primary program includes a baseline for heavy heavy-duty Regional vehicles that is a weighted average of 95% with 455 hp 15-liter engine with 10-speed manual transmission and 5% with a 350 hp 11-liter engine with a 6-speed automatic transmission. As an example of a technology difference, we have determined that regular HHD_R chassis may reasonably apply AES on average at a rate of 90 percent by MY 2027, whereas we find that AES is not feasible at all for a conventional coach bus. A diversified manufacturer choosing to certify a coach bus in the HHD_R subcategory with full GEM is likely to need credits from other types of vehicles to meet the standard on average. A non-diversified coach bus manufacturer would be unlikely to achieve the HHD_R primary program standard unless some very advanced technology is applied. Therefore we do not believe it is accurate to draw a comparison between the HHD_R primary program stringency of 16 percent and the coach bus MY 2027 stringency of 11 percent.

6.2.3.1 UCS Custom Chassis Recommendations

Organization: Union of Concerned Scientists (UCS)

On May 9, 2016, UCS emailed a 15-page document to EPA with recommendations regarding the custom chassis program, with the following introductory paragraph: “Our analysis of the proposal indicates that in the form outlined in the memo included in the docket, this provision would significantly undermine the vocational vehicle program under the medium- and heavy-duty vehicle standards. Furthermore, our analysis of the technology available to these vehicle classes indicates that even these specialized vehicles would be capable of achieving the average vocational vehicle standard by 2027. Therefore, we recommend that any provision focused on custom chassis be focused on small business considerations with an appropriate volume cap, preserving the integrity of rule while recognizing the complexity of the vocational vehicle market.” This comment document is available in the docket.181

181 See UCS Custom Chassis Recommendations, May 2016
Response:

We appreciate the thoughtful comments from UCS on custom chassis. While we have several areas of disagreement, the industry characterization with respect to manufacturers, vehicle miles traveled, and sales volumes are significant contributions to the record for this rule. We are not directly responding to the aspects of this comment document where UCS estimated percent reductions, emissions in grams per ton-mile and metric tons, or perceived “shortfalls” (other than select examples above). This is because the final Phase 2 GEM, including duty cycles, final technology packages, and other program revisions since the time of the NODA have rendered such comparisons no longer relevant. We appreciate that UCS offers these comments in the spirit of helping to answer the questions of what a reasonable cost-effective technology package might be, and whether market constraints prevent companies from competing effectively where some lack an ability to average (UCS page 1). Although we have strengthened the custom chassis program in many ways in response to compelling comment, we have not seen persuasive evidence that any of these vehicle types should be excluded from the custom chassis program.

School Buses

- We agree with UCS on stop-start. The 30% adoption rate on which the final (optional) standard is predicated is what UCS recommended and is more than the 15% penetration rate set out in the memo. Custom chassis may select ‘Yes’ in GEM for neutral idle where a DCT is installed. Also, we are including a 70% adoption pathway of AES.

- We disagree on aero. NREL found that operating patterns associated with school buses have low average speeds with frequent stops and high amounts of zero speed time, which is not consistent with driving patterns associated with vehicles likely to benefit from aerodynamic improvements. This is noted by UCS in its comment on page 4. If a bus OEM has a customer that intends to use these in a regional driving pattern and wants to get credit for aero they may elect to certify to the primary program.

- We disagree on weight. The bus OEMs submitted comment cautioning us against predating the standard on weight reduction due to constraints of safety standards. If a bus OEM uses lightweight wheels, this may be included as part of a compliance strategy.

- We partially agree on transmissions:
  - Although we disagree that we should predicate the standard on use of DCT, one of the benefits of current MHD DCT is the wide gear spread offered by 7 forward gears. We have finalized a path to partially recognize the benefit of transmissions with additional gears, using a fixed technology improvement and an adoption rate of 15%.
  - We disagree that shift strategy/integration is feasible for these. Sales volume is not a sufficient criterion for deciding if this is feasible. It would take a business partnership between the engine OEM and transmission supplier to develop the integrated product, who would then sell it to the independent chassis manufacturer. Although these buses may seem to be high volume compared to some other types of custom chassis, this is still a niche market.

- We disagree with the suggestion to predicate the standard on use of natural gas or downsized engines. We did not even predicate the primary vocational vehicle standards on either of these technologies. See Section 12 for responses to comments on natural gas. See Sections 3 and 4 for discussion of downspeeding for engines and tractors.

- Although we have several areas of disagreement with UCS, we have made the final standards for school buses more stringent than first presented in response to compelling comment, including a simplified method for recognizing transmission technology, increasing adoption of stop-start in
the projected compliance pathway, and including 70% adoption of AES. These buses now have
the most stringent of all the custom chassis standards.

Transit Buses

- We partially disagree on idle. Although we are applying an adoption rate of stop-start at 30% in
  the FRM (less than the 50% requested), this is the same as in the primary program for MHD-
  Urban and is more stringent than the 20% in HHD-Urban. Transit bus is the only subcategory
  where adoption of drive idle reduction technologies (neutral idle plus stop-start) add up to 100%.
- We partially agree on weight. We disagree that the package should be 2,000-3,000 lbs. That
  would involve components beyond the chassis for which we do not have data. The same
  lightweighting package that is considered as part of the primary program standards is now applied
  for transit buses in the final rules. Where a bus OEM wishes to gain credit for lightweighting a
  component that is not listed in our regulations, it may apply for off-cycle credit.
- We disagree that we should predicate the standard on use of 10-speed automated manual
  transmissions. AMT are generally not suited for urban applications, and as noted above, most
  transit buses service urban routes. Express commuter buses may drive in regional patterns;
  however, the bus OEM’s have told us that they do not design buses differently for these
  applications (essentially most are designed to be multi-purpose) because transit authorities may
  re-assign any bus on any day to a different route.
- We have altered the axle configuration in the baseline as recommended by UCS, so that transit
  buses in the custom chassis program will have their performance measured against a reference
  vehicle with a 4x2 axle configuration, rather than a 6x4 axle (UCS Note 16, page 5).
- We note with interest that commenter does not recommend including hybrids in the stringency of
  the standard for transit buses. We support this conclusion, although from a pure cost
  effectiveness perspective, hybrids appear equivalent to lightweighting. According to the source
  that UCS cites (TIAX 2009), the cost of UCS’ recommended 3,000-lb lightweighting package is
  on the order of $30,000.\textsuperscript{182} TIAX estimates this could provide three percent fuel efficiency
  benefit. TIAX also reports that unsubsidized costs of hybrid systems for transit buses are on the
  order of $200,000, likely providing at least 20% fuel efficiency. Both of these technologies thus
  fall in the range of $10,000 per percent improvement. By contrast, none of the technologies
  projected as part of the compliance pathway in the final rules for the primary Phase 2 vocational
  vehicle program exceed $3,000 per percent improvement.
- We disagree with the UCS claim that a sales cap of 200 vehicles per year would cover 80 percent
  of this market. Gillig certified over 1,700 class 6-8 vehicles in MY 2014.
- Although we have several areas of disagreement with UCS, we have strengthened the transit bus
  standards in response to compelling comment, including addition of modest weight reduction and
  defining a more representative baseline. With the improved baseline and more stringent
  standards, the opportunity for windfall credits is reduced.

Coach Buses

- Although we disagree that we should predicate the standard on use of AMT, commenters provide
  compelling evidence that applying transmissions with more than 6 gears can be a cost-effective

\textsuperscript{182} See Table 3-7 of TIAX 2009, indicating a cost of $10/lb for lightweighting packages over 2,000 lb.
technology for these vehicles. We have finalized a path to partially recognize the benefit of transmissions with additional gears, using a fixed technology improvement and an adoption rate of 15%.

- Although coach buses do have regional driving patterns, as noted earlier in this response, we are not convinced that the bolt-on technologies identified for box trucks could be feasible for buses. If a coach bus manufacturer wants to get credit for aero, it may elect to certify to the primary program and conduct A to B testing to demonstrate a fuel efficiency improvement.

- We partially agree on axles:
  - We have altered our baseline as recommended by UCS, so that coach buses in the custom chassis program will have their performance measured against a reference vehicle with a 6x2 axle configuration, rather than a 6x4 axle (UCS page 7).
  - We disagree that we should predicate the standard on use of a lower numerical axle ratio. We have not applied downspeeding in any of the primary vocational vehicle standards.

- We wish to note an omission in the industry characterization for coach buses. Although the chassis manufacturers are large businesses, some coach buses are foreign-made and the importers are small businesses. These importers have a great deal of responsibility in the certification process, and the burden on them should not be ignored.

- Although we have several areas of disagreement with UCS, we have strengthened the coach bus standards in response to compelling comment, including use of a simplified method for recognizing transmission technology and defining a more representative baseline. With the improved baseline and more stringent standards, the opportunity for windfall credits is reduced.

Refuse Trucks

- We disagree that we should predicate the standard on transmissions with more than 6 gears. Refuse trucks with neighborhood collection routes may rarely use a 6th gear, and would not see real world benefits from additional gears.

- Although we agree that weight reduction is feasible for refuse trucks, we see this as simply regulating the status quo. As noted by OshKosh in its comments on weight reduction (see 6.3.9 below), less weight is a huge market driver in the refuse sector. However, we have not concluded that lightweighting has occurred to such an extent that it should be considered in the vocational vehicle Phase 2 baseline.

- Disagree on Axles: We disagree that we should predicate the standard on use of a lower numerical axle ratio. We have not applied downspeeding in any of the primary program standards.

- Disagree on idle: in response to other compelling comment, we have reduced the adoption (i.e. projected technology penetration rate on which stringency is calculated) of stop-start from 50% in the memo to 20% in the FRM. This is now the same adoption rate as for HHD Urban vehicles in the primary program. Because we believe it is appropriate to offer a PTO over-ride for stop-start systems, and many refuse trucks use PTO to compact while driving, a relatively small fraction of refuse trucks are likely to see real world benefits from stop-start systems that are not part of a strong hybrid or enhanced stop-start system that offers e-PTO function.

- We disagree with UCS comments with respect to Autocar. Although we note Autocar’s comments that indicate their annual sales have a 5-year average of over 50% of vehicles with advanced drivetrains including natural gas and hybrids, we disagree that an annual sales cap of 200 would provide any degree of flexibility for Autocar’s conventional vehicles. First, a 5-year average of 50 percent could still mean that in any single year less than 10 percent of their 2,000
refuse trucks had advanced drivelines. Further, prior to producing vehicles (when certification occurs), Autocar will not know how many will actually be sold; they may simply know if they plan to certify one family in the primary program and one family in the custom program. For these reasons and others as outlined in Section 6, we disagree that refuse trucks should be forced to certify in the primary program, and we disagree that a sales cap is appropriate for custom chassis refuse trucks.

- Based on compelling comment from manufacturers, we have relaxed the refuse truck standards including less projected penetration of stop-start and ATIS.

Motor Homes

- Disagree on transmissions: With a regional drive cycle and very low annual miles driven, we do not agree that adopting advanced transmissions (such as 7-speed DCT as suggested by UCS) for motor homes would provide any benefit to the vehicle owner.
- Disagree on aero. Although motor homes do have regional driving patterns, we are not convinced that the bolt-on technologies identified for box trucks could be feasible for RV’s. If a manufacturer wants to get credit for aero, it may elect to certify to the primary program and conduct A to B testing to demonstrate a fuel efficiency improvement.
- We have considered UCS’ recommendation to differentiate between Class A, B, and C motor homes. We agree that Class A vehicles have many similarities with coach buses, although the VMT is much smaller and they tend to be manufactured in very small numbers, some less than 100 per year. However, we believe the UCS industry characterization of Class B and C motor homes is in error with respect to the manufacturers of these vehicles. The certifying chassis manufacturer is generally not any of those listed; rather, it would more likely be Ford, Daimler, or Spartan. Because our final custom chassis regulations require that the certifying entity identify the vehicle type up front, we believe this presents a challenge for large diversified manufacturers. Because we believe that the motor homes sold by large diversified manufacturers could reasonably apply the same technology package as those sold by specialty manufacturers, we expect that these could be credit-using vehicles in large diversified fleets where manufacturers are unable or unwilling to track this production separately. Although it was not our intention to disadvantage large businesses, we believe it is acceptable in that having this flexibility be less accessible by large manufacturers than small businesses is protective of the environment.

Cement Mixers

- Although we agree that weight reduction is feasible for cement mixers, we see this as simply regulating the status quo. As noted by OshKosh in its comments on weight reduction (see 6.3.9 below), less weight is a huge market driver for cement mixers. However, we have not concluded that lightweighting has occurred to such an extent that it should be considered in the vocational vehicle Phase 2 baseline.

6.3 Projected Vocational Vehicle Technologies, Effectiveness, and Cost

6.3.1 General Comments about Vocational Technologies

Organization: California Air Resources Board (CARB)
CARB staff notes that stop-start and transmission market penetrations are significantly affected by a switch from Alternative 3 to Alternative 4. However, these technologies are either already starting to penetrate the vocational marketplace or have prototypes and demonstrations in place as of today; therefore, CARB staff views the nine years of lead time until 2024 as ample time to meet the penetration goals that U.S. EPA and NHTSA have proposed.

**Organization:** Natural Resources Defense Council (NRDC)

Additional analysis by UCS describes opportunities for fuel consumption reductions with transmission improvements and aerodynamic device applications among regionally-operated vocational vehicles. When considered along with improvements to diesel and gasoline engines and hybrid effectiveness, the UCS analysis finds that vocational vehicles can reduce fuel consumption and emissions by at least 20 percent, a significant gain from reductions in the proposal of up to 16 percent.¹⁵ [EPA-HQ-OAR-2014-0827-1220-A1 p.6] /15/ Analysis presented in UCS comments to the proposal.

**Organization:** Union of Concerned Scientists (UCS)

As illustrated below (Table 5), the current levels of stringency can be met entirely with conventional technologies, which is inconsistent both with the agencies’ proposed pathway and their obligation under the Clean Air Act and Energy Independence and Security Act to set technology-forcing and maximum feasible standards, respectively. The agencies must therefore increase the stringency of the regulations. [EPA-HQ-OAR-2014-0827-1329-A2 p.19]

Diesel-powered vehicles can be improved by 20.6 percent over the Phase 1 baseline (compared to an NPRM value of 15.8 percent). Gasoline-powered vocational vehicles can be improved by 21.9 percent over the Phase 1 baseline (compared to an NPRM value of 13.4 percent).² [EPA-HQ-OAR-2014-0827-1329-A2 p.19] [Table 5, 'Recommended Vocation Vehicle Technology Penetration and Effectiveness in 2027', can be found on p.20 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

**Organization:** CALSTART

We believe vocational segments could cost-effectively accommodate higher efficiency than is proposed and could be prime segments for some advanced technology implementation [EPA-HQ-OAR-2014-0827-1190-A1 p.1]

Because of the simplified structure of the Phase 1 regulations and the shorter lead-time, most advanced technologies, including strategies such as hybrid, plug-in and electric powertrains important to the NOx emissions strategies of such regions as California, were not included to set the stringency of the rule. In the Alternative 3 proposed for Phase 2, the agencies assume for the assessment calculations that some advanced technologies will penetrate the medium- and heavy-duty truck fleet in the timeframe of the rule, notably start-stop systems and some hybridization. [EPA-HQ-OAR-2014-0827-1190-A1 p.3-4]

Some of the technology that could provide greater efficiency and carbon reductions – such as plug-in hybrid and electric systems – will likely not be needed at current stringency targets, even though they are critical to goals in California and some other regions. These technologies can provide payback in the correct applications already identified in the Phase 2 segmentation approach; and these technologies, in their second generation and dropping in price, can provide life cycle paybacks to fleets that fall within the agencies’ assessment framework. [EPA-HQ-OAR-2014-0827-1190-A1 p.9-10]
However, we are very concerned that the vehicle segments most conducive to these technologies, such as urban vocational, are the ones whose stringency levels are least likely to drive their use. Feedback we have received from multiple suppliers developing such technology is that they share this concern: the proposed stringency will not require their use. While we support the agencies’ performance-based rules and technology-neutrality, the issue being raised here is not the need to drive any one technology, but rather the fact that achievable reductions are being left off the table. Interestingly, in discussions with suppliers about what mechanisms, including rule credit tools, could most help them bring such technology forward, most strongly felt higher stringency was what would most effectively “pull” their technology forward. Indeed, they believe credits are meaningless in the absence of any need for their use, which is driven by greater reduction requirements. [EPA-HQ-OAR-2014-0827-1190-A1 p.4]

**Organization:** XL Hybrids

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 242.]

By contrast, we feel that vocational cost targets are reasonable because the weight scalings become a more significant factor there.

**Organization:** Environmental Defense Fund (EDF)

We recommend that the agencies set more rigorous standards for vocational vehicles that meaningfully encourage advanced technologies like hybridization and electrification. The vehicle standard should be strengthened by reflecting the innovation of these manufacturers and recognizing transmission improvements possible in the timeframe of the standards *[as well as many technologies extracted from this comment and placed elsewhere]*. If all of these technologies are combined, the standards could be improved by about 7%. A robust vocational vehicle standard in 2027 would provide plenty of lead-time to develop and test these advanced technologies. [EPA-HQ-OAR-2014-0827-1312-A1 p.38]

**Organization:** Navistar, Inc.

As discussed in the sections above, the assumptions that underlie the feasibility for vocational emission standards in the Proposed Rules are extremely optimistic. We have significant concerns regarding the assumed technology packages and penetration rates underlying the emission standards for vocational vehicles. As noted, there are entire applications for which there will be virtually no adoption of certain technologies. Refuse trucks and cement mixers simply cannot stop the engine during their operations. To assume any penetration in those applications is incorrect. [EPA-HQ-OAR-2014-0827-1199-A1 p.40]

Beyond that, the NPRM and RIA do not clearly identify the necessary steps in the technology development nor do they identify why the agencies believe that these technologies will be ready in the time allotted. The absence of this information is particularly notable in light of the additional uncertainties that come with the lack of clarity in this Proposed Rule stemming from the baseline changes and model year start date differences between vehicle and engine, [EPA-HQ-OAR-2014-0827-1199-A1 p.40]

**Organization:** Truck & Engine Manufacturers Association (EMA)

The agencies’ assumed penetration rates for hybrid powertrain systems are unrealistic. Manufacturers also question whether neutral-idle systems can be deployed at the agencies’ assumed rates, and, if so, the adverse impact they will have on vehicle and engine component wear. Similarly, there are questions and concerns regarding the application of stop-start systems in HHD vehicles, including the deterioration of
certain components, the availability of other systems to maintain cabin comfort and starter systems, and various OBD implications. Vocational vehicles also cannot effectively utilize 6x2 axle configurations given the vehicles’ need for traction and operation in tight spaces. In fact, almost all of the agencies’ foundational premises and methods for establishing the proposed vocational vehicle standards are flawed. [EPA-HQ-OAR-2014-0827-1269-A1 p.31]

**Organization:** Motiv Power Systems

The agencies have made significant improvements compared to the MY2014-2018 standards, particularly in providing additional market segmentation options that reflect a larger share of transient operation as well as the addition of an idle-only cycle. These changes to the regulatory test cycles better reflect the diversity of the vocational fleet and the duty cycles of our customers and will help identify the appropriate technology solutions for reducing fuel use from this sector. [EPA-HQ-OAR-2014-0827-1184-A1 p.1]

Nonetheless, there are several modifications that should be made to the proposal to more effectively incorporate hybrid and plug-in powertrains in the future vision of the medium- and heavy-duty truck sector, thereby more significantly reducing oil consumption and greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1184-A1 p.1]

The agencies’ pathway to meet the standards under the preferred alternative underestimates the potential reductions from conventional technologies, particularly integrated powertrains, which are most advantageous in transient operation. It also underestimates the potential reductions from hybrids—fleets often achieve levels of reduction exceeding the approximately 25% effectiveness assumed in the agencies’ analysis of hybrids on the GEM certification cycle. And, finally, the agencies have completely excluded plug-in electric technologies in the preferred alternative. Underestimating the potential reductions from the vocational vehicle fleet across the board has thus led to a stringency level that is significantly lower than what the industry can achieve in the timeframe of the rule. Motiv, in particular, plans to have thousands of all-electric vocational vehicles on the road within the timeframe of this rule, and without greater stringency in the vocational vehicle segment, there will be no value to the credits these vehicles could otherwise generate. As shown with Tesla, credits for zero-emission vehicles can be a major influencing factor in the market development of clean, zero-emission technology because they allow for some re-capture of the benefits provided by these vehicles to the general population. [EPA-HQ-OAR-2014-0827-1184-A1 p.1]

The conservative target in the agencies’ preferred alternative can be met purely with conventional technology. However, advanced technology vehicles are available today and should see a continued growth in market share as component prices fall and fuel price volatility continues to remain a fleet concern. The proposed rule, as currently crafted, misses an opportunity to fully capitalize on the oil and emission reductions that our technologies offer by not appropriately accounting for these technologies in the overall stringency of vocational vehicles. Therefore, the stringency of the vocational vehicle standard should be increased by at least 20% or more to help ensure the investments needed for moving beyond incremental improvements to conventional technology and promote the adoption of advanced alternative powertrain vehicles. Furthermore without increased stringency, the effectiveness of advanced technology credits is severely limited as there isn’t a market for such credits when the standard is easily obtainable. Without stricter regulations driving investment and innovation, only incremental improvements will be captured despite the potential for broad emission reductions. [EPA-HQ-OAR-2014-0827-1184-A1 p.2]

**Organization:** Oshkosh Corporation

**Vocational Vehicle GEM Inputs are Too Optimistic**

Page 1171 of 2127
The Phase II NPRM suggests a laundry list of items in Table V-17 through V-19 that manufacturers would use to meet the more stringent vehicle standards. EPA suggests that there may be additional technologies, but we believe that if there were viable and practical additional technologies, they would already be on the list. The fact is that major improvements to basic heavy duty vehicle components take a long time and significant funding to develop. The components required to transfer rotating power from an engine to the road have not changed significantly, in part because the laws of physics have been well understood for many years. Unlike engine improvements where advanced controls can be applied to a combustion cycle, the nature of gears, shafts, and bearings do not lend themselves to revolutionary change. [EPA-HQ-OAR-2014-0827-1162-A2 p.3]

Heavy duty vocational vehicles provide essential services hauling heavy loads at moderate speeds and in mixed on/off highway conditions. Vehicle configurations are not conducive to aerodynamic improvements, and low production volumes relative to line-haul vehicles limit the incentive for component suppliers to invest in improvements. It is clear that idle reduction technologies cannot be used in many vocational vehicles where the engine is needed to continue ancillary equipment operation even when the vehicle is stopped. Large Allison transmissions used in these applications already incorporate electronic controls and torque converter lock-up technologies. We therefore urge EPA to limit Phase II vocational vehicle mandates to those improvements that can be gained from the engine alone. If significant improvements in the efficiency of other major components such as transmissions or axles become available over the next decade, then further regulation can be considered in Phase III. [EPA-HQ-OAR-2014-0827-1162-A2 p.7]

**Response:**

The agencies have established final vocational vehicle standards that carefully evaluate and balance the competing views of the commenters on the issue of how strongly to promote advanced technologies. In the subsections that follow, we describe how we have strengthened the final standards in a robust way that is supported by a strong technical analysis and relies partly on adoption of mild hybrid systems, although the technology path we identify to achieve each standard is only one of many paths that may be chosen by manufacturers. As discussed in Section 6.2.2 above, we are not setting the same average percent stringencies for each subcategory as was proposed, and thus projected improvements in the Urban subcategories are generally greater than in Regional or Multipurpose (albeit from a higher-emitting baseline). This should establish a strong regulatory driver for technologies that perform best over this cycle. In addition, we have made revisions in response to comments that we believe have lowered some barriers to entry for manufacturers of developing technologies, including clarifications on obligations of secondary manufacturers (See RTC Section 1.4), improvements to test procedures for hybrid systems (see Section 2.4), and special provisions for some types of hybrid systems to have a lower hurdle in terms of OBD compliance (see Preamble XIII.A.1). Further, in addition to the final standards being more stringent than proposed, we are adopting larger advanced technology credit multipliers than the Phase 1 multipliers (See Section 1.4). We also note that for many vocational chassis manufacturers this Phase 2 program represents the first time they have been regulated (such as for small businesses). Even those who are complying with Phase 1 using a single off-the-shelf technology may need to plan for significant changes to meet the Phase 2 performance standards. In view of these factors, we have determined it would not be reasonable to adopt more aggressive standards than those in the final rule. See Section 6.3.3.3 for responses to comments specifically on hybrids, Section 6.3.6.1 for responses to comments on zero-emission vehicles, and Section 6.3.6.3 for responses to comments on plug-in hybrid PTO systems.

Regarding the specific comment about cement mixers and refuse trucks not being able to turn off their engines, we are adopting allowable over-rides for AES and stop-start technologies that include PTO operation. In the HHD Urban subcategory the projected adoption rate of AES in MY 2027 is only 70 percent recognizing that some heavy urban vehicles will encounter too many over-ride conditions to make
this technology feasible. For similar reasons, this subcategory has an adoption rate of stop-start in MY 2027 of 30%. This recognizes that the development of stop-start technology by MY 2027 is not expected to have progressed to an extent that it will be acceptable to the majority of owners whose vehicles are classified in this subcategory. Further discussion of on idle reduction is located in Section 6.3.4.

6.3.2 SI Vehicle Standards

**Organization:** Daimler Trucks North America LLC

**Baseline SI Vocational Engine and Vehicle Performance** - The agencies commented on the simplified manner in which the agencies set the HHD SI-powered vocational vehicle standards and requested comment on the merits of developing separate baseline levels and numerical standards for HHD vocational vehicles powered by SI engines, including any benefits that could be obtained by establishing a more representative baseline in order to avoid the risk of orphaning an SI vocational vehicle. 80 FR 40305. We share the agencies’ concern about an orphaned vehicle. The SI-powered HHD vehicles are generally low volume, low cost products for limited applications. Too stringent a standard could drive such vehicles out of the market, leaving low cost buyers to keep old vehicles in service much longer than they would have otherwise. We would be happy to work with the agencies in a confidential setting to characterize our current SI-powered products so that the agencies can develop a baseline. [EPA-HQ-OAR-2014-0827-1164-A1 p.76]

**Response:**

The agencies are not finalizing any HHD SI vocational vehicle standards. In response to comments expressing concern about orphaned vehicles as well as concerns about mismatched engine and vehicle useful life, we are finalizing six subcategories for SI vocational vehicles: three LHD and three MHD. Where a manufacturer wishes to certify a SI vocational vehicle with a GVWR over 33,000 lbs, the final regulations allow that vehicle to be certified in one of the MHD subcategories. Please see Section 1.4 for further discussion of comments related to mismatched engine and vehicle useful lives. Please see Section 3.3.2 for the agencies’ response to comments on the stringency of the separate SI engine standard. See further information on SI engines in vocational vehicles in the Preamble at Section V.C.1 b, and in the RIA Chapter 2.9.1.2.1.

6.3.3 Transmission Technologies

**Organization:** Allison Transmission

**EPA and NHTSA Should Account for Secondary Shift Schedules**

In the Proposed Rule, EPA and NHTSA have identified the final drive ratio as a possible attribute that could be used to identify how a vocational vehicle is intended to be used and hence, what regulatory subcategory the vehicle would be assigned to. The Proposed Rule provides that vehicles will be certified over the Multipurpose Duty Cycle, unless certain conditions warrant its certification under the Regional or Urban Cycles. One element of this determination (Equation V-1) is axle ratio (the drive ratio entered into GEM) another element is the transmission ratio, or the ratio of the top transmission gear that is not permanently locked out. [EPA-HQ-OAR-2014-0827-1284-A1 p.44]

Allison produces ATs that can program two distinct shift schedules into the Transmission Control Module (“TCM”). This is used to limit top vehicle speed in specialty vehicles during part of its normal operation. Consequently, this also raises the issue with respect to how vehicles that utilize such transmissions should
be classified. For example, Allison transmissions are widely utilized in dual station refuse trucks. Side load dual station refuse trucks have the ability to be driven from either the right or left sides, depending on the needs of the route. The left hand drive is used when driving the truck to or from the refuse pickup neighborhood. Once the truck reaches the neighborhood, the operator will switch to the right hand side drive. This allows the operator to closely line the truck up with the trash can and the side loader will automatically pick the can up and dump it in the truck. [EPA-HQ-OAR-2014-0827-1284-A1 p.44]

Since it is desirable to not allow these trucks to be driven at high speed on the road from the right hand station, the transmission for these vehicles is calibrated to limit the vehicle to a maximum of 3rd gear while the right hand station is active. When the left hand drive station is active, the transmission is calibrated to allow the transmission to be a 6-speed. In 2015, Allison is on pace to sell over 2500 transmissions configured in this manner. Although the primary use of secondary shift schedules is found in refuse trucks, Allison is also aware of this capability being used in concrete mixers and some airport emergency vehicles. Over the timeframe of this rulemaking, it is also possible that other uses could emerge. If one of the criteria to decide a vehicle’s regulatory subcategory is based on which top range is used most often, then the Proposed Rule would appear to require use of 3rd gear. With a 3-speed shift calibration, however, these vehicles would be assigned to the Urban classification. However, the Urban duty cycles are not consistent with the usage of the vehicle when not in the residential neighborhood. A 3 speed calibration will likely not be able to reach 55 mph. And, the top speeds of the transient portion of the cycle are significantly above the typical maximum operating speed in this mode. The result is the GEM determined CO2 metric will be unrealistic and significantly above the standard. [EPA-HQ-OAR-2014-0827-1284-A1 p.44-45]

Below is a chart that depicts how refuse trucks built in May and June of this year would fare with the current version of GEM. A refuse vehicle configured with an Allison 4500 Wide Ratio, 0.49 Loaded Tire Radius, 4.30 Axle Ratio and 6 speed calibration would be classified as Multi-Purpose. The GEM run for this configuration results in 217.6 gCO2/ton-mile. With the 2021 regulatory standard of 200, this configuration is 17.6 gCO2/ton-mile above the standard. That same vehicle with a 3 speed calibration, however, would be classified as Urban. The GEM run for this configuration results in 252.6 gCO2/ton-mile. With the 2021 regulatory standard of 198, this configuration is 54.6 gCO2/ton-mile above the standard; it would be impossible for other improvements to the vehicle itself to overcome this deficit. [EPA-HQ-OAR-2014-0827-1284-A1 p.45]

[Chart, 'Refuse Vehicle Evaluation - 6 speeds vs. 3 speeds', can be found on p.46 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

To address this situation, Allison would recommend that where there are vehicles with significantly different shift schedules between primary and secondary modes, EPA and NHTSA should provide a regulatory exception. Specifically, such vehicles with top gears greater than 1:1 would be classified via the calibration with the lowest gear ratio (highest speed) regardless of the predominance of which shift schedule is used most often. [EPA-HQ-OAR-2014-0827-1284-A1 p.46]

Response:

The method of assignment to subcategories in the final rules is not a function of final drive ratio as was proposed. The examples of vehicles using secondary shift schedules in the comment are concrete mixers, emergency vehicles and refuse trucks. As stated above in 6.2.3, one reason the agencies are adopting optional standards using simplified GEM is for cases where the typical duty cycle of the vocational application is poorly represented by the final test cycles, especially for non-diversified manufacturers. We believe that the examples given by the commenter fit this reasoning. If a manufacturer certifies a vehicle with a secondary shift schedule to the primary Phase 2 standards using full GEM, it may be to the
manufacturer’s advantage to conduct powertrain testing. If a regular transmission input file is used instead of powertrain testing, GEM should be run using a transmission input file with all the available gears of the shift schedule that is expected to be engaged for the greatest driving distance. This is consistent with the final regulations for vehicles with two-speed axles. The regulations also include a provision where in unusual circumstances, a manufacturer may ask to submit weighted average results of multiple GEM runs, as an off-cycle credit, to represent special technologies that no single GEM run can accurately reflect.

6.3.3.1 Architectural Improvements

Organization: Truck & Engine Manufacturers Association (EMA)

The agencies also have failed to account properly for the use of AMT instead of manual transmissions in vocational vehicles. More specifically, GEM is not currently configured to treat AMT any more favorably than a manual transmission system. This is at odds with the agencies’ representations and efficiency projections in the NPRM. (See 80 FR at 40297). It is also unclear whether (and why) the agencies are assuming that the use of AMT will require that a vocational vehicle be placed in the “Regional” category. This is another example indicating that the agencies’ Phase 2 program for vocational vehicles may not be sufficiently developed to be included in any final rule. [EPA-HQ-OAR-2014-0827-1269-A1 p.31-32]

Organization: Allison Transmission, Inc.

EPA has noted that adding two gears (e.g., an 8-speed AT vs. a 6-speed AT) is expected to have better fuel economy than the current transmissions. While you can just add additional ranges within the current gear ratio spread of a 6-speed transmission, a larger improvement can be achieved by increasing the total ratio spread of the 8-speed configuration. Allison configured an 8-speed transmission with a reasonably larger ratio spread, an appropriate engine and an appropriate axle ratio that would maintain equivalent vehicle performance.

Organization: Allison Transmission, Inc.

EPA and NHTSA lack a rational basis to provide more credits to automated manual (“AMT”) and dual clutch transmissions (“DCTs”) than fully automatic transmissions. Allison’s real world studies indicate that automatic transmissions (“ATs”) are as good as or better than AMT or DCTs in terms of greenhouse gas emissions and impact on fuel efficiency in most vocational applications and many tractor applications. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]

While the agencies have made considerable efforts to determine the costs of various technological pathways, there are unfortunate errors of such a magnitude so as to affect EPA and NHTSA’s evaluation of how soon a technology may be reasonably projected to be integrated into the medium- and heavy-duty market. For example, in the RIA for this rulemaking it is indicated that “[f]or vocational heavy HD regional vehicles, we have estimated the cost of a [dual clutch transmission (“DCT”)], relative to a manual transmission as being equal to the move from a manual transmission to an AMT or $3694 ([Direct Material Cost (“DMC”)), 2012$, in 2018, see 2.12.3.2 above].” Allison believes this cost estimate is not correct. The DMC for a DCT in tractors in 2018 is $12,676. Allison believes this is a more realistic estimate for Class 8 vehicles. For other vehicle classes, the DCT’s DMC is considered to be equal to the AT. Furthermore, the Volvo I-Shift DCT is substantially heavier and longer than the I-Shift AMT. Therefore, even if all other factors are ignored, the costs would be higher just due to the weight and size increase. [EPA-HQ-OAR-2014-0827-1284-A1 p.13]
EPA and NHTSA have requested comment on “all aspects” of the feasibility analysis that underlies the regulatory alternatives presented in the Proposed Rule. With respect to the projections of the relative emission impact of various transmission technologies, the agencies are proposing a 2% technology input for ATs, AMTs and DCTs for Class 7 and 8 vehicles. While Allison ATs can exceed this level (versus the baseline contained in the Proposed Rule) we believe it is a reasonable level to apply based on the record for this rulemaking for ATs and AMTs. Moreover, we do not believe that EPA and NHTSA have articulated any basis in the Proposed Rule to differentiate between the technology inputs that should be available to ATs and AMTs. [EPA-HQ-OAR-2014-0827-1284-A1 p.16][This comment can also be found in section 4.3 of this comment summary]

The Proposed Rule includes a 2.3% emission reduction credit for Class 8 vocational vehicles that are certified with the regional duty cycle if these vehicles include an AMT or DCT. ATs that are used in the same vehicles, however, would not qualify for any emission reduction credit. EPA and NHTSA do not have sufficient data or information in the record for this rulemaking to support this differential treatment between AMTs and ATs and, further, do not have any basis to grant DCTs a 2.3% credit since there is no data or technical assessment which supports such a credit. [EPA-HQ-OAR-2014-0827-1284-A1 p.17]

Although the basis for this difference is not entirely clear in the Proposed Rule, since AMTs and MTs share the same architecture Allison assumes that the 2.3% credit is due to the “automation” (i.e. consistent shift speeds) of the AMT transmission when compared to the MT transmission baseline. Allison ATs, however, control shifts in a consistent manner similar to an AMT and thus would result in at least the same or greater reductions in CO2 emissions. Moreover, while there are efficiency differences between an AMT and an AT, these differences are already captured in the GEM simulation model. [EPA-HQ-OAR-2014-0827-1284-A1 p.17]

Organization: Eaton Vehicle Group

Phase 2 does not prescribe technology and provides a flexible structure that allows OEM’s to use advanced powertrains, and their significant potential to save fuel, for regulatory compliance. Eaton believes that deep engine-transmission integration, Dual Clutch Technologies and ultra-efficient transmissions are cost-effective methods to save fuel and achieve compliance, without adding the weight, cost and complexity common to some new and/or un-tested technologies. Technologies available to the market today are only partially accounted for in the pathways to compliance and cost analysis. We believe that they offer OEMs increased flexibility to achieve the standards in the NPRM without any significant additional cost, thus reducing the technology and reliability risks required to comply with the proposed standards. [EPA-HQ-OAR-2014-0827-1194-A1 p.5][This comment can also be found in section 4.3 of this comment summary]

Organization: GILLIG LLC

The agencies have placed considerable emphasis on continuous improvements in transmission technology in setting the standards for 2021, 2024 and 2027. The total U.S. transit market has been very consistent at about 5000 units annually. For GILLIG this is fragmented on the component side by three different engines, three conventional transmissions and two main hybrid system offerings. Other transit bus manufacturers have major powertrain component options different from GILLIG. Investment in technology by all these powertrain component manufacturers is already considerable. Investment over and above todays levels not to mention the development time involved for 'Deep Integration' for this multitude of powertrain combinations for the low volume transit market will be difficult for these component suppliers to justify. The exit of Detroit Diesel engines from the transit market, leaving just one engine supplier, should serve as a reminder of what can happen when the cost of development and
compliance outweigh the business opportunities in a low volume market. There are only three automatic transmission suppliers currently in transit, we surely don't want to see one of them exit the industry under similar pressures. We feel the agencies adoption rate of improvements brought about through 'Deep Integration' are overly optimistic for transit buses. We feel the same about the agencies projected adoption rates of 8 speed, AMT, DCT and Strong Hybrid technology in transit buses. We are unaware of 8 speed, AMT or DCT technology programs underway that are specifically targeted for the rigors/duty cycle/life expectations of the U.S. transit bus market. Strong Hybrids have been a decreasing portion of our annual production every year since 2010 and now constitute less than 10% of the vehicles produced. The cost of these systems have steadily increased since inception and are many times the cost the agencies assumed in the Regulatory Impact Analysis. Overly optimistic fuel economy projections, high system costs and increasing system complexity have limited hybrid adoption in transit buses. With continually declining hybrid volumes in transit buses GILLIG questions if the market can continue to support both suppliers we use and if increased levels of required investment will be the tipping point for one of them to exit. We request the agencies again review their assumptions on technology improvements and adoption rates applicable specifically to transit buses. [EPA-HQ-OAR-2014-0827-1156-A1 p.3-4]

Phase 2 GEM accounts for additional vocational vehicle technologies to reduce CO2 and fuel consumption but unfortunately the majority are not improvements available to aid transit buses in meeting the new standards. The proposed rule only allows AMT and DCT transmission options for tractors and regional duty cycles, neither apply to transit and additionally we are unaware of either of these technologies being developed for transit buses where severe duty cycles and heavy retarder operation are the norm.

**Organization:** Navistar, Inc.

The assumed adoption rate of Dual Clutch Transmissions (DCT) in the Vocational HHD Regional family, starting at agencies’ estimated 22% in MY2021, is unrealistic. No HHD DCT is currently in production North America, nor has one even been announced. Furthermore, by the agencies’ own statement for Regional LHD and MHD: The low projected adoption rates of DCT reflect the fact that this is a relatively new technology for the heavy-duty sector, and it is likely that broader market acceptance would be achieved once fleets have gained experience with the technology.

The DCT penetration rate should be adjusted. It is also unrealistic to assume 99% adoption of electronic transmissions in MY2024 for the Vocational HHD Regional family. This conflicts with the statement that “75 percent of the transmissions would be either automated or automatic (upgraded from a manual).” It appears that DCT transmissions were left out of the summation of electrified transmissions. [EPA-HQ-OAR-2014-0827-1199-A1 p.38]

**Organization:** Volvo Group

Given the current and expected continuing high penetration rate of manual transmissions within Volvo Group’s vocational vehicles, as noted above, Volvo Group does not agree with either the baseline configuration or the stringency levels set for the HHD Urban and Multipurpose vocational subcategories that are incorrectly predicated on 100% penetration of ATs. The result of this is that both the baseline and the vehicles used to set stringency in these subcategories are erroneously presumed to include the full 2% improvement for the AT over the MT (as noted in the Preamble - section III.D.2.b.v). The baseline for HHD vocational vehicles should have a penetration weighting factor applied to the 2% credit attributed to an AT vs. an MT. Stringencies could then be set assuming some reasonable increased penetration of AT (or more likely, AT, AMT and DCT). Although Volvo Group questions the use of unsubstantiated penetration rates as a basis for setting stringency levels, given their inherent uncertainty, at a minimum
EPA should use similar penetration rates of MT, AT, AMT and dual-clutch transmissions (DCT) for setting HHD vocational stringencies as were used for Class 7 and 8 tractors (reference Tables III-8 to III-10 of the Preamble) and weighting the transmission penetration accordingly in establishing all stringency levels. [EPA-HQ-OAR-2014-0827-1290-A1 p.26]

Organization: Volvo Group

[This comment was submitted in the context of the custom chassis program]: “Need assurance that Manual and Automated Manual Transmissions will not only receive credit for neutral idle improvement, but also for efficiency benefit over an Automatic Transmission.”

Response:

We agree that adding gears to transmissions for transit buses is not practical, especially for those with exclusively inner-city drive cycles. We have adopted optional standards for transit buses that are largely blind to transmission improvements, for reasons described in above in Section 6.2.3 and RIA Chapter 2.9.3.

We appreciate Eaton’s comment about the cost-effectiveness of transmission improvements. We agree and it’s one reason that projected driveline improvements are a central part of the Phase 2 vocational vehicle program. We expect that with customers’ demands for reliable, durable products in this sector, advanced transmissions will be popular choices among manufacturers as they select technologies to apply in future years.

In response to comments, the fraction of manual transmissions in the HHD vocational baselines has been adjusted. See Section 6.2.1 above and Chapter 2.9.2 and 2.9.5.1.1 of the RIA. The agencies are projecting that the fraction of vocational vehicles that are sold with manual transmissions will decrease from nearly 40 percent today to under five percent by MY 2027. This translates to an 80 percent adoption rate of AMT, AT and DCT in the HHD Regional subcategory, which is less aggressive than at proposal where, as commenters noted, we projected 99 percent of the manual transmissions would be upgraded. The final projected adoption rates are based on an expectation183 that by MY 2027, any vehicles with manual transmissions will be certified in the Regional subcategory, as the projected adoption rate of non-manuals in Multipurpose reaches 100% in MY 2024. In the HHD Regional and Multipurpose subcategories where we project adoption rates of automated transmissions as upgrades to manuals, we project a technology effectiveness value of 2 percent over the driving cycles and zero at idle. Unlike at proposal, this is now applied as a penalty when simulating manual transmissions, not as an improvement when simulating AMT. In response to comments from Volvo and others, no fixed adjustment is applied to automatic transmissions or AMT in the final program. This relative performance difference between AMT, AT, and manuals is the subject of many comments for both tractors and vocational vehicles. See Section 4.3 of this response to comments and RIA Chapter 2.8.2.5 for further discussion of HHD manuals compared with equivalently spec’d automated manual transmissions. For reasons discussed in Section 6.5.1, we are constraining certification of MT and AMT in vocational vehicles only to Regional and Multipurpose subcategories (i.e. vocational vehicles with AMTs can certify only in the Regional and Multipurpose subcategories).

183 The final rule in fact contains constraints on certifying vocational vehicles with MTs in anything but the Regional subcategory.
Although we had predicated the proposed standards in part on adoption of dual clutch transmissions in all subcategories, the final vocational vehicle standards do not rely on adoption of DCT for purposes of establishing stringency. The agencies agree with Allison: we have been unable to obtain conclusive data that could justify a final vocational vehicle standard predicated on adoption of a DCT with a supportable level of improvement over an AT. Dual clutch transmissions have very recently become available for medium heavy-duty vocational vehicles and very little data are available on their design or performance. We anticipate that in the future, some designs may have features that make them perform similarly to AMT’s while others may have features that make them more similar to automatics with torque converters. The final vocational vehicle program thus allows chassis with DCT to be certified in any subcategory (including custom chassis), except that a vehicle with DCT may be certified using full GEM in the Urban subcategories only if certain criteria related to power-shifting are met (see Section 6.5.1).

Similar to our conclusions with respect to DCT, the agencies agree with Allison and have not been able to obtain conclusive data that could support a final vocational vehicle standard predicated on adoption of an AMT with a predictable level of improvement over an AT. Where we project adoption of automated transmissions in the two subcategories described above, we apply a cost associated with a HHD AMT compared with a manual, as well as an effectiveness that presumes the reference case is a vehicle with a manual transmission. As described in RIA Chapter 2.8.2.5, the agencies have evaluated Allison’s TC10 automatic transmission for use in tractors. Overall, the CO₂ emissions and fuel consumption have been found to be equivalent to a comparable Eaton AMT. However, because the TC10 efficiency is significantly greater than the average heavy-duty vocational automatic transmission in the market today, the agencies have selected default losses in GEM for vocational automatic transmissions that are higher than the losses in a TC10. Some vocational vehicles that utilize automatic transmissions with similar efficiency to the TC10 transmission may achieve similar CO₂ emissions and fuel consumption as a 10-speed HHD AMT by either using the results of the optional powertrain test (40 CFR 1037.550) or the optional transmission efficiency test (40 CFR 1037.565).

As at proposal, we are predicating the final vocational vehicle standards in part on adoption of transmissions with added gears in all subcategories except HHD Regional, because this subcategory is predominantly modeled with a 10-speed transmission, and vehicles already using that number of gears are not expected to see any real world improvement by increasing the number of available gears. School and coach buses certified as custom chassis using simplified GEM may enter a fixed improvement value for applying a transmission with a greater number of gears than in the baseline, because we project this technology to be feasible on these vehicles but not on the other custom chassis types. We have adjusted our projected effectiveness for this technology since proposal. As proposed, we are allowing GEM to determine the improvement, where manufacturers will enter the number of gears and gear ratios and the model will simulate the efficiency over the applicable test cycle. The agencies have revised GEM based on comment, and we are confident that it fairly represents the fuel efficiency of transmissions with different gear ratios. We have run GEM simulations comparing 5-speed, 6-speed, 7-speed, and 8-speed automatic transmissions where some cases hold the total spread constant, some hold the high end ratio constant, and some hold the low-end ratio constant, where all cases use a third gear lockup and axle ratios are held constant. We have observed mixed results, with some improvements over the highway cruise cycles as high as six percent, and some cases where additional gears increased fuel consumption. We are therefore using engineering calculations to estimate that two extra gears offers one percent improvement during transient driving and two percent improvement during highway driving. Weighting these improvements using our final composite duty cycles (zero improvement at idle), for purposes of setting stringency, we are estimating that this technology will improve vocational vehicle efficiency between 0.9 and 1.7 percent. See the RIA at Chapter 2.9.3.1.

In response to the comment about certifying custom chassis in simplified GEM with manual and automated manual transmissions, the agencies will allow manufacturers to select Yes in the input field for...
neutral idle when certifying custom chassis in simplified GEM with manual and automated manual transmissions, and an improvement will be calculated based on the default engine and the default automatic transmission embedded in the model. However the only other transmission-related improvement available for custom chassis is that associated with additional gears as mentioned above for school and coach buses.

6.3.3.2 Integration/Optimization

Organization: Truck & Engine Manufacturers Association (EMA)

The Proposed Phase 2 Standards assume that, at least with respect to many vocational vehicles, the powertrain test for certification will be used as manufacturers try to achieve the assumed fuel efficiency benefits (5%-7%) from “deep integration” of advanced engine and transmission systems. In those cases, then, the powertrain test will not be optional if manufacturers hope to achieve certification to the stringent vehicle emissions targets that the agencies have proposed. [EPA-HQ-OAR-2014-0827-1269-A1 p.39]

The agencies have not provided sufficient clarity on how “deep integration” is accomplished, nor have they demonstrated that it can achieve the assumed reductions in GHG remissions and fuel consumption.

The assumption that as of 2027 70% or more of vocational vehicles will utilize “deep integration” (Table V-15 references 100%) to achieve 5%-7% GHG/FE improvements grossly overestimates the penetration rate for deep integration – which is undefined and would require that nearly all vocational vehicles use the powertrain test for certification, which cannot and will not happen – and similarly overestimates the potential GHG/FE benefits from “deep integration,” and so is unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

The agencies assume that the powertrain test will be used extensively to take advantage of “deep integration” (a concept that the agencies do not define) between engine and transmission systems. As a result, the extensive use of “deep integration” and powertrain testing – which the agencies assume will increase to a 70% penetration rate by MY 2027 (see 80 FR at 40308; R1A, p. 2-137) – is another foundational assumption underlying the Proposed Phase 2 Standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.31]

That assumption, however, is not appropriate, as the agencies have grossly underestimated the burdens associated with the powertrain test. Manufacturers have estimated that they would have to conduct powertrain tests of more than 100 combinations of engines and transmissions (not 20 as the agencies assert) to find the combinations that could actually generate the proposed GHG/FE credits (5% to 7%) for “deep integration.” Moreover, that testing burden would increase by a factor of 10 if manufacturers sought to identify the best performing combinations (as opposed to worst-case baseline combinations for potential certification purposes). Additional increases to the testing burden would result from the testing required to support any running changes that could impact an engine family’s fuel consumption/GHG emissions. Thus, the agencies’ proposed standards, to the extent they are premised on the expanded use of powertrain testing (all to chase down a potential 5%-7% efficiency improvement from “deep integration”) are simply unworkable. [EPA-HQ-OAR-2014-0827-1269-A1 p.31]

Organization: Navistar, Inc.

There is also insufficient evidence that the deep integration benefits of powertrain testing are applicable across the board or even possible. The RIA does not explain in detail, other than to state that some
manufacturers, but presumably not others, can take advantage of this optimization. It seems highly speculative to assume substantial transmission improvements based on the record in the RIA.

The scope has been small and has not been applied across an entire population of trucks. We see this as a potential risk; and should the assumed benefits not be found via powertrain testing, this leaves manufacturers in a position where there will be little to fill the gap, specifically in the vocational vehicle segment. In any event, it clearly falls short of the obligation the agencies have to clearly set out the technical pathway that is achievable within the timeframe set in the Proposed Rule.

The agencies assume that this integration can achieve as much as 7% improvement; however, as the agencies at one point project that this can create improvements from 3.5 to 4.8 percent but then refer to a table that shows 4.7-6.7%, this appears to be inconsistent. In addition, we note that the RIA appears to double count some of the elements considered in deep integration. For example, the addition of two gears to a transmission may reduce the benefit of deep integration, as the transmission will inherently achieve a more optimal operation state due to the greater number of gears. We estimate that the addition of two additional gears to a deeply integrated system would not achieve the 2% benefit described in the RIA, but would instead only achieve a 1% improvement. [EPA-HQ-OAR-2014-0827-1199-A1 p.35-36]

It is unreasonable to assume greater than 90% of electronic transmissions in the Vocational HHD Regional family will be Transmission Improved in MY2027. This contrasts with an adoption rate closer to 50% as reflected in the statement “75 percent of the transmissions would be either automated or automatic (upgraded from a manual) with 70 percent of those also being deeply integrated by MY 2027.” Presumably, this has resulted in a double counting of the potential benefit. [EPA-HQ-OAR-2014-0827-1199-A1 p.38-39]

Organization: GILLIG LLC

GILLIG requests the agencies reconsider the Phase 2 proposed requirement for testing to quantify the CO2 and fuel economy improvements from transmission driveline optimization, architectural improvements and hybrid powertrain systems. Considering the low volume nature of the transit bus business and the multiple powertrain configurations (noted above), the cost and time to run these tests not just once but continually as the technologies evolve will be onerous. GILLIG has no emissions test cells and no emissions testing team. If we were to embark on this endeavor significant initial capital investment and ongoing operations costs would be incurred. Alternatively, this work would have to fall to the transmission and hybrid suppliers or a third party. Ultimately, with limited production volume over which to spread these costs, either path leads to significant cost increases to our end users and additional financial burden for tax payers. [EPA-HQ-OAR-2014-0827-1156-A1 p.4]

Organization: Oshkosh Corporation

The first and most optimistic technology is advanced transmission and engine integration. This approach matches the transmission control algorithms to the engine performance tailored to a specific duty cycle. While this may be practical for high volume line haul applications, we believe it is unlikely to succeed in the low volume vocational world. The myriad range of vocations lead to a corresponding myriad of duty cycles, engine and transmission makes, models, and power ratings. Creating specialized engine and transmission integration algorithms takes time, money, testing effort, and a market driver. Engine and transmission suppliers will have little interest in creating the literally hundreds of optimizations needed to cover the low volumes that each combination will represent.
The GEM calculation for 2027 assumes an 8.9% improvement in fuel efficiency coming from either making the transmission more efficient, or by optimizing the shifting coordination between the engine and transmission. Many heavy duty vocational trucks use an Allison automatic transmission to improve performance and reduce driver fatigue. This is especially true for vocations with a lot of stop-start activities. Allison has improved the efficiency of their transmission over the past decade by providing lockup capability and reducing the amount of time the transmission remains in torque convertor mode. In discussions with Allison they do not believe that much further efficiency can be gained beyond what they have already attained. [EPA-HQ-OAR-2014-0827-1162-A2 p.3-4]

As for the engine/transmission match optimization, we find several factors working against significant efficiency improvement.

- With the advent of electronically controlled transmissions, significant improvements have already been achieved.

- Optimization requiring hardware changes such as modified gearing ratios are unlikely based on the relatively low volume represented by each vocation, and the very high capital investment required to make new automatic transmission configurations. [EPA-HQ-OAR-2014-0827-1162-A1 p.4]

- Software changes to tweak each vocation may produce some benefit, but the sheer number of low-volume vocational duty cycles and engine/transmission combinations make it doubtful that the engine and transmission suppliers would be willing to invest the time for so many optimizations. [EPA-HQ-OAR-2014-0827-1162-A2 p.4]

- The control algorithms that will optimize fuel economy are diametrically opposed to those that optimize performance. A sluggish “economy” mode will not be acceptable to nearly all vocations that rely on good acceleration. Optimized performance for a bus, pickup and delivery truck, or waste collection vehicle is crucial to profitability. Optimized performance in a heavy truck or bus does not mean it is beating other vehicles off the starting line, it means it does not lag behind passenger cars as much as it otherwise would. When profitability hinges on the number of packages you deliver, the passenger schedule you keep, or the number of residential refuse containers you collect, the relatively small energy savings obtained by operating in economy mode will be far outweighed in the lost productivity of the vehicle. [EPA-HQ-OAR-2014-0827-1162-A2 p.4]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

The agencies’ estimate of 5% efficiency improvement, on average, from transmission integration (p. 40296), irrespective of transmission types, is too low. Such a blanket assumption fails to distinguish among the different transmission architectures and thus does not promote the most efficient technologies. Assign technology-specific effectiveness values for transmission and integration. [EPA-HQ-OAR-2014-0827-1280-A1 p.19]

Organization: Union of Concerned Scientists (UCS)

The average of a 6 percent improvement of the transmission measured via powertrain testing is much lower than is achievable in this timeframe. These levels are based on a comparison between Allison’s 6-speed AT and Eaton’s 7-speed DCT with the same axle—this assumption leads to a degradation in the performance of the Eaton transmission and is therefore incorrect. Comparing each transmission in its optimal configuration increases the average improvement by 1 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.21]
However, this comparison does not further account for the difference between the baseline transmission (5-speed AT) and the 6-speed AT, nor does it account for any future improvements to Eaton’s DCT (e.g., an 8-speed DCT under development). In their analysis, the agencies note an improvement of 2 percent simply for the addition of 2 gears—this should be a reasonable estimate of these two improvements. [EPA-HQ-OAR-2014-0827-1329-A2 p.21]

Correcting the data to reflect the appropriate powertrain results and accounting for improved gearing would raise the average powertrain improvement from 5.5 percent to 8.4 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.21]

**Organization:** Volvo Group

Regarding vocational vehicles, the RIA states: “The agencies thus project that transmission and driveline optimization would yield a substantial proportion of vocational vehicle fuel efficiency improvements for Phase 2. On average, we anticipate that efficiency improvements of about five percent can be achieved from optimization, sometimes called deep integration, of drivelines.” No further detail is offered as to what “deep integration” is or how it is achieved to substantiate the efficiency claim. Although we have been able to demonstrate on-highway tractor efficiency via engine-driveline integration, we have no such experience with vocational applications in transient operating conditions nor have we demonstrated anything close to 5% efficiency improvement. Since the agencies have offered no evidence beyond supposition that “deep integration” is either feasible or effective for vocational applications, it cannot be expected as a means to achieve the vocational vehicle standards nor should it be included in setting these targets. [EPA-HQ-OAR-2014-0827-1290-A1 p.26]

**Organization:** PACCAR, Inc

The proposed powertrain integration testing requirements are significantly more burdensome than the agencies’ estimate, particularly for PACCAR’s mix of vehicles. PACCAR has a minimum of 130 unique hardware combinations of powertrain and transmission, not counting engine ratings and transmission calibrations that would have to be considered for tested under the proposed rule. The cost of conducting such a large number of powertrain integration tests would be prohibitive. In the proposal, EPA estimated an average test cost of approximately $69,000 per test. If 70% of the 130 combinations needed to be tested to reach the 2027 vocational vehicle compliance, over $6.25 million of testing would be required every model year, as compared to the much lower 20 configurations or $1.4 million that the agencies’ estimate. The OEM burden will increase each time a mid-year calibration change impacts engine fuel consumption or transmission shift strategy. [EPA-HQ-OAR-2014-0827-1204-A1 p.21]

**Response:**

At proposal the agencies included shift strategy, aggressive torque converter lockup, and a high efficiency gearbox among the technologies defined as driveline integration that would only be recognized by use of powertrain testing. The agencies continue to believe that an effective way to derive efficiency improvements from a transmission is by optimizing it with the engine and other driveline components to balance both performance needs and fuel savings. In considering the comments and available information, we believe it is reasonable to project that transmissions may feature advanced shift strategies where they make use of an additional sensor to improve fuel efficiency by, for example, detecting payload or road grade. The final rules provide separate procedures for recognizing aggressive torque converter lockup or use of a high efficiency gearbox, so these are considered separately for purposes of setting standard stringency. As at proposal, we project that adoption of an advanced shift strategy can provide improvements over a powertrain test of seven percent over the transient cycle and two percent over each of the highway cycles.
Volvo maintained that the agencies did not set forth any reasoning to justify the efficiency improvements attributed to advanced shift strategies (i.e. deep integration). The agencies’ justification is fully set out in RIA Chapter 2.9.3.1.1. For example, as stated there, “[u]sing engineering calculations to estimate the benefits that can be demonstrated over the powertrain test, the agencies project that transmission shift strategies, including those that make use of enhanced communication between engine and driveline, can yield efficiency improvements ranging from three percent for Regional vehicles to nearly six percent for Urban vehicles. The calculation is an energy-weighted and cycle-weighted average improvement using cycle-specific CO₂ emissions reported in the GEM output file for baseline vehicles.”

One change in effectiveness we have made since proposal is accounting for zero effectiveness at idle. The way we have done this is to expand the energy-weighting approach described in RIA Chapter 2.9.3.1 that was used at proposal to also account for fuel burned at idle. The file documenting these calculations is available in the docket. In this way, each transmission technology effectiveness is subcategory-specific, including use of separate values for gasoline and diesel powertrains. The revised composite drive cycle weightings have also affected our estimates of the benefits of transmission technologies. In sum, since proposal the range of cycle-average effectiveness of driveline integration (aka shift strategy) has changed from 4.7-6.7 percent at proposal to 3.1-5.8 percent in the final rules. We do not agree with commenters that we need to set different effectiveness values for applying this type of upgrade to different types of transmission architectures. We believe these improvements are reasonable estimates of what can be achieved for AMT, DCT or AT. The next paragraph addresses our response regarding combining this with other technologies such as added gears.

The agencies have been careful to project adoption rates and effectiveness of transmission technologies in a way that avoids over-estimating the achievable reductions. For example, as we developed the packages, we reduced the adoption rate of advanced shift strategy by the adoption rate of integrated hybrids, and we reduced the adoption rate of transmission gear efficiency by the amount of non-integrated hybrids. This is because we do not project that any driveline will undergo testing over both the powertrain test and the separate transmission efficiency test. Because we have projected adoption of combinations of transmission technologies in some subcategories, the sum of adoption rates of individual transmission technologies may exceed 100 percent in some cases. Transmission improvements are central to the Phase 2 vocational vehicle program, second only to idle reduction. We are projecting that many vehicles will apply more than one technology that improves vehicle efficiency with respect to the transmission. For example, with a 50 percent adoption rate of torque converter lockup and a 70 percent adoption of high efficiency gearbox for Regional vehicles in MY 2027, some vehicles may need to - and could reasonably - apply both. We are careful not to double count benefits in our analysis. To avoid doing so for technologies that are not simulated in GEM, we have estimated effectiveness values using conservative values and have made them subcategory-specific using an energy-weighting approach described in the RIA Chapter 2.9.3.1. In addition, where we have used GEM to determine effectiveness, we have run test cases with vehicles that have other improvements already applied (including future engines, LRR tires, and lightweighting), so that the physics inherent to GEM will produce results that reflect vehicle-level dis-synergies; meaning the incremental improvement of adding first gear lockup, for example, is smaller on an improved vehicle than on a baseline vehicle. Further, instead of summing the combined efficiencies, we combine multiplicatively. Thus, we have fairly accounted for dis-synergies of effectiveness where multiple technologies are applied to a similar vehicle system (including in Navistar’s example of driveline integration adding a lesser benefit to a transmission with additional gears).

184 See spreadsheet file dated July 2016 titled, “FRM_Vocational-Standards_GEMpostprocess.xls.”
We disagree with OshKosh that transmissions programmed for economy mode must necessarily have sluggish acceleration. Acceleration rate management is only one of many possible strategies that could be employed by transmission manufacturers, and some technologies may be combined to maintain utility such as shift strategy plus additional gears. Also with respect to the comment that electronically controlled transmissions have already brought significant improvements to this sector, we agree in part; however, as with engines, this is a major vehicle component for which manufacturers are continually seeking to make improvements over time. Just because we were able to establish Phase 1 diesel vocational engine standards that sought to improve engines over the MY 2010 baseline by nine percent didn’t mean that we couldn’t project an additional four percent improvement for those same engines in Phase 2.

We proposed a 70 percent adoption rate of driveline integration in MY 2027 on the basis that this approach to improving fuel efficiency is highly cost-effective and technically feasible in a wide range of applications, and that the additional lead time would enable manufacturers to overcome barriers related to the non-integrated nature of businesses serving this sector. We received persuasive comments from manufacturers emphasizing the diversity of their product lines and the extent of testing that would be needed to apply this technology to 70 percent of their sales, and as a result we have reduced our projected adoption rate for this technology to 30 percent in MY 2027. In cases where an advanced shift strategy can be applied to a popular powertrain, manufacturers may be able to sell a significant amount of their vehicles with this technology without needing to undergo development and testing for a large number of powertrain families. Also in response to comments, we are adopting a transmission efficiency test to recognize improved mechanical gear efficiency and reduced transmission friction, where the test results can be submitted as GEM inputs to override the default efficiency values. Because this test can be conducted with a bare transmission without needing to be paired with an engine, each test will be valid for a much broader range of vehicle configurations than are test results for a powertrain test (See Section 2.4.2 for responses to comments on powertrain families), and thus it is reasonable to project an adoption rate for high-efficiency vocational transmissions in MY 2027 of nearly 70 percent. The agencies project vehicle fuel efficiency can be improved by one percent from improved transmission gear efficiency in all cycles except idle (no improvement). Actual test results are likely to show that some gears have more room for improvement than others, especially where a direct drive gear is already highly efficient.

Commenters requested that the minimum torque converter lockup gear be enabled as a GEM input without requiring powertrain testing. In response, final GEM also includes an input field for torque converter lockup gear. The agencies project vehicle fuel efficiency can be improved up to three percent on a cycle average for torque converter lockup in first gear compared with lockup in third gear. Using the library of agency transmission files, GEM gives a different effectiveness value in every subcategory, reasonably reflecting the gear ratios, drive cycle, and torque converter specifications. Manufacturers will obtain slightly different results with their own driveline specifications.

We agree with the commenter that transmission suppliers are unlikely to invest R&D funds into optimization of low volume drivelines. That is one reason why we are not projecting any adoption of advanced shift strategy/driveline optimization for vehicles in the custom chassis program. However, we do expect that transmission manufacturers will be able to design improved gear efficiencies in some products for which the cost of driveline optimization would not be reasonable. These may be recognized during certification through the separate transmission efficiency test procedure.

In response to comments about the cost of powertrain testing, the agencies have updated our estimates of a per-test cost, as described in the Preamble to this rulemaking in Section IX and the RIA Chapter 7.1.1.2 and RIA Chapter 7.2.1.2. At proposal the agencies estimated the capital costs of new test cells and test cell upgrades at $16.6 million, representing 6 test cell upgrades and 5 new powertrain testing facilities.
For the final rules we are retaining these estimates and have adjusted the dollar year to $2013 so the new estimate is $16.8 million for one-time expenses incurred at the beginning of the Phase 2 program.

At proposal we estimated the operating costs of powertrain testing at $69,000 per test, and we projected three manufacturers would each conduct 20 tests per year for an annual operating cost associated with powertrain testing of $4.1 million (see draft RIA at 7.1.1.2). In estimating compliance costs for the final rules, we have considered information from commenters and revised downward the per-test cost to $40,000 for powertrain testing, which is an average value that includes some in-house testing (costing less) and some contracted testing (costing more). In estimating the operating costs associated with annual powertrain testing for the final rules, we have determined that a 30 percent average adoption rate by MY 2027 can be achieved with 10 tests annually beginning with the first implementation year of Phase 2 for an annual total of $400,000 for vocational powertrain testing. We believe this is reasonable, not a vast underestimation as claimed by commenters, because the final standards do not rely as heavily on advanced shift strategy/driveline optimization as was proposed, and this path to compliance will likely be chosen only by a few manufacturers. Also, manufacturers who pursue this path will gain experience each year and learn how best to apply this technology to their products, so even if we underestimate early-year testing costs, we do not expect the average annual testing costs to greatly exceed $400,000 for vocational powertrain testing.

Because we estimate manufacturers will be able to apply test results from the transmission efficiency test more broadly than results from the powertrain test, we have estimated these costs using an annual frequency of 11 tests at a per-test cost of $24,600, for an annual total of $270,600 for vocational transmission testing. These compliance costs as well as compliance costs estimated for the tractor program are described in the final RIA at Chapter 7.1.1.2 and RIA Chapter 7.2.1.2.

Please see Section 2.4.2 of this response to comment document to read our responses on comments related to the powertrain test procedure itself.

### 6.3.3.3 Hybrids

**Organization:** California Air Resources Board (CARB)

Currently, XL Hybrids and Crosspoint Kinetics have commercially-available hybrid systems for both new purchases and existing vehicle conversions. XL Hybrids currently has hybrid systems for box trucks (Ford E-350/E-450 cutaway, Ford E-450 strip chassis), Reach walk-in commercial vans (Isuzu/Utilimaster), cargo vans and passenger wagons (Chevy Express 2500/3500, GMC Savana 2500/3500, Ford E-150/E-250/E-350, Ford Transit), shuttle buses (Ford E-350/E-450 cutaway, Ford E-450 strip chassis, GM 3500/4500 cutaway (available September 2015)), and commercial stripped chassis (F59 super duty) for walk-in van fleets. Crosspoint Kinetics currently has hybrid systems for a variety of new class 3-7 trucks and buses, including a retrofit option for existing vehicles. Their systems have been tested and approved at Altoona and have been certified by the Federal Transit Administration.

CARB staff believes that if there is a projected demand created by regulatory Phase 2 (Alternative 4) requirements, these two companies, and likely other companies, would make additional hybrid systems available for the targeted heavy-duty truck and van sector. Since the basic hybrid system designs from XL Hybrids and Crosspoint Kinetics have been proven in actual fleet operations, additional demands for their products would lower the price of hybrid technologies due to increased production. The technology could also be more economically designed for other vehicle platforms, creating additional growth and development for hybrids in general. [EPA-HQ-OAR-2014-0827-1265-A1 p.68]
Organization: United Parcel Service (UPS)

The specific market penetration rates that concern UPS, given our particular fleet, are listed below and UPS strongly recommends reduction of these MPRs: Certain Market Penetration Rates for MHD Vocational Vehicles are Questionable

Electrification and Hybridization (18% in 2027)

UPS agrees with ATA's following comments on this point: 'To date, the only heavy-duty vocational applications that have demonstrated commercial viability are urban bus applications where public dollars are available. Despite several manufacturers developing hybrid technology that is production-ready, potential customers who had positive experience with demonstrators could not make the business case for additional purchases due to exorbitant costs. Hybridization remains the most expensive technology option under Phase 2 ranging from $23,904 to $18,534 in 2021 and 2027 respectively. Heavy-duty hybrid penetration is essentially non-existent outside the municipal arena. If the agencies still wish to include vocational vehicle hybridization market penetration rates, ATA recommends treating these technologies as advanced technologies and not assess specific MPRs under the rule. ATA further expands upon the need for the agencies to retain advanced technology credits under the Phase 2 Rule below.'

UPS also agrees that EPA/NHTSA should treat these technologies as advanced technologies, not assign them MPRs, and should give them advanced technology credits. We would add in this category natural gas and software controlled, engine/transmission uncoupling. The latter technology is potentially very low-cost and yet impressive in improving fuel efficiency. Note that the use of natural gas should be viewed in light of the possible use of pipeline ready bio-methane, which UPS is already doing. If an adoption rate is truly needed, then UPS would suggest an adoption rate for natural gas of about 5.5%.

UPS urges EPA to adopt a broad flexible definition of 'hybrid'. The definition of that term should include launch assist, and electric generation by an internal combustion engine that only operates when the vehicle is stationary or that is 'geo-fenced' to comply with urban emission/congestion requirements. (UPS is procuring such stationary electric generation and geo-fenced electric hybrid vehicles now). [EPA-HQ-OAR-2014-0827-1262-A1 p.6]

Organization: Truck Renting and Leasing Association

Hybrids. The agencies have assumed hybrid technology will be adopted by the vocational vehicle sector for compliance, and that up to 18 percent of vehicles certified in the Multi-Purpose and Urban subcategories will have this technology by 2027 (See page 40309). In addition the agencies note that hybridization is estimated to range between $15,000 and $40,000 per vehicle for vocational vehicles (See page 40313). In general, hybrids have proven to be much too costly relative to their benefit and should not be considered a viable technology in Phase 2.[EPA-HQ-OAR-2014-0827-1140-A1 p.5]

Organization: Oshkosh Corporation

While there was much excitement over the potential for hybridization in heavy trucks during the early 2000s, enthusiasm for hybrid technology in the commercial sector has all-but disappeared. The TMC Hybrid Truck Task Force of the American Trucking Association tracked the hybrid trends in vocational trucks biannually over the past 15 years. This task force officially disbanded this fall due to an almost total lack of interest. Fleets that adopted hybrid chassis found that projections of fuel economy improvements were over-stated, and increases in initial investment and maintenance costs made the business case untenable. The business case fell apart the minute government tax advantages ran out. Even
with the tax breaks, the case for heavy truck hybrids did not make business sense. Additional weight, complexity, cost, and maintenance all detracts from the potential savings in fuel. [EPA-HQ-OAR-2014-0827-1162-A2 p.5]

**Organization:** Daimler Trucks North America LLC

The agencies requested comment on the expected costs to accelerate hybrid development to meet the projected adoption rates of Alternative 4. 80 FR 40320. As we comment elsewhere, we recently dropped out of the hybrid market. The systems proved too costly relative to their benefit, and the hybrid OBD certification obstacles were too great. In light of this history, we think it unlikely that we would be able to meet the expected sales volume of hybrids in Alternative 3, much less Alternative 4. [EPA-HQ-OAR-2014-0827-1164-A1 p.75]

**Organization:** National Waste & Recycle Association

The solid waste industry is extensively pursuing technologies to lower fuel consumption such as hybrid power trains. The Phase 2 proposal, page 40297, left column, states that refuse haulers are well suited for hybrid powertrains because of the significant amount of stop-and-go activity, engine idling and PTO usage. While the adoption of hybrid powertrains has moved slowly in this industry due to cost and technological limitations, the industry continues to pursue this option and encourages the agencies to consider creating viable incentives for truck owners to make the investment in this technology. [NHTSA-2014-0132-0071-A1 p.7]

**Organization:** Navistar, Inc.

Alternative 3 also presumes extremely aggressive technology adoption rates. This is particularly the case for the use of hybrid powertrains in the vocational vehicle sector. The NPRM is based on 18% of urban and 18% of multi-purpose vocational vehicles utilizing hybrid powertrains by 2027. As we note in our discussion on hybrids, this is not likely to be feasible. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

The adoption rate for hybrid vocational vehicles is essentially zero today because of low fuel prices and the significant regulatory burden that hybridization faces in the commercial vehicle space. As one of the first companies to market commercial hybrid vehicles, we know there is little evidence to suggest our customers will be willing to buy vocational hybrids in sufficient numbers to meet the standard in 2027. In fact, at its highest, the penetration rate for hybrids never exceeded 1%. Predicating this alternative on the assumption that hybrid adoption rates will reach 18% by 2024, instead of 2027 will inject significant risk into the technology path that the NPRM lays out for vocational vehicles to achieve compliance. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

Navistar led the initial development and deployment of electric and hybrid vehicles beginning in 2007. Navistar’s leadership in this area is defined by introduction of the first commercially available plug in hybrid school bus, as well as an all-electric Class 4 pick-up and delivery vehicle (eStar) and a range of hybrid electric trucks equipped with the recently newly developed Eaton AMT/Hybrid system. Navistar was the only manufacturer to certify for sale, diesel hybrid vehicles under the stringent CARB interim hybrid certification procedure. This experience has provided Navistar with a unique perspective on the issues and opportunities facing hybrid vehicle development. [EPA-HQ-OAR-2014-0827-1199-A1 p.39]

Navistar respects the agencies’ desire to promote strong hybrid systems; however, hybrid applications are limited by their considerable cost and inability to optimize for the diverse vocational applications segment. This limitation is acknowledged in the Agency’s response in the RIA. This segment represents
the broadest range of combined mobile, stationary (EPTO) applications and duty cycles. The resulting complexity makes it difficult, if not impossible, to demonstrate the proposed GHG differential improvement of 25\% for urban vocational vehicles and 22\% for Multi-Purpose vocational vehicles. [EPA-HQ-OAR-2014-0827-1199-A1 p.39]

Customer demand for these products will be tempered by the cost, packaging, payload and range tradeoffs for a given vocational application. Generally with the increase in differential fuel economy, these tradeoffs become more costly, complex and specialized for a given fleet. Underlying in each of these permutations is the NOx compliance risk, and potential warranty obligation associated with the ability to maintain adequate aftertreatment conversion temperature. While it is possible to optimize an aftertreatment system for a given hybrid application, production volumes may not be sufficient to justify the considerable expense of performing a full certification and deterioration factor determination exercise. These costs will naturally increase as the proliferation of hybrid options increase. [EPA-HQ-OAR-2014-0827-1199-A1 p.39]

Finally, the cost of any hybrid system must compete directly with alternative fuel options (CNG, LNG and LPG) which offer competitive or better cost per mile fuel economy savings along with reduced GHG emissions. In many cases the resulting payback interval and warranty cost exposure are lower than equivalent hybrid systems. This is supported by Navistar’s previous experience when hybrid sales volumes peaked in 2009 and 2010 when fuel prices were reaching historic levels, then declined as fuel prices decreased and with the increased availability of alternative fuel options. For these reasons Navistar believes the agencies’ expectation for hybrid vehicle penetration are overstated and do not account for the cost, complexity, warranty exposure and alternative fuel vehicle options currently available in the market. [EPA-HQ-OAR-2014-0827-1199-A1 p.40]

Organization: Allison Transmission, Inc.

The agencies should make several changes related to hybrid vehicles. Assumed adoption rates for this technology are overstated. At the same time, EPA and NHTSA should be careful not to create new regulatory barriers for hybrids, including onboard diagnostic requirements and additional testing for nitrogen oxides (“NOx”). [EPA-HQ-OAR-2014-0827-1284-A1 p.3]

Allison has several concerns in this area. First, the likelihood of a 5\% adoption of hybrid technologies in the MD/HD sector must be seen as remote. Early adopters had poor experiences with initial market entrants that led to several hybrid manufacturers withdrawing from the market. This has resulted in a general reluctance by vehicle manufacturers to offer a hybrid powertrain given low market demand. Even if EPA and NHTSA seek to promulgate “technology forcing” regulations, there will be a lingering resistance to adopting hybrids due to what is widely perceived as market failure. The 2010 NAS Report validated the history of these market behaviors. [EPA-HQ-OAR-2014-0827-1284-A1 p.10]

Allison supports provisions of the Proposed Rule that would end specific Phase 1 incentives for hybrids, fuel cell and electric vehicles (“EVs”). We concur with the agencies that the potentially large credits that may be available for such vehicles through certification of very low emission rates should provide sufficient incentive for improved introduction of such vehicles into the commercial MD/HD fleet. In addition, Allison believes that hybrid vehicles should be certified on a duty cycle on the same basis as non-hybrid vehicles because the vehicles must perform the same work regardless of the powertrain technology. [EPA-HQ-OAR-2014-0827-1284-A1 p.51]

As the agencies indicate at the beginning of the Proposed Rule, the Phase 2 standards are intended to be technology-forcing. While the agencies’ ability to require technology-forcing standards is not
unbounded, manufacturers should not receive what could amount to a “double credit” of meeting their compliance obligations through hybrids, fuel cell and electric vehicles are receiving additional credits on account of this action. In addition, we would note that expanded delegated assembly for vehicles is an additional avenue whereby new technologies can be introduced into the market. [EPA-HQ-OAR-2014-0827-1284-A1 p.51]

With regard to comparable certification, the agencies recognize that vocational vehicle GEM test cycles are “expected to better recognize hybrid technology effectiveness than the Phase 1 hybrid test cycle, especially in the Urban subcategory.” EPA and NHTSA are proposing to remove the chassis test option for the Phase 2 rule (although proposed regulations would allow for the generation of advance technology credits through “A” to “B” chassis testing). Allison believes the best course of action to integrate hybrid vehicles into the fleet is to implement equivalent testing and certification of hybrid and non-hybrid vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.51-52]

Assumed Hybrid Adoption Rates in Alternative 4 Are Unreasonable and Unsupported

EPA and NHTSA have requested comments on the expected costs to accelerate hybrid development in order to meet the projected adoption rates in Alternative 4, i.e., a 5% overall penetration rate in 2024 for hybrids in vocational vehicles. To achieve an overall 5% adoption rate of hybrid technology, the economics of the hybrid ownership would have to substantially change over the period of time covered by this rulemaking. Sustained progress in reducing battery costs would be needed along with decreases in motor costs, and progress in reducing inverter costs. In addition, other external elements would be needed such as a significant increase in fuel cost (to increase demand) and/or additional subsidies for hybrid vehicle purchases. Past history concerning hybrid adoption should breed caution. For example, even though transit buses have had hybrid systems available for over a decade (supported in many cases by subsidies), the adoption rate of hybrids in the U.S. transit bus market is only 13.2%. [EPA-HQ-OAR-2014-0827-1284-A1 p.52]

In their report “Strategic Analysis of the Global Hybrid and Electric Medium-and Heavy duty Truck Market,” Frost and Sullivan published that supplier-level costs for batteries were $600-650/kWh in 2014 and predicts $400-450/kWh in 2022. This cost level requires passenger car production volumes and a plug-in sized battery. Additionally, batteries for non-plug-in hybrids are more expensive per kWh. Inverter and controller costs are expected to increase from 2014 levels “due to a shift in propulsive power from diesel engine to electric motor, thereby increasing complexity of power management in trucks.” (This report, NE0C-18, was published in December 2014). With respect to motors, Frost and Sullivan predict a slight to no reduction from 2014 to 2022. EPA must consider that motor costs are largely driven by the cost of copper and permanent magnet rare earth materials (or their replacement materials which are under development for future motor applications). These raw material costs are not controllable by hybrid vehicle manufacturers. [EPA-HQ-OAR-2014-0827-1284-A1 p.52]

A significant investment is required to reduce the cost of batteries, which are a key system cost driver. Battery cost predictions over the past decade have been optimistic and Allison has doubt as to the future projections being achieved for HDV. Batteries do not follow Moore’s Law and there is no accepted model for predicting battery costs over time. Cost data is not publicly available; however, the MSRP of a replacement Toyota battery pack has remained at $2588 ($1976/kWh) since September, 2008. Also, a global consulting firm retained by Allison, reported in 2008 that the Eaton hybrid battery and battery management system cost $4000/kWh and its costs would substantially decline in the future. Instead of Eaton realizing a large cost reduction for batteries, they exited the U.S. hybrid market in 2014. Since EPA is projecting far into the future, there is great uncertainty based on not realizing prior projections as to the realistic cost and volumes that will be achieved. [EPA-HQ-OAR-2014-0827-1284-A1 p.52-53]
Additionally, EPA and NHTSA should recognize that many of the cost reductions from the automotive industry are not directly scalable to the heavy duty manufacturers. As discussed in other sections of our comments, a heavy-duty vehicle has a very demanding duty cycle, which in turn, requires much more challenging design requirements for robustness. Also, the emissions regulatory life of HDVs is much longer than LDVs. The economies of scale from volume are not realized in a relatively low volume market. Allison’s hybrid experience is that the cost levels expected from scaling automotive cost levels are not achievable in heavy-duty hybrid systems. To illustrate this point, the MSRP of a non-plug-in Toyota Prius battery pack is $2589. Scaling that same battery pack to account for the additional modules and controllers of an HHD vocational vehicle would be $20,712, but the MSRP is $45,884. The battery pack alone is higher than the DMC for a strong hybrid as shown in Table 2-182 of the RIA. Allison believes that a factor of 2-4X would be more appropriate for non-plug-in hybrids and 1.5-2X for plug-in hybrids when scaling DMC from LDV to HDV. [EPA-HQ-OAR-2014-0827-1284-A1 p.53]

Organization: Parker Hannifin

Parker Hannifin appreciates the opportunity to submit comments on this important matter. For all of the reasons stated above, Parker urges the EPA to increase the expectations of efficiency standards and include hydraulic hybrid technology in the equation to better the consumers, industry, and environmental impact. [EPA-HQ-OAR-2014-0827-0725-A1 p.3]

It is important to note that the 40% reduction in fuel consumption and emissions in Class 6-8 vehicles proposed in the new rule is not something for the future. It is happening now. Parker has developed and is actively marketing a hydraulic hybrid medium- and heavy-duty vehicle transmission that is currently achieving and surpassing the 40% reduction in fuel consumption and emissions sought in the new rule. [EPA-HQ-OAR-2014-0827-0725-A1 p.2]

Parker’s hydraulic hybrid transmission replaces a conventional transmission to propel the vehicle by mechanical and hydraulic power. Every time the driver presses the brakes, the hydraulic hybrid transmission system captures and stores that energy. When the driver presses the throttle, the stored energy is used to propel the vehicle. [EPA-HQ-OAR-2014-0827-0725-A1 p.2]

Parker’s hydraulic hybrid transmissions are in use in medium- and heavy-duty vehicles in municipalities and large fleets across the country. These refuse fleets are averaging 43% reduction in fuel consumption and emissions, with some individual fleets exceeding 50% in fuel consumption and emissions reductions. Vehicles with the Parker transmission are operating in large fleets (like UPS and FedEx) and smaller fleets (like Waste Industries), as well as with municipalities as diverse as Orlando, FL, Tacoma, WA, Baltimore, MD, Oberlin, OH, and Loveland, CO. A total of 246 such systems are on the road today. Weather and climate have no impact on the superior performance of Class 6 to Class 8 vehicles using the Parker transmission. [EPA-HQ-OAR-2014-0827-0725-A1 p.2]

Other direct benefits these fleets have realized from using vehicles with the Parker transmission include:

-Virtual elimination of brake dust (a harmful bi-product) from the air because the hydraulic hybrid transmission controls truck speed instead of the brakes; [EPA-HQ-OAR-2014-0827-0725-A1 p.2]

-Scheduled brake replacements changed from once every four months to once every six years (or more), saving ten thousand dollars or more per year per vehicle; [EPA-HQ-OAR-2014-0827-0725-A1 p.2]
Duty cycle efficiency improvements of 5-10%, meaning vehicles with Parker’s drivetrain do more work in the same amount of time as vehicles with traditional diesel drivetrains or the same amount of work can be done with fewer vehicles; and [EPA-HQ-OAR-2014-0827-0725-A1 p.2]

-No infrastructure investment required to operate the system [EPA-HQ-OAR-2014-0827-0725-A1 p.2]

Parker’s hydraulic hybrid transmission is based on proven technology. There are more than 200 medium- and heavy-duty vehicles (parcel delivery and refuse) operating with the Parker transmission today. They have collectively accumulated more than 250,000 hours of run time and 1.5 million miles on the road. The fuel consumption and emissions reductions results are real-world, on-road results, not theoretical or lab-based. [EPA-HQ-OAR-2014-0827-0725-A1 p.2]

Organization: Natural Resources Defense Council (NRDC)

Vocational vehicles stringency should be strengthened to account for improvements available in hybridization. [EPA-HQ-OAR-2014-0827-1220-A1 p.5]

Organization: Environmental Defense Fund (EDF)

Wrightspeed currently has the capacity to convert diesel-and-automatic-transmission powertrain to a turbine-electric, plug-in series hybrid. These innovative trucks hold the potential- today- to “save 50% to 90% in fuel over a straight diesel powertrain.”162 XL Hybrid recently announced its XL3 Hybrid System for Ford Transit vans. The hybrid electric drive system offers fuel and greenhouse gas emission savings- today- of 20%.163

Organization: Autocar, LLC

CNG and Hybrid Power. As set forth in the introduction to this letter, Autocar is an industry leader in the integration of fuel-efficient CNG engines and hybrid power units11 in refuse trucks and street sweepers. The positive effects of CNG and hybrid technology on fuel efficiency and pollutant emissions are widely recognized and are acknowledged in the Proposed Regulations. Autocar’s applications may be more suited to CNG and hybrid power than other vocational applications. But these sophisticated technologies come with a significantly higher purchase price. Autocar and its customers actively participate in CNG and hybrid incentive programs from coast to coast. These programs have been successful in bridging the cost gap between diesel trucks and CNG or hybrid trucks and infrastructure. We encourage the agencies to build on that proven success and provide additional incentives for the purchase of CNG and hybrid trucks, for Low-speed/Frequent-stop Vehicles as well as other vocational and non-vocational vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.15]

Organization: American Trucking Associations (ATA)

Electrification and Hybridization (18% in 2027)
To date, the only heavy-duty vocational applications that have demonstrated commercial viability are urban bus applications where public dollars are available. Despite several manufacturers developing hybrid technology that is production-ready, potential customers who had positive experience with demonstration projects could not make the business case for additional purchases due to exorbitant costs. Hybridization remains the most expensive technology option under Phase 2 ranging from $23,904 to $18,534 in 2021 and 2027 respectively. Heavy-duty hybrid penetration is essentially non-existent outside the municipal arena. If the agencies still wish to include vocational vehicle hybridization market penetration rates, ATA recommends treating these technologies as advanced technologies and not assess specific MPRs under the rule. ATA further expands upon the need for the agencies to retain advanced technology credits under the Phase 2 Rule below. [EPA-HQ-OAR-2014-0827-1243-A1 p.9]

**Organization:** Truck & Engine Manufacturers Association (EMA)

The assumptions of a 22-25% fuel efficiency improvement from hybrid systems over the powertrain test (which has not been run by many manufacturers), and an overall hybrid system adoption rate of 10% for vocational vehicles (stemming from an adoption rate of 18% in the Multi-Purpose and Urban vehicle subcategories) are grossly over-stated, premised on significantly underestimated costs, and not supported by current data. [EPA-HQ-OAR-2014-0827-1269-A1 p.71-72]

The agencies' Proposed Phase 2 Standards for vocational vehicles are premised on the significant development and utilization of “strong hybrid” systems. The agencies define strong hybrid systems as those that combine two significant sources of propulsion, one using a combustible fuel (like diesel fuel or gasoline) and one that is rechargeable, either during operation (such as through regenerative braking) or through a supplemental power source (for battery recharging at the end of the vehicle’s work day). As the agencies note in the RIA (at page 2-34): [EPA-HQ-OAR-2014-0827-1269-A1 p.60]

A hybrid drive unit is complex and consists of discrete components, such as the electric traction motor, transmission, generator, inverter, controller and cooling devices. Certain types of drive units may work better than others for specific vehicle applications or performance requirements....Despite the significant future potential for hybrids, there are no simple solutions applicable for each heavy-duty hybrid application due to the large vocational fleet variation. [EPA-HQ-OAR-2014-0827-1269-A1 p.60]

Despite noting the very substantial complexities and costs associated with deploying hybrid systems in vocational vehicles, the agencies have proceeded to significantly overestimate the future market penetration of hybrid systems in crafting the Proposed Phase 2 Standards for vocational vehicles. More specifically, the agencies are assuming the following penetration rates and unit costs for “strong hybrid” systems: [EPA-HQ-OAR-2014-0827-1269-A1 p.60]

The agencies are further assuming that, where deployed, the hybrid systems will generate efficiency gains of 25% for Urban vocational vehicles, and 22% for Multi-Purpose vocational vehicles. The assumed efficiency gains are premised on unrealistic vocational duty cycles that significantly over-estimate the amount of transient operation, at least with respect to Class 8 vocational vehicles (for which detailed field data have been provided to the agencies). Nevertheless, the agencies have incorporated those projected
efficiency gains into the agencies’ determination of the Proposed Phase 2 Standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.60]

The agencies’ assumptions regarding the deployment and penetration rate of strong hybrid systems in heavy-duty vocational vehicles also are not realistic. Thus, to the extent that the Proposed Phase 2 Standards for vocational vehicles are premised on those assumptions, those standards are unrealistic as well. [EPA-HQ-OAR-2014-0827-1269-A1 p.60]

To date, the only heavy-duty application where hybrid systems have been deployed with any measure of success is for urban buses. However, that application is truly unique, since a wide array of public funds are available to cover the very significant incremental costs associated with hybrid systems. [EPA-HQ-OAR-2014-0827-1269-A1 p.60]

At the same time, it is very telling that hybrid systems have not been deployed successfully to any significant measure in residential refuse haulers. That is an application seemingly well-suited to the deployment of hybrid systems, since refuse haulers function primarily over a transient cycle with almost constant stop-start operations to support energy recovery with regenerative braking. Even so, and by way of example, the New York City Department of Sanitation, which has run a number of demonstration programs with hybrid systems provided by a major manufacturer, could not make a viable business case for operating a hybrid fleet due to overall cost considerations. Indeed, given the total incremental launch costs for heavy-duty hybrid vocational vehicles – in the range of $60,000 to $100,000 per vehicle – it is unrealistic to assume any large scale cost-effective penetration of hybrid systems. [EPA-HQ-OAR-2014-0827-1269-A1 p.61]

In that regard, it is important to recognize that a refuse hauler’s typical payload is approximately 11 tons or 22,000 pounds. At the same time, a strong hybrid system’s net weight (net of transmission replacement) is approximately 2,000 pounds, resulting in a payload loss of roughly 10%. The net result to fleet operators is very significant. In essence, 11 hybrid waste haulers are required to carry the same aggregate payload of 10 non-hybrid waste haulers. This calls into question EPA’s postulated 25% gains in overall efficiency, as well as EPA’s cost estimates, which failed to account for the need for additional vehicles and the related additional maintenance and labor costs. The Agency also failed to account for the corollary 10% increase in criteria pollutants from the resultant increased number of hybrid vehicles in operation, which is yet another offset against the Agency’s assumptions. Lastly, refuse haulers that have a reduced payload would need to make more frequent trips to landfills to dump their reduced loads. Those more frequent on-highway drive cycles mean that the refuse hauler would spend less time in the stop-go duty cycle that is well-suited to hybrid operation. All of these factors lead to the clear conclusion that the agencies are significantly overestimating the assumed penetration rates for hybrid systems in vocational vehicles. [EPA-HQ-OAR-2014-0827-1269-A1 p.61]

The passenger car experience informs this issue as well. In light-duty applications, the weight impacts of hybrid systems can be readily offset by their fuel savings, and there are no vocational work constraints or heavy loads that need to be accounted for. Nonetheless, even in the passenger car market, the penetration rate for hybrids is still only approximately 3% of U.S. sales, notwithstanding more than 17 years of product availability. Given this 3% penetration rate in the much more favorable light-duty market, it is difficult to accept as either reasonable or realistic the agencies’ assumed 18% penetration rate for vocational hybrid vehicles over a 6-year time period (2021-2027). [EPA-HQ-OAR-2014-0827-1269-A1 p.61]

Another factor that the agencies have not fully accounted for is the potential impact that hybrid systems can have on NOx emissions. In particular, hybrid systems can result in a heavy-duty vehicle’s operation at
lower average power. Such operation can impact the function of SCR systems. Moreover, with the increasing focus on NOx, it can be anticipated that even greater optimization of SCR systems will be necessary, which will make the countervailing impacts of hybrid systems that much more difficult to accept. [EPA-HQ-OAR-2014-0827-1269-A1 p.61]

In sum, the agencies’ assumed penetration rates for hybrid systems deployed in vocational vehicles are not realistic. To the extent that the Proposed Phase 2 Standards are premised on those assumptions, those standards will be similarly unrealistic and unreasonable as well. Consequently, and as noted previously, the unrealistic assumptions behind the agencies proposed standards for vocational vehicles lend additional support to the conclusion that the agencies should consider the option of maintaining the Phase 1 program for vocational vehicles until a better-reasoned supplemental rulemaking process can be undertaken. [EPA-HQ-OAR-2014-0827-1269-A1 p.61-62]

Organization: PACCAR

Another technology that offers improvements in both fuel efficiency and emission reduction is hybridization. PACCAR’s history with hybrid technology was a niche market application appealing to “green” companies as long as incentives offset the cost of the technology. The low volumes was not based on performance, but rather the combination of the payback of the high initial cost based on the limited number of gallons saved in low mileage pick up-and-delivery applications and on the concern over resale value, since at some point in the vehicle’s life the battery must be replaced at a significant cost to the owner. Many potential purchasers are reluctant to become the second or third owner of these vehicles, particularly if the battery has not already been replaced, as this is viewed as an extremely high cost of ownership that makes non-hybrid used vehicles more attractive. Based on this experience and feedback from our customers, PACCAR is not optimistic that this technology will gain anything but marginal acceptance. [EPA-HQ-OAR-2014-0827-1204-A1 p.3]

Organization: Daimler Trucks North America LLC

Adoption Rates for Hybrids in Alternative 4 - The agencies requested comment on the expected costs to accelerate hybrid development to meet the projected adoption rates of Alternative 4. 80 FR 40320. As we comment above, we recently dropped out of the hybrid market. The systems proved too costly relative to their benefit, and the hybrid OBD certification obstacles were too great. In light of this history, we think it unlikely that we would be able to meet the expected sales volume of hybrids in Alternative 3, much less Alternative 4. Therefore, we recommend against Alternative 4. [EPA-HQ-OAR-2014-0827-1164-A1 p.97] Hybrids – In section 2.4.4.5 of the RIA, the agencies state that “industry is currently developing many variations of hybrid powertrain systems.” We think that is a mischaracterization of the market, given that most major manufacturers have pulled out of the hybrid market due to a lack of business partners and purchasers—quite the opposite of developing (new) variations. We did develop a hybrid system for our Super Truck vehicle but found it infeasible for production. In conclusion, we disagree with the agencies’ characterization of the hybrid market, and we think that hybrids should not be used as the premise for vehicle standards. 2.4.4.5 of RIA [EPA-HQ-OAR-2014-0827-1164-A1 p.97]

Costs of Hybrids are Underestimated – The agencies seem to dramatically underestimate the costs of hybrids. In particular, when we used to sell hybrid vehicles, the full-vehicle up-charge for the hybrid system was between [redacted], depending on the vehicle and its features. So the agencies’ estimate of $5,571 is less than [redacted]% of the price. Although we prefer not to use the agencies’ method of ignoring the per-vehicle up-charge for technologies and instead spreading that cost across the entire fleet of vehicles, at an 18% penetration rate (the agencies’ assumed rate) the hybrid cost should be at least $[redacted],000 (18% x $[redacted],000). Even under this analysis, the cost-benefit analysis is much
different than the agencies assumed. But under a more realistic analysis, where the entire hybrid cost is borne by the hybrid purchaser and not spread across the fleet, the cost-benefit is far worse. For this reason, we recommend against including hybrids in standard setting. [EPA-HQ-OAR-2014-0827-1164-A1 p.97]

**FCRs for Hybrids** – We have several concerns about the way that the agencies developed FCRs for hybrids, especially considering how heavily the hybrid FCRs factor into standard setting. First, the agencies assumed a hybrid FCR of 22 to 25% on the Phase 2 test cycles based upon NREL measurement of 28% on the NYC Composite Test Cycle. 80 FR 40297. This test cycle has a very high kinetic intensity, such that it may overestimate achievable FCRs for hybrids. Similarly the use of HTUF4 data may fail to capture the actual fuel savings possible on the agencies’ test cycles. We recommend that if the agencies intend to continue to premise the standards on hybrids that the agencies base FCR values on tests using the correct duty cycles. Second, we recommend that the agencies perform these tests with batteries aged to represent the worst-case FCR over the vehicles’ useful lives, as the agencies would require manufacturers to certify. Taking optimal test data to represent full useful life emissions is not appropriate. Third, and similarly, we recommend that the agencies not measure the optimal hybrid configurations for generating FCR numbers, as manufacturers will be unable to do so. Rather, manufacturers will have to certify the worst-case configuration of a family of hybrid vehicles. So while the best tests might show 22 to 25% FCRs, if the worst show 10%, then the standards must be set based on 10% as that is how manufacturers will certify. [EPA-HQ-OAR-2014-0827-1164-A1 p.81]

**Organization:** Volvo Group

As part of the NoDA release the agencies proposed a simplified model for evaluating the benefit of hybrid systems (HD GHG Simple Hybrid Model v4 - EPA-HQ-OAR-2014-0827-1725). In our review of the simplified model, Volvo noted two primary concerns. First, the agencies have assumed 100% efficiency for the batteries ability to absorb and release energy, as well as not accounting for additional electrical system inefficiencies. Second, the agencies’ accounting for drag and friction appear to only account for tire rolling resistance and aerodynamic drag, without accounting for the additional mechanical inefficiencies such as oil churning, gear efficiencies, etc. Without accounting for the noted concerns Volvo does not believe this model is acceptable as a calculation tool for use in stringency determination. [EPA-HQ-OAR-2014-0827-1928-A1 p.20]

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)

ACEEE strongly supports the inclusion of a modest number of hybrid vehicles in the compliance package for the vocational vehicle standards. Many vocational vehicles spend a significant amount of time in idling and in stop-and-go operation, making them suitable candidates for hybridization. We agree with the agencies’ estimate of 22-25% improvement from hybridization using the powertrain test (p. 40297).

**Organization:** American Council for an Energy-Efficient Economy (ACEEE) et al.

The agencies recently uploaded a physics-based simple hybrid model, which can be used to quickly estimate the potential fuel savings for different vocational hybrid designs. It is clear from this model that there is a wide range of hybrids that can result in significant fuel savings, even those with relatively small batteries as would be found in a mild hybrid. [EPA-HQ-OAR-2014-0827-1896-A1 p.5]

Mild hybrids were not discussed in the proposal as part of the compliance package; however, as is evident from this modeling, these cheaper hybrid variants could offer much of the same benefit in certain applications at reduced cost. We strongly encourage the agencies to include mild hybridization as part of
its compliance package in addition to cost-effective full hybrid application, as already identified in the proposal. [EPA-HQ-OAR-2014-0827-1896-A1 p.5]

**Organization:** Eaton Vehicle Group

Hybrids did not penetrate the commercial vehicle landscape, in spite of the Phase 1 ATC program. This is due to a combination of high battery costs and low fuel prices. According to the current EIA analysis, fuel prices are expected to stay low in the foreseeable future. However, the Hybrids potential to reduce fuel consumption and CO2 emissions still exists, and under specific economic and regulatory circumstances, hybrid sales thrive, e.g., in China. For the US market, we see a combination of factors needed to re-ignite the hybrids business: lower battery costs and increased efficiency of the hybrid systems for Class 6-8, lower cost mild hybrid powertrains in Class 3-5, and continued regulatory pull. Our market penetration assumptions for the end of this decade are pessimistic. We are encouraged by steady progress in battery costs driven by light duty applications, but we also observed recently a reduction in sales in that segment, putting in question the timing of lower cost battery availability. On the other hand, the proposed standards in the vocational space are likely to drive significant hybrid adoption as the conventional powertrain improvements are realistically limited to approximately 10-12% fuel consumption reduction in the Mixed and Urban categories, while the MY2027 standards call for a 1416% overall fuel consumption reduction. [EPA-HQ-OAR-2014-0827-1194-A1 p.17]

For Class 3-5 vehicles, it is possible replace Diesel engines with downsized hybrid gasoline powertrains. A form of mild hybridization for such situations is described [Benjey 2015]², where a low-voltage and low-power system (48V and 6kW) is used to provide significant electrically generated boost at low engine speed. This enables 12% fuel consumption reduction over a baseline MD diesel powertrain under drive conditions, with the further added value of an engine-off at idle. Because of the low voltage system and simplified emissions controls of gasoline engines, such systems should not increase vehicle cost. [EPA-HQ-OAR-2014-0827-1194-A1 p.18]

In the Class 6-7 urban segment, there is a potential to further increase the MD hybrid system value through deeper integration with the vehicle controls and the use of predictive methods to optimize the electrical versus engine power distribution. This enables a 10-15% improvement of the hybrid fuel savings through advanced controls, i.e., without incremental costs of weight to the conventional hybrid system [Patil 2015]³. [EPA-HQ-OAR-2014-0827-1194-A1 p.18]

From a regulatory perspective, we agree with the EPA approach to Hybrids, namely that these should be powertrain tested for actual fuel consumption. We believe that while the EPA is looking at not continuing the Advanced Technology Credits program for Hybrids after 2021, the Hybrid market is still very fragile and driven by the cost of fuel. As we look toward a long period of lower cost fuel as predicted by the EIA, we do not see market conditions improving for Hybrid commercial vehicles except for a few mild Hybrid applications in the Class 3-4 segment. We are not optimistic that Hybrid technology will evolve significantly before the rule comes into effect, a situation similar to 2012-13 when the slump in Hybrid sales occurred. We believe contributing factors included hybrid OBD requirements during the low-volume phase of commercialization and unclear battery warrantee associated with useful life requirements that shifted development resources away from Hybrid cost reduction. [EPA-HQ-OAR-2014-0827-1194-A1 p.18-19]

**Recommendation:** The EPA and CARB should develop an OBD and battery warrantee strategy for Hybrids that should stay in place until sufficient numbers of Hybrid-equipped vehicles are on the road. As the NPRM requires powertrain testing for Hybrids, it may be opportune that OBD requirements are
replaced with the requirement to demonstrate there is no backsliding in criteria emissions on the powertrain test data. [EPA-HQ-OAR-2014-0827-1194-A1 p.19]

Odyne

Odyne believes that improvements in drivetrain, hybrid control system optimization – both from technology advancements and increased data incorporation of workday assumptions, and duty-cycle optimization – along with continually decreasing costs for components (as EPA has very accurately estimated going forward) and continuing volatility in fossil fuel prices will drive the value proposition for hybrid deployment in the coming years. Odyne believes hybrids will play a larger role in fleet procurement in the next decade at efficiency rates higher than is currently modeled in Scenario Three’s assumptions. [EPA-HQ-OAR-2014-0827-1239-A1 p.4] [This comment can also be found in EPA-HQ-OAR-2014-08267-1372, p.230.]

In addition, the accounting for the efficiency improvements from hybrid technology is not as clear as it could be in the proposed GEM model. Odyne would welcome the opportunity to work with the EPA on best practices and potential pathways for modeling fuel efficiency increases from various applications of hybrid PTO mode, in addition to hybrid propulsion. [EPA-HQ-OAR-2014-0827-1239-A1 p.6-7] [This comment can also be found in EPA-HQ-OAR-2014-08267-1372, p.232.]

Odyne believes that future hybrid systems will be capable of reducing fuel consumption and GHG emissions by 50% or greater at paybacks of 3 years by 2021 and 2 years by 2027 for vocational multipurpose, urban, and potentially other classes of trucks. We believe that hybrid projections assumed by the EPA in its draft rule – including effectiveness rates of —25% and paybacks from 4-6 years – can and should be strengthened in light of this and other stakeholder data and analysis. We welcome the opportunity to work with the EPA on assumptions made in the final rulemaking from cost projections and performance data Odyne can offer. [EPA-HQ-OAR-2014-0827-1239-A1 p.17]

EPA: Mild hybrid - A small, engine driven (through a belt or other mechanism) electric motor/generator/battery combination to enable features such as start-stop, energy recovery, and launch assist. [EPA-HQ-OAR-2014-0827-1239-A1 p.35]

Or

EPA: Mild hybrid electric vehicle means a hybrid electric vehicle that has start/stop capability and regenerative braking capability, where the recovered energy over the Federal Test Procedure is at least 15 percent but less than 65 percent of the total braking energy, as measured and calculated according to § 600.116–12(d). [EPA-HQ-OAR-2014-0827-1239-A1 p.35]

EPA Strong hybrid - A powerful electric motor/generator/battery system coupled to the powertrain to enable features such as start-stop, and significant levels of launch assist, electric operation, and brake energy recovery. For HD pickups and vans, the engine coupled with the strong hybrid system would remain unchanged in power and torque to ensure vehicle performance at all times, even if the hybrid battery is depleted. [EPA-HQ-OAR-2014-0827-1239-A1 p.35]

Or

EPA Strong hybrid electric vehicle means a hybrid electric vehicle that has start/stop capability and regenerative braking capability, where the recovered energy over the Federal Test Procedure is at least 65
percent of the total braking energy, as measured and calculated according to § 600.116–12(d). [EPA-HQ-OAR-2014-0827-1239-A1 p.35]

Odyne: If changes reflected in our comments above on start/stop are made, then changes are not needed for hybrids. Otherwise, we would suggest adding “or other means to eliminate fuel consumption when the vehicle is stopped.” The same considerations for Mild Hybrid should be applied to Strong Hybrid and it should mention heavy-duty trucks as well. [EPA-HQ-OAR-2014-0827-1239-A1 p.35-36]

Response:

The agencies are including hybrid powertrains as a technology on which some of the vocational vehicle standards are predicated. We proposed ten percent overall adoption of strong hybrids by MY 2027, which meant approximately 18 percent adoption in the Multipurpose and Urban subcategories in that model year. The agencies also discussed mild hybrid availability in the Preamble (80 FR 40298). In consideration of comments from Eaton, ACEEE, UPS, Odyne and others expressing familiarity with and support for consideration of mild hybrids in the standards, we have determined that mild hybrids are more likely than strong hybrids to succeed initially in the vocational sector. Accordingly, the stringency of the final standards is not predicated on use of strong hybrids, but does reflect deployment of mild hybrid systems at a rate of 14 percent in the Multipurpose and Urban subcategories in MY 2027.

We appreciate the comments from manufacturers of hybrids including Odyne, Parker, XL Hybrids, Eaton, and others who supported including hybrids in the stringency of the Phase 2 vocational vehicle program. We believe that the drive cycles and test procedures for recognizing hybrids in the final program are significantly improved since Phase 1, and should provide good opportunities for marketing these products. We appreciate comments in support of hybrids from those with the fleet perspective, including UPS and CalStart, as these customers can give the true measure of whether the products are worthwhile. We recognize the concerns of commenters who cautioned against consideration of hybrids in developing standard stringency, including OshKosh, Daimler, Allison, TRALA, EMA, Paccar, and Navistar. In particular, the comments from Navistar provide an excellent summary of the challenges presented by this technology. In considering all these comments as well as other supporting information, we believe that manufacturers and suppliers will be able to overcome these challenges to a large extent in the timeframe of Phase 2. Furthermore, the technology path we have identified is only one of many that may be pursued.

We are projecting adoption of two types of mild hybrids, defined using system parameters based on actual systems commercially available in the market today. We have taken into consideration the concerns of secondary manufacturers by assuming that some mild hybrid systems will be integrated with an engine sufficient to enable use of an engine stop-start feature, while some mild hybrids will not be integrated and these “bolt-on” systems will only provide transient benefits (i.e. benefits under transient operating conditions) related to regenerative braking. We also have reconsidered our effectiveness estimation method as a result of comments. Instead of relying on previously published road tests over varying drive cycles, we are applying engineering calculations to account for defined hybrid system capacities and inefficiencies over our certification test cycle. We are using a spreadsheet model that calculates the recovered energy of a hybrid system using road loads of the default baseline GEM vehicles over the ARB Transient test cycle. See RIA Chapter 2.9.3.1.3 for details regarding the assumed motor and battery capacity, swing in the state of charge, and system inefficiencies. We appreciate the comments from Volvo and ACEEE regarding the agencies’ analysis of mild hybrid effectiveness as detailed in the draft
spreadsheet model that was released around the time of the NODA. In response to comments, we have amended the model to include additional inefficiencies. The projected cycle-weighted effectiveness reflects an assumption of zero effectiveness under highway cycles. For the non-integrated models, the same system was assessed for all weight classes (not scaled up for heavier vehicles); however, for the integrated models with stop-start we have scaled up the system specifications to account for the larger road loads, to ensure the projected effectiveness is not decreased for systems on heavier vehicles relative to that projected for lighter vehicles. As described in the RIA Chapter 2.11.7.2, these costs have been scaled up by the curb weight of the vehicles. However, in analyzing different system designs using the spreadsheet model we found that some systems were limited only by the motor, and costs of motors may not need scaling to the same degree as other components. Therefore, we believe that our hybrid system manufacturing costs are conservative. In considering the costs relative to the technology effectiveness, we estimate the cost per percent reduction of mild hybrids to be on the order of the cost per percent of adding two gears for Class 8 Urban vocational vehicles. For Class 6-7 Urban vocational vehicles we estimate the cost per percent of an integrated mild hybrid with stop-start to be on the order of the cost per percent of advanced shift strategy for a conventional powertrain, and the non-integrated bolt-on to be on the order of adding two transmission gears. For class 2b-5 Urban vocational vehicles we estimate the cost per percent of an integrated mild hybrid with stop-start to be about half of the cost per percent of advanced shift strategy for a conventional powertrain, and the non-integrated bolt-on to be on the order of electrified accessories. Actual cost-effectiveness for the individual user will depend on many things including the annual miles driven by the vehicle owner under transient conditions.

We received many comments on the feasibility of hybrids for refuse trucks. The National Waste & Recycle Association, Parker, and Autocar commented in support of hybrids for the refuse sector, while EMA’s comments point out examples where hybrids have failed to meet expectations for refuse fleets. We believe these conflicting viewpoints can be reconciled by consideration of technology and duty cycles. In a meeting with Effenco, the agencies discussed confidential information based on telematics data obtained from refuse fleets indicating that some refuse drive cycles have such low kinetic intensity that the energy available for recapture from regenerative braking was not worth pursuing. Importantly, the efficiency with which a system captures and reuses braking energy depends on its design -- including whether it is battery-electric, capacitor-based, or hydraulic. Further, for drive cycles where the speed between stops is under 10 miles/hr, Effenco found capacitor-based stop-start technology to be more cost-effective than its previously-tested hybrid systems. Effenco observed these low-speed driving patterns for some neighborhood refuse collection trucks and some inner-city transit buses. Effenco’s comments on stop-start systems can be found in Section 6.3.4, below. As noted by OshKosh in its comments above (see Section 6.1.5), there are many types of refuse trucks with many duty cycles serving a variety of purposes related to collecting and hauling refuse and recycled materials in communities across the U.S. Therefore it is entirely possible that some portions of the refuse fleet may be well suited to various hybrid systems and/or stop-start systems, and some may not be. For discussion of comments related to hybrids on vehicles certified to the optional custom chassis standards, see Section 6.2.3.

Although the final Phase 2 vocational vehicle program reflects certain estimates that are more stringent than those proposed, the projected hybrid adoption rate is less aggressive than proposed. The Alternative 4 path would have projected 10 percent strong hybrids overall by MY 2024, which at proposal was estimated at 18 percent in the Multipurpose and Urban subcategories. Although we agree with CARB that there are companies selling small volumes of hybrids today, we disagree that projecting an optimistic

---

186 See spreadsheet file titled, “HD GHG Simple Hybrid Model v7.xlsx”.

hybrid adoption rate in the early years of the Phase 2 program would induce higher sales of those systems in the short term. There are complex market barriers to adoption of hybrids, not the least of which is that few if any chassis OEM’s build these, and business relationships with second stage manufacturers are virtually nonexistent today. As noted by Daimler in its comments, one of the reasons it dropped out of the hybrid market was related to the hybrid OBD certification obstacles. See Section 14.3.1 and 14.3.3 for responses to comments about hybrid OBD. Although there is a (costly and time-consuming) path that has been successfully navigated by some manufacturers to obtain hybrid OBD approval, this will likely remain a significant market barrier to hybrid adoption for many years.

Responses to comments on hybrid PTO systems are found in section 6.3.6.3 below. Where a hybrid system is capable of improving vehicle efficiency while driving as well as while parked in PTO mode, the certifying manufacturer may submit powertrain test data as well as data from the hybrid PTO test procedure, and would be eligible for both types of credits. See Section 6.1.1 for responses to comments on NOx emissions from workday idle, see Section 15.8 for responses to comments on NOx from hybrids.

6.3.4 Workday Idle Reduction Technologies

This section addresses comments relating to three workday idle reduction technologies: neutral idle, stop-start, and automatic engine shutdown. See Section 6.3.6.3 for comments relating to electrified power take-off systems, which reduce high-idle emissions through electrification of the PTO function.

Organization: Allison Transmission, Inc.

EPA and NHTSA Should Not Assume Adoption of Idle Reduction Technologies For Emergency Vehicles

EPA and NHTSA have requested comment on whether the agencies should assume any market adoption rate for idle reduction technologies for emergency vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.48]

Allison does not support inclusion of an adoption rate for idle reduction technologies in emergency vehicles; instead we would urge a large degree of caution in this area due to the possible introduction of operational risk. For example, it could be possible for emergency lights and sirens to drain batteries to the point where a restart of the engine could not be commanded. The existence of such risks weighs heavily against any incremental gains that might accrue through reduction emissions from such specialized vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.48]

Additionally, a typical emergency vehicle duty cycle would result in much less use of the idle reduction technologies than for vehicles in the commercial sector. For a typical duty cycle, when vehicles are “on their way to an emergency,” stops are not made and distances may not be long given the practice of dispatching nearby vehicles. Although there can be “normal” driving on the return trip from an emergency run, as well as some routine daily driving daily to ensure all equipment is working, the unique use pattern of these vehicles would prevent a significant amount of the benefits to be derived from idle reduction technologies. [EPA-HQ-OAR-2014-0827-1284-A1 p.48]

Allison’s OEM customers, who manufacture safety and emergency vehicles, have also conveyed their concern for implementing idle reduction technologies that may introduce this operational risk for their end-user customers. Emergency responders always expect to be able to promptly complete every emergency run; the best course of action in this rulemaking would be to not assume any adoption rate for idle reduction technologies and instead, allow the emergency vehicle market to consider when such technology is useable with acceptable levels of any risk. [EPA-HQ-OAR-2014-0827-1284-A1 p.48]
Organization: Fire Apparatus Manufacturers’ Association (FAMA)

FAMA does not support idle reduction technology in fire apparatus for the following reasons: [EPA-HQ-OAR-2014-0827-1163-A1 p.1]

- Shutting off the engine at every stop will not be practical for fire apparatus where every second counts on the way to an emergency. [EPA-HQ-OAR-2014-0827-1163-A1 p.1]

- HVAC is powered by the engine and used to keep the occupant areas warm in the winter and cool in the summer. This provides an essential place for firefighters to recover after exposure to the elements. [EPA-HQ-OAR-2014-0827-1163-A1 p.1]

- Firefighters keep the engine running to maintain pump pressure so that it is available when needed. [EPA-HQ-OAR-2014-0827-1163-A1 p.1]

- The water pump is powered by the engine. Pump water circulation in cold weather keeps the water in the tank and lines from freezing [EPA-HQ-OAR-2014-0827-1163-A1 p.1]

- Hydraulic pumps for aerial operator are powered by the engine. Hydraulic fluid circulation keeps the fluid warm and avoids sluggish aerial device operation. [EPA-HQ-OAR-2014-0827-1163-A1 p.2]

- Engine idling maintains battery charge when operating warning lights, communication equipment, and other current draw at the scene. [EPA-HQ-OAR-2014-0827-1163-A1 p.2]

FAMA does not support idle reduction technology in ambulances for the following reasons: [EPA-HQ-OAR-2014-0827-1163-A1 p.2]

- Shutting off the engine at every stop will not be practical for ambulances where every second counts on the way to an emergency and while in transit to the hospital. [EPA-HQ-OAR-2014-0827-1163-A1 p.2]

- HVAC is powered by the engine and used to keep the cab and patient compartment warm in the winter and cool in the summer. This is critical for patient care. HVAC in ambulances also includes air filtering and decontamination that protects patients and EMTs. [EPA-HQ-OAR-2014-0827-1163-A1 p.2]

- Engine idling maintains battery charge when operating warning lights, communication equipment, medical equipment and other current draw at the scene. [EPA-HQ-OAR-2014-0827-1163-A1 p.2]

Response:

We agree with commenters that the workday idle technologies considered in this rulemaking are not feasible on emergency vehicles. For an idle reduction technology to match the needs of an emergency vehicle, it would need to perform additional battery load management functions. If an emergency vehicle were to be built with such a system, and if it met the criteria in the regulations for AES, the manufacturer may obtain certification credit for it in GEM. Otherwise, off-cycle credit may be requested.

6.3.4.1 Stop Start

Organization: Daimler Trucks North America LLC
GEM Inputs for Stop-Start Technologies – We are not certain that we understand how GEM credits stop-start. As we understand: First, for any engine, there are two idle points in the fuel map, one with no load and one with torque converter load. If the engine has stop-start functionality, then the fuel rate is zero at idle points. If we understand correctly, then the stop-start approach may overestimate fuel savings, in that any stop-start system will take some time to shut off (based on light-duty vehicle experience). How to properly credit that technology, without over-crediting it, is something we should discuss with the agencies. [EPA-HQ-OAR-2014-0827-1164-A1 p.63]

Criteria for Stop-Start Approval - The agencies request comment on an appropriate definition of stop-start technologies for vocational vehicles. 80 FR 40300. Recognizing that there are no heavy-duty stop-start technologies on the market right now, we think that it might be difficult to perfectly define the qualifying criteria. However, we wish to avoid the scenario like we had with innovative technology certification in Phase 1, when we had to go through numerous lengthy discussions with [redacted] To avoid unnecessary certification burden, and to avoid the error of failing to qualify a truly fuel-saving technology for the credit it deserves, we recommend that the agencies stick to a simple definition. For example, a vehicle should get stop-start credit if its engine will automatically stop itself rather than idle under some conditions and will turn itself back on when the driver requests torque. The agencies need not define what the conditions are, given that manufacturers might need to limit the stopping functionality under different sets of conditions, such as when the air conditioner is operating or when a hydraulic system demands power for on-vehicle vocational work. Although the agencies might be concerned that the engine will not shut off in all instances of zero torque demand, the agencies should rest assured that if a manufacturer installs a starter system, electrical system, HVAC, etc. capable of operating when the engine is off, then the manufacturer will try to return the vehicle owner's investment by maximizing the associated fuel savings. In short, the agencies should use as generic a definition as possible, because they are safe in the knowledge that the systems will maximize fuel savings to the extent technically possible. [EPA-HQ-OAR-2014-0827-1164-A1 p.67]

Organization: GILLIG LLC

Regarding the Stop/Start Idle Reduction Strategy, we see this as a strong hybrid only strategy at this point and only with some modifications to how long and how frequently after zero vehicle speed it can be employed. Transit buses transport people in extreme hot and cold environments and maintaining conditioned air in the bus at layovers or extended bus stops for passenger comfort and safety is essential. Currently, idling the engine or drawing power from a sizeable battery pack such as those employed with strong hybrids are our only options for maintaining interior climate control. [EPA-HQ-OAR-2014-0827-1156-A1 p.2-3]

Organization: Bosch

Stop-Start - Bosch supports the inclusion of an Idle Cycle, such as the one outlined in the draft Regulatory Impact Analysis (RIA) section 3.4.2.3, to recognize the benefits of stop-start technology for Vocational Vehicles. [EPA-HQ-OAR-2014-0827-1466-A2 p.10]

Bosch further suggests that recognition of the benefit of stop-start for other vehicles, such as urban delivery vehicles, should be included in the regulation. In cases where lower fuel rates during idle cannot be easily quantified on these vehicles, for inclusion in the Greenhouse Gas Emission Model (GEM), an off-cycle credit should be assigned. [EPA-HQ-OAR-2014-0827-1466-A2 p.10]

Organization: Effenco Hybrid Solutions
Another comment regards the cost estimates for stop-start technologies. While “Stop-start systems can be viewed as having a place on the low-cost end of the hybridization continuum” as it is mentioned in the RIA section 2.9.3.4, one can appreciate that a minimum of additional hardware is required to deliver enough power to frequently and seamlessly restart a large engine as well as to keep accessories and equipment operational with the engine turned off. We believe that with volume and integration, the incremental costs of stop-start technologies for vocational vehicles will range between $5,000 and $10,000 in MY 2027 vs the $1,374 estimated by the agencies. [EPA-HQ-OAR-2014-0827-1148-A1 p.3]

Finally, the fuel efficiency improvements that we measured on the field with our Active Stop-Start technology range between 11 and 30% depending on duty cycles. We would be glad to provide the agencies with additional data on this matter. [EPA-HQ-OAR-2014-0827-1148-A1 p.3]

**Organization:** Allison Transmission, Inc.

The technological adoption rates for Alternative 3 are too ambitious in several areas, in addition to the rate that is assumed for adoption of Stop-Start technology. Thus, Alternative 4 should be rejected and Alternative 3 modified to account for slower adoption of Stop-Start technology than projected. [EPA-HQ-OAR-2014-0827-1284-A1 p.15]

Allison also believes the DMC is understated for engine Stop-Start in all three of the vocational categories, LHD, MHD, and HHD vehicles. The 25% upward scaling factor is insufficient to address the differences between LDV and HDV. The duty cycle for a work truck is much more severe than HD pickups and vans which results in larger components. Also, the vocational vehicle volume is much lower than HD pickups and vans so the economies of scale are not able to be realized. Costs will increase from LDV’s due to the high degree of design and integration of new components among the vehicle manufacturer, engine manufacturer, and transmission manufacturer to assure that the system is reliable, but more importantly, safe. It is anticipated that many components will need to be redesigned to be durable based on the number of additional cycles imposed by Stop-Start operation. The 25% upward scaling factor from each vehicle size to the next is believed to be too low due to the non-linearity of cost as vehicle size increases. [EPA-HQ-OAR-2014-0827-1284-A1 p.14]

Allison believes the costs associated with an adoption rate of 70% are also understated. Vocational vehicles that operate in climates with temperature extremes have situations where a truck operates at idle in order to provide heating and/or air conditioning for the work crew. In these situations, the cost of additional technology to provide power for the HVAC system is not included in EPA’s and NHTSA’s analyses. Energetics Incorporated conducted an idle-reduction study in vehicles operated by New York Department of Transportation. This study reported that costs for a system to provide cab heat was $8995. A basic system with only Stop-Start capability, i.e. no heat or exportable power, cost $1995, which is consistent with Allison’s projections for an entry-level system for an LHDV. Most vehicles had a payback in excess of 5 years, with approximately half of the vehicles studied, having a payback less than 10 years. [EPA-HQ-OAR-2014-0827-1284-A1 p.14]

Allison is aware of a stop-start system that is used with the 3000 Series and 4000 Series TM transmissions in Class 8 refuse trucks and terminal tractors. Effenco’s Active Stop-StartTM system’s current installed cost is in the $30,000-$35,000 range. Although Effenco plans to reduce this cost by half, it is still reflective of the complexity to implement this technology on HHD vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.14]

In addition, while Allison does not have data that would confirm whether 70% of vocational vehicles could adopt Stop-Start technologies without impacting their specific work functions, Energetics was also
not able to draw a conclusion for the NYSDOT fleet. Instead, this review noted that “[l]ong-term
monitoring may also provide a clearer picture of which vehicles need certain auxiliary vehicle functions
that requires the engines running to perform their job.” Even so, it is clear that certain vehicles, such as
refuse packers, fire trucks, concrete mixers and other specialized vehicles are very unlikely to adopt
technology to turn off engines at stop. Although Stop-Start equipment may be theoretically available to
such vehicles, the energy requirements of the vehicles are so large as to preclude electrified options at
reasonable costs. This calls into question the ability to reach a 70% penetration rate assumed by the

Allison Transmission

Consistent with comments that Allison submitted with respect to the Proposed Rule, we are concerned
that EPA has projected overly-aggressive adoption rates for stop-start [for custom chassis] based on the
technology reach and the high costs of start-stop systems in the time frame of Phase 2 rules. [EPA-HQ-
OAR-2014-0827-1892-A1 p.5]

There are two factors which make these assumed rates overly optimistic. First, given the nature of the
heavy-duty industry, high technology adoption rates require close cooperation between vehicle OEMs,
engine manufacturers, major component suppliers and body builders. It is simply unrealistic to believe
that the high projected adoption rates for engine stop-start are feasible given these interactions and the
fact that the end market for vehicles drives production. Second, for at least some vehicles, high adoption
rates for engine stop-start may not be possible in the time frames projected. For example, projecting that
refuse vehicles will achieve 50% penetration by Model Year 2027 does not account for the large increase
in the cost and weight of such vehicles since some energy storage is expected to be required to power the
pack cycle. Other types of heavy heavy-duty (“HHD”) vehicles may have relatively low annual
production volumes, making it difficult to recoup the added cost of engine stop-start technology. [EPA-
HQ-OAR-2014-0827-1892-A1 p.5]

**EPA and NHTSA Should Incorporate Regulatory Definition of Stop-Start Technologies**

Within the discussion of workday idle reduction technologies, EPA and NHTSA have requested comment
concerning an appropriate definition of Stop-Start technologies for vocational vehicles. Allison
recommends that the agencies incorporate a specific definition for Stop-Start technologies. We believe
that such technologies can be defined in a straightforward manner as follows: [EPA-HQ-OAR-2014-
0827-1284-A1 p.46]

Stop-Start Technology means (a) a computer controlled event that occurs when a vehicle is stopped with
no (or low) driver demand for propulsion torque and when fuel is not flowing to the engine; (b) which
allows for restart of the engine; and (c) is capable of being off for the entire stopped time in the ARB

EPA must recognize that some conditions as determined by a computer may prevent the engine from
stopping each time the conditions defined above are met. This may include, but not be limited to extreme
grades, engine and transmission operating temperatures, and emission control-related parameters. [EPA-

**Organization:** Waste Management (WM)

**WM is Concerned that EPA Assumptions Regarding Technology Penetration May not be Reflective
of Vocational Refuse Fleets**
As discussed above, heavy-duty refuse trucks are not typical of most vocational fleet vehicles. Some of the technologies that the agencies assume will penetrate all vocational vehicle fleets may not be workable for refuse trucks. For example, start/stop technology would be highly problematic for our operations. When a refuse vehicle stops and idles, the vehicle is still engaging in significant work lifting heavy loads, and operating a trash compactor and heavy doors. The trucks stop often, with commercial refuse vehicles averaging about 100 stops per day, while residential refuse vehicles may make between 800-1200 stops per day. Our trucks burn more than 30 percent of the total fuel used while stopped and operating heavy vehicle accessories to service the customer. [EPA-HQ-OAR-2014-0827-1214-A2 p.7]

The agencies need to recognize that vehicles with a significant power take-off (PTO) load will not be able to accommodate start/stop technology. In section 3.7.4 of the Regulatory Impact Analysis, the agencies assert that “typical PTO systems require no more than 19 kW at any time.” WM disagrees with this assertion in regard to refuse trucks. Our refuse trucks routinely require a range of 36kW to 80kW power level to supply significant hydraulic system demands. While some vocational vehicles might be able to use start/stop technology in combination with electric PTO (ePTO) to operate smaller accessories or lift lighter loads, a refuse vehicle will require a large electric motor and a large battery with significant storage capacity to enable the vehicle to lift heavy dumpsters or operate a heavy-duty compactor. Such additions to a refuse truck might offset the benefits of weight reduction technologies and significantly increase vehicle costs. We also note that ePTO technologies are not used anywhere in our fleet or by any major refuse company that we are aware of. Therefore, we believe that assuming significant penetration of ePTO technology or start/stop technology into the refuse sector would be overly optimistic. [EPA-HQ-OAR-2014-0827-1214-A2 p.7]

Organization: Navistar, Inc.

Stop-start technology is defined under proposed section 1037.520(f)(8) as a vehicle system that shuts off the engine under idle conditions within 30 seconds of a vehicle coming to a stop. The application and benefits of stop-start strategies must carefully weigh the fuel savings benefit against the impact on durability and operator safety of engine emissions components. These strategies must have sufficient engine, aftertreatment and occupant protections in place such that any fuel cost savings are a net benefit for the owner/operator without compromising safety. [EPA-HQ-OAR-2014-0827-1199-A1 p.32-33]

There are certain operating conditions in which a stop-start strategy are not recommended for mission-critical operations, these would include any PTO operation, emergency vehicle, utility truck, concrete mixer, refuse applications and many off road applications including utility and digger derrick. Loss of power to the PTO during normal mobile or stationary work operations can have severe safety implications for the driver/operator and or passenger/worker. In such cases a PTO inhibitor would preclude any start stop operation and associated fuel savings. [EPA-HQ-OAR-2014-0827-1199-A1 p.33]

Engine and aftertreatment durability protections should inhibit or aggressively control start stop operation. For example, the periods during a DPF regeneration or when an aftertreatment warm up strategy is in process each represent normal operating modes when maintaining fuel and or exhaust flow to the aftertreatment system is critical to ensuring long term durability and effective emissions conversion. These limits would need to account for other engine parameters, such as coolant, oil and ambient air temperature where it is important to achieve and maintain normal operating temperature. [EPA-HQ-OAR-2014-0827-1199-A1 p.33]

Engine turbocharger failures due to coking can occur during a high load, hot shut down events when the cooling and lubricating oil is removed. When this occurs the lubricating oil can partially volatilize leaving a layer of coked oil on the bearing surfaces. With repeated occurrences the bearing clearances and
turbocharger performance decrease. This in turn affects the turbocharger efficiency and by extension engine efficiency, as well as durability. With the cost and complexity of turbocharger systems increasing, the impact of a single turbocharger failure can add several thousand dollars and can easily offset any fuel economy benefit to be gained from an aggressive stop-start strategy. [EPA-HQ-OAR-2014-0827-1199-A1 p.33]

Assurance of customer comfort (heat/AC/other accessories), as well as safety for vehicles operating on steep grades, off road and for vehicles using air brakes must be taken into consideration. Advisable steps might include allowing start/stop strategies to monitor the vehicle orientation, battery state of charge and accessory power loads and adjust start/stop operation accordingly. This would ensure there is sufficient power to operate any engine-off accessories up to a point where the battery capacity has reached a critical point. At that critical point the engine would need to be restarted automatically to maintain normal vehicle operation. [EPA-HQ-OAR-2014-0827-1199-A1 p.33]

In some cases where the stationary electrical demands are high, customers may elect to install additional batteries to ensure that their extended engine off operation does not compromise the ability to restart the vehicle. This added weight may partially negate the fuel efficiency impact of any stop-start system. Finally, underlying all of these durability and safety concerns is the cost of upgrading or replacing engine starters which need to be resized to accommodate the higher frequency of starting events. Additional costs of upgrading alternators and battery capacity would also need to be addressed depending on the application and on customer demands. [EPA-HQ-OAR-2014-0827-1199-A1 p.33-34]

As previously mentioned air brake equipped vehicles will need sufficient inhibit features to allow the application or release of the service brakes in order to operate the vehicle safely. The threshold limit would need to be set reasonably high to account for vehicle foundation brakes as well as any trailers and associated system leakage. In addition some fleets--e.g. heavy haul, refuse, mixer trucks and tow trucks--may elect to have this feature set as a programmable parameter to ensure maximum safety is maintained. [EPA-HQ-OAR-2014-0827-1199-A1 p.34]

In every instance, the concept of increasing fuel economy by adding seemingly simple features like engine stop-start comes with a broad range of concerns that can impact vehicle safety, functionality, engine and emissions component durability and passenger comfort. An integrated approach must be taken to develop this functionality in order to ensure that any incremental fuel economy benefit is achievable without any underlying customer cost or inconvenience. [EPA-HQ-OAR-2014-0827-1199-A1 p.34]

**Organization:** Truck & Engine Manufacturers Association (EMA)

The assumptions that as of 2027 70% of Class 7 and 8 vocational vehicles will utilize stop-start technologies and 30% of those vehicles will utilize neutral-idle technologies are grossly overstated and not supported by current data, and so are unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

“Stop-start” technology is defined under proposed section 1037.520(f)(8) as a vehicle system that shuts off the engine under idle conditions within 30 seconds. Proposed section 1036.501(g)(2) also would allow manufacturers to run emissions tests of engines with the engine turned off during the idle portions of test cycles, based on good engineering judgment, if the engine is to be used in a vehicle with stop-start technology. [EPA-HQ-OAR-2014-0827-1269-A1 p.48] EPA anticipates that stop-start technology will reduce fuel consumption from 0.5% to nearly 7%, depending on duty cycle, with the greatest reduction over the Urban duty cycle. In the NPRM, the agencies assume that stop-start systems will be deployed in 100% of vocational vehicles in MY 2024-2027. However, a detailed spread sheet from the RIA shows that the agencies actually project that start-stop technologies will be applied at varying penetration rates
significantly less than 100% (i.e., ranging from 5% to 85%) in the several different vocational vehicle categories over the 2021-2027 time period.

Application of stop-start technology is more challenging for HHD vehicles than for MHD vehicles where systems are more likely to be implemented. In Table 2-177 of the RIA, the agencies provide cost estimates for stop-start technology for HHD vehicles, starting at $1444 in MY 2024, and reducing to $1374 in MY 2027. The agencies’ cost estimates, however, have not fully considered the impacts on engine or vehicle components for HHD vocational vehicles. For example, previous HHD engine tests with high numbers of stop-start cycles have resulted in high wear of various engine components, particularly main and rod bearings. In addition, an enhanced starter system may be required and, even then, replacement of the system could be anticipated one or more times during the HHD vehicle’s full useful life. There would need to be alternative power sources to support not just power steering, cabin heat, and transmission pressure, but also cabin cooling, lights and other functions – recognizing that idle times can be quite extended for vocational vehicles waiting to perform their functions. Given all of this, the actual cost for stop-start technologies in HHD vocational vehicles could be materially higher than the agencies’ estimate. [EPA-HQ-OAR-2014-0827-1269-A1 p.49]

Due to the lack of fully-demonstrated stop-start technologies in heavy-duty vehicles, an expectation of significant deployment – let alone up to 85% – appears to be unreasonable. Moreover, since a significant part of the vocational vehicle fuel savings is predicated on uncertain rates of deployment of start-stop systems, attaining compliance with the Proposed Phase 2 standards for vocational vehicles will be uncertain to that same extent. [EPA-HQ-OAR-2014-0827-1269-A1 p.49] /3/ A number of over-rides and exemptions will need to be provided in the “stop-start” definition to account for ambient temperatures and other relevant factors, and the agencies and manufacturers will need to define more clearly the operative entry and exit conditions for stop-start systems.

Organization: Oshkosh Corporation

By 2027, the table V-19 plan assumes a 70% adoption rate in the multi-purpose category. The NPRM suggests a savings of 3%: “Based on these projected adoption rates and the effectiveness values described above in this section, we expect overall GHG and fuel consumption reductions from workday idle on vocational vehicles to be approximately three percent in MY 2027.” While this approach may be practical in some vocations, it will be completely impossible in others leading us to believe that the percent savings is overstated. For example, shutting off a concrete mixer engine will stop the drum from rotating and risk the concrete setting up in the drum. Shutting off the engine at every stop will not be practical for fire apparatus where every second counts on the way to the emergency. Refuse trucks need the engine running when they stop to operate collection and packing equipment. [EPA-HQ-OAR-2014-0827-1162-A2 p.4]

Organization: Odyne Systems LLC

EPA has development definitions for various technologies and processes included in the draft Phase Two rule, and has requested comment on the draft definitions. Odyne has proposed definition changes on a number of these as described below. [EPA-HQ-OAR-2014-0827-1239-A1 p.33]

EPA: Seeking comment on a definition for Start / Stop technology, “equivalent technology that eliminates fuel consumption when the truck is in drive but stopped.” [EPA-HQ-OAR-2014-0827-1239-A1 p.33]
Odyne: A start-stop system, or stop-start system, automatically shuts down and restarts the internal combustion engine to reduce the amount of time the engine spends idling, or reduces the load on the engine during the idle event, thereby reducing or eliminating fuel consumption and emissions when the vehicle’s motion is stopped. [EPA-HQ-OAR-2014-0827-1239-A1 p.33]

Odyne would like the flexibility to electrically power the rotation of the prime mover without consuming fuel during stops in order to continue powering accessories such as the transmission fluid pump, oil pump, brakes, HVAC, steering or other systems that may derive their power from the rotating engine. [EPA-HQ-OAR-2014-0827-1239-A1 p.33]

EPA:
(i) Stop-start technology for vocational vehicles. Phase Two vocational vehicles qualify for reduced emissions in GEM modeling if the engine shuts down no more than 30 seconds after the onset of any of the following conditions: [EPA-HQ-OAR-2014-0827-1239-A1 p.34]

(A) The vehicle’s brake is depressed at a zero-speed condition. [EPA-HQ-OAR-2014-0827-1239-A1 p.34]

(B) A vehicle with automatic transmission goes into “Park.” [EPA-HQ-OAR-2014-0827-1239-A1 p.34]

(ii) Neutral-idle technology for vocational vehicles. A Phase Two vocational vehicle with an automatic transmission qualifies for reduced emissions in GEM modeling if the vehicle goes into neutral (or reduces torque equivalent to being in neutral) at a zero-speed condition. [EPA-HQ-OAR-2014-0827-1239-A1 p.34]

(iii) Extended-idle reduction. If your sleeper cab is equipped with idle reduction technology meeting the requirements of § 1037.660 that will automatically shut off the main engine after 300 seconds or less. [EPA-HQ-OAR-2014-0827-1239-A1 p.34]

Odyne: In item (i) we recommend focusing on the desire to reduce fuel and emissions and not focus on how that is actually accomplished. As we described in the proposed definition for Start / Stop load could be reduced on the engine instead of stopping it. This would allow the engine to keep turning and reduce the need for electrification of the engine driven components and still accomplish the same results. This would be similar to how the transmission reduces the load on the engine except for it would be handled by another system (i.e. – hybrid system). [EPA-HQ-OAR-2014-0827-1239-A1 p.34]

Organization: Volvo Group

Throughout the regulatory process Volvo has continually stated objection to engine start-stop feasibility for Heavy-Heavy Duty engines. In Volvo’s comments to the NPRM we stated: [EPA-HQ-OAR-2014-0827-1928-A1 p.12]

“Test of less than 50,000 stop-start cycles [on Heavy-Heavy Duty engines] have resulted in failures of critical engine bearings and overhead systems. We don’t even know the range of problems that will surface with this mode of operation, much less if there are feasible solutions. At a minimum, we must anticipate a need for improvements (that have not been developed) to all bearing surfaces, lubrication, and starter systems...Engine development costs will be very high since stop-start cycling tests can only be accelerated by a limited amount before the failure mechanisms are altered.” [EPA-HQ-OAR-2014-0827-1928-A1 p.12-13]
The agencies’ assessment of this technology does not consider impacts on engine durability, reliability, or even suitability for a specific weight class. [EPA-HQ-OAR-2014-0827-1928-A1 p.13]

In section 2.9.5.1.4 of the Regulatory Impact Analysis to the NPRM the agencies state

“We are projecting a five percent adoption rate of stop-start in the six MHD and LHD subcategories for MY 2021 and zero for the HHD vehicles, because this technology is still developing for vocational vehicles and is most likely to be feasible in the early years of Phase 2 for vehicles with lower power demands and lower engine inertia. Stopping a heavy-duty engine is not challenging. The real challenge is designing a robust system that can deliver multiple smooth restarts daily without loss of function while the engine is off. Many current light-duty products offer this feature, and some heavy-duty manufacturers are exploring this. The agencies are projecting an adoption rate of 15 percent stop-start across all subcategories in the intermediate year of MY 2024. The agencies are projecting this technology to have a relatively high adoption rate (70 percent as stated above) by MY 2027 because we see it being technically feasible on the majority of vocational vehicles, and especially effective on those with the most time at idle in their workday operation. Although we are not prepared to predict what fraction of vehicles would adopt stop-start in the absence of Phase 2, above in draft RIA Chapter 2.9.3 the agencies explain why we are confident that this technology, which is on the entry-level side of the hybrid and electrification spectrum, will be widely available in the Phase 2 time frame.” [EPA-HQ-OAR-2014-0827-1928-A1 p.13]

The agencies use the press releases in footnote 146 to Chapter 2 as evidence that stop-start technology will be feasible during the regulatory period for all heavy-duty engines and applications. The referenced Ford press release from December of 2013 references Ford Motor Company’s target to have stop-start engine technology on 70% of vehicles by 2017, while the Allison-Cummins announcement of July 2014 is in reference to a “demonstration” of stop-start technology on a Cummins Ethos 2.8L spark ignited engine running on E85 and backed by an Allison 2000 series automatic transmission. [EPA-HQ-OAR-2014-0827-1928-A1 p.13]

Ford Motor Company’s 2015 monthly sales volume reports for the U.S. can be seen in the table below. From these reports it is noted that Ford Motor Company’s total U.S. volume for its Ford and Lincoln Brands was over 2.6 million vehicles. Ford Heavy Trucks and Transit vans would all be subject to the Phase II heavy duty GHG rule. Only a portion of the F-series and E-series vehicles would meet the definition of a heavy-duty vehicle given in 40 CFR 1037.801 and not be excluded from the rule by 40 CFR 1037.5. Unfortunately, it was not possible to discern how many of the F- and E-series vehicles would be certified to 40 CFR 1037; however, even assuming that the excluded Ford F-150 accounted for 50% of the total F-series population and the all E-series vans were included, the resultant percentage of Ford Motor Company’s 2015 U.S. sales that would be subject to the HD GHG rule would be slightly less than 22% of the total. Since the Ford Motor Company is targeting 70% of their total U.S. sales volume to have stop-start engine technology, their entire vehicle population covered under the HD GHG Phase II regulation would not be affected. [EPA-HQ-OAR-2014-0827-1928-A1 p.13-14]

[Table 4 can be found on p.14 of docket number EPA-HQ-OAR-2014-0827-1928-A1]
In the case of the Allison-Cummins announcement, it is a significant stretch to associate demonstration of a technology on a Light-Heavy Duty spark ignition engine with commercial feasibility on a Heavy-Heavy Duty compression ignition engine. According to the release, Cummins accumulated only 1,500 hours of operation over a 2 ½ year period. In addition, the release notes that “to complete on-road validation testing” the vehicle was subjected to a two-month demonstration on California roads; if this testing were additional to the 1,500 hours we could estimate an additional ~650 hours (12 hours per day, 6 days per week, for 9 weeks). It must be noted that a single engine or vehicle, even approximating 2,150 hours of operation, is not a statistically valid sample to determine either reliability or durability to meet the demands of a mature production technology. In short, the continued reference in the release to a “demonstration” shows this effort was to show the technology could provide a benefit, not that it was reliable or durable. [EPA-HQ-OAR-2014-0827-1928-A1 p.14]

In addition, the agencies have not investigated what would be required to develop HHD engine systems to withstand the potential 10-times, or more, increase in engine start cycles. The only discussion noted in the RIA or Preamble to the Proposed Rule was around additional battery capacity (see also RIA Section 2.4.8.2). As such, Volvo still asserts that there is insufficient evidence to suggest that stop-start engine technology is feasible on a Heavy-Heavy Duty engine at any time within the regulatory period. [EPA-HQ-OAR-2014-0827-1928-A1 p.14]

As noted in the RIA section quoted above and repeated in Preamble Chapter V(C)(2)(b)(iv) and Table V-17, the agencies are not projecting penetration of engine stop-start in HHD vehicles for 2021. Their reasoning is that the technology is “still developing” and is “most likely feasible” only for LHD and MHD in the early years of Phase II; however, they have predicated Custom Chassis compliance on penetrations of stop-start technology in 2021 for transit buses, school buses, and refuse, all of which have a high percentage of Class 8 volumes. It is not then acceptable to require Custom Chassis manufacturers with no ability to average outside a Custom Chassis sub-category to meet any penetration of a technology without which they would either need to have substantially higher penetrations of other credited technologies, or would not be able to comply. This will be further compounded by the agencies’ increase in idle times for vocational duty cycles, as the NPRM value for stop-start improvement factor was 7% under the NPRM urban duty cycle, which will substantially increase under increased idle. [EPA-HQ-OAR-2014-0827-1928-A1 p.14]

For all of these reasons Volvo does not believe that start-stop engine technology is feasible in any Heavy-Heavy Duty context and further asserts that, even if the technology were proven feasible, it should not be relied upon in the Custom Chassis proposal due to the limited GEM inputs available for compliance. [EPA-HQ-OAR-2014-0827-1928-A1 p.15]

Organization: Volvo Group

Start/stop technology is described as: ‘...the engine shuts down no more than 30 seconds after the onset of any of the following conditions:

(A) The vehicle’s brake is depressed at a zero-speed condition.

(B) A vehicle with automatic transmission goes into “Park.”’

No Class 8 vehicle or engine has ever demonstrated capability of running in this mode for even a reasonable portion of its full expected lifetime of more than one million miles. A vocational vehicle could easily be subjected to hundreds or more such events in a full day of operation (UPS reports more than 1000 such stops per day for delivery vehicles in urban traffic) and millions of cycles in its life. No tests
have ever been documented to demonstrate continued functionality over even 10% of these cycles. Test of less than 50,000 stop-start cycles have resulted in failures of critical engine bearings and overhead systems. We don’t even know the range of problems that will surface with this mode of operation, much less if there are feasible solutions. At a minimum, we must anticipate a need for improvements (that have not been developed) to all bearing surfaces, lubrication, and starter systems. In addition, unless provision is made to allow continued engine operation when air conditioning is deployed, auxiliary AC systems will need to be deployed. Engine development costs will be very high since stop-start cycling tests can only be accelerated by a limited amount before the failure mechanisms are altered. None of this has been considered in the casual assumptions that such systems are readily available for deployment. [EPA-HQ-OAR-2014-0827-1290-A1 p.20]

Response:

The agencies proposed to predicate the vocational vehicle standards in part on 70 percent adoption of stop-start in MY 2027. Our assessment of workday idle reduction technologies has been refined since proposal, and part of this refinement includes less reliance on adoption of stop-start than at proposal.

Stop-start is a technology that requires an integration between engine and vehicle systems, and is seeing increasing acceptance in today’s passenger vehicle market. The agencies are aware that for a vocational vehicle’s engine to turn off during workday driving conditions, there must be a minimal reserve source of energy to maintain engine-protection and safety functions such as power steering, transmission pressure, engine lubrication and cooling, among others. As such, stop-start systems can be viewed as having a place on the low-cost end of the hybridization continuum. 80 FR 40300. However we must be clear to distinguish this technology from the AES described below. Stop-start technologies will be recognized only over the drive idle cycle and the transient cycle in GEM, not the parked idle cycle. This is a change since proposal because we had proposed only a single idle cycle during which a stop-start system could have qualified for reduced emissions during modeling if it turned off the engine either while stopped in traffic or while parked. The addition of a second idle cycle (i.e. both parked idle and drive idle) has allowed us to distinguish stop-start from AES as two very different technologies with different test cycles, different over-rides, different costs, and different effectiveness.

In the final rules, there are differences between drive idle and parked idle in many respects. See RIA Chapter 2.9.3.4, RIA Chapter 3.4.2, and the NREL duty cycle report for more information about the different idle cycles. One example of a difference in over-rides is that stop-start does not have an over-ride related to ambient temperature, because the period of zero speed during which the engine may be off is relatively short, on the order of seconds to minutes, compared with the period of parked idle engine off that could be on the order of minutes to hours. The different over-rides may be reviewed in the regulations at 40 CFR 1037.660. Another example of a difference is in the fueling rate. During the parked idle cycle the fueling rate represents the vehicle being out of gear, either in neutral or park depending on the transmission type. This fueling rate can be significantly lower for some vehicles than the fueling rate that occurs while stopping in traffic in a drive idle situation, because of the torque applied by some transmissions when in gear. Another difference is in effectiveness, where stop-start is assumed to have a 90% effectiveness over the drive idle cycle, and AES is assumed to have an 80% effectiveness over the parked idle cycle. See RIA Chapter 3.4.2.3.

For stop-start in the final rules, the purpose of the additional hardware is to protect the engine for short duration stops such as at traffic lights, not to power accessories such as HVAC systems while the vehicle is parked. We are not aware of stop-start systems that are commercially available for conventional vocational vehicles today, but this feature is available as part of some current hybrid systems. Effenco is a supplier who is demonstrating today a capacitor-based stop-start system with on-board electronics.
sufficient to protect a HHD engine and even power a PTO. Allison correctly noted that Effenco’s system is currently selling for prices that are more expensive than we are projecting. Effenco’s comment suggests that by MY 2027 the incremental manufacturing costs will be in a range that is three to six times the agencies’ estimate for stop-start systems on class 8 vehicles. However, Effenco’s system delivers more sophisticated functions than we believe are necessary for most vocational vehicles, especially with the overrides that we are allowing. See Section 11.3 for responses to comments on the agencies’ cost analysis including R&D and markups.

Volvo’s comments about the feasibility of stop-start for HHD engines (generally 11L and larger) include concerns about engine development costs for durability testing and other challenges; however, they do not actually show the technology to be infeasible. We appreciate these comments that help us understand that before this technology can be made widely available, testing must be conducted to show reliability of systems and components including starters, lubrication, and bearing surfaces. It’s possible that some time may also be needed for development work where manufacturers elect to shift away from reliance on batteries for starting the engine and begin to rely instead on ultracapacitors, which do not have the same problems with cold weather operation and long term fatigue as do batteries. We agree with commenters that this type of development work would likely be part of bringing this technology to the vocational vehicle market, and thus we have included costs for similar upgrades to those described for all sizes of engines, not just for those over 11L. In the event that an engine manufacturer needs to delay adoption of stop start to roll these changes into a planned engine platform redesign, we believe our relatively modest adoption rates of 20 to 30 percent in MY 2027 will accommodate this.

Volvo is inaccurate in claiming in its comments that we had cited press releases for stop-start on light-duty vehicles and LHD demonstration vehicles as evidence that stop-start will be feasible for all vocational vehicles. We cited Ford’s announcement as evidence that this technology is currently available on light-duty vehicles, and we cited the Cummins-Allison press release as evidence that some HD manufacturers are exploring this technology (See 80 FR 40310). At proposal we reasoned that those developments and other facts led us to conclude that stop-start would be technically feasible on a majority of vocational vehicles by MY 2027. After considering comments and accounting for the revised idle cycles, the agencies are projecting only 20 percent adoption of stop-start for HHD vehicles other than Regional, and 30 percent for non-Regional LHD and MHD vehicles in MY 2027. We are confident heavy-duty stop-start systems for conventional vehicles will be feasible on these vehicles at these rates in the time frame of Phase 2. Where stop-start is relied upon as part of a certified configuration with components installed by a secondary manufacturer, these will be subject to specifications and installation instructions of the certifying manufacturer (See 40 CFR 1037.621 and 1037.622).

The effectiveness of stop-start as recognized in GEM will be evaluated on an engine-specific basis, with a five second shutoff assumed as it is run in GEM during the transient cycle. During the separate drive idle cycle a 90 percent effectiveness is assumed. This addresses commenters’ concern about over-estimating the effectiveness of this technology, and is appropriate because we expect a wide variety of stop-start solutions to be deployed in the vocational vehicle market, and we anticipate modest use of over-ride conditions, which include an over-ride for PTO use. Setting a shorter duration before shutdown could over-estimate the reductions achieved by this technology in use. We believe this is a fair way to represent that the system may not have the designed effectiveness under all conditions. As with neutral idle and AES technologies, stop-start can reasonably be applied for vocational vehicles where this feature would not frequently encounter an over-ride condition. Vehicles with very little driving in transient conditions

---

or with high PTO operation can apply this technology, although they would see reduced effectiveness in use.

As noted above, we are projecting zero adoption of stop-start for Regional vocational vehicles, and this also includes motor homes and coach buses certified to the optional custom chassis standards, as these vehicles have characteristically regional driving patterns. Cement mixers must continually rotate the drum using the PTO while underway, and we are not aware of any electrified PTO system that could meet the performance needs of a cement mixer without adding an unacceptable amount of weight to a vehicle in this highly weight-sensitive application. Emergency vehicles have sophisticated onboard electronics that would make designing a stop-start system very complex, and because these vehicles accumulate so few miles, it does not seem cost-effective to develop this technology for this application. For the other custom chassis that typically have urban driving patterns, we have determined that stop-start is feasible for school buses, transit buses, and refuse trucks. See Preamble at V.C.2.b. For school buses, we concluded that the reasoning we applied to determine that MHD Urban vehicles in the primary program can adopt this at a rate of 30 percent in MY 2027 is also valid for school buses.

Although Gillig commented that current market offerings of stop-start for transit buses are only available as part of a full hybrid package, our reasoning pertaining to development of this technology in the time frame of Phase 2 also applies to transit buses. Engines for transit buses are typically medium heavy-duty 9-liter engines, and because commenters primarily raised concerns about lead time in the context of HHD engines, we expect MHD engines will need less lead time than HHD engines in terms of developing robust non-hybrid stop-start systems. This makes sense because the smaller engines have less rotational inertia and thus may not need as many engineering design upgrades, and with shorter regulatory useful lives these may not need as extensive durability testing as HHD engines. Further, where a hybrid system with a stop-start feature is installed on a transit bus using the custom chassis option, the manufacturer will be eligible to obtain reduced emissions for stop-start without needing to perform powertrain testing, because the technology may be credited in GEM via the default engine. We thus believe it is reasonable to project that by MY 2027, 30 percent of custom chassis transit buses will have stop-start systems that are part of either conventional or hybrid drivelines.

Refuse trucks that routinely compact waste throughout their neighborhood collection activity would likely either experience the PTO over-ride condition too frequently to make stop-start cost-effective, or manufacturers may elect to install a system similar to Effenco’s that has been designed with the refuse vocational vehicle in mind. As noted above in Section 6.3.3.3, there are a wide variety of refuse drive cycles, and some may lend themselves to stop-start better than others. Along with the variety of duty cycles comes a variety of engines typically powering refuse trucks, from 9 to 13 liters, some of which may need less lead time than others in terms of developing robust non-hybrid stop-start systems. As with transit buses, chassis manufacturers certifying refuse trucks to the optional custom chassis standards may enter Yes in the input field in GEM for stop-start (whether part of a conventional or hybrid system) and the effectiveness will be computed based on the default 350 hp engine with 5-speed HHD automatic transmission. We thus believe it is reasonable to project that by MY 2027, 20 percent of custom chassis refuse trucks will have stop-start systems that are part of either conventional or hybrid drivelines.

6.3.4.2 Neutral Idle

Organization: Allison Transmission, Inc.

Allison believes that the Direct Material Cost (“DMC”) assumptions for Neutral-Idle are understated. EPA assumes that no additional hardware is required for this capability. At the time when the transmission baseline configuration was established, however, all fully automatic transmissions did not
have the hardware needed for Neutral-Idle. Thus, there is obviously an increased cost associated with this capability. Specifically, a vehicle sensor is also necessary to assure the brakes are “on” in order to activate Neutral-Idle. Allison believes that a more appropriate DMC assumption is $100. [EPA-HQ-OAR-2014-0827-1284-A1 p.14]

Organization:  Daimler Trucks North America LLC

GEM Inputs for Neutral Idle

We are not certain that we understand how GEM credits neutral idle. As we understand: First, for any engine, there are two idle points in the fuel map, one with no load and one with torque converter load. If the transmission has a neutral idle, then at any idle time-step in GEM, the fuel consumption rate is the no load rate; otherwise, it is the loaded rate. If we understand correctly, then the neutral idle approach is correct. [EPA-HQ-OAR-2014-0827-1164-A1 p.63]

Organization:  Oshkosh Corporation

With respect to Neutral Idle, the NPRM states that “Based on GEM simulations using the currently proposed vocational vehicle test cycles, the agencies estimate neutral idle for automatic transmissions to provide fuel efficiency improvements ranging from one percent to nearly four percent, depending on the regulatory subcategory.” This approach shifts the transmission to neutral whenever the engine is at idle. Certain vocational trucks spend a lot of time at idle, but the transmission is already in neutral, and the engine power is performing work at that time. This technology is not feasible for Concrete and Refuse for the same reasons described in our comments under stop-start. [EPA-HQ-OAR-2014-0827-1162-A2 p.5]

Organization:  Truck & Engine Manufacturers Association (EMA)

The assumptions that as of 2027 30% of Class 7 and 8 vocational vehicles will utilize neutral-idle technologies are grossly overstated and not supported by current data, and so are unreasonable. [EPA-HQ-OAR-2014-0827-1269-A1 p.71]

“Neutral-idle” is also described in that proposed regulatory section, and refers to a system that automatically shifts a vehicle “into neutral (or reduces torque equivalent to being in neutral) at zero-speed condition.” Apparently, the agencies anticipate that neutral-idle technology will be offered by one or more automatic transmission suppliers in the timeframe for the Phase 2 Standards, but it is unclear by which suppliers, at what cost, and with what restrictions on vehicle operations.

As an initial matter, vehicle manufacturers should not be held responsible for determining whether a particular transmission meets the agencies’ rather vague definition of “neutral-idle” systems. Rather, the agencies should require transmission manufacturers to provide a certification that a given transmission system meets the “neutral-idle” criteria. Similarly, the agencies should hold the transmission manufacturer responsible if that certification later proves to be incorrect, just as pertains with respect to tire manufacturers under Phase 1. [EPA-HQ-OAR-2014-0827-1269-A1 p.48]

EPA estimates that neutral-idle will reduce fuel consumption by 1% to 4% for vocational vehicles. In the NPRM, the agencies assume that neutral-idle will be used in 100% of vocational vehicles in MY 2021 (although it is only applicable to automatic transmissions). (See Tables V13 through V-15, reproduced below). However, a detailed spread sheet from the RIA shows that the agencies actually project that neutral-idle technologies will be applied at varying penetration rates significantly less than 100% (i.e., ranging from 5% to 85%) in the several different vocational vehicle categories over the 2021-2027 time
period. A screen shot of the agencies’ spread sheet is included below. [EPA-HQ-OAR-2014-0827-1269-A1 p.49]

**Organization:** Volvo Group

Although we have some indication that a “neutral idle” automatic transmission may be available from one manufacturer, we do not know the cost, reliability, or performance of this product. With this situation, we cannot endorse or support the contention that all automatic transmissions can offer this feature by MY 2021. In addition, it is unclear as to how a vehicle manufacturer could ensure that any particular transmission meets the requirements for neutral idle, stated as: [EPA-HQ-OAR-2014-0827-1290-A1 p.21]

“A Phase 2 vocational vehicle with an automatic transmission qualifies for reduced emissions in GEM modeling if the vehicle goes into neutral (or reduces torque equivalent to being in neutral) at a zero-speed condition.”

If the agencies intend to provide credit for this technology and to include it in stringency expectations, provision should be made for suppliers to certify that the technology is approved for the credit. [EPA-HQ-OAR-2014-0827-1290-A1 p.21]

**Response:**

Neutral idle may be programmed on any automatic transmission, and can reasonably be applied for vocational vehicles where this feature would not frequently encounter an over-ride condition. The adoption rates we project for this technology are described in Section V.C.2.b (iv) of the Preamble and RIA Chapter 2.9.5.1.4. Neutral idle is essentially a transmission technology, but it also requires a compatible engine calibration. Torque converter automatic transmissions traditionally place a load on engines when a vehicle applies the brake while in drive, which we call curb idle transmission torque (CITT). When an engine is paired with a manual or automated manual transmission, the CITT is naturally lower than when paired with an automatic, as a clutch disengagement must occur for the vehicle to stop without stalling the engine. The engineering required to program sensors to detect the brake position and vehicle speed, and enable a smooth re-engagement when the brake pedal is released makes this a relatively low complexity technology that can be deployed broadly. Allison provided information in its comments that the agencies’ cost estimates for neutral idle were too low. We have revised our costs upward for neutral idle in response to Allison’s comment and specifically have included the cost of a sensor.

Allison has publically available information about its transmissions that feature neutral at stop, including its FuelSense Plus and FuelSense Max products. The only concern we have heard from stakeholders about performance is that without some engineering adjustments, a re-engagement bump when returning to drive from neutral may produce a minor driver annoyance. Based on currently available information, we expect neutral idle technology to be available in the near term for many vehicles, and we expect technology or engineering to minimize a re-engagement bump should not meaningfully increase the lead time or cost of this technology.

An example of an allowable override is if a vehicle is stopped on a hill. Skilled drivers operating manual transmissions can safely engage a forward gear from neutral when stopped on upslopes with minimal roll-

---

back. With an AT, the vehicle’s computer would need to handle such situations automatically. In addition, engagement of the PTO while driving will be an allowable over-ride condition. In the Phase 2 certification process, transmission suppliers will attest whether the transmission has this feature present and active, and certifying entities will be able to enter Yes or No as a GEM input for the applicable field.

The effectiveness of the neutral idle technology will be calculated using data points collected during the engine test, using the appropriate fueling over the drive idle cycle and the transient cycle. This technology has no effect on the parked idle cycle, thus it need not have any effect on vehicle operation while parked to qualify in GEM.

We agree with OshKosh that this technology is not feasible for cement mixers. As this is a drive idle technology and cement mixers must rotate the drum at all times while underway, a reduced torque at zero vehicle speed would not be possible without a very advanced (and prohibitively costly) e-PTO system. However, we disagree with OshKosh with respect to refuse trucks. There are a wide variety of refuse drive cycles. Refuse vehicles that may benefit from neutral idle may be front loaders and those that must convey a fully compacted load across town after completing a neighborhood collection route. We are projecting 50 percent adoption of neutral idle on refuse trucks in the custom chassis program by MY 2027, which is considerably less than the 70 percent adoption projected for HHD Urban vehicles in the primary program. See Preamble at V.C.2.b.

Because we are considering stop-start and neutral idle to be mutually exclusive on a per-vehicle basis (see RIA Chapter 2.9.5.1.4), the sum of adoption rates for these two technologies does not exceed 90 percent in MY 2027. Neutral idle adoption rates start at 50 percent in MY 2021 because we expect this technology will not need much lead time, if any (given that the technology already exists, is commercially available, and does not present significant engineering challenges). By MY 2027 the adoption rate of neutral idle does not exceed 70 percent because we are not projecting it to be combined with stop-start on a vehicle. Although these may be combined in GEM, any additional effectiveness during the ARB transient and drive idle cycles would be very small. An exception to the projected 90 percent maximum adoption rate is transit buses, where we believe all vehicles of this type can reasonably apply some form of drive idle reduction technology.

6.3.4.3 Automatic Engine Shutdown

Organization: Alliance of Idle Mitigation Technologies

Idling is an activity that occurs in the off duty cycle. A more comprehensive scheme is needed to ensure that the credit awarded for vehicle efficiency reflects what happens in the real world, and that unintended consequences do not extinguish the businesses that are already doing a great job reducing the very waste that the rule intends to curb – and our business are quickly growing. The Alliance is not directly regulated by the fuel efficiency standard, but it deserves a seat at the table. The agencies did confer with a diverse group of industry and stakeholders, however, our companies were not part of that dialogue, nor were we permitted to attend the Small Business Administration roundtable created to evaluate the unintended effects of the proposed rule, in as much as we are not OEMs. [EPA-HQ-OAR-2014-0827-1311-A1 p.1]

Fuel efficiency standards are a relatively straightforward calculus involving only OEMs, until it endeavors to regulate the off-duty cycle behavior of idling. We believe that extra participation of the idle reduction industry is required in order to form the most effective method of addressing the wasteful

---

The final GEM input file allows users to apply multiple idle reduction technologies within a single vehicle configuration.
practice of idling. Please consider further deliberations with us prior to adoption of the final rule. [EPA-HQ-OAR-2014-0827-1311-A1 p.2]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

The real world use of idle shutdown on cement mixers must be taken into account in the final regulations. [EPA-HQ-OAR-2014-0827-1895-A1 p.3]

Organization: ABC Bus Companies, Inc.

The climate control of passenger compartments during the loading or unloading process is essential in Passenger Carrying Vehicles just as it is on airplanes or trains. Extreme seasonal weather conditions and temperatures can dictate vehicle idling operations to ensure the health and welfare of passengers being transported in these vehicles. Putting passengers on an extremely HOT or COLD could prove harmful to passengers. In addition, ADA wheel chair lift operation can require that engines be running while these passengers are loaded and unloaded into a motorcoach. Most over-the-road coaches also have to provide rest room facilities for passengers. Mandating AES standards for (PCV's) could adversely affect the health of the traveling public. [EPA-HQ-OAR-2014-0827-1430-A2 p.3]

The NREL should consider the PCV operation as described above to help define this vocational vehicle test cycle. [EPA-HQ-OAR-2014-0827-1430-A2 p.3]

Response:

Automatic engine shutdown (AES) is an engine technology that is widely available in the market today, but has seen more adoption in the tractor market than for vocational vehicles. Although we did not propose to include this technology as part of the technology packages used to develop standard stringency and cost, we received many comments suggesting that it would be appropriate to do so. Some commenters may have conflated the concept of stop-start with AES, such as a comment we received asking us to consider the on-board need to power accessories while the vehicle is in stationary mode. We believe that automatic engine shutdown is effective and feasible for many different types of vehicles, depending on how significant a portion of the work day is spent while parked. Most truck operators are aware of the cost of fuel consumed while idling, and importantly, the wear on the engine due to idling. Engine manufacturers caution owners to monitor the extent of idling that occurs for each work truck and to reduce the oil change interval if the idle time exceeds ten percent of the work day. Accordingly, many utility truck operators track their oil change intervals in engine hours rather than in miles. The agencies are adopting an allowable AES over-ride for PTO use. We are also adopting an allowable AES over-ride if the battery state of charge drops below a safe threshold. This would ensure there is sufficient power to operate any engine-off accessories up to a point where the battery capacity has reached a critical point. Where a vocational vehicle has such extensive stationary accessory demands that an auxiliary power source is impractical or that an over-ride condition would be experienced frequently, we do not consider AES to be feasible. Examples include coach buses, motor homes, transit buses, refuse trucks, concrete mixers, and emergency vehicles. To make AES practical for a coach or transit bus, for example, a much larger auxiliary power source would be needed than the one projected as part of this rulemaking. We have based the school bus standards in part on adoption of AES because although many school buses have voluntarily adopted idle reduction strategies for other reasons, we do not believe many have tamper-proof automatic shutdown systems. See Section V.C.2.b (iv) of the Preamble and RIA Chapter 2.9.5.1.4.
In the Phase 2 certification process, engine suppliers will attest whether this feature is present and tamper-proof, and certifying entities will be able to enter Yes or No as a GEM input for the applicable field. As with neutral idle described above, the effectiveness of AES will be calculated in GEM using data obtained through engine testing. The appropriate data points over the parked idle cycle will be used for calculating the fueling.

6.3.5 Lower Rolling Resistance Tires

Organization: Daimler

**Lower Rolling Resistance Tires** - The agencies request comment on the use of the adjustment factor for LT tires. We have no comment on this topic except to say that the agencies should now have enough information to set tire Crr targets for each regulatory sub-category based on the RSCs’ needs and without extrapolation. [EPA-HQ-OAR-2014-0827-1164-A1 p.79]

Organization: GILLIG LLC

We believe with regard to tire rolling resistance that transit buses should be treated separately from the rest of the vocational vehicles. The average speed of transit buses is lower than the other vehicles in the vocational vehicle category. If Phase 2 is going to continue to use tire rolling resistance as a GEM input, then the decrease in tire rolling resistance associated with lower vehicle speeds needs to be accounted for in the GEM calculation for CO2 and fuel efficiency. [EPA-HQ-OAR-2014-0827-1156-A1 p.3]

Organization: National Automobile Dealers Association (NADA)

The Phase 2 proposal significantly overestimates the potential for vocational vehicle LRRTs uptake. For those vocational customers where LRRT use may be technologically acceptable, their higher cost may not be, given the number of miles and speeds driven. For example, many vocational vehicle purchasers spec tires with heavy-duty sidewalls designed to resist damage in stop/go, urban, heavy-load, bad weather, and off-road operating conditions. Since LRRTs often trade sidewall durability and traction for lower weight, they are not appropriate for vocational customers whose operations place a premium on durability, traction and/or safety. Given these constraints, NADA/ATD suggests that the projected MY 2027 vocational vehicle LRRT MRP be reduced by half. [EPA-HQ-OAR-2014-0827-1309-A1 p.9]

Organization: National Waste & Recycle Association

We are disappointed in the agencies continued advocacy of low rolling resistance tires as the primary fuel efficiency solution for vocational vehicles in the face of evidence that these tires do not offer fuel efficiency benefits for refuse vehicles. [NHTSA-2014-0132-0071-A1 p.2]

The agencies continue to place great reliance on the use of low rolling resistance tires to achieve the fuel consumption standard for the universe of vocational vehicles. Yet the NAS report noted that low rolling resistance tires “do not generate the same level of fuel savings for drive cycles that include frequent stops and starts as for drive cycles with minimal amounts of braking” and that as a result of these factors, the contribution of rolling resistance to truck fuel use is less in delivery trucks and still less in refuse haulers…” (see NAS, page 115) and that “the use of low rolling resistance tires has some application in

---

191 We will consider non-tamper-proof AES as off-cycle technologies for a lesser credit. See 40 CFR 1037.610.
refuse packers, but their low vehicle speed profile and the need for good traction makes the application questionable” (see NAS, page 141). [NHTSA-2014-0132-0071-A1 p.7]

Nonetheless, the agencies state, see page 40299, right column, that “vocational vehicles are likely to see the most benefits from reduced tire rolling resistance with they are driving at 55 mph” and that “both vocational vehicles tested had greater benefits of LRR tires at 100 percent payload than when empty.” As noted above, refuse trucks have patterns of extensive stopping. In addition, while those trucks can travel at 55 mph on the way to a transfer station or landfill, highway driving provides a small percentage of their road travel time. Finally, refuse trucks fill up throughout the day and only achieve 100 percent legal payload at the end of the route. As a result, we do not anticipate any fuel efficiency savings from lower rolling resistance tires. [NHTSA-2014-0132-0071-A1 p.7]

**Organization:** Michelin North America, Inc.

The 'conventional wide base' (sometimes known as 'wide base singles' or 'super singles' sizes), e.g. 385/65, 425/65 and 445/65, are different from the NGWBS75 mph speed rated tire technology in use today. These 'conventional wide base singles' or 'super singles' are not typically known for fuel efficiency and long haul highway applications in the North American market and have speed ratings of 62, 65 or 68 mph. They are mostly targeted for vocational on-off road and urban applications where they offer a larger single mount load capacity (steer) or some weight reduction on drive and trailer applications. [EPA-HQ-OAR-2014-0827-1286-A1 p.3]

The above clarification will assist users to select the appropriate tires for their needs. [EPA-HQ-OAR-2014-0827-1286-A1 p.3]

**Organization:** UPS

UPS fully supports the following excerpt from ATA's comments and notes that our concern focuses on Class 6 truck tires. We approve taking weight out of the tread, but not from the tire casing: [EPA-HQ-OAR-2014-0827-1262-A1 p.6]

'Tire rolling resistance must be tailored to each vehicle subcategory. This especially holds true with respect to Class 4-6 vocational vehicles. SmartWay tire verification focuses on in-use highway applications — not vocational operations. Class 6 tires currently have a heavy-rub band on the sidewall to prevent sidewall damage largely caused by excessive scrubbing against curbs during urbanized hauls. Thicker sidewalls help maintain casing integrity and affords fleets the ability to get close to four subsequent retreads. LRRTs typically do-away with thicker side bands to lower tire weight (in the range of 30%) and get better fuel economy test track results. Unfortunately, fleets do not deliver goods on test tracks and even the best drivers have contact with curbs throughout their delivery schedules. [EPA-HQ-OAR-2014-0827-1262-A1 p.6]

'The four tire levels set out under the rule will have shorter useful lives and will minimize recap opportunities. As referenced prior, it takes 23 gallons of oil to manufacture a new tire and only 8 gallons to retread — a statistic that cannot be ignored in undertaking both carbon and fuel use analyses under the proposal. If better tire rolling resistance levels can in fact be achieved while maintaining heavy-rub bands needed for greater casing integrity and durability, ATA would be in a better position to support the vocational tire requirements set out under the rule. [EPA-HQ-OAR-2014-0827-1262-A1 p.6]

'Finally, many vocational applications need to go off-road at construction sites, mining operations, landfills, and similar locales. The transition to LLRTs would not satisfy customer needs for adequate
traction in these environments. ATA requests that the agencies conduct independent and robust studies of new LRRT generation tires in advance of their entry into the marketplace to assess safety, traction, and availability.’ [EPA-HQ-OAR-2014-0827-1262-A1 p.6]

Organization: California Air Resources Board (CARB)

The Phase 2 proposal for emergency vehicles allows emergency vehicles to continue to use tires meeting only Phase 1-level Crr performance. While CARB staff understands the unique functionality, performance, and reliability criteria applicable to emergency vehicles, it also believes that as tires with Phase 2-level Crr values become more readily available in the market place and at a lower cost, emergency vehicle manufacturers will be able to overcome remaining technical challenges associated with the use of lower-rolling resistance tires in the emergency vehicle sector, particularly in the latter years of the Phase 2 program. As such, CARB staff proposes U.S. EPA and NHTSA to consider provisions, utilizing a phase-in approach, to require the use of tires meeting lower Crr levels than required by Phase 1, in the emergency vehicle sector. [EPA-HQ-OAR-2014-0827-1265-A1 p.139]

Organization: American Trucking Associations (ATA)

Lower Low Rolling-Resistance Tires (50% 6.9 Crr Steer Tires in 2027; 15% 6.5 Crr Drive Tires in 2027)

Tire rolling resistance must be tailored to each vehicle subcategory. This especially holds true with respect to Class 4-6 vocational vehicles. SmartWay tire verification focuses on in-use highway applications – not vocational operations. Class 6 tires currently have a heavy-rub band on the sidewall to prevent sidewall damage largely caused by excessive scrubbing against curbs during urbanized hauls. Thicker sidewalls help maintain casing integrity and affords fleets the ability to get close to four subsequent retreads. LRRTs typically do away with thicker side bands to lower tire weight (in the range of 30%) and get better fuel economy test track results. Unfortunately, fleets do not deliver goods on test tracks and even the best drivers have contact with curbs throughout their delivery schedules. [EPA-HQ-OAR-2014-0827-1243-A1 p.9]

The four tire levels set out under the rule will have shorter useful lives and will minimize recap opportunities. It takes 23 gallons of oil to manufacture a new tire and only 8 gallons to retread – a statistic that cannot be ignored in undertaking both carbon and fuel use analyses under the proposal. If better tire rolling resistance levels can be achieved while maintaining heavy-rub bands needed for greater casing integrity and durability, ATA would be in a better position to support the vocational tire requirements set out under the rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.9]

Finally, many vocational applications need to go off-road at construction sites, mining operations, landfills, and similar locales. The transition to LRRTs would not satisfy customer needs for adequate traction in these environments. ATA requests that the agencies conduct independent and robust studies of new generation LRRTs in advance of their entry into the marketplace to assess safety, traction, and availability. [EPA-HQ-OAR-2014-0827-1243-A1 p.9]

Organization: Oshkosh Corporation

Phase 1 is already mandating improvements, and we believe that by 2017, further rolling resistance improvements will not be possible without degrading the traction capabilities that most vocational trucks require. Even if rolling resistance could be reduced without sacrificing traction, the proposal correctly
points out that the tire manufacturers have little incentive to put research into those tire sizes appropriate, only for low volume vocational applications.

The 2027 upper limit values of 6.4 for steer tires and 7.0 for drive tires are lower than the averages we currently see for our concrete mixer tires. Since concrete mixers must often operate off-road in muddy job sites, it is essential that maximum traction be maintained. A number of other vocational vehicles must also be able to operate both on-road and off-road. Further rolling resistance improvements may not be possible without degrading the traction capabilities beyond an acceptable range. Even if rolling resistance could be reduced without sacrificing traction, the NPRM points out correctly that tire manufacturers have little incentive to put research into those tire sizes appropriate for low-volume vocational applications only. [EPA-HQ-OAR-2014-0827-1162-A2 p.5]

Since implementation of Phase I, we have not seen any vocational vehicle tire changes from suppliers. The CRR values provided at the beginning of Phase I are still the same values provided today. Consider that the larger market for truck tires is not those purchased by the OEM for new vehicles, but rather the replacement and re-tread markets. Neither the OEM nor the EPA can control the tires purchased for replacement, so tire manufacturers can continue to see significant market sales of current high CRR tires regardless of pressure by small volume vocational truck OEMs. We question whether implementation of Phase II will cause tire suppliers to place any emphasis on CRR improvements for the low-volume tire models that serve our vocations. [EPA-HQ-OAR-2014-0827-1162-A2 p.5]

**Organization:** Rubber Manufacturers Association (RMA)

**RMA Evaluation of GEM Inputs for Tires (non-speed restricted) for Vocational Vehicle Fitments**

RMA appreciates that the agencies collected data to better understand the rolling resistance performance of tires that are equipped on vocational vehicles for purposes of this rule. Yet, the data collected does not represent the breadth of vocational vehicle applications and appropriate tire fitments. [EPA-HQ-OAR-2014-0827-1304-A1 p.16]

Some tire fitments in the vocational vehicle segment are designed for low speed, heavy load applications where rolling resistance is not a key design parameter since typical use would not yield meaningful fuel economy benefits and other tire performances are more critical. After evaluation of member company data showing rolling resistance of tires for certain vocational fitments, RMA concludes that the same GEM inputs should not be used for all tires used on vocational vehicles. [EPA-HQ-OAR-2014-0827-1304-A1 p.16]

RMA collected rolling resistance data from its member companies for several tire size and load range combinations for both steer/all-position and drive tires. In particular, RMA evaluated tires with rim diameters of 17.5 to 24.5 inches across several load ranges where current rolling resistance performance may not be equivalent to the proposed GEM tire inputs for vocational vehicles. After its review, RMA recommends that the agencies consider adjusting the GEM inputs and resulting fuel economy and resulting GHG emission limitations for drive tires installed on vocational vehicles. [EPA-HQ-OAR-2014-0827-1304-A1 p.16]

**The Agencies’ Proposed GEM Inputs for Steer/All-position Tires (non-speed restricted) are Appropriate**

Figures 7 and 8 show the rolling resistance coefficients for each of the tire size/load range combinations evaluated for steer/all-position tires. Based on the data in Figure 7 and Figure 8, RMA concludes that the
proposed GEM inputs for steer/all-position tires are appropriate. Although not all current tires will meet the 2021 GEM input value (7.1 kg/T), it seems achievable. [EPA-HQ-OAR-2014-0827-1304-A1 p.17]

[Figure 7, 'Distribution of Rolling Resistance Values of Steer/All-Position Tires for Vocational Vehicles', p.17 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

[Figure 8, 'Analysis of Rolling Resistance Values for Steer/All-Position Tires for Vocational Vehicles', can be found on p.18 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

The Agencies Should Adjust the GEM Inputs for Drive Tires (non speed-restricted) and Resulting Limits for Vocational Vehicles

RMA also collected rolling resistance data for drive tires used in vocational vehicle applications, presented in Figures 9 and 10. Of significance, nearly half of the values are higher than the baseline value (7.7 kg/T) proposed by the Agency. The vast majority of products represented would require major redesign in order to meet the proposed GEM Inputs for 2021, 2024 and 2027. [EPA-HQ-OAR-2014-0827-1304-A1 p.18]

RMA believes the drive tire GEM inputs are not appropriate, given the performance demands placed on these tires. As shown in Figure 9 and Figure 10, the average RRc for many current vocational drive tires do not meet even the 2017 baseline target. That is because the design parameters for drive tires, and especially for certain types of vocational drive tires, inherently cause them to have significantly higher rolling resistance than their all position counterparts. In order to perform their intended function of providing driving traction, drive tires are designed with tread block or lug type tread patterns that tend to increase rolling resistance and with tread depths that are substantially (up to 50%) deeper than for comparable all position tires. Furthermore, a number of tires that are considered “vocational” are designed for on/off road applications, with heavier tire constructions and with tread compounds designed to resist cutting and tearing, which inherently cause higher rolling resistance than typical highway treads. Because of the very nature of what makes a drive tire a functional drive tire, we propose that the agencies revise the GEM inputs for drive tires for vocational applications. [EPA-HQ-OAR-2014-0827-1304-A1 p.19]

[Figure 9, 'Distribution of Rolling Resistance of Drive Tires for Vocational Vehicles', can be found on p.19 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

[Figure 10, 'Analysis of Rolling Resistance Values for Drive Tires for Vocational Vehicles', can be found on p.20 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

In order to assess what revised GEM inputs might be more appropriate for drive tires used in vocational vehicle applications, RMA used the steer/all-position data it collected as a guide. RMA evaluated the percentage of products surveyed that would meet the baseline targets and the various GEM inputs for 2021, 2024 and 2027. RMA then compared the steer/all-position percentages with the percent of drive tires that would meet the baseline and GEM inputs proposed. Figure 11 shows the results of this analysis. It is apparent that the proposed GEM inputs would be much more severe, in terms of impact to the industry, for drive tires than for steer/all-position tires. As discussed above, due to the performance demands on drive tires, it would be very difficult to meet the proposed GEM input levels. RMA proposes that the Agency set the GEM inputs for drive tires for vocational vehicles by targeting a similar percentage of current products that can meet the GEM inputs set for future model years 2021 and 2024, or 8.3 and 8.1 kg/T, respectively. This proposal is shown in green in Figure 11. For 2027, RMA does not believe this same approach is warranted, given the performance needs of drive tires for vocational vehicles.
vehicles. Instead it recommends that the 2027 GEM input target be set at a level where roughly 50 percent of current products could meet the level, 7.5 kg/T. [EPA-HQ-OAR-2014-0827-1304-A1 p.20-21]

[Figure 11, 'Percent of Current Steer and Drive Tires that Would Meet Proposed GEM Inputs for Vocational Tires', can be found on p.21 of docket number EPA-HQ-OAR-2014-0827-1304-A1]

Vocational trucks and non-van type trailers, and by extension the tires on them, are designed for specialized kinds of work over a wide range of specialties. Expectations will be that the tires will continue to perform in a manner that facilitates the truck performing its tasks effectively. In other words, it is not generally acceptable to trade off one performance parameter in order to improve another such as rolling resistance. These tires are designed with features that enable them to perform effectively in their specialized applications, and a number of those features add to the tire’s rolling resistance. It will take significant time and effort to identify or develop new materials and design features that can reduce rolling resistance and still maintain current dynamic performances. [EPA-HQ-OAR-2014-0827-1304-A1 p.34]

Organization: Volvo Group

In the technology packages anticipated to set Phase 2 stringency levels, the agencies have further relied on unreasonable expectations for lower rolling resistance tires in all regulatory subcategories. Tire manufacturers have continued to claim that they are able to balance tire life, safety, and traction concerns; however, as the agencies have noted in the Regulatory Impact Analysis section 2.4.3.1, tires with higher rolling resistance are likely designed to address only some of these concerns. We continue to hear customer feedback that low rolling resistance tires often lack adequate traction. The reality is that many of the features that provide for traction, especially deep lugs and pliable sidewalls, also create high rolling resistance, but without these features many customers are finding that attaining adequate traction is nearly impossible under many of the demanding conditions that trucks and tractors experience, such as snow and off-road. Customers have stated that, in some cases, they are being pushed into low rolling resistance tires at the point of sale only to be left with no choice but to replace the tires with higher rolling resistance, traction tires immediately after taking delivery of the new vehicle. [EPA-HQ-OAR-2014-0827-1290-A1 p.21]

In addition, heavy-duty fleets expect to retread tires as many as five times and have concerns that tire casing durability may be compromised with low rolling resistance (LRR) tires. Retreading saves cost and about two thirds of the oil required to produce a new tire (reported to be between 22 and 44 gallons depending on tire size). [EPA-HQ-OAR-2014-0827-1290-A1 p.21]

In the Preamble section V(C)(1)(a)(iii), the agencies again note the trade-offs between low rolling resistance and traction, as well as the fact that in vocational applications many customers value traction over decreased rolling resistance. The agencies go on to state, however, that input from tire manufacturers indicates that performance parameters will not be affected by Phase 2 LRR tires. It is unclear how these claims have been validated, but given the tire manufacturers’ inability to deliver on these same claims for Phase 1 it is not likely there will be significant advancement made prior to the implementation of Phase 2 to justify the levels used to set stringency. [EPA-HQ-OAR-2014-0827-1290-A1 p.21-22]

After the promulgation of the Phase 1 regulation the agencies performed independent testing of tire coefficient of rolling resistance (CRR) values and determined that the average values for vocational tires were 7.8 for drive tires and 6.7 for steer, with tires available at approximately +/- 20% of these values, including wide based singles suitable for vocational applications. The agencies did not, however, discuss the feasibility of these tires across the staggering array of vocational vehicle types and applications in the regulated vehicle range from Class 2b to 8. The agencies only offer what they deemed as a conservative
assessment of projected adoption rates that does not differ by weight class. As a solely HHD vocational vehicle manufacturer the Volvo Group in North America does not believe that a tire appropriate in one weight class may be appropriate for another, or that a tire appropriate for a highway box truck (of which Volvo Group manufactures few) is suitable for use in an on/off-road HHD vocational vehicle. Due to these concerns Volvo Group does not believe the proposed adoption rates in Table 2-54 of the RIA are feasible for the Volvo Group product mix nor do we believe that the AB&T flexibility should be construed as a means to meet stringency requirements within a regulatory subcategory of vehicles, e.g. Class 8 urban vocational, when those stringencies are predicated on a mix of technologies deployed across the entire range of weight classes and vocational subcategories. [EPA-HQ-OAR-2014-0827-1290-A1 p.22]

Tables 2-188 and 2-190 of the RIA show Alternative 3 HHD vocational tire package costs calculated with a penetration of “Level 3” and “Level 4” steer tires from 2021 and 2024 respectively and drive tire penetrations from 2024 and 2027. Section III.D.iii of the Preamble defines tire CRR “levels” as follows: [EPA-HQ-OAR-2014-0827-1290-A1 p.22]

- “Level 1 rolling resistance performance represents the threshold used to develop SmartWay designated tires for long haul tractors.”
- “Level 2 threshold represents an incremental step for improvements beyond today’s SmartWay level and represents the best in class rolling resistance of tires we tested.”
- “Level 3 values represent the long-term rolling resistance value that the agencies predicts (sic) could be achieved in the 2025 timeframe.” This last step provides a 25% improvement over Level 2.

No definition of “Level 4” was provided in either the RIA or the Preamble to the regulation and there was no inclusion in the tractor cost or stringency tables of any Level 4 penetration. [EPA-HQ-OAR-2014-0827-1290-A1 p.22]

It is unclear from the cost determinations whether these levels of tire CRR values were actually considered in the penetration and stringency considerations. Table V-16 of the Preamble does not suggest anything beyond a 20% improvement in steer CRR and a 15% improvement in Drive CRR for 2027. Volvo Group requests clarification of this issue. [EPA-HQ-OAR-2014-0827-1290-A1 p.22]

With respect to highway tractor and heavy-haul tractor penetration and stringency setting the agencies show penetration of Level 3 tires starting in MY 2021. It is unclear how this can be possible given the agencies own determination that this technology “could” be achieved only in the 2025 timeframe. [EPA-HQ-OAR-2014-0827-1290-A1 p.22]

These comments were submitted by Volvo in the context of the custom chassis program: “Mixer tire Crr levels are not appropriate for off-road use and should reflect the same level as Emergency vehicles. Need to accommodate Crr averaging for Transit and Coach buses that have single drive and single drive/dead axle configurations.” [EPA-HQ-OAR-2014-0827-1928-A1 p.15]

**Organization:** Navistar, Inc.

Similar to the tractor tires, vocational vehicles will not necessarily see the benefit from Level 2 and 3 low rolling resistance tires and will trade-off other desired attributes such as traction for on-off highway operation and durability. Therefore, achieving the predicted penetrations for these tire levels will be extremely challenging for many applications [EPA-HQ-OAR-2014-0827-1199-A1 p.40]
Two strategies in the Phase 2 proposal are of particular concern; tires and hybridization. [EPA-HQ-OAR-2014-0827-1309-A1 p.9]

Response:

In consideration of comments, we are changing our projected adoption rates of LRR tires on vocational vehicles from proposal, by differentiating the tire rolling resistance improvement level by both weight class and duty cycle, recognizing that heavier vehicles designed for highway use can generally apply tires with lower rolling resistance than other vehicle types, and will see a greater benefit during use. We disagree there is a direct trade-off between traction and rolling resistance. As stated in the RIA Chapter 2.8.3.2, tire design requires balancing performance, since changes in design may change different performance characteristics in opposing directions. A single performance parameter can easily be enhanced, but an optimal balance of all the criteria would require improvements in materials and tread design at a higher cost, as estimated by the agencies. We agree with Volvo and other commenters that rolling resistance is less of a priority for some vehicles with off-highway duty cycles. Accordingly, the final rules project adoption of tires with less advanced levels of CRR for vehicles in Urban and some custom chassis subcategories, recognizing the special needs of these applications.

We include tire maintenance costs at intervals of 40,000 miles (vocational vehicles) and 200,000 miles (tractors and trailers). Those maintenance costs include the same incremental costs as the new tire, so our maintenance costs could potentially be conservative if the maintenance intervals are the same with retreads as with new tires.

We disagree with comments questioning the ability to retread low rolling resistance tires. In discussions with EPA’s SmartWay team, tire manufacturers have claimed that their low rolling resistance tires are as retreadable as those with higher rolling resistance. There is no evidence in the record indicating otherwise. The comments themselves contain assertions which are not documented. EPA followed up and asked fleets and others for data regarding this topic, but no data were provided. Although there may be individual tire models that do not perform as well in terms of retreadability, we do not believe this is a systematic issue related to low rolling resistance tires. If (contrary to our view) there is, in fact, a loss of tire casing durability and, therefore, a need to replace tires earlier (rather than just replacing treads at the same interval), then at most the agencies’ costs may be slightly underestimated. See Section 5.3 for responses to other comments related to tire maintenance. See Section 11.3 for responses to comments about other types of maintenance costs.

The RMA comments included CRR values for a wide range of vocational vehicle tires, for rim sizes from 17.5 inches to 24.5 inches, for steer/all position tires as well as drive tires. The RMA data, while illustrating a range of available tires, are not sales weighted. The 2014 certification data include actual production volumes for each vehicle type, thus both steer and drive tire population-weighted data are available for emergency vehicles, cement mixers, school buses, motor homes, coach buses, transit buses, and other chassis cabs. The certification data are consistent with the RMA assessment of the range of tire CRR currently available. We also agree with RMA’s suggestion to set a future CRR level where a certain percent of current products can meet future GEM targets. We disagree with RMA that the MY 2027 target should be a level that 50 percent of today’s products can meet. With programmatic averaging, such a level would mean essentially no improvements overall from tire rolling resistance, because today when manufacturers comply on average, half their tires are above the target and half are below. Further, with Phase 2 GEM requiring many more vehicle inputs than tire CRR, manufacturers have many more degrees of freedom (i.e. available potential compliance paths) to meet the performance standard than they do in
Phase 1. None of the rolling resistance levels projected for adoption in MY 2027 are lower than the 25th percentile of tire CRR on actual vocational vehicles sold in MY 2014. Thus, we believe the improvements will be achievable without need to develop new tires not yet available.

In the final rules, the agencies are using Error! Reference source not found. the descriptors 1v through 5v to refer to levels of rolling resistance among the population of tires installed on vocational vehicles. Level 1v is considered a baseline level and ranges from 7.5 to 8.1 kg/ton. Level 5v represents the greatest degree of improvement projected in this rulemaking and ranges from 5.8 to 6.29 kg/ton. Levels 2v, 3v, and 4v fall in between, and the corresponding ranges are presented in Table V-15 of the Preamble. The agencies have defined these levels for purposes of estimating the manufacturing costs associated with applying improved tire rolling resistance to vocational vehicles. These levels are not applicable for estimating degrees of improvement or costs of LRR tires on tractors, trailers, or HD pickups and vans as part of this rulemaking. Furthermore, these levels do not represent the full range of tire CRR available for vocational vehicles. There are both steer and drive tires on certified vocational vehicles today with CRR ranging from 5 kg/ton to 15 kg/ton. This technology is also feasible on all custom chassis, with similarly larger improvements feasible for coach buses and motor homes with typically regional drive cycles, and similarly smaller improvements feasible for school and transit buses, refuse trucks, and concrete mixers with typically urban drive cycles. Absent specific data on tires for refuse trucks, we have considered the comments and are thus projecting LRR levels for refuse trucks that are equivalent to those projected for transit buses: Level 1v through MY 2026 and level 3v beginning in MY 2027.

In response to comments about the projected CRR levels for concrete mixers, these are based on actual certification data from MY 2014 submitted by custom chassis manufacturers who manufacture these vehicles and designated them as such in their production reports. They exhibited very different characteristics than those observed for tires on emergency vehicles.192

With respect to the comment about averaging CRR values where a vehicle (such as transit or coach) has either single drive and single drive/dead axle configurations, GEM will require CRR levels to be entered in two places or three depending on the axle configuration specified (ie 4x2, 6x4). This is true for both simplified as well as full GEM.

The final tire packages recognize the variety of tire purposes and performance levels in the vocational vehicle market, and maintain choices for manufacturers to use the most efficient tires (i.e. those with lowest rolling resistance) only where it makes sense given these vehicles’ differing purposes and applications.

6.3.6 Electrification

6.3.6.1 Zero-Emission Trucks & Buses (Battery-Electric & Fuel Cell)

Organization: CALSTART

Electric vehicles - The agencies proposed to allow certification of electric vehicles without testing and without a cap on sales above which upstream emissions are counted. 80 FR 40331. We agree with the agencies' approach. Electric heavy-duty vehicles are now and for the foreseeable future a low volume, niche product. The agencies should smooth the way to their production with a minimum of certification requirements and as relaxed of standards as possible. Similarly, the EPA proposed to continue to deem

192 See memorandum dated May 2016 on Vocational Vehicle Tire Rolling Resistance Certification Data
electric vehicles as having zero CO2, CH4, and N2O emissions as well as zero fuel consumption. 80 FR 40331. We think that this is the correct approach to best stimulate the market. [EPA-HQ-OAR-2014-0827-1164-A1 p.100]

Organization: Environmental Defense Fund (EDF)

Fully electric local delivery trucks are also viable today. Pepsi operates more than 250 of these trucks, including 176 Smith Electric trucks. [EPA-HQ-OAR-2014-0827-1312-A1 p.37-38]

165 Smith Electric website at: http://www.smithelectric.com/customer-stories/fritolay/

Organization: BYD Motors

The majority of electric vehicles will be deployed in the vocational vehicle segment of the rule. It is BYD’s belief that the proposed stringency level for vocational vehicles, in and of itself, will not result in fleets investing the time and capital necessary to bring advanced technologies to market. Therefore, BYD supports either increased stringency levels and/or more rapid implementation. [EPA-HQ-OAR-2014-0827-1182-A1 p.2]

The conservative target in the agencies’ preferred alternative can be met purely with conventional technology and therefore misses an opportunity to fully capitalize on the oil and emission reductions that our electric trucks offer. BYD proposes that the stringency of the vocational vehicle standard should be increased to at least 20% to help ensure the investments needed for moving beyond incremental improvements to conventional technology and to promote the adoption of advanced alternative powertrain vehicles. [EPA-HQ-OAR-2014-0827-1182-A1 p.2]

Organization: Center for Biological Diversity

We are encouraged to see that the Proposed Rule has significantly expanded the technologies that were included in the standards for vocational vehicles beyond those in Phase 1, but there are still important technologies that have been omitted. As the agencies note, vocational vehicles will benefit greatly from use of strong hybrid powertrains. But technology is progressing rapidly: all-electric vocational vehicles are quite literally around the corner. The recent CALSTART program, a program of the California Energy Commission, has promoted low-GHG medium and heavy-duty vehicles in various capacities. One is an all-electric, non-cabled bus with hands-free rapid charging. Furthermore, the California Air Resources Board is actively working on a zero-emission bus rule, and a number of demonstration buses are already on the road. Notably, commercialization is predicted for 5 years from now – before the start date for implementation of the Proposed Rule. Electric buses are not limited to California: there are close to 30 lines across the United States that currently use electric-propulsion buses. [EPA-HQ-OAR-2014-0827-1460-A1 p.9]

Buses are not the only vocational vehicles that benefit from battery electric technology. There are over 500 battery electric medium- and heavy-duty vehicles in California and about a 1000 nation-wide. These as well as plug-in electric hybrid vocational vehicles are being used by a number of major companies, including United Parcel Service (“UPS”) and FedEx. These fleets have provided ample demonstration
that electrification is a viable option for a wide range of vocational vehicles. Thus, the technology-forcing nature of the statutes requires the agencies to include all-electric options for vocational vehicles in setting the stringency of the medium- and heavy-duty truck standards. [EPA-HQ-OAR-2014-0827-1460-A1 p.10]

**Organization:** California Air Resources Board (CARB)

While a BEV does not require an engine, exhaust system, or emission controls, it does require the addition of other components such as an electric motor, various electronics, and a battery pack. Of these, the battery pack comprises the vast majority of the cost. Because of the battery pack, BEVs currently have a substantial net incremental cost. The incremental cost is the cost of the BEV over and above the cost of a comparable conventionally-fueled vehicle. U.S. EPA and NHTSA present the incremental costs (2012 dollar) of EVs, and projects how it anticipates these costs will change in the foreseeable future. [EPA-HQ-OAR-2014-0827-1265-A1 p.96]

While U.S. EPA and NHTSA’s anticipated cost reduction approach on the part of the balance-of-components seems reasonable, CARB staff believes that significantly greater cost reductions will be realized in the future due to declining battery costs. Over the last several years, battery costs have declined substantially, and ongoing efforts on the part of academia and industry continue to reduce costs through materials changes, manufacturing improvements, and cost reductions associated with increased volumes, and are projected to continue to do so. CARB staff believes that U.S. EPA and NHTSA’s cost projections overestimate the likely costs of these vehicles in the post 2020 timeframe because of the significant reductions in anticipated battery costs. [EPA-HQ-OAR-2014-0827-1265-A1 p.96-97]

CARB staff believes that medium- and heavy-duty BEVs have a significant role to play in the near future, especially for vehicles operating in the optimal duty cycle identified for BEVs (defined routes, lots of starts and stops, high idle time, and lower average speeds). A variety of medium- and heavy-duty BEVs are now available for purchase, including shuttle buses, school buses, and transit buses, and demonstration vehicles are in use in drayage, garbage collection, and other applications. While CARB staff agrees that BEVs are not yet suitable for long-haul trucking, more localized urban opportunities for BEVs abound. CARB staff is currently pursuing battery electric and fuel cell electric requirements for buses and last mile delivery trucks, and will continue to pursue the maximum feasible BEV penetration in other applications. For more information, please see CARB’s battery and fuel cell electric technology assessment, which will be posted at http://www.arb.ca.gov/msprog/tech/report.htm when available. [EPA-HQ-OAR-2014-0827-1265-A1 p.97]

CARB disagrees with US EPA and NHTSA’s comment that electric trucks will not be widely commercially available in the timeframe of the proposed rule, particularly with respect to urban and miscellaneous vocational vehicles. U.S. EPA and NHTSA cite cost as one of the key factors in this determination. While CARB staff agrees that higher up-front capital costs will be a significant deterrent to zero emission truck and bus deployment in the coming decade, California is taking steps to address this challenge. [EPA-HQ-OAR-2014-0827-1265-A1 p.97]

California must meet several air quality, climate, and petroleum reduction targets in the 2030 timeframe that will require a broad transformation of our light-, medium- and heavy-duty fleets to utilize zero- and near-zero-emission technologies. In recognition that this transformation will not come simply or cheaply, California is investing hundreds of millions of dollars annually to develop and deploy zero-emission vehicle technologies. Plug-in hybrid and zero-emission passenger car sales in our State have increased dramatically in the past five years, from a few hundred in 2010 to over 200,000 sold as of mid-2015. California Governor Jerry Brown’s Executive Order B-16-2012 sets a target of deploying 1.5 million
zero-emission vehicles by 2025, including zero-emission trucks and buses, and California’s Zero-Emission Vehicle Action Plan identifies implementation strategies and milestones for achieving this goal. [EPA-HQ-OAR-2014-0827-1265-A1 p.97-98]

While the heavy-duty sector will be much more challenging than the light-duty sector, we are implementing key strategies needed to shift trucks and buses to utilize hybrid and zero-emission technology where practical. California’s Sustainable Freight Transport Initiative: Pathways to Zero- and Near-Zero Emissions Discussion Document recognizes that in order to meet our public health mandates, climate goals, and economic needs, the transition to a less-polluting, more efficient, modern freight transport system is a preeminent policy objective for the State of California – and will continue to be so for several decades to come. It will require us to make steady and continual progress in moving both domestic and international cargo in California more efficiently, with zero emissions everywhere feasible, and near-zero emissions with renewable fuels. [EPA-HQ-OAR-2014-0827-1265-A1 p.98]

California Senate Bill 1204 (Lara, Chapter 524, Statutes of 2014) establishes the California Clean Truck, Bus and Off-Road Vehicles and Equipment Technology Program to fund development, demonstration, pre-commercial pilot, and early commercial deployment of zero- and near-zero-emission technologies. In June 2015, CARB approved a $350 million funding plan for fiscal year 2015-16 utilizing GHG Reduction Fund and AQIP monies. The GHG Reduction Fund provides an ongoing source of funding which California can invest in zero- and near-zero-emission transportation solutions. Previous year’s investments have resulted in over 2,000 hybrid and zero-emission heavy-duty vehicles now deployed in California, mostly in delivery truck vocations. [EPA-HQ-OAR-2014-0827-1265-A1 p.98]

We believe the NPRM should recognize California’s critical need for, and commitment to, accelerated deployment of zero-emission heavy-duty vehicle technologies. We anticipate California will address capital cost and other barriers to zero-emission truck and bus deployment through a robust strategy portfolio of targeted incentives, complementary regulations, and other approaches. CARB staff believes that zero-emission trucks and buses will likely begin to be widely commercially available in California in the Phase 2 timeframe, particular in urban and local delivery vocations. Given that California represents about ten percent of the nation’s truck and bus market, this is not an insignificant development, even in the context of a federal Phase 2 program.

Other States and localities are also recognizing the need for zero-emission truck and bus technologies to meet more stringent eight-hour ozone standards and local air quality and health goals. New York State and the City of Chicago, for example, have followed California’s lead by implementing similar funding programs to accelerate deployment of zero-emission truck and bus technologies. While we expect California will lead the nation in making zero-emission truck and bus technologies a reality, we also anticipate, much like other states have “opted in” to California’s light-duty passenger car zero-emission vehicle program, our heavy-duty zero-emission vehicle program and strategies may also be a model for other states. We recommend that U.S. EPA and NHTSA recognize California’s needs for, and commitment to, deployment of zero-emission heavy-duty vehicles in the 2025 to 2030 timeframe, with the expectation for significant zero-emission truck and bus deployment in the urban vocational and miscellaneous vehicle vocations. [EPA-HQ-OAR-2014-0827-1265-A1 p.99]

CARB staff believes the NPRM is overly pessimistic regarding the future of heavy-duty FCEVs. CARB believes that zero-emission technologies will be able to demonstrate greater applications, range, durability, and reliability by 2021. CARB staff is currently developing a fuel cell electric technology assessment, which will be posted at http://www.arb.ca.gov/msprog/tech/report.htm when available. In developing the fuel cell electric technology assessment, CARB staff has concluded heavy-duty FCEVs have the potential to become a prime candidate for zero-emission transportation, especially for vehicle
types that travel long distances. It is reasonable to expect that fuel cell electric technology will likely be transferred to other heavy-duty applications in the near future, which will help foster broader commercialization. [EPA-HQ-OAR-2014-0827-1265-A1 p.100]

Fuel cell electric buses are already in the early commercialization stage today and have demonstrated robust service records. As detailed in Attachment 4 – Active and Planned Fuel Cell Electric Vehicles Demonstrations, various demonstrations of heavy-duty FCEVs have been funded through federal, state, and local programs. Fuel cell electric transit buses have been demonstrated worldwide over the last two decades, with promising results. Currently, there are 24 (of which 18 are in California) demonstrated fuel cell electric buses and 22 (of which 8 are in California) planned demonstrations fuel cell electric buses in the U.S. In addition, there are 45 (of which 22 are in California) fuel cell electric trucks that are currently being demonstrated or are planned to be demonstrated in the U.S. To encourage further development of fuel cell electric technology in other heavy-duty on-road applications, a number of agencies including the U.S. Department of Energy, California Energy Commission, and South Coast Air Quality Management District have recently and are currently funding heavy-duty fuel cell electric demonstration projects, including demonstrations involving electric drayage trucks. CARB will make available approximately $25 million for near-zero- and zero-emission drayage trucks and at least $25 million for zero-emission trucks and buses in 2015. By 2021, CARB staff expects heavy-duty FCEVs will be in commercial or pre-commercial phases, depending on the vocation. However, as new technology is often more expensive, it is important to provide adequate incentives to the market at the early stage. In California, we have and will be utilizing a variety of financial incentives along with regulatory programs. We urge U.S. EPA and NHTSA to consider a similar strategy to increase the volume of heavy-duty FCEVs, reduce their cost, and establish corridor fueling networks. CARB is interested in working collaboratively with U.S. EPA and NHTSA on this effort. [EPA-HQ-OAR-2014-0827-1265-A1 p.100-101]

Organization: California Air Resources Board (CARB)

Comment – Current and future status of all BEV; standards should assume some use of all EVs

In the NPRM, U.S. EPA and NHTSA confirm that BEVs have advantages over their conventionally-fueled counterparts in terms of efficiency, torque, regenerative braking opportunities, and low noise characteristics, but also notes that they are limited by weight, range, and cost. Because of the high cost and developing nature of this technology, U.S. EPA and NHTSA do not project that fully electric vocational vehicles will be widely commercially available in the time frame of the proposed rules, and the proposed standards are not based on any level of adoption of this technology. Yet U.S. EPA and NHTSA do indeed project some use of these technologies as is noted “While the agencies have not premised the proposed Heavy-Duty Phase 2 tractor standards on hybrid powertrains, FCEVs, or BEVs, we also foresee some limited use of these technologies in 2021 and beyond.” (page 40253 of the NPRM) In acknowledging the projected use of BEVs but not including their use in setting appropriate emission standards, U.S. EPA is leaving potential emission benefits on the table. CARB staff believes that the GHG standards should incorporate limited penetration rates for these advanced technologies, particularly for vocational vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.49]

While CARB staff agrees with U.S. EPA and NHTSA’s assessment of the advantages and limitations of current medium- and heavy-duty EVs, CARB staff is significantly more optimistic about the potential penetration of BEVs into the market during the Phase 2 timeframe. CARB staff believes that the current status of heavy-duty zero-emission vehicles is more advanced than U.S. EPA and NHTSA project. In the NPRM, U.S. EPA and NHTSA state “[W]e have not found any all-electric heavy-duty vehicles that have certified by 2014. As we look into the future, we project very limited adoption of all-EVs into the
market.” (page 40159 of the NPRM) “In our assessment, we have observed that the few all-electric heavy duty vocational vehicles that have been certified are being produced in very small volumes in MY2014.” (page 40331 of the NPRM) “[T]he agencies do not project fully electric vocational vehicles to be widely commercially available in the time frame of the proposed rules. For this reason, the agencies have not based the proposed Phase 2 standards on adoption of full-electric vocational vehicles.” (page 40304 of the NPRM) CARB staff believes these assessments are not as optimistic as the status of the technology indicates. [EPA-HQ-OAR-2014-0827-1265-A1 p.49-50]

In our medium- and heavy-duty BEV technology assessment, CARB staff investigated the current status of the technology. We specifically looked at transit bus applications, school bus applications, medium-duty trucks and shuttle buses (8,501-14,000 lbs GVWR and heavy-duty trucks (>14,000 lbs GVWR). We found that battery all-electric transit buses are commercially available, with over 2,600 of battery all-electric buses worldwide. New orders are placed regularly. Urban transit buses are an ideal application for battery all-electric heavy-duty vehicles because they operate on fixed routes of normally short distances, perform frequent stop and start driving which is needed for regenerative braking, maintain low average speeds which helps to preserve the battery power, and return to a general base or facility at the end of the day which enables overnight charging. Electric transit buses are currently available from BYD, New Flyer, and Proterra, while Nova’s new electric bus model is in demonstration. CARB is developing advanced transit fleet requirements, which will be predicated on the widespread use of electric transit buses. CARB staff believes that the Phase 2 GHG standards should assume the penetration of electric transit buses into the nationwide fleet. [EPA-HQ-OAR-2014-0827-1265-A1 p.50]

School buses are not yet as commercially available as transit buses. The TransTech SSTe type A school bus is available for purchase, however, and Lion, a Canadian company, has recently released the eLion type C school bus. Electric school buses have the potential for significant market penetration in the next 5 to 10 years, well within the timeframe of the Phase 2 GHG regulations. CARB has funded three electric school bus demonstrations to date, starting in fiscal year 2011/12 and those projects have been completed, with buses now transporting children daily. The final reports from these projects are posted on CARB’s Air Quality Improvement Program (AQIP) Advanced Technology Demonstration Project webpage at: http://www.arb.ca.gov/msprog/aqip/demo.htm. [EPA-HQ-OAR-2014-0827-1265-A1 p.50]

There are hundreds of BEVs in the medium-duty (8,501-14,000 lbs GVWR) vocational category already operating on California’s roads; such vehicles are in the early commercialization stage. Vehicles in this category are being utilized in an optimal duty cycle for BEVs, urban delivery, and have CARB incentives to promote adoption. For example, to reduce the incremental costs of zero-emission vehicles, CARB has been providing financial incentives to fleets statewide through programs such as California’s Hybrid and Zero-Emission Truck and Bus Voucher Incentives Project (HVIP). Since HVIP’s launch in 2010, CARB has provided over $10 million to funding nearly 400 heavy-duty BEVs.25 CARB staff expects widespread penetration of BEVs into some parts of the market place in the next 5 to 10 years. Therefore, CARB staff believes it would be appropriate to assume some market penetration of BEVs in this class in the timeframe of the Phase 2 GHG regulations. [EPA-HQ-OAR-2014-0827-1265-A1 p.50-51]

Expanding BEV technology into additional applications in the heavy-duty truck segment (other than buses) will require further developments in battery technology and lower vehicle component costs overall. It is not expected that BEVs will penetrate into the long-haul trucking market in the next several decades without significant advances in battery energy density and BEV recharging technologies. CARB staff agrees it is reasonable to presume no significant market penetration in the regulatory timeframe for long haul class 7 and 8 tractors. There are electric drayage trucks in demonstration phases, as well as electric refuse trucks, but CARB staff agrees it is likely that commercial BEV penetration in these applications will be limited during the next decade. [EPA-HQ-OAR-2014-0827-1265-A1 p.51]
However, CARB staff believes it is appropriate to push technology development. Electric vocational vehicles have been demonstrated effectively; stringent emission requirements would further promote their use. CARB staff encourages U.S. EPA and NHTSA to continue to evaluate appropriate different technologies and approaches that can achieve substantial emission reductions. Over the past decade, heavy duty fleets have made substantial investments to adopt modern, lower-emitting vehicles. Today, as noted above, zero-emission vehicles such as battery electric and fuel cell electric buses are in the early commercialization phase. Demonstrations are underway across the State in a wide array of heavy-duty applications including drayage trucks, delivery trucks, and school buses. State incentives are in place that are encouraging the development and adoption of these technologies, increasing production volumes, fostering innovation, and reducing costs. For more information, please see CARB’s battery and fuel cell electric technology assessment that is currently in development and will be posted at http://www.arb.ca.gov/msprog/tech/report.htm when available. [EPA-HQ-OAR-2014-0827-1265-A1 p.51]

While CARB staff acknowledges that the present populations of medium- and heavy-duty vocational BEVs are low, these numbers are expected to increase significantly in the Phase 2 timeframe. For example, CARB staff plans to propose purchase zero-emission requirements for last-mile delivery vehicles in 2020, which will significantly increase demand for these vehicles. Yet U.S. EPA and NHTSA’s proposed emission standards are not based on the inclusion of any zero-emission vehicles under either Alternative 3 or the more accelerated Alternative 4. To assume no penetration in the selected Alternative does not reflect market trends and results in a loss of potential GHG emission reductions by setting the emission standard less stringent than would be appropriate with the inclusion of these vehicles. CARB staff notes that even with the higher upfront capital cost of EVs, the anticipated savings in operation and maintenance costs allows payback of the initial investment and significant market penetration for medium- and heavy-duty vehicles operating in an “optimum” BEV duty cycle (defined routes, lots of starts and stops, high idle time, and lower average speeds) can occur in the Phase 2 timeframe. Therefore, CARB staff recommends that U.S. EPA and NHTSA set emission standards that are based on the inclusion of an electric vocational vehicle penetration rate of at least 1 percent, which is a third of the rate projected for Alternative 5 in the NPRM. [EPA-HQ-OAR-2014-0827-1265-A1 p.52]

Organization: California Air Resources Board (CARB)

In the NPRM, U.S. EPA and NHTSA confirm that BEVs have advantages over their conventionally-fueled counterparts in terms of efficiency, torque, regenerative braking opportunities, and low noise characteristics, but also notes that they are limited by weight, range, and cost. Because of the high cost and developing nature of this technology, U.S. EPA and NHTSA do not project that fully electric vocational vehicles will be widely commercially available in the time frame of the proposed rules, and the proposed standards are not based on any level of adoption of this technology. Yet U.S. EPA and NHTSA do indeed project some use of these technologies as is noted “While the agencies have not premised the proposed Heavy-Duty Phase 2 tractor standards on hybrid powertrains, FCEVs, or BEVs, we also foresee some limited use of these technologies in 2021 and beyond.” (page 40253 of the NPRM) In acknowledging the projected use of BEVs but not including their use in setting appropriate emission standards, U.S. EPA is leaving potential emission benefits on the table. CARB staff believes that the GHG standards should incorporate limited penetration rates for these advanced technologies, particularly for vocational vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.49]

While CARB staff agrees with U.S. EPA and NHTSA’s assessment of the advantages and limitations of current medium- and heavy-duty EVs, CARB staff is significantly more optimistic about the potential penetration of BEVs into the market during the Phase 2 timeframe. CARB staff believes that the current status of heavy-duty zero-emission vehicles is more advanced than U.S. EPA and NHTSA project. In the
NPRM, U.S. EPA and NHTSA state “[W]e have not found any all-electric heavy-duty vehicles that have certified by 2014. As we look into the future, we project very limited adoption of all-EVs into the market.” (page 40159 of the NPRM) “In our assessment, we have observed that the few all-electric heavy duty vocational vehicles that have been certified are being produced in very small volumes in MY2014.” (page 40331 of the NPRM) “[T]he agencies do not project fully electric vocational vehicles to be widely commercially available in the time frame of the proposed rules. For this reason, the agencies have not based the proposed Phase 2 standards on adoption of full-electric vocational vehicles.” (page 40304 of the NPRM) CARB staff believes these assessments are not as optimistic as the status of the technology indicates. [EPA-HQ-OAR-2014-0827-1265-A1 p.49-50]

In our medium- and heavy-duty BEV technology assessment, CARB staff investigated the current status of the technology. We specifically looked at transit bus applications, school bus applications, medium-duty trucks and shuttle buses (8,501-14,000 lbs GVWR and heavy-duty trucks (>14,000 lbs GVWR). We found that battery all-electric transit buses are commercially available, with over 2,600 of battery all-electric buses worldwide. New orders are placed regularly. Urban transit buses are an ideal application for battery all-electric heavy-duty vehicles because they operate on fixed routes of normally short distances, perform frequent stop and start driving which is needed for regenerative braking, maintain low average speeds which helps to preserve the battery power, and return to a general base or facility at the end of the day which enables overnight charging. Electric transit buses are currently available from BYD, New Flyer, and Proterra, while Nova’s new electric bus model is in demonstration. CARB is developing advanced transit fleet requirements, which will be predicated on the widespread use of electric transit buses. CARB staff believes that the Phase 2 GHG standards should assume the penetration of electric transit buses into the nationwide fleet. [EPA-HQ-OAR-2014-0827-1265-A1 p.50]

School buses are not yet as commercially available as transit buses. The TransTech SSTe type A school bus is available for purchase, however, and Lion, a Canadian company, has recently released the eLion type C school bus. Electric school buses have the potential for significant market penetration in the next 5 to 10 years, well within the timeframe of the Phase 2 GHG regulations. CARB has funded three electric school bus demonstrations to date, starting in fiscal year 2011/12 and those projects have been completed, with buses now transporting children daily. The final reports from these projects are posted on CARB’s Air Quality Improvement Program (AQIP) Advanced Technology Demonstration Project webpage at: http://www.arb.ca.gov/msprog/aqip/demo.htm. [EPA-HQ-OAR-2014-0827-1265-A1 p.50]

There are hundreds of BEVs in the medium-duty (8,501-14,000 lbs GVWR) vocational category already operating on California’s roads; such vehicles are in the early commercialization stage. Vehicles in this category are being utilized in an optimal duty cycle for BEVs, urban delivery, and have CARB incentives to promote adoption. For example, to reduce the incremental costs of zero-emission vehicles, CARB has been providing financial incentives to fleets statewide through programs such as California’s Hybrid and Zero-Emission Truck and Bus Voucher Incentives Project (HVIP). Since HVIP’s launch in 2010, CARB has provided over $10 million to funding nearly 400 heavy-duty BEVs.23 CARB staff expects widespread penetration of BEVs into some parts of the market place in the next 5 to 10 years. Therefore, CARB staff believes it would be appropriate to assume some market penetration of BEVs in this class in the timeframe of the Phase 2 GHG regulations. [EPA-HQ-OAR-2014-0827-1265-A1 p.50-51]

Expanding BEV technology into additional applications in the heavy-duty truck segment (other than buses) will require further developments in battery technology and lower vehicle component costs overall. It is not expected that BEVs will penetrate into the long-haul trucking market in the next several decades without significant advances in battery energy density and BEV recharging technologies. CARB staff agrees it is reasonable to presume no significant market penetration in the regulatory timeframe for long haul class 7 and 8 tractors. There are electric drayage trucks in demonstration phases, as well as electric
refuse trucks, but CARB staff agrees it is likely that commercial BEV penetration in these applications will be limited during the next decade. [EPA-HQ-OAR-2014-0827-1265-A1 p.51]

However, CARB staff believes it is appropriate to push technology development. Electric vocational vehicles have been demonstrated effectively; stringent emission requirements would further promote their use. CARB staff encourages U.S. EPA and NHTSA to continue to evaluate appropriate different technologies and approaches that can achieve substantial emission reductions. Over the past decade, heavy duty fleets have made substantial investments to adopt modern, lower-emitting vehicles. Today, as noted above, zero-emission vehicles such as battery electric and fuel cell electric buses are in the early commercialization phase. Demonstrations are underway across the State in a wide array of heavy-duty applications including drayage trucks, delivery trucks, and school buses. State incentives are in place that are encouraging the development and adoption of these technologies, increasing production volumes, fostering innovation, and reducing costs. For more information, please see CARB’s battery and fuel cell electric technology assessment that is currently in development and will be posted at http://www.arb.ca.gov/msprog/tech/report.htm when available. [EPA-HQ-OAR-2014-0827-1265-A1 p.51]

While CARB staff acknowledges that the present populations of medium- and heavy-duty vocational BEVs are low, these numbers are expected to increase significantly in the Phase 2 timeframe. For example, CARB staff plans to propose purchase zero-emission requirements for last-mile delivery vehicles in 2020, which will significantly increase demand for these vehicles. Yet U.S. EPA and NHTSA’s proposed emission standards are not based on the inclusion of any zero-emission vehicles under either Alternative 3 or the more accelerated Alternative 4. To assume no penetration in the selected Alternative does not reflect market trends and results in a loss of potential GHG emission reductions by setting the emission standard less stringent than would be appropriate with the inclusion of these vehicles. CARB staff notes that even with the higher upfront capital cost of EVs, the anticipated savings in operation and maintenance costs allows payback of the initial investment and significant market penetration for medium- and heavy-duty vehicles operating in an “optimum” BEV duty cycle (defined routes, lots of starts and stops, high idle time, and lower average speeds) can occur in the Phase 2 timeframe. Therefore, CARB staff recommends that U.S. EPA and NHTSA set emission standards that are based on the inclusion of an electric vocational vehicle penetration rate of at least 1 percent, which is a third of the rate projected for Alternative 5 in the NPRM. [EPA-HQ-OAR-2014-0827-1265-A1 p.52]

A 1 percent penetration for zero-emission vocational vehicles in 2024 is reasonable, given that, as detailed above, zero-emission vocational vehicles are already on the road in California (9 years ahead of 2024), and all-electric transit buses and delivery vehicles are in the early commercialization stage. Given the long lead time of the Phase 2 regulation, CARB staff believes it is reasonable to include zero-emission advanced technology vehicles in setting the stringency of the standards. [EPA-HQ-OAR-2014-0827-1265-A1 p.55-6]

CARB staff believes the NPRM is overly pessimistic regarding the future of heavy-duty FCEVs. CARB believes that zero-emission technologies will be able to demonstrate greater applications, range, durability, and reliability by 2021. CARB staff is currently developing a fuel cell electric technology assessment, which will be posted at http://www.arb.ca.gov/msprog/tech/report.htm when available. In developing the fuel cell electric technology assessment, CARB staff has concluded heavy-duty FCEVs have the potential to become a prime candidate for zero-emission transportation, especially for vehicle types that travel long distances. It is reasonable to expect that fuel cell electric technology will likely be transferred to other heavy-duty applications in the near future, which will help foster broader commercialization. [EPA-HQ-OAR-2014-0827-1265-A1 p.100]
Fuel cell electric buses are already in the early commercialization stage today and have demonstrated robust service records. As detailed in Attachment 4 – Active and Planned Fuel Cell Electric Vehicles Demonstrations, various demonstrations of heavy-duty FCEVs have been funded through federal, state, and local programs. Fuel cell electric transit buses have been demonstrated worldwide over the last two decades, with promising results. Currently, there are 24 (of which 18 are in California) demonstrated fuel cell electric buses and 22 (of which 8 are in California) planned demonstrations fuel cell electric buses in the U.S. In addition, there are 45 (of which 22 are in California) fuel cell electric trucks that are currently being demonstrated or are planned to be demonstrated in the U.S.

To encourage further development of fuel cell electric technology in other heavy-duty on-road applications, a number of agencies including the U.S. Department of Energy, California Energy Commission, and South Coast Air Quality Management District have recently and are currently funding heavy-duty fuel cell electric demonstration projects, including demonstrations involving electric drayage trucks. CARB will make available approximately $25 million for near-zero- and zero-emission drayage trucks and at least $25 million for zero-emission trucks and buses in 2015. By 2021, CARB staff expects heavy-duty FCEVs will be in commercial or pre-commercial phases, depending on the vocation. However, as new technology is often more expensive, it is important to provide adequate incentives to the market at the early stage. In California, we have and will be utilizing a variety of financial incentives along with regulatory programs. We urge U.S. EPA and NHTSA to consider a similar strategy to increase the volume of heavy-duty FCEVs, reduce their cost, and establish corridor fueling networks. CARB is interested in working collaboratively with U.S. EPA and NHTSA on this effort. [EPA-HQ-OAR-2014-0827-1265-A1 p.100-101]

Response:

Given the high up-front costs and the developing nature of this technology, the agencies do not project that it is feasible or reasonable for fully electric heavy-duty vocational vehicles to be widely commercially available without heavy subsidies in the time frame of the final rules. The comment by EDF that Pepsi operates a small number of zero-emission vehicles is not evidence that the technology is cost-effective, commercially available, or technically feasible for a particular subcategory. Nor does this comment indicate what the projected future adoption rate should be. This comment simply presents evidence that a fleet owner is willing to test the vehicles on a demonstration basis. The commenter did not mention whether Pepsi took this risk in the absence of monetary subsidies, or what level of satisfaction Pepsi has had with the maintenance on these vehicles.

For these reasons, the agencies have not based the Phase 2 standards on adoption of full-electric vocational vehicles. Although we agree that some vocational applications may see attractive long term cost scenarios for electric trucks or buses when considering maintenance savings, we do not have sufficient information to project a market adoption rate for any specific subcategory. Further, although our final cost analysis does include maintenance savings from reduced oil changes for engine-off idle reduction technologies, we have not quantified the maintenance savings of a full electric vehicle compared to a conventional diesel. We appreciate the comments that provided information of this nature,
and we expect that better dissemination of this information could lead to further adoption of this technology in the market.

The agencies take the point that it is appropriate to create regulatory incentives for use of these advanced electrification technologies. As described above in Section 1.4.1 and in the Preamble in Section I.C.1.(b), we have adopted an advanced technology credit multiplier applicable to both BEVs and FCEVs, in response to comment. In addition, to the extent these technologies are brought to market in the time frame of the Phase 2 program, there is currently a certification path for these chassis from Phase 1, as described in Section V.D of the Preamble, in EPA’s regulations at 40 CFR 1037.150 and NHTSA’s regulations at 49 CFR 535.8.

### 6.3.6.2 Electrified Accessories

**Organization:** Autocar, LLC

**Electric Components.** Autocar submits that there is potential for certain chassis components to be powered by the electrical system rather than the engine; however, we do not have access to research or data proving that electrifying components such as cooling fans and A/C compressors would lead to an improvement in fuel economy in a Low-speed/Frequent-stop Vehicle. [EPA-HQ-OAR-2014-0827-1233-A1 p.15]

**Bosch**

**Highly Efficient Alternators** - Bosch proposes that recognition of the benefits of efficient electrical charging systems (specifically alternators) should be included in the regulation. Bosch proposes creation of a standard component-level test for alternators to determine their efficiency, and establishment of a minimum efficiency level that must be attained, in order for an off-cycle credit to be applied. [EPA-HQ-OAR-2014-0827-1466-A2 p.11]

**Organization:** American Automotive Policy Council

**MAC Efficiency in Class 7, Class 8, and Vocational Truck Regulations**

EPA included fuel savings from improved air conditioner credits in setting the standards for Class 7 and Class 8 heavy trucks, as well as vocational vehicles: “Compared to 2017MY air conditioners, air conditioners with improved efficiency compressors will reduce CO2 emissions by 0.5 percent.” (80 Federal Register 40221). The difficulty of the standards was increased over time due to the forecast phase-in of these improved MAC systems (80 Federal Register 40228). [EPA-HQ-OAR-2014-0827-1238-A1 p.18]

For regulatory compliance, an improvement factor of 0.5% is given to vehicles with “high-efficiency” air conditioner compressors, defined as either electric compressors or improved mechanical compressors. High-efficiency compressors are an input variable in the GEM model which results in a 0.5% fuel consumption reduction, thereby de facto giving Class 7, Class 8 and vocational trucks the benefit of a pre-defined and pre-approved off-cycle fuel consumption credit for these compressors (80 Federal Register 40631). (Note: reference to 86.1868-12(h)(5) in the NPRM appears to be incorrect since that section covers improved evaporators and condensers whereas the correct reference would be to compressors with reduced reheat 86.1868-12(h)(1)). [EPA-HQ-OAR-2014-0827-1238-A1 p.18]
Clearly, the agencies recognize the environmental benefits that can be achieved from vehicle air conditioner efficiency improvements, and has included incentives within this NPRM for Class 7, Class 8 and vocational truck regulations to achieve these benefits through a simple pre-defined credit.

Organization: California Air Resources Board (CARB)

Comment - Emission credits for electrified accessories for vocational vehicles

U.S. EPA and NHTSA have not included electrified accessories as a component of the GEM model for vocational vehicles and instead propose to only allow manufacturers to apply for off-cycle credits for the technology. CARB staff sees electrified accessories as a viable technology to improve emissions in the vocational sector and believes it should be included in the overall stringency standards and GEM model. As stated in the NPRM, electrified accessories can result in a 2 to 4 percent fuel consumption benefit in vocational applications. CARB’s recently released report on heavy-duty drivetrain and vehicle efficiency backs these findings up, suggesting a 1 to 3 percent benefit from electrified accessories. This technology is feasible as it has already been demonstrated in various applications. With the long lead time of the Phase 2 regulation, CARB staff believes that the production volumes for electrified accessories can substantially increase if pushed by regulatory action, raising the production volumes and significantly lowering the costs, which will make this technology a cost-effective approach to reduce CO2 emissions. [EPA-HQ-OAR-2014-0827-1265-A1 p.48]

U.S. EPA and NHTSA are proposing vocational stringencies of 16 percent fuel consumption improvement by 2027. Electrified accessories could allow the proposed stringencies to be significantly tightened in certain vocational applications and should be included in the final rule. By only allowing off-cycle credits for electrified accessories, U.S. EPA and NHTSA are leaving out fuel reduction benefits from a technology that will be readily available in the Phase 2 timeframe. [EPA-HQ-OAR-2014-0827-1265-A1 p.48]

The NPRM and CARB’s Technology Assessment notes that electrified accessories can deliver a 1 to 3 percent fuel consumption benefit in vocational applications; however, U.S. EPA and NHTSA are currently only allowing off-cycle credits for this technology. As U.S. EPA and NHTSA’s Phase 1 rule did not consider electrified accessories either, this full 1 to 3 percent benefit can be obtained in the Phase 2 rulemaking. CARB staff recommends a fuel consumption benefit of 2 percent be applied to electrified accessories. CARB staff also notes that not every vocational application will be suited to best use this technology, therefore, CARB staff recommends a conservative penetration rate of 50 percent in the final MY stringency.

Response:

Although we did not propose to allow pre-defined credit for electrified accessories on vocational vehicles as was proposed for tractors, we agree with commenters that this is appropriate for vocational vehicles. Although the agencies are projecting that some electrified accessories will be necessary as part of the development of stop-start idle reduction systems for vocational vehicles, we did not propose to account for any efficiency improvements due to this electrification, only the improvements from turning the engine off. The final vocational vehicle standards are predicated in part on adoption of electrified accessories in all subcategories, where a pick list is available for manufacturers to choose applicable technologies and to enter a fixed improvement value in GEM.

In addition to the comments provided by ICCT, the agencies are relying on the TIAx 2009 technology report, CARB’s Driveline Optimization report, and the 2010 NAS report to assign fixed improvement
values for specific components for which we were able to quantify an improvement due to electrification. Because there are numerous mechanical components on a HD vehicle that could be electrified and the information from commenters and available literature does not generally identify the incremental improvement from each component, the pick list is short. Because the GEM algorithm for determining the fuel benefit of stop-start idle reduction does not account for any e-accessories, vehicles certified with stop-start are also eligible to be certified using an improvement value in the “Other” column. By MY 2027 the projected adoption rate is 15 percent of electrified accessories that achieve one percent improvement, applicable in all subcategories excluding custom chassis. Although we believe some components could be electrified for some custom chassis, we do not have sufficient information to estimate an incremental cost associated with electrifying the more complex systems on custom chassis such as buses, or to project a specific adoption rate for this type of improvement.

6.3.6.3 E-PTO

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)

We would like to see consideration and adoption of electric power-take-off (e-PTO) hybrids for certain vocational segments. These e-PTO technologies can provide more than 10-14% additional savings, provided they are accommodated with a hybrid-PTO test procedure, since their benefits cannot be captured in a powertrain test. Consider including e-PTO hybrids in the compliance package for appropriate vocational segments. This would support a stronger vocational vehicle standard for 2027. [EPA-HQ-OAR-2014-0827-1280-A1 p.19]

**Organization:** Gaines, Linda

In my judgement, the proposed metrics are inappropriate. My main concern is that work trucks like buckets are being rated on a g/t-mi basis, when their main product is work at a site rather than goods movement. A more appropriate measure would evaluate emissions per hour of actual work, depending on the type of equipment. Work trucks undergo many up-fits before they are put into use, and these can impact the base engine’s fuel economy. For instance, the truck may be up-fitted as a plug-in hybrid with a battery (charged from the grid) that not only powers the bucket, but also supplies power during driving, thus reducing fuel consumption on the road as well as during work at a site. The proposed regulations do not recognize this type of actual fuel-economy improvements; the same truck could alternatively be equipped with a bucket to be run by idling the main engine, emitting significantly more CO2. The proposed regulations would not distinguish between these very different trucks. It would be desirable to provide an incentive for efficiency improvements that can be added onto work trucks. [EPA-HQ-OAR-2014-0827-1357-A1 p.1]

**Organization:** Natural Resources Defense Council (NRDC)

In the vocational vehicle market, there is a significant opportunity for fuel consumption and carbon pollution reductions from the application of hybrid systems, both as part of the drivetrain and for use as power-takeoff (PTO) devices in non-driving applications, such as when bucket trucks are moving workers and refuse trucks are gathering and compressing garbage. NRDC recommends that the Phase 2 standards stringency incorporate the benefits from PTO application and use during vehicle certification where the certifying manufacturer can show that the appropriate PTO technologies will be applied to the vehicle. The agencies should also account for the PTO use in calculations of potential strong hybrid penetration. A PTO device integrated to a hybrid drivetrain could improve the cost-effectiveness of a strong hybrid application. The improved cost-effectiveness of the full system would lead to higher market penetration...
of hybrid and PTO systems overall and justify strengthening the vocational vehicle standards. [EPA-HQ-OAR-2014-0827-1220-A1 p.5-6]

**Organization:** Environmental Defense Fund (EDF)

Many vocational truck configurations are excellent candidates for these technologies, and are being applied on vocational trucks today. Odyne, a Wisconsin-based manufacturer of electric and hybrid electric propulsion systems for heavy trucks, currently produces a truck that promises annual fuel savings of up to 50% for class 7 trucks with extensive use of the power take-off mode. This currently available solution can cut fuel consumption by 1,750 gallons per year.\(^{161}\)

161 See http://www.odyne.com/benefits/reduced-fuel-cost.html

**Organization:** Union of Concerned Scientists (UCS)

The agency’s effectiveness estimate comes from an assessment of hybrid effectiveness over the GEM duty cycles using a powertrain test. In contrast, the NGO effectiveness estimate considers real world operation. This is an especially important distinction because two of the classes of vehicle with which both the agencies and the NGO community have identified as a primary application of hybrids (refuse trucks and bucket trucks) use a significant fraction of fuel operating power-take-off (PTO) devices. The agency did not consider hybrid or electric PTO operation when assessing the fuel savings potential of hybridization. This has a significant impact on the effectiveness of hybridization. [EPA-HQ-OAR-2014-0827-1329-A2 p.19]

Hybrid PTO effectiveness. Vehicles with a hybrid or electric PTO (ePTO) do not use the powertrain test but a separate “Hybrid PTO” test procedure. This would significantly change the assumed effectiveness of a hybrid refuse or bucket truck. According to UCS analysis (Attachment A), ePTO would provide additional effectiveness of 10.1 percent for multipurpose vehicles and 14.4 percent for urban vehicles. [EPA-HQ-OAR-2014-0827-1329-A2 p.19]

It seems likely that many of the Urban Heavy-Duty vocational vehicles EPA and NHTSA have identified as being hybridized in the timeframe of this rule will also have hybrid PTO operation. According to the Vehicle In Use Survey (VIUS), 16.4 percent of light-heavy-, 38.2 percent of medium-heavy-, and 66.4 percent of heavy-heavy-duty vehicles have a PTO system (United States Census Bureau 2004). According to our population assumptions, this yields a total fraction of vehicles with PTO of nearly 195,000. Applying the fractions above just to the hybrids already assumed by EPA, combined with the increased effectiveness for ePTO-enabled hybrids listed above, would increase the overall hybrid effectiveness from between 22.9 and 25.6 percent up to 24.2 to 32.7 percent, depending on vehicle class and type. [EPA-HQ-OAR-2014-0827-1329-A2 p.19 and p.21]

Changes to hybrid penetration. Incorporating the fuel economy benefit of the PTO operation will also affect the uptake of these vehicles. Real world operation of refuse trucks has been shown to exceed 40% effectiveness over its conventional powertrain equivalent, and by including only the test equivalent effectiveness, the agencies have underestimated the overall cost-effectiveness, and therefore penetration, of hybrids. [EPA-HQ-OAR-2014-0827-1329-A2 p.21]

Using the increased effectiveness of the ePTO-enabled hybrids but matching the same marginal cost-per-effectiveness ($/%) improvement of the agencies analysis for multipurpose and urban hybrids would increase the penetration from 18 percent up to between 19 and 23 percent, again depending on vehicle class and type. [EPA-HQ-OAR-2014-0827-1329-A2 p.21]
E-PTO Systems Have Entered Into Mainstream Procurement and Offer Significant Petroleum and Greenhouse Gas Emissions Savings that Should Be Recognized in the Phase 2 Program

In section V.C.1.c.iv of the proposed Phase 2 Program, EPA and NHTSA seek “comment and data relating to the population and energy storage capacity of plug-in e-PTO systems.” In response, EEI offers the following comments: [EPA-HQ-OAR-2014-0827-1327-A2 p.15]

- e-PTO systems have entered into mainstream procurement: [EPA-HQ-OAR-2014-0827-1327-A2 p.15]
  - EEI member companies committed to the Fleet Electrification Initiative reported purchasing approximately 350 e-PTO systems for their 2015 procurement plans, all in the Class 4-8 categories, with the majority in Class 5. At least one of our member companies now purchases e-PTO systems for all applicable work truck applications.

- e-PTO systems offer significant fuel and greenhouse gas savings: [EPA-HQ-OAR-2014-0827-1327-A2 p.15]
  - As EEI notes in its whitepaper Electric Transportation: Utility Fleets Leading the Charge, e-PTO systems directly displace petroleum with grid-sourced electricity at a rate of approximately 0.8 to 1.2 gallons of fuel per hour of idling.

  - Given the fuel savings mentioned above, e-PTO systems can deliver payback periods well within the useful life of the vehicle; the EEI white paper assumes a 5-year payback in a Class 5 application and a 7-9 year payback in a class 7 application.
  - Beyond the fuel savings, e-PTO systems offer a number of additional benefits including: reduced maintenance costs due to reduced engine hours, quiet operation that allows trucks to work in noise restricted locations, and eliminating the need for a worksite electric generator due to exportable power capability.

- e-PTO systems are available from multiple vendors in a variety of capacities: [EPA-HQ-OAR-2014-0827-1327-A2 p.15-16]
  - e-PTO systems without drivetrain integration are available from Terex and Altec e-PTO systems with drivetrain integration (more commonly referred to as a “plug-in hybrid” configuration) are available from Odyne, Eaton and Allison Transmissions
  - To use one example, the Jobsite Energy Management System (JEMS) from Altec is available in 6 kWh, 10 kWh, 15 kWh, and 18 kWh capacities
  - Include e-PTO systems among the technologies used in the standard setting for vocational vehicles [EPA-HQ-OAR-2014-0827-1327-A2 p.16]

Estimate of annual sales of hybrid systems on vocational trucks with a PTO, with ROI of 3 years in 2021 and ROI of 2 years in 2027

An estimated 145,000 PTOs were installed on medium and heavy duty vocational trucks in both 2012 and 2013 as described earlier. Odyne used the same number of PTO sales as an estimate in 2021 and 2027. Based upon an ROI of 3 years and 2 years, the sales of hybrid systems should be significantly higher in 2021 and 2027 compared to current hybrid sales that have significantly longer ROI. Other desirable operating characteristics including reduction in CO2, reduction in NOx, quiet stationary operation of
equipment due to keeping the engine off during PTO use, and better acceleration should help improve user demand. [EPA-HQ-OAR-2014-0827-1239-A1 p.16]

Odyne estimates that approximately 7,500 units capable of 50% or greater GHG emission reductions in 2021 could be sold based upon the system prices shown in table 2, which equates to approximately 5% of the overall PTO market of 145,000 units for medium and heavy duty vocational trucks. [EPA-HQ-OAR-2014-0827-1239-A1 p.16]

Odyne estimates that approximately 15,000 units capable of 50% or greater GHG emission reductions in 2027 could be sold based upon the system prices shown in table 3, which equates to approximately 10% of the overall PTO market of 145,000 units for medium and heavy-duty vocational trucks. [EPA-HQ-OAR-2014-0827-1239-A1 p.16]

[Table 3, ‘Estimated Sales Volume Based on Price, ROI and Market Size’, can be found on p.18 of docket number EPA-HQ-OAR-2014-0827-1239-A1]

Organization: Odyne Systems LLC

Odyne believes that by not building the proposed standard methodology for vocational vehicles on the use of hybrid PTO mode (anti-idle technology), the EPA could miss out on a significant opportunity to increase full workday fuel efficiency for vocational vehicles. The segment of the vocational chassis market using Power Take-offs (PTOs) is significant. Odyne and other industry estimates put the annual PTO-enabled vehicle market at between 145,000-195,000 annually, with the potential of upwards of 15% of those vehicles being enabled with an e-PTO. [EPA-HQ-OAR-2014-0827-1239-A1 p.5-6] [This comment can also be found in EPA-HQ-OAR-2014-08267-1372, pp.231-232.]

For draft rule effectiveness and market penetration projections, by subjecting hybrid e-PTO enabled vehicles to a separate test outside of the powertrain, this drastically reduces overall technology effectiveness as assumed by EPA of the vehicle. According to analysis done by the Union of Concerned Scientists, e-PTO would provide additional effectiveness of 10.1% for multipurpose vehicles and 14.4% for urban vehicles. For Urban Heavy-Duty Vehicles that EPA assumes will be hybridized within compliance periods of this rule, Odyne would imagine a large portion of these vehicles having PTO operation. Additional analysis done by UCS shows that when incorporating additional effectiveness from e-PTO operation in hybrids would improve overall hybrid effectiveness from 22.9-25.6% up to 24.2-32.69%, depending on vehicle class and type. For market penetration, including the assumed effectiveness improvements described above would increase market penetration for multipurpose and urban hybrids from 18% up to 19-23%, again depending on vehicle class and type. [EPA-HQ-OAR-2014-0827-1239-A1 p.6]

Estimated Annual PTO Market

Odyne is pleased to provide additional information to the EPA regarding the number of new medium and heavy duty vocational vehicles produced with installed power take-offs. [EPA-HQ-OAR-2014-0827-1239-A1 p.7]

Medium and Heavy duty work trucks are defined by Odyne as vocational trucks over 14,000 pounds GVWR that drive to one or more worksites and operate equipment that receives power from the truck at the worksite. Work trucks typically use Power take-offs (PTOs) and idling engines (prime mover diesel engines in most cases) to deliver power to equipment, but may also use independently operating engine driven generators to supply electricity to tools or other equipment. Equipment maybe mounted to the
truck, including but not limited to aerial bucket lifts, cranes, digger derricks, compressors, air handling systems, pumps, refuse compactors, hydraulically powered dump bodies, etc. The PTOs deliver power from the engine to truck mounted equipment. [EPA-HQ-OAR-2014-0827-1239-A1 p.7]

The number of PTOs installed annually on medium and heavy duty trucks represents a significant portion of the number of vocational trucks sold annually that operate in both a driving mode and a stationary worksite mode with at least one engine typically idling. Some trucks may power truck mounted equipment by using an additional truck mounted engine, often a generator. Odyne recommends that the fuel consumption and GHG emissions of additional vehicle mounted engines should be included in regulations so that all technologies are evaluated equally and operators are not incentivized to use less efficient options that fall outside of regulations. [EPA-HQ-OAR-2014-0827-1239-A1 p.7-8]

The number of medium and heavy duty vocational trucks sold with PTOs is large and presents an excellent opportunity to deploy cost effective technology to reduce GHG emissions. [EPA-HQ-OAR-2014-0827-1239-A1 p.8]

According to Odyne estimates, there are an estimated 145,000 Vocational medium and heavy-duty work trucks sold yearly with an installed PTO. [EPA-HQ-OAR-2014-0827-1239-A1 p.8]

According to the National Truck Equipment Association (NTEA) 2013 Annual Manufacturers Shipments Survey, Power Take-off (PTO) shipments totaled approximately 277,000 units for both 2012 and 2013. [EPA-HQ-OAR-2014-0827-1239-A1 p.8]

Of the total number of PTOs shipped per the survey, Odyne worked with the NTEA and used U.S. Census Bureau, Vehicle Inventory and Use Survey (VIUS) data to estimate the total PTOs installed on new class 4–8 vocational trucks. [EPA-HQ-OAR-2014-0827-1239-A1 p.8]

Odyne used the following methodology to estimate that approximately 145,000 PTOs are installed on new vocation trucks in the U.S. annually: [EPA-HQ-OAR-2014-0827-1239-A1 p.9]

Based upon discussions with the NTEA, not all of the 277,000 PTOs that were shipped by PTO manufacturers in both 2012 and 2013 were installed on new class 4 – 8 vocational trucks sold in the U.S. In order to estimate the number of PTO units installed on new class 4 – 8 vocational trucks in the U.S., Odyne reviewed data from the most recent U.S. Census Bureau, Vehicle Inventory and Use Survey (VIUS) working with the NTEA. The NTEA estimates that approximately 85% of PTO units sold per the NTEA survey were sold in the U.S. Odyne multiplied the 277,279 units reported to be shipped in 2013 from the survey by 0.85 resulting in an estimated 235,687 PTO units that are sold in the U.S. Based on conversations with the NTEA, approximately 2/3 of the PTOs shipped were installed on new trucks, the remaining 1/3 were estimated to be used as service replacement PTO units. Odyne then multiplied the 235,687 estimated PTO units sold in the U.S. by 2/3 to arrive at an estimated 157,125 PTO units installed on new vehicles in the U.S. The installed units are distributed among a variety of vocational vehicles in different weight classes. In order to estimate the number of PTO units installed annually on new medium and heavy duty vocational trucks, Odyne used data from the most recent U.S. Census Bureau. According to the Census Bureau survey, approximately 93% of PTOs in use are installed on class 4 – 8. Using that ratio, Odyne then multiplied the 157,125 PTOs estimated to be installed on new trucks in the U.S. by 0.93, arriving at an estimated 146,342 PTO units installed in 2013 on new Class 4 – 8 vocational vehicles. Finally Odyne rounded the total of 146,342 down to 145,000 units. The average number of PTO’s installed yearly will vary depending upon the number of Class 4 – 8 vocational trucks sold annually, the intended use of those vehicles and other factors. [EPA-HQ-OAR-2014-0827-1239-A1 p.9-10]
In real world applications of vocational vehicles deployed with Odyne hybrid technology, we have seen fuel efficiency improvements of 46% in driving alone, and 64% in fuel savings when accounting for the average full workday; including driving, idling, and hybrid power take off (PTO) activities. Based on testing paid for by the U.S. Department of Energy and the state of California, Odyne technology currently delivers up to 64% lower CO2 and 95% lower NOx emissions (based on a customer’s full workday, depending on vehicle configuration and duty cycle) than non-hybrid medium and heavy duty trucks meeting current standards. Additional independent laboratory testing showed 51% and 41% reductions in CO2 and 71% and 80% reductions in NOx (based on average full workday, specific vehicle configuration and duty cycle). Odyne believes co-benefits beyond fuel efficiency improvements and greenhouse gas reductions, like Odyne technologies verified ability to reduce NOx emissions, should be valued in the Phase Two rulemaking, especially given potential future regulatory actions from EPA and current developments from CARB on NOx. [EPA-HQ-OAR-2014-0827-1239-A1 p.3-4] [This comment can also be found in EPA-HQ-OAR-2014-08267-1372, pp.229-230.]

Odyne has conducted internal market penetration and payback projections for its hybrid system based on the full workday. Of a potential between 145,000 to 195,000 PTO-enabled vehicles sold annually (range represents Odyne and other stakeholder estimates), we project at an average system cost of $10,000 and ROI of 2 years by 2027, Odyne technology could capture upwards of 15% of the marketplace. Details on assumptions made to reach these projections are included in the below section “Rule Methodology Assumptions.” [EPA-HQ-OAR-2014-0827-1239-A1 p.4]

Analysis of data from the U.S. Department of Energy Project regarding the use of Plug-In Hybrid Systems on Medium and Heavy Duty Vocational Vehicles showed that the average required Power and Energy of the hybrid system needed to deliver a 50% reduction in GHG emissions for the applications in the project was less than 10 kWh of energy at the worksite. Approximately 5 kWh was consumed to provide an average of 2.8 hours of all electric PTO operation and the remainder provided energy for reduced fuel consumption during driving and for idle reduction. In total, 10 kWh of energy from the battery system provided an average of over 1.7 hours of operation without idle and 2.8 hours of engine off time operating equipment, for a total of 4.5 hours of engine off savings. Power measurements during testing and field operation showed that average electrical power requirements to meet the 50% reduction in GHG emissions were 20 kW of sustained electrical power from the electrical motor for time periods beyond 2 minutes and peak power of up to 31 kW for short periods during hybrid driving and stationary modes, typically less than 2 minutes in duration. [EPA-HQ-OAR-2014-0827-1239-A1 p.10-11]

U.S. Department of Energy project entitled Plug-In Hybrid Medium-Duty Truck Demonstration and Evaluation Program, with reference project number DOE FOA-28, award number EE0002549 and South Coast Air Quality Management District (SCAQMD) contract number 10659. Please contact Mark Kosowski at EPRI (mkosowski@epri.com) or John Petras at Odyne Systems, LLC (john.petras@odyne.com) for additional information about the DOE project.

The power and energy requirements to deliver a 50% reduction in GHG emissions for vocational work trucks operating in a driving mode and a worksite stationary mode in the DOE project were typically lower than the power and energy requirements required for similar savings in GHG emission for duty cycles composed of all driving. Most of the vocational vehicles monitored were observed to have very high idle times related to worksite operations. [EPA-HQ-OAR-2014-0827-1239-A1 p.11-12]

Using the measured requirements of power and energy determined from the data provided by 1Hz telematics units on over 100 operational plug-in hybrid systems on medium and heavy duty vocational trucks, Odyne developed high-level component specifications that would match the power and energy
requirements needed to attain the high GHG reductions and then worked with industry input to approximate the cost of the system in 2020 and beyond. [EPA-HQ-OAR-2014-0827-1239-A1 p.12]

Projected component costs in 2020-2021 are shown in Table 2 below of a system that is capable of providing savings of 12 to 15% of driving fuel consumption and a 100% savings in fuel consumed during stationary operation of truck mounted equipment at worksites, resulting in a total savings of over 50% for typical duty vocational duty cycles with truck mounted equipment. Daily fuels savings would be expected to be over 4 gallons, which is similar to the results attained in the U.S. DOE project. [EPA-HQ-OAR-2014-0827-1239-A1 p.12]

[Table 1, ‘Higher Voltage System year: 2021’, can be found on p.12-13 of docket number EPA-HQ-OAR-2014-0827-1239-A1]

Charge Depletion Versus Sustaining Testing

The current test procedure 40 CFR 1037.510/540 is a charge sustaining procedure. This procedure could be sufficient for a HEV application, but not for a PHEV application. In Odyne’s PHEV application we do not charge the system all the way back to full in the field and handle charging primarily with plug-in charging from the power grid. Odyne would recommend that the test procedures used in a final rule account for scenarios with a charge depleting battery system, to be recharged from the grid in off hours, results in real world overall fuel efficiency increases. We also recommend that the test procedure allow flexibility to alter the test procedure as needed to account for the type of system/technology and its typical workday (i.e. – drive cycle, duty cycle, application load, dyno/PEMS, etc.). [EPA-HQ-OAR-2014-0827-1239-A1 p.24]

Response:

Although the primary program does not simulate vocational vehicles over a test cycle that includes PTO operation, the agencies are adopting a revised hybrid-PTO test procedure. See 76 FR 57247 and 40 CFR 1037.540. Recall that we regulate vocational vehicles at the incomplete stage when a chassis manufacturer may not know at the time of certification whether a PTO will be installed or how the vehicle will be used. Chassis manufacturers may rarely know whether the PTO-enabled vehicle will use this capability to maneuver a lift gate on a delivery vehicle, to operate a utility boom, or merely to keep it as a reserve item to add value in the secondary market.

The work by NREL to characterize idle behavior of PTO-equipped vehicles indicates that for about 10 percent of workdays analyzed (165 of 1570 work days), zero PTO use was recorded. Further, for about half of the work days, PTO utilization was one hour or less. Although these data are exclusively for trucks working in utility applications, we would expect this subset to represent vehicles with a high likelihood of using the PTO and an operating profile most likely to benefit from adoption of technologies that can reduce PTO fuel use. In considering the difficulty of identifying these vehicles at the incomplete stage as well as the available duty cycle information, we have concluded it would not be reasonable to require every vocational vehicle to certify over a standard test procedure with a PTO cycle in it.

Thus, we are not basing the final standards on use of technology that reduces emissions in PTO mode. In cases where a manufacturer can certify that a PTO with an idle-reduction technology will be installed either by the chassis manufacturer or by a second stage manufacturer, the hybrid-PTO test cycle may be utilized by the certifying manufacturer to measure an improvement factor over the GEM duty cycle that otherwise applies to that vehicle. In addition, the delegated assembly provisions will apply (see Section I.F.2 of the Preamble and Section 1.4.4 of this response to comments).
The agencies agree with commenters that a charge-depleting test cycle is more appropriate where the technology is essentially a plug-in hybrid. The calculations recognize fuel savings over a portion of the test that is determined to be charge-sustaining as well as a portion that is determined to be charge-depleting for systems that are designed to power a work truck during the day and return to the garage where recharging from an external source occurs during off-hours. We partnered with DOE-NREL to characterize the PTO operation of nearly 100 trucks with over 1,000 total operating days, and our final regulations include a utility factor table based on these data for use in determining the effectiveness of a hybrid PTO system. Manufacturers wishing to conduct testing as specified may apply for off-cycle credits derived from e-PTO or hybrid PTO technologies. See RIA Chapter 3 for a discussion of the revisions to the PTO test cycle.

### 6.3.7 Tire Pressure Systems

**Organization:** Autocar, LLC

*Tire Pressure Monitoring.* Autocar believes there is potential for increased fuel efficiency if automatic tire pressure monitoring systems are developed for use in Low-speed/Frequent-stop Vehicles. Although current technology is designed for safety and reduced tire replacement cost (which also has a positive environmental impact), future technology could be effective in maintaining optimum tire pressure. [EPA-HQ-OAR-2014-0827-1233-A1 p.15]

**Organization:** Tirestamp, Inc.

It should be noted that automatic tire inflation systems plumbed through the axle are currently available only for trailers. ATIS for trucks, tractors, and buses must be plumbed externally. Due to their high maintenance and propensity for damage, they are not of interest to U.S. fleets. Advanced TPMS integrated with telematics are ideal for these vehicles. [EPA-HQ-OAR-2014-0827-1255-A1 p.4]

**Organization:** Rubber Manufacturers Association (RMA)

Providing efficiency benefits to only ATIS technology neglects the benefits of correctly using TPMS. In addition, both ATIS and TPMS should carry the same benefit in terms of CO2 and fuel consumption reduction. TPMS can also provide the applications to the other Class 2b – 6 medium- and heavy-duty vehicles encompassed in the proposed Phase 2 fuel efficiency standards, in addition to the overall tire performances. [EPA-HQ-OAR-2014-0827-1304-A1 p.30]

**Organization:** Cline (representing AIR CTI)

Then Tire Pressure Maintenance is the minimum that is must be fitted and regulated. The pressures must be set to optimize the truck and trailer. Central Tire Inflation is required on trucks that travel empty regularly, like dump trucks, bulk grain trucks, tankers, low loaders. When empty, semi trailers are currently dangerous. Brake balance, significant overly braked, and ridiculously over inflated tires create a condition that jack knives are probable. Any truck working off highways needs CTI too. Either will eliminate almost every blow out and alligators that litter our highways, if we’re lucky, or kill, if not. [EPA-HQ-OAR-2014-0827-0803-A2 p.5]

**Organization:** Volvo Group
In setting vehicle stringencies, the agencies have predicated the standards for tractors on adoption of Automatic Tire Inflation Systems (ATIS), while giving no consideration to Tire Pressure Monitoring Systems (TPMS). [EPA-HQ-OAR-2014-0827-1290-A1 p.23] [This comment can also be found in section 4.3 of this comment summary]

All commercial vehicle operators are well aware of the increased fuel consumption, maintenance costs, downtime, and safety concerns associated with operating a heavy vehicle with under-inflated tires. These concerns have been much more significant given the volatile diesel prices, the pricing pressure on fleets due to an unstable economy and consolidation within the industry, the continued ratcheting of safety regulations, and the rising costs of liability, all within the last decade. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

In Section 2.4.3.3 of the RIA the agencies noted that “although most fleets understand the importance of keeping tires inflated, it is likely that a substantial proportion of trucks on the road have one or more underinflated tires.” Their evidence of this assertion are two studies, one industry survey conducted by checking pressures at a truck stop in 2002, and another study conducted by the Federal Motor Carrier Safety Administration (FMCSA) in 2003. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

The agencies have based their lack of credit provisions for TPMS on this outdated data, as well as their assertion that TPMS requires user interaction to re-inflate a tire to the appropriate pressure and therefore a driver “may” continue to operate a vehicle with underinflated tires, even to their final destination. However, in light of continually increasing pressures on fleets to reduce total costs of operation in order to be profitable, Volvo Group disagrees that two studies dating from 12 to 13 years in the past are truly relevant in the decision making process of today’s fleets. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

In addition, given the poor reliability of past ATIS systems, we are skeptical of supplier’s claims of current or future reliability improvements to these systems. Fleets are even more skeptical than truck OEMs, as an ATIS air leak results in increased fuel consumption due to a compressor cycling more frequently and also in potentially significant downtime of the vehicle, even more so than a tire blowout. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

To incentivize truck operators to maintain tire pressure on vehicles equipped with a TPMS system, fleets have the ability to monitor fuel consumption remotely, including the ability to identify causes for increased fuel consumption. This capability is expected to motivate drivers to properly maintain tire pressure on TPMS equipped vehicles. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

For these reasons Volvo Group believes that the agencies should provide the same 1% efficiency credit for TPMS as given to ATIS. Volvo Group does not believe this inclusion should be included in the baseline efficiency assumptions or result in a stringency increase, as these systems are an alternative to ATIS, are not credited today, and the evolution of the remote tracking systems has only recently made them more likely to result in a positive corrective action. [EPA-HQ-OAR-2014-0827-1290-A1 p.23]

**Organization:** Bendix Commercial Vehicle Systems, LLC

TPMS is already available as a factory installed option at all the major truck/tractor OEMs (including Daimler, Kenworth, Navistar, Mack, Peterbilt and Volvo) as well as trailer, bus, and motorcoach manufacturers.

**Organization:** American Trucking Associations (ATA)
TPMS have not historically been included in the EPA’s SmartWay program since the agency had no way to determine the effect these systems have on fuel economy unless each requesting fleet provided a clear description of how it would respond to alerts. This information was necessary so that the EPA could calculate the resulting fuel savings. However, much has transpired since the inception of the SmartWay Program. The Federal Motor Carrier Safety Administration (“FMCSA”) has studied TPMS since 2006. It found that these systems accurately reported inflation pressure values within 2 to 3 psi of the measured value and accurately warned of low pressure within 2 to 3 psi of the expected threshold. In 2007, the performance and durability of TPMS was examined in a field test using transit buses. This study found that TPMS-equipped buses did not experience increased average tire pressure due to diligent tire pressure maintenance and the location of the TPMS display is essential to impact tire maintenance practices, fuel economy, and tire life. [EPA-HQ-OAR-2014-0827-1243-A1 p.14]

Due to the advances that have been made in TPMS 2.0 systems and the impact they have on fuel economy and greenhouse gas emissions, the Tire & Wheel (S.2) Study Group of ATA’s Technology and Maintenance Council (“TMC”) requests that TPMS 2.0 systems, tire pressure monitoring systems that are integrated with telematics, be included in the technology options provided under Phase 2. Without inclusion of this technology, there will be no system available in the TMC standard to address tire inflation pressure for powered vehicles since ATISs that are plumbed inside an axle (a market requirement by US fleets) are currently only available for trailers and an advanced technology that can seriously impact GHG emissions will be overlooked. [EPA-HQ-OAR-2014-0827-1243-A1 p.15]

Certain tires loads, especially on heavy-hauls, have working tire pressures exceeding the capabilities of on-board compressors. Additional on-board compressor tanks can cost $800 and add an additional 150 pounds of weight. Consideration should be given to exempt certain trailers from using ATIS and instead allow the use of TPMS as previously discussed. [EPA-HQ-OAR-2014-0827-1243-A1 p.24]

Response:

The agencies did not propose to base the vocational vehicle standards on the performance of tire pressure monitoring systems (TPMS). However, we received comment that we should consider this technology. In addition to similar comments related to tractors and trailers, RMA commented that TPMS can also apply to the class 2b – 6 vehicles, and if the agencies add TPMS to the list of recognized technologies, that this choice should also be made available to class 2b-6 vehicles. Bendix commented that TPMS is a proven product, readily available from a number of truck, bus, and motorcoach OEMs. Autocar commented that TPMS is useful for refuse truck applications. Tirestamp said that TPMS is ideal for trucks and buses that are unable to apply ATIS due to difficulties plumbing air lines externally of the axles. The agencies find these comments to be persuasive. As a result, we are finalizing vocational vehicle standards that are predicated on the performance of TPMS in all subcategories, including all custom chassis except emergency vehicles and concrete mixers. Available information indicates that it is feasible to utilize TPMS on all vocational vehicles, though systems for heavy vehicles in duty cycles where the air in the tires becomes very hot must be ruggedized so that the sensors are protected from this heat. Such devices are commercially available, though they cost more. To account for this in our analysis, we have projected a lower adoption rate for TPMS in Urban vehicles than for Regional or Multipurpose vehicles, rather than by increasing the overall estimated cost and applying an equal adoption rate.

The agencies did not propose to base the vocational vehicle standards on the performance of automatic tire inflation systems (ATIS), otherwise known as central tire inflation (CTI). However, we did receive comment indicating that it is feasible for some vocational vehicles to use this technology. Air CTI commented that central tire inflation is not only feasible but enhances safety on vehicles such as dump trucks and heavy haul vehicles that need higher tire pressures under certain driving conditions, such as
when loaded, but need lower tire pressures when running empty or operating off-road. Tirestamp commented that ATIS can be plumbed externally for trucks and buses, but such systems have a propensity for damage and Autocar has provided information about how much extra weight this plumbing adds to the chassis. ATA commented that some onboard air pressure systems may not be able to pressurize tires sufficiently for very heavy vehicles. The primary vocational vehicle standards are not predicated on any adoption of this because the agencies do not have sufficient information about which chassis will have an onboard air supply for purposes of an air suspension or air brakes. ATIS would logically only be adopted for vehicles that already need an onboard air supply for other reasons. Comments received for custom chassis were supportive of standards predicated on ATIS for buses with air suspensions. These comments are again persuasive. As a result, we are basing the optional standards for refuse trucks, school buses, coach buses, and transit buses in part on the adoption of ATIS. Although many motor homes have onboard air supply for other reasons making ATIS technically feasible, it is sufficiently costly that it is not practically feasible. Furthermore, for the same reasons stated above about the disadvantages of installing external plumbing for ATIS on some trucks and buses, we have determined it is not feasible for emergency vehicles or concrete mixers. Nonetheless, we are allowing vocational vehicles including all custom chassis to obtain credit for the performance of ATIS through a GEM input.

We are assigning a fixed improvement in GEM for use of TPMS in vocational vehicles of one percent for Regional vehicles including motor coaches and RV’s (the same as for tractors and trailers) and 0.9 percent for Multipurpose, Urban, and other custom chassis vocational vehicles, recognizing that the higher amount of idle is likely to reduce the overall effectiveness for these vehicles. We are assigning a fixed improvement for ATIS of 1.2 percent for Regional vehicles including motor coaches and RV’s (the same as for tractors and trailers) and 1.1 percent for Multipurpose, Urban, and other custom chassis vocational vehicles, recognizing that the higher amount of idle is likely to reduce the overall effectiveness for these vehicles. (The difference in estimated effectiveness for TPMS and ATIS reflects the degree of driver involvement necessary for TPMS). These values will be specified as GEM inputs in the column designated for tire pressure systems.

6.3.8 Axle Technologies

Organization: Daimler Trucks North America LLC

Axle Driveline Inputs - On whether the agencies should allow this choice. (Drive axle ratio would be a user input). Agreed, make the drive axle a user input. 80 FR 40323. [EPA-HQ-OAR-2014-0827-1164-A1 p.62]

On whether we should require GEM to be run twice, once with each axle ratio, where the output over the highway cycles would be used from the run with the lower axle ratio, and the output over the transient cycle would be used from the run with the higher axle ratio. GEM should be run twice as the EPA suggested, once with each axle ratio, where the output over the highway cycles would be used from the run with lower axle ratio, and the output over the transient cycle would be used from the run with the higher axle ratio. 80 FR 40323. [EPA-HQ-OAR-2014-0827-1164-A1 p.62]

Axle Packages – The agencies assume 75% penetration in vocational vehicles of advanced axle lubricant formulations and request comment any vocational vehicle applications for which use of advanced lubricants would not be feasible. 80 FR 40320. Advanced lubricants for most 'normal' vocational applications would likely provide sufficient coverage against axle damage. However we don’t have knowledge yet for severe vocational applications. Extreme conditions and vehicle applications like artic oil field vehicles may need special fluids. Therefore, we agree with the agencies’ proposal not to assume
full penetration of advanced axle lubricant formulations, but we do not know that 75% is the right penetration rate. [EPA-HQ-OAR-2014-0827-1164-A1 p.97]

**Organization:** Lubrizol Corporation

Higher-performing lubricants will play an important role in helping the OEMs comply with the Phase 2 Rule. Indeed, as shown in Figure 1 below, many of the technologies and strategies that will be used by the OEMs will require HPLs to operate cleanly, efficiently, and without compromising equipment performance and durability. [EPA-HQ-OAR-2014-0827-1325-A1 p.2][This comment can also be found in section 1.4.2 and 4.3 of this comment summary] [Figure 1 can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1325-A1]

**Organization:** GILLIG LLC

Transit buses don’t have tandem drive axles so the improvement options for Single Drive axle in a 6x2 and Part Time single drive axle in a 6x2 are not applicable to transit buses. More testing is required before we will know if Low Friction Axle Lubricant, another technology improvement option, is viable for transit for the same reasons. Transit bus duty cycles have a high number of stops and starts and significant retarder/backside gear loading making lubricant viscosity at all temperatures very important to gear and bearing life. To that point, transit bus end users expect 300k miles without a major axle overhaul.

**Organization:** Volvo

Relative to vocational 6x2 deployment, there are two key issues that preclude use of 6x2 axle configurations. First, the vast majority of vocational vehicles use leaf springs rather than air springs. Axle load shifting, essential to a functional 6x2 system, is accomplished via regulating the pressure in air springs and is therefore infeasible when using leaf springs. Second, the vast majority of HHD vocational trucks and tractors spend some time off-road. Less than 2% of Volvo Groups annual volume of HHD straight trucks and vocational tractors are used solely on-highway, with the remaining percentage spending some time off-road. In a HHD vocational application with any off-road operation the inability to shift load makes a 6x2 axle configuration unacceptable unless the system is a part-time 6x2 with a disconnect. Currently, such systems under development disconnect the inter-axle driveshaft, to gain efficiency by bypassing the inter-axle differential. It is unclear how much benefit this type of system would provide unless there were multiple disconnects (i.e. at the inter-axle driveshaft, and at each differential output or wheel end) since, without multiple disconnects, the internals of the non-driven axle would still rotate and cause churning and frictional losses at likely the same levels as a driven axle. There is no currently available system with this type of multiple disconnect architecture and it is unclear whether this is a part of any major axle manufacturers’ technical roadmaps. We are very concerned however, that such a system would be very costly, heavy, fraught with reliability and durability problems, and would require significant development rendering it infeasible in the vocational HHD Regional subcategory. [EPA-HQ-OAR-2014-0827-1290-A1 P.29]

**Organization:** Oshkosh Corporation

The two axle-related improvements discussed in the NPRM are a switch from 6x4 to 6x2 configurations, and improved efficiency from advanced lubricants.

While we have no data to either support or reject the potential for axle lubricant improvements, there is a definite objection to expecting a shift to 6x2 configurations. This checkbox will not work for most vocational trucks that spend part of their life in off road environments, such as job sites, landfills, power
line paths, et cetera. The axle configuration is a customer-specified option, not a design selection by the manufacturer. In our experience, customers do not specify a 6x4 configuration unless they need it for mobility at job sites, emergency scenes, or for pushing snow. [EPA-HQ-OAR-2014-0827-1162-A2 p.4]

Response:

In response to persuasive comment on the proposal to assign a fixed 0.5% improvement for use of low friction axle lubricants, the agencies are adopting a separate axle efficiency test procedure that manufacturers may perform to measure axle gear efficiency improvements. These test results may be entered into GEM for an improved efficiency over the test cycles. Our market adoption rate for this technology has decreased since proposal down to 30% in MY 2027, indicating that we expect axle suppliers to only offer high-efficiency axles for their most high production volume products, especially those that can serve both the tractor and vocational market. Therefore, we believe it is unlikely that high-efficiency axles will be adopted in custom chassis applications. See responses to UCS comments above in Section 6.2.3.1 for specific adjustments that have been made relative to axles on custom chassis. If a custom chassis vehicle is certified to the primary program standards using full GEM, the alternate axle efficiency GEM inputs will be available.

The agencies proposed to base the HHD vocational vehicle standard on some use of both part time and full time 6x2 axles. In response to persuasive comment on the application of the permanent 6x2 configuration for vocational vehicles, we are predicating the final vocational vehicle standards in part on use of the part-time 6x2 (axle disconnect) for vehicles in the primary program using full GEM. The disconnect configuration is one that keeps both drive axles engaged only during some types of vehicle operation, such as when operating at construction sites or in transient driving where traction especially for acceleration is vital. In response to comments, the final regulations require that the input and output of the disconnectable axle must be mechanically disconnected from the drive shaft and the wheels to qualify. Instead of calculating a fixed improvement as at proposal, the agencies have refined GEM to recognize this configuration as an input, and the benefit will be actively simulated over the applicable drive cycle. Effectiveness based on simulations with EPA axle files is projected to be as much as one percent for HHD Regional vehicles. Based on CBI information from axle suppliers, we are confident this technology will be commercially available in the time frame of this rulemaking.

In response to ACEEE comments and other stakeholder feedback about axle configurations on coach buses, we are establishing a baseline for these vehicles in the custom chassis program with permanent 6x2 axle. To the extent that any motor homes and coach buses with GVWR over 33,000 lbs are built with two rear axles, either the axle disconnect or permanent 6x2 could potentially be applied as technologies because these vehicles generally operate on paved roads and may not need the traction of a 6x4. However we have not included this in the technology package for motor homes because incurring the costs associated with this technology did not appear justified for RV’s based on the information before us.

In response to comments about two-speed axles, the agencies are adopting regulations to instruct a manufacturer to enter the ratio that is expected to be engaged for the greatest driving distance. The regulations also include a provision where in unusual circumstances, a manufacturer may ask to submit weighted average results of multiple GEM runs to represent special technologies that no single GEM run can accurately reflect.

6.3.9 Weight Reduction

Organization: PACCAR
PACCAR is also supportive of the weight savings approach that is included in the NPRM for vocational vehicles. [EPA-HQ-OAR-2014-0827-1204-A1 p.31]

Organization:  Motor & Equipment Manufacturers Association (MEMA)

Lightweighting – There are opportunities to further expand the options for lightweighting. Specifically, MEMA recommends an adjustment to the GEM calculations for fully loaded applications, given that 1000 lb. of lightweighting in a vocational application can result in over 3 percent GHG emissions avoidance through reduced trips. (Emissions avoidance due to lightweighting can be easily calculated by dividing the weight reduction by the payload, then multiplying by the fully loaded service time, or, for a vocational application, 0.5 x 1,000/15,000). Thus, this benefit should be accounted for appropriately in the GEM. [EPA-HQ-OAR-2014-0827-1274-A1 p.8]

Organization:  American Iron and Steel Institute

Regarding vocational vehicles, the agencies propose Phase 2 weight reduction technologies with specific values for material type, but also do not indicate the derivation of this data. All of these values serve a regulatory purpose by allowing a credit for different vehicle components, based on the type of vehicle involved. They also implicitly apply a deficit to any materials or components that are not listed, or listed incorrectly. Therefore, like the weight reduction options for trailers, EPA must supply a basis for these values in the record for this rulemaking or it cannot incorporate them within a final rule. EPA’s currently proposed weight reduction values cannot be finalized given the lack of supporting technical analysis regarding their calculation. In addition, EPA should review the research material we have submitted for the docket with respect to the weight and performance benefits of lightweight steel components. While much of this analysis involves components utilized in the LDV sector, we believe that comparable components and parts in medium- and heavy-duty vehicles would demonstrate similar results. EPA should therefore utilize this information to substantially adjust upward its estimates of the benefits of lightweight steel components in Table V-29 of the draft proposed regulations. In the alternative, AISI would recommend that EPA and NHTSA eliminate all weight reduction technology crediting for component parts. As described above, the component parts for which it is proposed that GEM assign a weight reduction benefit lack a sufficient technical basis in the record for this rulemaking. Values contained in Table V-29 are not representative of realistic mass reductions. Among other deficiencies, the table values do not scale weight reduction to the actual size of the part making them inherently arbitrary in a rulemaking that covers a wide range of truck sizes, uses and GVWR. Thus, while we first believe that EPA and NHTSA should incorporate life cycle analysis and adjust weighting accordingly, if this path is not taken by the agencies, the only reasonable result should be to eliminate the weight reduction inputs in their entirety. [EPA-HQ-OAR-2014-0827-1275-A1 p.15]

Organization:  National Ready Mixed Concrete Association (NRMCA)

Finally, the proposal fails to accurately take into account heavy-duty, class 8, straight truck weight challenges, such as concrete mixer trucks. [EPA-HQ-OAR-2014-0827-1146-A1 p.2]

Organization:  Newell Coach Corporation

Weight reduction benefits would be negligible given our GVWRs while costs would be high. Credits from other manufacturers may not be available or, if available, be extremely expensive given the cost of technology required for compliance. [EPA-HQ-OAR-2014-0827-1319-A1 p.1]

Organization:  Allison Transmission, Inc.
EPA and NHTSA must consider the weight of vehicle components in a consistent manner. The weight of hybrid systems should be accounted for, including the weight differentials for different types of hybrids. [EPA-HQ-OAR-2014-0827-1284-A1 p.3]

**EPA and NHTSA Should Account For Weight of Hybrid Systems**

EPA and NHTSA have proposed to continue the weight reduction approach contained in the Phase 1 rule under which fixed weight reductions are prescribed for using certain lightweight materials in vehicle components. A fixed weight increase is also proposed for natural gas-fueled vehicles to reflect the weight increase associated with natural gas tanks. In order to be consistent in EPA’s and NHTSA’s regulatory approach, however, the agencies must also assess and incorporate consideration of weight with regard to hybrid vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.61-62]

Vocational vehicles exhibit a wide variation in weight when looking at differences based on the powertrain. To illustrate this point, data from two transit bus manufacturers were compared based on powertrain differences. For the New Flyer Xcelsior, the weight increase of going from a diesel to a hybrid, and going from diesel to CNG range from 2500-3000 lb. Going from a diesel to EV is 5000 lb. Gillig, on the other hand, downsizes the engine when going from a diesel to a hybrid, so effectively; there is no weight increase with the hybrid. [EPA-HQ-OAR-2014-0827-1284-A1 p.62]

[Tables, 'Vehicle weights in pounds' and 'GILLIG Low floor BRT', can be found on p.62 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

Since buses are unique in their design and duty cycle when compared to other vocational vehicles, other truck hybrid powertrains shown in RIA Table 2-49 were evaluated based on weight. All systems have at least a 300 lb. weight penalty up through Class 5. Class 6-7 is estimated to be at least 800 pounds. The data also suggests that hydraulic hybrids are heavier than battery electric systems. The hydraulic hybrids in Class 2b-5 are 500-750 lb. heavier and the Class 6-7 system is 1650 lb. heavier than a conventional powertrain. [EPA-HQ-OAR-2014-0827-1284-A1 p.62]

[Table, 'Hybrid system weight comparisons for trucks', can be found on p.63 of docket number EPA-HQ-OAR-2014-0827-1284-A1]

Based on this data, Allison recommends that EPA include a weight penalty for hybrids and electric vehicles in an equivalent manner as was proposed for natural gas vehicles. Allison also recommends that if an engine is downsized through the use of technology, then this is recognized as a weight savings which would offset the additional weight of the hybrid system. [EPA-HQ-OAR-2014-0827-1284-A1 p.63]

**Transmission Housing Weight Reduction Values In Widespread Use Should Be Eliminated**

The agencies have requested comment as to whether any lightweight vocational vehicle comments are in such widespread use that they should be excluded from the list of components for which GEM could be used to assign an improvement value. In this regard, Table V-29 Proposed Phase 2 Weight Reduction Technologies for Vocational Vehicles includes a weight reduction for transmission cases to go to either high strength steel or aluminum. The baseline vocational vehicle includes an automatic transmission for all sub-categories except for HHD Regional. Automatic transmissions already include an aluminum case. Allison recommends that the weight savings for the transmission housing, and clutch housing be eliminated for these subcategories because the aluminum configuration has been standard for many years. [EPA-HQ-OAR-2014-0827-1284-A1 p.64]
Also in the GEM predefined modeling parameters for all vocational vehicles, 50% of any weight reduction claimed is added as additional capacity back into the payload. Transit buses don’t have a typical payload like other vocational vehicles might; they haul people and only so many people physically fit on a transit bus. Any weight reductions claimed for transit buses should be credited fully to the vehicle for CO2 reduction and fuel economy gains unlike other vocational vehicles. [EPA-HQ-OAR-2014-0827-1156-A1 p.2]

In regards to weight reduction for school buses there are some things to consider. School buses are very different than other motor vehicles in that they are subject not only to Federal Motor Vehicle Safety Standards (such as FMVSS 220 – School bus rollover protection specific to only school buses) but also to individual State Specifications. Many of these state specifications require certain construction standards and many state specifications dictate the material used and in some cases even require minimum material thickness for different areas of the vehicle. [EPA-HQ-OAR-2014-0827-1287-A1 p.1]

In addition to specific materials and construction standards some states have performance standards above and beyond the federal standards. Some examples of performance standards in addition to FMVSS include: Kentucky’s side intrusion standard and Colorado’s body racking load standard. These additional and varying requirements above and beyond FMVSS could create some very unique challenges to reduce the vehicle weight and still meet the desired performance standards. [EPA-HQ-OAR-2014-0827-1287-A1 p.1-2]

School buses are governed by certain states as to which material can be used for certain components. Some states will require the use of steel and also determine the minimum thickness for a particular component. One example is from the state of North Carolina as referenced from the following document “North Carolina School Bus and Activity Bus Specifications” (November 14, 2013), which states on page 40: “Construction – It is the intent of these specifications to describe a Type – C school bus that shall be basically of all steel construction or of some other material which has at least equivalent strength of all steel construction as certified by the bidder” (emphasis added). We recommend the agencies remove the need of lightweight materials for school buses and adjust the emission target accordingly. [EPA-HQ-OAR-2014-0827-1164-A1 p.53]

The agencies request comment on whether the HD Phase 2 program should recognize that weight reduction of rotating components provides an enhanced fuel efficiency benefit over weight reduction on static components. As opposed to just carrying around weight from a static component, objects that rotate require energy for that rotation and should be treated accordingly. [EPA-HQ-OAR-2014-0827-1164-A1 p.51]

- Weight Reduction Packages in Widespread Use - The agencies request comment on whether any lightweight vocational vehicle components are in such widespread use that we should exclude them
from the list of components for which a GEM improvement value would be available. We think that the agencies captured a large number of inputs and perhaps captured all of them, without going too far to list components that are in widespread use. Quite the opposite, we think that the agencies should continue the practice established in Phase 1 where, if a manufacturer has a lighter component for which the manufacturer wishes to get weight reduction credits, the manufacturer should simply make a showing that the component is lighter than the agencies’ baseline in order to get credits. 80 FR 40311. [EPA-HQ-OAR-2014-0827-1164-A1 p.51]

- **Weight Reduction Inputs** - The agencies request comment on all aspects of weight reduction approaches including potential weight increases as a byproduct of technology application. 80 FR 40324. We think that it is appropriate for the agencies to factor into account weight increases that are a byproduct of technologies. For example, with waste-heat recovery, the increased engine efficiency is eroded through increased vehicle weight, and the agencies must factor this into account—particularly in standard setting. In a confidential setting, we can give numbers from Super Truck for an estimate of a waste heat recovery system. Similarly, with hybridization, the addition of batteries and motors will, all else equal, add weight to the vehicle. (Clearly if the hybrid system allows for removal of, for instance, the alternator, then the hybrid may be weight neutral. But the fact that omission of parts does not get weight credit reinforces the flawed nature of the agencies’ weight reduction proposal). In any case, the agencies overestimate hybrid benefits without including this weight penalty in the regulations. [EPA-HQ-OAR-2014-0827-1164-A1 p.51]

**Organization:** ABC Bus Companies, Inc.

Motorcoaches have been mandated to implement Phase 1 Emission Standards, as well as ADA wheel chair lift and wheel chair passenger restraint systems, ambulatory passenger seat belt Standards, just to name a few. These mandated Standards have significant weight penalties and no allowances have been made by Federal or State highway agencies of infrastructure limits to the motorcoach industry. Weight penalties of Phase 2 have yet to be determined. These changes, along with Phase 1 changes, should receive consideration from the National Highway System as related to weight standards, which are not lumped in with truck weight standards. [EPA-HQ-OAR-2014-0827-1430-A2 p.2]

**Organization:** Oshkosh Corporation

The seventh and last checkbox involves weight reduction. For applications like concrete or refuse, less weight is already a huge market driver. The plan suggests a switch to aluminum rims as a most likely possibility, but front discharge concrete mixers and fire apparatus already use 100 percent aluminum rims.

Another suggestion involves redesigning structural components using higher strength steel, but the inherent thinner material are more rapidly degraded by corrosion and exacerbate a major problem in the trucking industry already caused by the increased use of liquid de-icing agents.

**Organization:** National Waste & Recycle Association

**Structural needs:** Durability is an essential requirement for refuse trucks. The frame of the truck body must be strong enough to withstand the pressures exerted internally when the compaction unit is operating. In addition, a refuse truck must be durable enough to travel on a wide variety of roads including residential and commercial streets, arterial highways, dirt or gravel roads in rural areas and alleys that may or may not be paved. Road quality can range from newly constructed to badly pot-holed. Roads can be slick or dry depending on weather conditions. Some refuse trucks are even pressed into duty as snow plow trucks. [NHTSA-2014-0132-0071-A1 p.3]
Nonetheless, the truck must be able to travel these roads, collect its material and take it to a transfer station or landfill for garbage, a materials recovery facility for recyclables or a compost facility for yard waste. The heavy weight of a refuse truck is caused in part, by the need to meet these severe and varying operational realities. As a result, refuse trucks have limited opportunities for weight reduction through the use of lighter weight materials. [NHTSA-2014-0132-0071-A1 p.3]

**Organization:** National Waste & Recycle Association

We are also disappointed that the agencies fail to recognize the impact of federal weight law on refuse trucks. A refuse truck starts out empty and fills up. Due to the unique characteristics of the refuse truck, the Federal truck weight laws impose a limited allowable “payload” for refuse. Unfortunately a number of the options to reduce fuel consumption that are promoted by the agencies increase the empty weight of the truck and therefore decrease the payload and will result in additional trucks on the road. To make matters worse, NHTSA proposed increasing the weight of an empty refuse truck by 200 pounds in a Federal Register proposal released ten days after the publication of this greenhouse gas and fuel efficiency proposal. [NHTSA-2014-0132-0071-A1 p.2]

Most importantly, new technologies add to the curb weight of the truck. A hybrid power train can add as much as 3000 pounds to the curb weight of a refuse truck. The fuel tanks and other equipment for alternate fuels add a smaller, but still significant amount of weight, as noted in Table V-29, page 40325. [NHTSA-2014-0132-0071-A1 p.4]

The unique impact of Federal truck weight regulations on refuse trucks

Under Federal law (see U.S. Code Title 23, chapter 1, subchapter 1, Section 127) commercial motor vehicles are subject to Federal size and weight regulations. Long haul tractor trailers, for instance, can have a gross weight of 80,000 pounds on the national highway system. Solid waste industry vehicles, however, have a much lower weight limit because of their shorter wheelbase. [NHTSA-2014-0132-0071-A1 p.5]

The shorter wheelbase is an absolute necessity in order to meet the level of maneuverability demanded by waste collection operations. These trucks must negotiate narrow alleys, residential cul-de-sacs and tight areas within commercial and industrial sites. They must be able to place large containers in very precise locations. In some cases such as compactor/containers, the placement tolerance is as little as several inches. Yet this short wheelbase, combined with a need to avoid excessive flexural effects on bridges caused by heavy, clustered, concentrated axle loads, also leads to very strict truck weight requirements under Federal law. [NHTSA-2014-0132-0071-A1 p.5]

Under the Federal Bridge Formula B, 51,000 pounds is the legal weight limit on the national highway system for 3 axle waste industry collection vehicles. While some states have higher weight limits that were “grandfathered” into the Federal law when it was first enacted in 1956, they are the exception, not the rule. The practical reality is that the national highway system is so extensive and grandfathers are so limited, that the legal weight limit for the vast majority of the solid waste fleet is approximately 51,000 pounds, even though their rated weight capacity is considerably higher. [NHTSA-2014-0132-0071-A1 p.5]

As a result, whenever additional weight is added to the empty weight of a solid waste collection truck, whether as a result of additional emission control equipment, a hybrid power train to improve fuel efficiency, tanks and other unique equipment necessary to use alternative fuels such as compressed or liquid natural gas in place of diesel fuel, or equipment such as brake retarders used to improve braking
performance, the empty weight of the truck is increased and the payload weight of the truck is decreased. Additional collection trucks will be needed, more fuel will be consumed and more emissions created. [NHTSA-2014-0132-0071-A1 p.5]

Meeting truck weight laws is an operational and legal imperative for the solid waste industry. We realize that neither EPA nor NHTSA have regulatory authority over truck weight limits. Yet, the Phase 2 proposal shows a great deal of faith in the ability of refuse trucks to find weight savings. See, for instance, page 40301, left paragraph “The agencies project that refuse trucks, construction vehicles, and weight-limited regional delivery vehicles could reasonably apply material substitution for weight reduction.” The proposal goes on to say that “a reduction of 200 lbs may offer a fuel efficiency improvement of approximately 1 to 2 percent.” [NHTSA-2014-0132-0071-A1 p.5]

This industry has worked tirelessly with our suppliers to reduce the weight of our trucks with the hope of increasing their productivity under existing truck weight laws. However, we would note that on July 23, ten days after the Phase 2 proposal was printed in the Federal Register, NHTSA released in the Federal Register a proposal concerning “Rear Impact Protection, Lamps, Reflective Devices, and Associated Equipment, Single Unit Trucks” (see Federal Register, July 23, 2015, pages 43663 – 43694). According to the agency, the proposed addition of rear underguard protection would add a “minimum to average increment weight” of 169 – 210 pounds (see Table 2, page 43673). In other words, if adopted, this new safety requirement would wipe out the potential fuel savings from weight reduction estimated by the agencies in this proposal. Needless to say, we are frustrated by the conflicting signals sent by the agencies in regard to the most desirable weight of a refuse truck. [NHTSA-2014-0132-0071-A1 p.5-6]

Organization: Autocar, LLC

In addition to clean-engine technology, Autocar has adopted other methods to achieve fuel efficiency and therefore reduce emissions, while meeting the particular vocational needs of its customers. For example, Autocar provides the most weight-efficient configurations in its class to reduce fuel consumption while allowing larger payloads (which therefore, require fewer trips to a landfill or transfer station). For the customer teams that drive and maintain our products, Autocar provides extensive training tools for operators, technicians and managers to ensure that emissions components function as designed and remain compliant with emissions regulations. Consistent with EPA and NHTSA’s advocacy for use of available technologies, Autocar is releasing new telematics and tire inflation monitoring technology, and continues weight reduction initiatives through improved body integration and use of alternative materials; these initiatives have been embraced in our niche markets. [EPA-HQ-OAR-2014-0827-1233-A1 p.6]

Organization: National Ready Mixed Concrete Association (NRMCA)

In the proposal, EPA and NHTSA suggest weight reduction as a viable method to meet the proposal’s requirements. While NRMCA does not disagree with this approach, NRMCA objects to its feasibility as applied to ready mixed concrete trucks. Due to the reality of the necessary configuration of trucks hauling ready mixed concrete, combined with current regulations from numerous other United States regulatory bodies, weight poses a very unique and continuing challenge to the industry. [EPA-HQ-OAR-2014-0827-1146-A1 p.4] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.242-243.]]

The necessity for manufacturing a ready mixed concrete truck with the lowest possible weight has existed as a market force since the inception of the federal bridge formula for truck weight restrictions on federal-aid highways. Manufacturing a light-weight mixer truck that meets all regulatory compliance thresholds and can still haul a full load remains a constant challenge of innovation and creativity. The proposal makes assumptions about heavy-duty truck weights in order to make suggestions about how weight
reduction can be applied to meeting the proposal’s requirements. These assumptions, in the case of ready mixed concrete trucks are incorrect and miss the reality of a mixer truck’s true tare and payload weights by thousands of pounds. For example, the maximum weight allowed on federal-aid highways is 80,000 lbs. spread over a calculated number of axles. However, due to structural design and specialized equipment installed on mixer trucks for handling such a heavy product, under federal weight limits a typical ready mixed concrete truck ends up weighing considerably less than the allowable threshold. The realities of truck weight regulations leave little extra room for carrying payload. According to EPA’s and NHTSA’s assumptions these tolerances are roughly 3,000 to 6,000 lbs. lighter than what is true for mixer truck weights. [EPA-HQ-OAR-2014-0827-1146-A1 p.4-5] [This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p.243.]

In addition to the federal weight tolerances, structural designs and necessary specialized industry equipment, along with previous emission regulation requirements that have added weight to mixer trucks, the overall acceptable weight of mixer trucks has reached its limit. Not to mention, this current weight of mixer trucks includes and takes into account the weight changes needed to comply with Phase I and all of the alternative material suggestions mentioned in the Phase II proposal. All of these weight considerations have pushed ready mixed concrete producers to running mixer trucks, in many cases, with a .002% margin of weight threshold. Meaning, under such weight conditions, a truck merely getting dirty will put it over legal weight limits and risk non-compliance. [EPA-HQ-OAR-2014-0827-1146-A1 p.5] [This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.244-245.]

Furthermore, the nature of hauling and delivering ready mixed concrete gives way to various driving conditions, road conditions, weather conditions and construction site conditions. Due to such realities, mixer trucks are designed to meet this inevitable rough and tough wear and tear atmosphere. Such a design requires materials that can handle these stresses and keep trucks moving; these materials invariably add weight to a ready mixed concrete truck. [EPA-HQ-OAR-2014-0827-1146-A1 p.5] [This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.244-245.]

Many of the methods EPA and NHTSA suggest in both Phase I and Phase II for complying with the proposal are already being implemented by the industry, and numerous other suggestions in Phase II are simply not practical for mixer trucks, leaving technology that has yet to be invented or perfected the method the industry most likely will have left at its disposal for complying with Phase II. To this end, NRMCA recommends that EPA and NHTSA, instead of pushing weight reductions, advocate for increased weight tolerances in amounts large enough to offset the weights of new equipment and technology that will be employed for compliance with Phase II. NRMCA would like to remind EPA and NHTSA that such a precedent already exists for auxiliary power units and idling-reduction technology in many states. [EPA-HQ-OAR-2014-0827-1146-A1 p.5-6] [This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p.245 and p.246.]

The consequence of adding more weight to mixer trucks for Phase 2 compliance results in achieving the opposite goal of Phase 2. Simply put, if the industry is forced to reduce payload in order to meet low weight tolerances, the industry will then be forced to use more trucks, making more trips to deliver the same amount of ready mixed concrete. More trips means increased emissions, increased fuel consumption, more trucks sitting in traffic, and longer hours for industry drivers. [EPA-HQ-OAR-2014-0827-1146-A1 p.6] [This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp. 245-246.]

Organization:  Aluminum Association

The Aluminum Association is committed to producing high quality, accurate information for OEMs as well as the EPA and other regulatory agencies on the benefits of aluminum lightweighting in the
transportation sector. Mass reduction using aluminum has emerged as a proven and cost effective technology for achieving improved road vehicle fuel economy and CO2 emissions performance and in the past 40 years aluminum use in light and heavy-duty vehicles has increased steadily. In the truck and trailer market specifically, aluminum use has nearly doubled since the recession of 2009 and is trending back toward record levels last seen in the late 1990s and early 2000s. Growth in the use of aluminum in the truck and trailer market has been accommodated utilizing existing production capacity, and where needed, with the addition of new capacity, and the aluminum industry has consistently demonstrated the ability to match supply with demand, including the previous growth of aluminum demand in the aerospace, packaging, and auto transportation sectors. In the auto transportation sector for example, the aluminum industry has publicly announced over 1.5 billion pounds of capacity expansion to come on line by 2018 to support that industry’s growth. The long lead times in the proposed rule that require ultimate compliance in the 2027 model year also provide ample opportunity for the alignment of aluminum product supply with any potential for increased demand due to the implementation of lightweighting opportunities in the truck and trailer market. [EPA-HQ-OAR-2014-0827-1260-A1 p.1-2][This comment can also be found in section 4.3 of this comment summary]

The aluminum industry is also continuously improving its product offering to the heavy truck and trailer transportation market to maximize the benefits of using aluminum in lightweighting applications. Recently, these have included – [EPA-HQ-OAR-2014-0827-1260-A1 p.2]

- Alcoa’s introduction of the ‘ULTRAx Ultra-ONE’ forged aluminum wheel – This wheel is 47% lighter than a comparably sized steel wheel and weighs in at only 40 pounds, thus enabling its potential to save over 1400 pounds in Class 8 service. [EPA-HQ-OAR-2014-0827-1260-A1 p.2]
- Alcoa’s introduction of a new aluminum alloy, ‘Magna-Force’ which is up to 17% stronger than the 6061 alloy it replaces in transportation applications. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
- Novelis’ introduction of the ‘Advanz’ 7000 series next generation high strength aluminum alloy designed to enhance vehicle lightweighting and safety. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
- Sapa’s development and introduction of new aluminum extrusion applications in a variety of tractor componentry including sleeper cabs, seat frames, entry steps/deck plates, and aerodynamic fairings. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
- Rio Tinto’s commissioning of their enhanced state-of-the-art aluminum smelting facility in Kitimat, BC operating solely on clean, renewable, hydropower and using efficient AP40 pot technology to supply aluminum to transportation and other markets in North America and around the world. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

The industry is also pursuing new aluminum joining methods that will enable increased integration of aluminum and non-aluminum components into next generation vocational and heavy-duty vehicles. All the activities noted above continue the aluminum industry’s long history of working with transportation market manufacturers throughout the supply chain to develop vehicle efficiency improvement solutions and that work will continue and become ever more important under the recently proposed Phase 2 standards. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

Lightweighting is well-recognized in the proposed rule as a means to increase trucking efficiency and there are three primary ways that this occurs – [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

1) It lowers rolling resistance, which means it takes less energy to start the vehicle moving and then overcome the friction of its contact with the road, [EPA-HQ-OAR-2014-0827-1260-A1 p.3]
2) It allows carriers to add more cargo to each truck, which reduces the number of trucks on the road and/or trips that need to be made, and, [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

3) It facilitates the adoption of other efficiency technologies, such as trailer tails and side skirting, as it can negate the concerns about the added weight of those technologies. [EPA-HQ-OAR-2014-0827-1260-A1 p.3]

Response:

The agencies are predicating the final vocational vehicle standards in part on use of material substitution for weight reduction. The agencies have created a menu of vocational chassis components with fixed reductions in pounds that may be entered in GEM when substituting a component made of a more lightweight material than the base component made of mild steel. The pre-defined weight reduction values may be found in the regulations at 40 CFR 1037.520. We are adopting as proposed a GEM allocation of half the weight reduction to payload and half to reduced chassis weight.

It is unclear whether the comment from MEMA is asking the agencies to allow manufacturers to get credit for fleet owners loading vehicles fully instead of applying the default payloads that are not fully loaded values. In order to allow use of non-standard payloads in a regulatory context such as GEM, the agencies would have needed to give notice and take comment on recognition of technologies for improving freight efficiency beyond the control of the vehicle manufacturer. These are out of scope of this rulemaking. However, when a manufacturer replaces a conventional component with one made of a lighter material, GEM calculates a benefit by increasing the payload of the vehicle as well as removing weight from the chassis. See Section 2.2 for responses to comments on how GEM allocates weight reduction inputs.

The menu of components with pre-defined weight reduction credit includes fewer items than proposed, in response to comments from Allison that aluminum transmission cases and clutch housings are standard for automatic transmissions. We have considered the comments from Meritor on the appropriate weight reduction value for use of high strength steel brake drums, and the values in the lookup tables at 40 CFR 1037.520 have been updated accordingly for both tractors and vocational vehicles. See Section 4.3 of this RTC for more discussion of those comments. The value for light weight wheels has increased since proposal based on compelling comment from the Aluminum Association (See Section 5.4). In response to the AISI comments with concerns that the values in the vocational weight reduction lookup table are not justified, we have adjusted the values for some components. We were unable to find any data in the supporting documents submitted as part of public comment from AISI that could support changing any of the values in the regulatory weight reduction lookup tables for Phase 2 vocational vehicles. Instead, we have relied on technical feedback from expert members of the Aluminum Transportation Group. We interpret the AISI comments as generally desiring greater weight reduction values for high-strength steel components on LHD and MHD vocational vehicles, as well as generally desiring less disparity between values for similar components made of aluminum. We had great uncertainty at proposal in our approach of scaling down weight reduction values from the HHD tractor values adopted in Phase 1 to all weight classes of vocational vehicles. Because of this uncertainty, we had deviated from the recommendations of the expert members of the Aluminum Transportation Group to propose conservatively small improvement values for components on LHD and MHD vehicles. After reconsidering those early recommendations in light of comments, we believe we had been overly conservative in some respects and have thus adopted revised values in the final regulations that we believe are responsive to AISI comments with respect to

193 See email in the docket dated March 2015 with attached vocational lightweighting table.
cross-members and frame rails. The manufacturers have the option of requesting off-cycle credits for lightweighting technologies that are not included in 40 CFR 1037.520. To clarify Daimler’s comment, what we are allowing through this process is not a demonstration of the amount of weight by which the new component is lighter than the agencies’ baseline. Rather, the demonstration includes the weights of both a baseline component and a lightweighted component.

The projected improvements due to weight reduction factored into the stringency of the final rules are changed from proposal, where we believed lightweight components would be adopted more narrowly. The final rules project that as many as 50 percent of vocational vehicles can apply aluminum wheels (or reduce an equivalent weight) by MY2027. The agencies project that all vocational vehicles in the primary program can reasonably apply this level of material substitution for weight reduction. Our projected adoption rate is revised upward from the proposed adoption rate of less than 10 percent because the technology package is smaller (fewer pounds removed than the proposed 400 lbs) and aluminum wheels are widely feasible. We agree with commenters that concrete mixers and refuse trucks are very weight-sensitive applications, and to a large extent have already lightweighted their chassis as much as practicable. Upon consideration of the comments, the only custom chassis vehicle type for which we are predicating standards on lightweighting is transit buses. Where a manufacturer has already applied lightweighting in its current fleet, it will be eligible to enter an improved weight value in Phase 2 GEM for use of components that are on our final menu in the regulations, and this menu is fully available for custom chassis as well. Our Phase 2 vocational vehicle baseline configurations assume that no lightweight materials are used, because the Phase 1 program did not recognize this technology. In response to Gillig’s comment that weight reduction should be allocated fully to a lighter chassis for transit buses and not to increased payload due to the number of passengers not being dependent on chassis weight, we agree in concept; however, this is a feature we were unable to program in GEM. Nonetheless, manufacturers of transit buses will get full credit for any weight reduced because the value entered in GEM will cause both the numerator to be reduced and the denominator increased. Thus, although the method of calculation may not reflect real world bus payloads, the end result gives fair and full credit for this technology.

In response to Daimler’s comment requesting recognition of an enhanced fuel efficiency benefit for weight reduction of rotating components over weight reduction on static components, the agencies were unable to program this feature in GEM given the available information. In order to assign an appropriate value, we would need to know the geometry of the component and whether it had any gearing between it and the road. We would also need to know the absolute weight of the component, not just the relative improvement as is done today. We would also need to change the method of allocating reduced weight to the chassis and the payload, since the enhanced benefit would only apply to the chassis and not to the payload. Manufacturers may instead apply for off-cycle credit for such technologies.

In response to comments asking for revisions to the regulations regarding weight penalties for certain technologies, we are adopting a final program that differs from what we proposed. The agencies are not finalizing a weight penalty for any components since this would require detailed information on conventional and light-weight vehicle components to establish a baseline and the weight reduction potential for each component. The agencies also are not providing a default weight reduction value to transmission type due to the variety of transmissions in the vocational market today. Although we are not requiring a weight penalty in GEM at the time of certification for any technology, the agencies have accounted for increased weight due to projected adoption of some technologies (i.e. for vocational vehicles we accounted for added weight in subcategories where hybrid systems are projected) as part of our inventory modeling with the MOVES model.

6.3.10 Other Technologies
Organization: CALSTART

Pick List for Vocational Segments. Another flexibility mechanism that is needed in the vocational space, and for which there is precedence already in the rule structure, is the use of a defined “pick list” or menu of technologies that can be included in the GEM model. Such lists exist and are called out for Class 7 and 8 but limitedly at best for vocational. We are aware of, and support, the major manufacturers of Class 2B and 3 vehicles who will be proposing the use of and some specific technologies for a “pick list” in these segments. Some of the technologies they are leveraging from light duty include high efficiency lighting, engine heat recovery, active aerodynamic improvements, active engine warm up and engine start-stop. We would strongly encourage and request the agencies to allow for the broader development of such “pick lists” for other vocational segments. Indeed, this might be another approach to technologies such as those mentioned earlier (work site idle) to be more easily included. An OEM could more easily take credit for the later stage inclusion of such technologies if such a streamlined list was available, and it would further motivate suppliers and chassis OEMs to connect on this issue. [EPA-HQ-OAR-2014-0827-1190-A1 p.7]

That said, because of the comprehensive nature of the rule and the limited timeline for study and response, such a formal list has not yet been created or coordinated. CALSTART would be very willing to assist with assembling or identifying such a list during the work to complete the final rule language. Technologies might include such varied approaches as post transmission hybridization, work site idle reduction, fuel-saving trash compaction strategies, etc. [EPA-HQ-OAR-2014-0827-1190-A1 p.7]

However, we are also concerned with information we have heard that implies such a pick list is “locked” and cannot easily change or be updated during the rule timeline. Given the pace of technology innovation, and the long time horizon of the proposed rule (still functioning more than a decade from today), we strongly urge the agencies to build in flexibility in the form of simplified provisions for regularly updating or adding to the pick lists, without having to reopen the rule itself. We are concerned that without such an ability to be periodically updated with new technologies, and only allowing what is known today, the rule is further constrained from including innovation. We realize there are other ways to bring in innovative technology, such as “off cycle” credits, but that can involve lengthy, costly and often specialized testing that can be significant barriers to small manufacturers and suppliers, who are often the ones bringing new capabilities forward. [EPA-HQ-OAR-2014-0827-1190-A1 p.7-8]

Organization: Volvo Group

Need the ability to certify off-cycle technologies to assure compliance if the EPA’s technology and penetration assumptions are not correct.

Organization: Enevo Inc.

Enevo provides logistics solutions to the refuse management industry using sensors to report the fullness level of commercial refuse dumpsters and public space containers. Refuse hauling collection routes can be optimized based on the sensor data, so containers are collected at or near full. Enevo has managed to increase efficiency of refuse hauling routes by 30-50% in the cities we operate in. [EPA-HQ-OAR-2014-0827-1285 p.1]

Enevo is a strong proponent of operating truck fleets in a more efficient manner and is in favor of the Phase II greenhouse gas and fuel efficiency standards for medium and heavy-duty trucks. We encourage the EPA and fleet operators to look beyond the truck for additional fuel savings. Routing optimization and logistics software is available for both delivery and collection routes for various types of commercial
fleets. These innovative technologies are able to determine the most efficient route based on real-time inputs and help navigate the driver to their destination. Less idle time, less time on the road and better use of trucks will contribute to overall emissions reduction. We would like to see provisions for these types of technologies included in the standards. [EPA-HQ-OAR-2014-0827-1285 p.2]

**Organization:** Bosch

**eHorizon** - we support the inclusion of 3-5% credit for Electronic Horizon (eHorizon), technology, depending on the algorithm developed by the end customer. [EPA-HQ-OAR-2014-0827-1466-A2 p.9]

As currently designed, eHorizon systems consist of an integrated hardware and software module installed in heavy commercial vehicles to mitigate fuel consumption. State-of-the-art eHorizon hardware and Horizon data from highly accurate 3D maps (provided by Bosch) demonstrate on average a reduction in fuel consumption of 4% during normal driving, along with a proportional reduction in GHG together with eHorizon algorithm (developed by the OEM) to generate an ideal driving pattern for a given route. [EPA-HQ-OAR-2014-0827-1466-A2 p.10]

Algorithms (developed by the OEM) calculate this ideal pattern using map data along with data from the vehicle’s engine and transmission control units (from Bosch), then instruct the vehicle’s cruise control system to adjust speed and gear switching to navigate the desired route in the most efficient way. A vehicle equipped with the eHorizon module is able to recognize, for example, changes in altitude and road curvature and make early adjustments to the driving pattern in anticipation of these changes which results in fuel savings and reductions in GHG. [EPA-HQ-OAR-2014-0827-1466-A2 p.10]

Simulations conducted by Bosch in the EU supports the finding of 4% average fuel savings with a maximum 5% savings noted, with annual GHG emission reduction of 4.5 tons and 7.5 tons respectively. Real data results from Bosch customers using large multi-axel trucks (40 tons) equipped with eHorizon technology shows saving of up to 5% in fuel. [EPA-HQ-OAR-2014-0827-1466-A2 p.10]

Methods employed to reduce gasoline engine CO2 output in passenger cars and light trucks should apply similarly in the MD class. For instance, the application of direct injection and turbo charging combined with downsizing has already been shown to be effective when applied in the light truck market. In addition, the implementation of high speed transmissions in the MD segment (i.e., 8-10 speed automatic) increases the opportunities for gasoline engines to run at the most efficient load points. Due to the high cost of development of these specialized transmissions, it may be that some incentive is required to move the market towards this solution. [EPA-HQ-OAR-2014-0827-1466-A2 p.11]

We further suggest an adaptable approach that incentivizes the transfer of new technologies designed for light duty vehicles into MD/HD vehicles. [EPA-HQ-OAR-2014-0827-1466-A2 p.11]

**Organization:** California Air Resources Board (CARB)

The flexibility provisions for class 4-8 vehicles include off-cycle credit provisions. Several technological approaches have been identified that would seem to merit inclusion, whether incorporated as a line-item in GEM or through available off-cycle credits. Solar controls are not specifically listed as they are for class 2b3, but the RIA clearly states (page 2-47 of the RIA) they could be considered for credits if the effectiveness can be suitably demonstrated. CARB believes this is a reasonable approach. Because of the uncertainties surrounding estimates of effectiveness of solar control approaches in the heavy-duty fleet, it is appropriate to require demonstration of benefit in a specific case before granting credits for vehicles in these vehicle classes. See CARB docket letter dated December 3, 2014 for a thorough discussion of

**Response:**

We agree with commenters suggesting that some technologies can be pre-defined for credit in GEM. Where we have been able to define a fixed improvement value along with a qualifying definition for the technology as improved over a known baseline, we are making this available for certification of Phase 2 vocational vehicles, such as is described in Section 6.3.6.2 for electrified accessories, in Section 6.3.7 for tire pressure systems, and Section 6.3.10.1 for aerodynamic fairings.

For technologies where we have not been able to accurately ascertain a pre-defined credit amount, manufacturers may request and demonstrate eligibility for off-cycle credits. In response to requests to develop a streamlined path for off-cycle technology approval, we are not making fundamental changes from the proposal at this time; however, we remain open to working with stakeholders to look for ways to simplify the process. (The pre-defined list, itself, of course represents a significant simplification of the off-cycle process). Just as some technologies that were considered off-cycle for Phase 1 are being adopted as primary technologies in Phase 2, the agencies may revise the regulation in a future rulemaking to create a more direct path to recognize technologies currently considered off-cycle. For example, although we are including specific provisions to recognize electrified power steering pumps and air conditioning compressors, recognizing other types of electrified accessories would require the manufacturer to go through the off-cycle process. However, it is quite possible that the agencies could gather sufficient data to allow us to adopt specific provisions in a future rulemaking to recognize other accessories in a simpler manner. Please see Section 1.4.2 for complete responses to our comments on off-cycle credits, and see Section 2.1 for responses to comments about future changes to GEM.

We are not able to recognize route optimization software in this rulemaking. This type of technology is outside of the regulatory framework of this HD National Program.

Please see Section 4.3 for the agencies’ response to comments on solar load management technologies.

**6.3.10.1 Aerodynamics**

**Organization:** American Automotive Policy Council

**Phase 2 GEM 2b-5 Fixed Aerodynamics Improvement Credits**

The Phase 2 2b-5 GEM model is structured such that there is little to no opportunity to reduce aerodynamic loads beyond the 2017MY baseline of 5.4 m\(^2\)CdA. See GEM user instructions page 17, table 8 & 9 for details. Given the importance of aerodynamic horsepower relative to the 55 mph and 65 mph fuel consumption in GEM, AAPC recommends that an aerodynamic improvement option be added to the Phase 2 GEM picklist with a scalable g CO2/ton-mile improvement based upon the aerodynamic package installed on the vehicle. [EPA-HQ-OAR-2014-0827-1238-A1 p.34]

The graph below illustrates CO2 saving in gCO2 / ton-mile vs Aerodynamic HorsePower reduction relative to the ‘17MY 2b-5 vocational baseline on the 55, 65, and ARB cycles. [EPA-HQ-OAR-2014-0827-1238-A1 p.34] [Graph of CO2 saving can be found on p.34 of docket number EPA-HQ-OAR-2014-0827-1238-A1]
Given that aerodynamic improvements upwards or in the range of 10 – 20 horsepower are possible on the 55mph and 65 mph cycles, AAPC suggests a scalable aerodynamic credit based on 1 HP Aerodynamic Reduction for LHD and MHD vocational vehicles per the following table: [EPA-HQ-OAR-2014-0827-1238-A1 P.35] [Table of aerodynamic reduction can be found on p.35 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

Organization: Environmental Defense Fund (EDF)

The vehicle standard should be strengthened by incorporating more appropriate advanced aerodynamic improvements on vehicles that travel at high speeds.

Organization: Daimler Trucks North America LLC

Aerodynamics for Vocational Vehicles - The agencies request comment on 1) allowing a manufacturer to obtain an improved GEM result for vocational vehicles by certifying that a final vehicle configuration will closely match one of the configurations on which the agencies' testing was conducted, and where the improvement would be based on installation of specific aerodynamic devices for which the agencies have pre-defined effectiveness through this testing program, and 2) this potential approach to providing credits for aerodynamic aids to vocational box trucks. 80 FR 40303. We think that, given the agencies' approach of regulating truck manufacturers (i.e., manufacturers of chassis cabs for vocational vehicles as opposed to the final stage manufacturers), it would be inappropriate to regulate or reward aerodynamic treatments on vocational vehicles. In other words, the regulated entities do not install the truck bodies (e.g., the boxes of box vans); a large number of secondary manufacturers do. Therefore, truck manufacturers would have to take out delegated assembly contracts with this large number of secondary manufacturers, which would be a burden on truck manufacturers and would not be related to our business of building chassis cabs; it would be inserting us into a different business. If the agencies want to regulate parts installed by body builders, then the agencies should regulate body builders. And the agencies can do so with more authority than we vehicle manufacturers can. [EPA-HQ-OAR-2014-0827-1164-A1 p.60-61]

Organization: California Air Resources Board (CARB)

Research done at NREL shows that improved aerodynamics on vocational vehicles can result in significant fuel consumption reductions as high as 8 percent during cruise cycles. CARB staff recommends that a value of 3.5 percent be included in the vehicle stringency for regional vocational vehicles and 1 percent for multipurpose vocational vehicles due to aerodynamic devices. These values are in line with the observed fuel consumption benefit that front fairings and skirts achieved on the Urban Dynamometer Driving Schedule (UDDS) test cycle and CARB staff transient test during the NREL study, cycles similar to that of what Phase 2 proposes to use to simulate regional and multipurpose vocational vehicles, respectively. CARB staff notes that the vocational subcategory contains a vast range of regional and multipurpose vehicles and that while most regional vehicles will benefit from these technologies, not all vehicles (such as urban vocational) will be able to take advantage of the improved fuel efficiency of improved aerodynamics. Based on this fact and the research done at NREL, CARB staff believes that almost all regional vocational vehicles can benefit from aerodynamics, whereas only about half of the multipurpose subcategory can benefit from the aerodynamic devices, and is recommending penetration rates of 90 percent for regional vehicles and 50 percent for multipurpose vehicles. Vocational aerodynamic improvements are discussed further below under the comment entitled “Vocational aerodynamics: credit for aerodynamic devices on vocational box trucks.” [EPA-HQ-OAR-2014-0827-1265-A1 p.55]
The NPRM requests comment on the approach to provide credits for aerodynamic devices on vocational box trucks. The Phase 1 standards did not address the aerodynamic characteristics of vocational vehicles; instead, vocational vehicles were assumed in the GEM model to have default aerodynamic characteristics, and manufacturers did not have the opportunity to obtain credits for installation of aerodynamic devices on vocational vehicles. The Phase 2 proposal still includes only default aerodynamic characteristics for vocational vehicles in GEM, but does allow manufacturers to apply for credit for some aerodynamic improvements to some vocational vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.56]

CARB staff appreciates and supports U.S. EPA and NHTSA offering vocational aerodynamic credits to manufacturers in Phase 2; however, we recommend the proposed Phase 2 standards be modified to include actual aerodynamic characteristics for the vocational vehicles that travel most at high speeds (the regional and multipurpose subcategories), and we recommend aerodynamic improvements for these vocational vehicles be included when setting the Phase 2 standards. CARB funded work to support Phase 2 development assessing various aerodynamic drag reduction technologies and proving their ability to reduce fuel consumption. Aerodynamic devices such as skirts and fairings are readily available in the marketplace for vocational vehicles; hence, there is no issue of technological feasibility. Not including potential aerodynamic improvements for these vocational vehicles, which spend much of their operation at high speeds where aerodynamics are important, represents a significant missed opportunity. As discussed further below, aerodynamic improvements to regional vocational vehicles could yield up to an 8 percent CO2 and fuel consumption reduction on some duty cycles, and 6 percent in real world operation. Considering that U.S. EPA and NHTSA took into account improvements such as low friction axle lubricants that get only a 0.5 percent benefit when setting the proposed standards, it seems inappropriate to ignore potential aerodynamic improvements in standard setting. [EPA-HQ-OAR-2014-0827-1265-A1 p.56-57]

If U.S. EPA and NHTSA are unwilling to modify the Phase 2 standards for regional and multipurpose vocational vehicles to include aerodynamic improvements, at a minimum, CARB staff recommends allowing generation of aerodynamic improvement credits more broadly than proposed. As the proposal is currently structured, such credits are allowed only in extremely narrow circumstances and CARB staff believes the credits would offer little if any incentive for manufacturers to actually pursue such aerodynamic improvements. [EPA-HQ-OAR-2014-0827-1265-A1 p.57]

The discussion below provides information on the following topics:

- Availability of aerodynamic improvements for vocational vehicles;
- Data on potential fuel consumption reductions achievable via use of aerodynamic improvements;
- Potential additional Phase 2 GHG reductions if vocational aerodynamics were included; and
- Why vocational aerodynamic credits should be offered more broadly than proposed.

Availability of aerodynamic improvements for vocational vehicles

The aerodynamics of vocational vehicles can be improved either through changes to the shape of the vehicle during manufacture or through addition of aerodynamic devices such as skirts after manufacture. [EPA-HQ-OAR-2014-0827-1265-A1 p.57]

As CARB staff has shared with U.S. EPA, at least one heavy-duty vocational truck manufacturer, Ford Motor Company (Ford), the second largest U.S. manufacturer of class 3 trucks, is interested in improving
aerodynamics of vocational vehicles. Ford has investigated potential drag reduction and fuel consumption reduction achievable via improvements to some of their customers’ vocational box trucks and has shared that data with U.S. EPA and CARB staff. [EPA-HQ-OAR-2014-0827-1265-A1 p.58]

CARB staff also gathered information regarding aerodynamic devices and their applicability to vocational vehicles through literature reviews and stakeholder discussions. We contacted vocational aerodynamic technology manufacturers, including Deflecktor, Freightwing, Ridge Corporation, SOLUS, Vorbblade, Wabash Composites, Air Flow Deflector, Nose Cone, Laydon Composites, Fleet Engineers, Transtex, etc. Most of them produce devices, specifically skirts, for use on trailers. However, many indicated their devices could be customized to fit on vocational vehicles, and some have sold devices for use on these types of vehicles. For example, Freightwing and Ridge Corporation, who sell side skirts for box trucks intended to achieve a 2 to 4 percent reduction in fuel use, indicate their skirts can be used on any box truck as long as equipment underneath, such as storage boxes, lifts, etc., does not interfere and there is adequate space between axles. [EPA-HQ-OAR-2014-0827-1265-A1 p.58]

We also contacted vocational fleets, including Waste Management, Aramark, Cintas, U-haul, and Pepsi/Frito Lay, to learn about their experience in using trucks with aerodynamic controls. Some had purchased vocational trucks with aerodynamic controls for their fleets. For example, Pepsi/Frito Lay reported that in the field their aerodynamic improvements had given them 1 to 1.5 percent fuel savings. In its class 3 Sprinter truck design, Frito Lay changed the box geometry, added side skirts, and a front lip. In its class 6 trucks, it installed nose cones. [EPA-HQ-OAR-2014-0827-1265-A1 p.58]

Data on potential fuel consumption reductions achievable via use of aerodynamic improvements

CARB staff gathered available data on the drag and fuel consumption reductions achievable via aerodynamic improvements to vocational vehicles. For example, we obtained data from Auto Research Center, a research facility in Indianapolis that provides various test services including but not limited to wind tunnel testing and computational fluid dynamics. Auto Research Center met with us and discussed their current fuel economy efforts specific to vehicle aerodynamics. Auto Research Center tested an aerodynamic technologies package that included various aerodynamic devices such as side skirts, fairings, and others for a class 5 box truck. The box truck was tested in a wind tunnel with data recorded at yaw angles of 0, 3, and 6 degrees. The resulting percentage fuel economy savings at 55 mph were 2.5 percent with top fairing, 1.3 percent with side skirts, 0.5 percent with wheel covers, and 2.2 percent with smooth underfloor. We shared this data with U.S. EPA staff in June 2015. [EPA-HQ-OAR-2014-0827-1265-A1 p.58-59]

After gathering available data, we concluded there was a paucity of data concerning the effectiveness of aerodynamic technologies for vocational vehicles. To help fill the gap, CARB contracted with U.S. Department of Energy’s NREL to perform coastdown and on-road test runs with and without aerodynamic devices such as skirts, front and rear fairings, and wheel covers to quantify their potential benefits for class 6 and class 4 box trucks. A report describing NREL’s findings is attached. The most important findings are summarized below: [EPA-HQ-OAR-2014-0827-1265-A1 p.59]

• All devices except wheel covers showed a benefit: There were six coastdown test configurations: 1) baseline, no aerodynamic device, 2) wheel covers, 3) front fairing, 4) chassis skirts, 5) front fairing and skirts, and 6) front fairing and skirts and wheel covers. All test configurations, except adding just wheel covers, indicated a statistically significant change in total road load force in the 45–68 mph range. Front fairings and chassis skirts were the most effect devices tested, with both showing improvements on the order of 6 percent individually for total road load force. When front fairings and skirts were tested together, the improvement increased to 8 to 10 percent. [EPA-HQ-OAR-2014-0827-1265-A1 p.59]
• Emission benefits up to 8 percent, depending on duty cycle: To determine the significance of their aerodynamic devices in real world operation of vocational vehicles, NREL applied their test results to a variety of test cycles commonly used for vocational vehicles. As shown in the chart below, for vocational cycles that contain a significant portion of high speed driving, the potential benefits of aerodynamic devices can be significant, up to 8 percent. [EPA-HQ-OAR-2014-0827-1265-A1 p.59]

[Figure 3 can be found on p.60 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

CARB staff appreciates that U.S. EPA and NHTSA referenced the data from CARB and NREL testing in the Phase 2 proposal. We encourage U.S. EPA and NHTSA to utilize other vocational aerodynamic data that they have obtained from other sources (e.g., Ford and Auto Research Center data), which will help particularly in the class 3 to 5 categories. [EPA-HQ-OAR-2014-0827-1265-A1 p.60]

The potential emission reductions from use of aerodynamic devices on vocational vehicles are significant and – in CARB staff’s opinion – too large to ignore in Phase 2. To estimate the potential impact of vocational aerodynamics on actual vocational vehicle emissions, we made an estimate of this impact in two ways. First, we used actual duty cycle data from NREL’s Fleet DNA (a database of commercial fleet vehicle operating data) for 553 days of driving data from 36 delivery trucks and, as shown in Table 12 below, and detailed in the attached spreadsheets, found that these trucks could achieve more than a 5 percent reduction in fuel consumption via use of aerodynamic devices. [EPA-HQ-OAR-2014-0827-1265-A1 p.60]

[Table 12 can be found on p.61 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

Next, we modeled potential reductions for vocational vehicles modeled in CARB’s EMFAC database. Using duty cycles for medium heavy-duty out-of-state and instate trucks with GVWR less than or equal to 26,000 lbs, we arrived at similar results to those for the NREL fleet DNA data, potential fuel consumption reductions of about 6 percent. Given that the total reductions from vocational vehicles for the proposed Phase 2 program are only 16 percent, ignoring potential fuel consumption and emission reductions of 6 percent is clearly a significant and regrettable missed opportunity. [EPA-HQ-OAR-2014-0827-1265-A1 p.61]

Why vocational aerodynamic credits should be offered more broadly than proposed

U.S. EPA and NHTSA have proposed that credits for aerodynamic improvements be available to manufacturers only of trucks whose configuration and dimensions are essentially identical to those CARB and NREL tested and only for aerodynamic devices of identical weight to those tested. U.S. EPA and NHTSA neglected to consider other relevant data submitted to them during development of the Phase 2 standards (including data from Ford and Auto Research Center, mentioned above). [EPA-HQ-OAR-2014-0827-1265-A1 p.61]

In addition, the proposed method is overly restrictive and will inappropriately limit the vehicles that could receive any credit for using vocational devices to ones essentially identical to the two trucks CARB and NREL tested. We believe this restriction would make the aerodynamic credit provisions unlikely to be used widely, or at all, by vocational vehicle manufacturers. We also believe this restriction ignores the physical reality that devices such as skirts are likely to provide fuel economy benefits for trucks of a variety of frontal areas, lengths, and shapes. Although as discussed above CARB staff recommends that aerodynamic improvements be included when setting the standards for vocational vehicles and in GEM, should U.S. EPA and NHTSA decline to do that, at minimum, we recommend allowing credit for all class 3 to 7 straight trucks with a van or box shaped body. [EPA-HQ-OAR-2014-0827-1265-A1 p.62]
CARB staff believes the data available show convincingly that aerodynamic devices can reduce fuel consumption and GHG emissions from vocational vehicles and believes credit for such devices should be offered more broadly, not just to trucks identical to the two we tested. Especially given the diversity of vocational vehicles offered in the market, it would not be feasible to perform testing on every possible vehicle, coupled with every aerodynamic device, nor would such testing be a good use of scarce public agency resources. NREL concluded, “as long as the box sits above the rear wheels without a wheel well, there will likely be a spot for chassis skirts, and as long as the box extends above the front cab, there will likely be an opportunity for a front fairing. These devices may vary in size and aerodynamic benefit for different platforms, but the benefit likely has a closer tie to vehicle shape and body style rather than a specific weight class or dimension.”

Elsewhere in the Phase 2 rulemaking, U.S. EPA and NHTSA use similar logic to what we are proposing to justify how aerodynamic data for 53-foot dry vans can be translated to vans and box trailers in lengths different than 53 feet (page 40261 of the NPRM and 40 CFR 1037.501(g)). Putting aerodynamic devices (i.e., skirts) on vocational trucks is similar to putting skirts on trailers, and hence it is unclear why U.S. EPA and NHTSA did not apply this same logic to vocational aerodynamics.

CARB staff also believes U.S. EPA and NHTSA are overly restrictive in limiting credit to devices of equivalent weight to those tested. We recommend allowing credit for aerodynamic devices of differing weights because their weight varies for various types of vehicles and brands of devices. We recommend that U.S. EPA and NHTSA follow an approach for vocational aerodynamic devices similar to the approach they describe on pages 40280 to 40281 of the published NPRM for trailer aerodynamic devices. Under that approach, device manufacturers could certify their aerodynamic devices, then chassis manufacturers, including secondary manufacturers, can install the aerodynamic devices and obtain credits without having to retest for every individual vehicle. The approach also lays out the procedures for combining the effects of several devices.

To facilitate application of the test data available to a broader variety of vehicles, we recommend U.S. EPA and NHTSA consider use of a percent delta coefficient of drag x area (CdA) instead of a flat CdA. CARB staff recommends using a ratio approach by applying a percent CdA change, not an m2 CdA. For example, if we tested a vocational truck and found that a skirt could reduce CdA 6 percent, then a smaller or bigger truck could apply that same percent change to their CdA. We encourage U.S. EPA and NHTSA to consider this ratio approach.

Organization: Union of Concerned Scientists (UCS)

The agencies have identified the “delegated assembly” pathway as applicable to manufacturers of aerodynamic device—this means that chassis manufacturers can work with any of a number of aerodynamic device manufacturers to get credit for the use of these devices in the right application. The agencies have also submitted to the docket research that indicates the potential for up to 5.4 percent improvement for light and medium heavy-duty vehicles that utilize aerodynamic devices. Since there is a clear pathway for the inclusion of this cost-effective technology and evidence of its effectiveness, it should be included in assessing the feasible level of reductions in the timeframe of this rule.

We have estimated the cost of the full aerodynamic package identified by agencies for Light and medium heavy-duty vehicles to cost just under $2,500 (Table 7). This is lower than a previous estimate of $3,000 (TIAX 2009) but is consistent with the trend in trailer aerodynamic devices.
However, because this package reflects differential costs greater than the average compliance pathway for Class 3-7 vocational vehicles, it is clear that these technologies would only be applied to a subset of vehicles for which the technology is cost-effective. According to VIUS, 6.2 percent of Class 3-7 vocational vehicles travel greater than 36,000 miles annually, averaging 52,657 miles. This average value is more than twice the average for vocational vehicles overall, and these high mileage vehicles all would qualify as “regional” vocational vehicles. The 5.1- to 5.4-percent additional improvement beyond what the rule would achieve in 2027 would save these high mileage vocational vehicles hundreds of dollars in fuel per year. At low fuel prices ($2.50/gallon), applying aerodynamic devices to a high mileage regional Class 3-7 vocational vehicle in 2027 would still have a payback of under 5 years, discounting future savings at 5 percent. At $3.50/gallon, that payback drops to between 2.5 and 3.5 years for Class 3-7 regional vehicles—and this is assuming today’s prices for aerodynamic technology. These 6.2 percent of Class 3-7 vehicles represent 25 percent of the regional vocational fleet of light and medium heavy-duty vehicles. Incorporating the improvements from aerodynamic devices applied to these vehicles would increase the overall stringency for vocational vehicles by 0.3 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.23]

[Table 7, 'Cost of Vehicle Aerodynamic Devices', can be found on p.23 of docket number EPA-HQ-OAR-2014-0827-1329-A2]

Response:
The agencies did not propose to include aerodynamic improvements as a basis for the Phase 2 vocational vehicle standards. However, we did request comment on an option to allow credits on a very limited basis for use of aerodynamic devices such as fairings. We found public comments from AAPC compelling in terms of adopting this as an optional credit. Because the method we are adopting for recognizing this technology in GEM scales conservatively, we are able to accommodate comments from AAPC and CARB requesting that aerodynamic reductions be recognized for a broader range of vehicles than was proposed.

Based on testing supported by CARB, the agencies have developed a list of specific aerodynamic devices with pre-defined improvement values (in delta $C_D$A units). See Chapter 2.9.4.1 of the RIA and the NREL report submitted by CARB. In response to comments, we are allowing a wider range of vehicles to be eligible to use this option (and thus expanding credit opportunities, as suggested in the comments). The final regulations specify that Regional vocational vehicles in any weight class may use this option, as long as the frontal area and vehicle length are larger than the specified minimum (see 40 CFR 1037.520(m)). By basing the size restrictions on minimum values rather than a narrow range of dimensions as was proposed, the final approach to this credit option is also better aligned with the approach used in the trailer program. As discussed in the RIA Chapter 2.10.2.1.2.6, the performance of aerodynamic devices on shorter trailers tends to be poorer than performance on longer trailers. As part of the trailer analysis, the devices (such as skirts) were sized appropriately for the vehicles, so that longer trailers had proportionately longer skirts. While we would expect this trend to also hold for vocational vehicles, we do not have data on longer vehicles and therefore we are setting final improvement values that are valid for vehicles at least as large as those tested, where we can be confident the rules don’t over-credit the use of pre-defined devices on larger/longer configurations.

Due to the small number of configurations and technologies tested, a fixed change in $C_D$A is being adopted for only three devices. Although we reviewed the wind tunnel data from ARC and Ford, we were unable to make use of these other data sources in the final regulations. The data from ARC included combined wind tunnel results for packages of aerodynamic improvements on a single vehicle and were not device-specific. The Ford data were from wind tunnel testing of single devices as well as combined packages of devices on two vehicles, neither of which are similar to the vehicles tested by CARB. The Ford vehicles are smaller than the ones tested by CARB and the fairings are comparatively smaller with corresponding effectiveness values. Although we are not adopting pre-defined improvement values for devices and vehicles based on the data from Ford, we do consider the Ford data to be corroborative of the approach being adopted.

Manufacturers using this credit provision may enter the specified delta $C_D$A as an input to GEM for eligible vehicles, and the simulation will determine the effectiveness over the drive cycle. Using this approach, we do not need to set a scaled benefit for different sizes of vehicles. When a vehicle weight class and subcategory are entered, a default chassis mass, payload, and $C_D$A are simulated in GEM. When the pre-defined delta $C_D$A is entered as an input, the simulation returns a resulting improved performance specific to the given chassis configuration. Using this approach, GEM will logically return a smaller improvement for larger vehicles. If a percent $C_D$A improvement value were used as requested by CARB instead of delta $C_D$A, then the simulated effectiveness on larger vehicles would likely not diminish, and could even increase. This is because if GEM computed a given percent improvement of the larger default $C_D$A that is in GEM for a heavier vehicle, the change in $C_D$A would be greater. This would not be a conservative approach, and when extrapolating beyond test data, the agencies prefer to

---

be conservative. Manufacturers wishing to receive credit for other aerodynamic technologies or on other vehicle configurations may seek credit by conducting A to B testing as specified in the regulations at 40 CFR 1037.527. Although in actual operation the added weight of aerodynamic fairings may reduce the operational benefits of these technologies when driving at low speeds, the agencies are not applying any weight penalty as part of the certification process for vocational aerodynamic devices.

The final Regional composite duty cycle in GEM for vocational vehicles has a weighted average speed of 38 mph, increased from the average speed at proposal due to a heftier 56 percent composite weighting of the 65 mph drive cycle. The agencies have learned from the NREL duty cycle analysis that vocational vehicles with operational behavior of a regional nature accumulate more miles at highway speeds than previously assumed. Using GEM simulation results, the agencies estimate the fuel efficiency benefit of improving the C\text{D}_A of a Class 6 box truck by 0.6 m$^2$ (approximately 11 percent from a default C\text{D}_A of 5.4 m$^2$) at approximately five percent over the Regional composite test cycle. This same delta C\text{D}_A simulated in GEM on a class 8 Regional vocational vehicle results in an overall improvement of less than four percent because the default C\text{D}_A in GEM for class 8 vocational vehicles is 6.86 m$^2$ so the change in C\text{D}_A is only nine percent.

We disagree with many of the requests and assertions in CARB’s comments. First, we disagree that there is no issue of technical feasibility for applying aerodynamic fairings just because they are commercially available. Feasibility for rulemaking purposes must consider barriers to application such as compatibility with a chassis configuration. CARB’s comments include information gained from conversations with suppliers who noted that skirts can be used on any box truck as long as equipment underneath, such as storage boxes, lifts, etc., does not interfere and there is adequate space between axles. These are real world barriers to adoption of this technology that must be considered. Further, where a box truck chassis has a cab-over-engine design, some front fairings could interfere with tilting the cab forward as needed to perform engine maintenance.

We similarly disagree with CARB’s assertion that almost all Regional vocational vehicles can apply this technology. UCS suggests that six percent of class 3-7 vocational vehicles could see real world benefits from use of aerodynamic devices, based solely on the VIUS survey of miles travelled (estimated by UCS to be 25 percent of LHD and MHD Regional vehicles). The agencies would need more specific fleet information than this before projecting technology adoption rates. For example, if the devices we are considering are bolt-on fairings rather than integrated redesigns, then eligible vehicles would be those with chassis to which such fairings may be reasonably affixed. Coach buses (motorcoaches) are clear examples of vehicles that would certify as Regional. However the typical bus design has low side clearance chassis that often house under-carriage luggage compartments. Thus, bolt-on side skirts as considered for box trucks would seem infeasible for these buses. Another example of a vehicle that has frequently been characterized as having a Regional drive cycle is a drayage tractor. These typically haul marine containers to and from rail yards using specialized chassis that are often owned by the shipping company. These unusual boxes on unusual chassis may be incompatible with any of the aerodynamic fairings considered by commenters. Before an adoption rate for a technology can be projected for purposes of regulatory standard-setting, information about the fraction of the fleet that is compatible with the technology must be available, and commenters have not provided this information; nor have the agencies been able to develop such information.

We agree with CARB that the Phase 2 program includes many technologies that seem to offer small improvements, such as axle lubricants. We have included many technologies in the vocational vehicle technology packages that have high initial costs, and some will have smaller improvements in efficiency than others. Although we have pointed to one possible pathway, we have set the performance-based Phase 2 standards in a way that enables manufacturers to select the mix of technologies that will be most suitable for their products. Using the cost estimate provided by UCS ($2,500) and an estimated
effectiveness between four and six percent, the use of aerodynamic devices would likely fall in a range of cost-effectiveness similar to ATIS for Regional vocational vehicles. ATIS is a technology that we are also not projecting as part of standard-setting (except for custom chassis where more details are known about the vehicles). All of the above reasons have led the agencies to conclude that aerodynamic improvements should not be factored into the stringency of the Phase 2 program, and should be made available only as an optional credit at this time.

In response to Daimler’s concerns regarding delegated assembly, we agree that by regulating vocational vehicles at the incomplete stage when a chassis manufacturer may not know what type of body will be fitted on the chassis, this is a possible barrier to adoption of aerodynamic improvements. As described in the NPRM, we are requiring chassis manufacturers employing this option to provide assurances to the agencies that these devices will be installed as part of the certified configuration, even if the installation is completed by another entity. We expect that this option will only be chosen by manufacturers that can overcome these market barriers, which is another reason why it is not considered as part of stringency. We received many comments on the requirements for secondary manufacturers as they apply for vocational aerodynamics as well as other technologies that may be specified by a chassis manufacturer but installed later. See Section 1.4.4 for responses to delegated assembly comments.

6.4 Exemptions and Exclusions
6.4.1 Small Businesses and Small Volume Producers

Organization: Innovus Enterprise LLC

Additional Comments: On page 40295, there is a discussion about chassis manufacturers, small volume manufacturers and small businesses and a request for comments on alternate approach and sales volume threshold. We can say this: There is often a convolution of the terms “small volume” and “small entity.” There are cases where a large manufacturer, with resources normally far exceeding that of the small business, is as a small volume producer, offered flexibility on compliance issues. We are of the opinion that only small volume producers who also qualify as a small entity be the thrust for regulatory flexibility. [EPA-HQ-OAR-2014-0827-1116-A1 p.7]

A request for comment was posed asking for a means to determine what would constitute the correct quantity that amounts to “small volume.” We suggest using a formula based on a percentage of market sales in that particular industry; industry being the particular one that a certificate is sought. Actually, it seems the same question is posed every time small volume flexibility is posed - what is the correct or fair quantity? We have developed such a formula and parameters for a program which could apply to all small volume conditions throughout the CAA program. We can share this with the Agency and further discuss if they are interested. [EPA-HQ-OAR-2014-0827-1116-A1 p.7]

On page 40545, paragraph (x) Custom Chassis Manufacturers, a request is made for suggestions as to a low volume exception. We are fully supportive of this exemption for small entity/small volume custom chassis manufacturers. We feel that a volume of 200 vehicles per year could be adequate since it is consistent with the other like categories. Additionally, we think there could also be some qualifying factor such as: The exemption is warranted when the feasibility to employ fuel saving and emission reduction technologies are beyond the capability of the small entity to reasonably engineer. Or, the vehicles operate in a manner essentially making them incompatible with fuel saving and emission reduction technologies. The recordkeeping, reporting and labeling could follow along the line of that in 1037.631. [EPA-HQ-OAR-2014-0827-1116-A1 p.7]

Organization: Association for the Work Truck Industry (NTEA)
**Emergency Vehicles**

We agree with the concept of differing standards for emergency vehicles. This small population of vehicles is critical to society. Ensuring their continued operation is a legitimate public safety issue. [EPA-HQ-OAR-2014-0827-1187-A1 p.5]

**Organization:** Truck & Engine Manufacturers Association (EMA)

EMA supports the proposed less stringent requirements for emergency vehicles, which requirements would focus on the use of low rolling resistance tires. The unique performance requirements and applications for emergency vehicles make it infeasible to implement the full Phase 2 program for those vehicles. However, EPA should expand the definition of emergency vehicles beyond just ambulances and fire trucks. EMA also requests that the agencies establish simplified consistent labeling requirements for emergency vehicles (just as for non-emergency vehicles), including through the elimination of requirements for emissions control identifiers. [EPA-HQ-OAR-2014-0827-1269-A1 p.45]

**Organization:** Volvo Group

It is unclear why motor homes, cement mixers, and emergency vehicle chassis could be certified to a family not requiring use of GEM, while this option would not be available for other Custom Chassis types.

Single weight class assumptions are not correct, as some Class 8 Motor Coaches are completed as Motor Homes and thus a manufacturer could not average between the two if they were certified to Class 7.

**Organization:** E-ONE

Giders are an important product in the emergency vehicle industry. An emergency vehicle, while critical to saving lives in the event of an emergency; typically does not drive very many miles over the lifetime of the vehicle. The industry standard of the lifetime of an emergency vehicle is 10 to 20 years in which an emergency vehicle may only have traveled 10-50,000 miles, although it is not uncommon for an emergency vehicle of 30+ years of service to have the same amount of miles. E-ONE has found that the durability of engines in class 8 emergency vehicles far surpass the longevity of the chassis that they power, this can be attributed to the extreme environment that these vehicles have to endure. Having the ability to purchase a glider allows municipalities with limited financial resources capable of maintain a fleet that is required to save lives. [EPA-HQ-OAR-2014-0827-1185-A1 p.1]

**Organization:** Fire Apparatus Manufacturers’ Association (FAMA)

**Emergency Vehicle Proposal**

FAMA supports the language in the Phase II proposal concerning emergency vehicles that limits regulation of emergency vehicles to the Phase I levels. This approach works in the best interest of both the users of emergency vehicles (fire fighters, EMTs, etc…) and members of the public who become recipients of the services rendered using emergency vehicles. [EPA-HQ-OAR-2014-0827-1163-A1 p.1]

**Organization:** Navistar, Inc.
Navistar supports the proposed requirements for emergency vehicles, which essentially vocational vehicles. The unique performance requirements and applications for emergency vehicles make it infeasible to implement the full Phase 2 program for those vehicles and we support this establishment of this unique segment. Navistar also requests that the agencies establish simplified labeling requirements for emergency vehicles (just as for non-emergency vehicles) as noted above in the discussion of Labelling. [EPA-HQ-OAR-2014-0827-1199-A1 p.40-41]

Organization: Allison Transmission, Inc.

Low Volume Exemption Should Allow for Deployment of Advanced Technologies

The agencies have requested comment on whether different standards and simplified compliance procedures should apply to custom chassis manufacturers. Allison generally supports flexibility in implementing Phase 2 standards in order to recognize the varied nature of the MD/HD market -- there are many specialized vehicles that may be “purpose-built” to perform certain tasks. The limited number and specialized nature of such vehicles means that there would be marginal environmental gains from regulating such vehicles on a comparable basis to higher volume production vehicles. In addition, excessive burdens could inhibit innovation driven by some low-volume manufacturers. [EPA-HQ-OAR-2014-0827-1284-A1 p.49]

EPA and NHTSA Should Consider Limited, Low-Volume Exemption

Allison believes that providing a less stringent standard for small volume chassis manufacturers is appropriate. Allison further believes the basis for this flexibility should be to allow small volume manufacturers the ability to continue operations until they grow to a size where applying more stringent standards is appropriate. Using the Phase 1 rule as a guide, a sales volume strategy similar to the Phase 1 three year rolling average of vocational tractor sales would be a reasonable approach (it is assumed the threshold would be different). [EPA-HQ-OAR-2014-0827-1284-A1 p.50]

Allison does not favor additional lead time as the only solution for flexibility for small volume manufacturers. In our experience, the challenge for small volume manufacturers is typically a lack of resources. If a small manufacturer lacks the resources (or ability to add resources) to address increasingly stringent standards, the situation is unlikely to change simply based on allowing an additional one or two years for compliance. Instead, additional lead time coupled with less stringent standards represents a balanced approach to addressing this issue. [EPA-HQ-OAR-2014-0827-1284-A1 p.50]

The low overall volume of custom chassis manufacturers may inhibit their ability to benefit from averaging, banking and trading (“ABT”) systems. ABT systems work to provide flexibility if a manufacturer has a number of different vehicles which may underrun or exceed regulatory standards. In a low volume scenario, a specialty vehicle manufacturer simply may not be able to generate enough credits within the time period required. In such a situation, a theoretical recourse would be to purchase credits for compliance, but realistically, such might be unavailable since larger companies may desire to retain such credits for their own future compliance or be otherwise reluctant to sell such credits to a smaller competitor. [EPA-HQ-OAR-2014-0827-1284-A1 p.50]

In addition, EPA and NHTSA should consider the additional testing burden that might result from small volume manufacturers creating different types of vehicles which may not have all attributes measurable through GEM, thus necessitating powertrain testing in order to demonstrate compliance or generate
EPA and NHTSA Should Consider Low-Volume Phase-In

The agencies should additionally consider providing for a limited period of time (e.g., 18 months) and a limited volume (e.g., 500 vehicles) as a “phase-in” period for low-volume manufacturing of advanced technology, during which time less stringent standards would apply. Under this concept, once the time or volume limit was reached, the phase-in period would end and full compliance with the emission and fuel efficiency standards established by the final rule would be required. [EPA-HQ-OAR-2014-0827-1284-A1 p.50]

This flexibility should be allowed for all manufacturers, regardless of size or type since the object of the phase-in period is to encourage innovation. Allowing for a phase-in period would improve the ability of the marketplace to explore innovative technologies - and potentially large gains in emissions and fuel efficiency performance - while limiting any potentially negative impacts on GHG emissions and fuel use. The concept should not be confused with the simplified compliance procedures proposed for low volume manufacturers. While these procedures are helpful, they do not fully address the multiple barriers to entry faced by new technology. [EPA-HQ-OAR-2014-0827-1284-A1 p.50-51]

Organization: School Bus Manufacturers Technical Council

For the years of 2010-2014, the average number of large school buses produced each year was 26,368 units. Given the reasons stated above and the relatively small volume of school buses produced each year, we respectfully request that the agencies consider allowing school buses to meet some of the less stringent standards as being proposed for emergency type vehicles. [EPA-HQ-OAR-2014-0827-1287-A1 p.2]

Organization: Autocar, LLC

Autocar is a small business that should be exempt from Phase 2. In 2011, the agencies determined that its small size justified a deferral from compliance from the Greenhouse Gas Emissions Standards and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 1 regulations (“Phase 1”) for Autocar. The relevant facts remain the same, and Autocar’s size, volume and product lines continue to justify an exemption or different standards for its vehicles.[EPA-HQ-OAR-2014-0827-1233-A1 p.2]

The estimated costs and payback for compliant technologies may inhibit industry adoption. Autocar does not have access to data that would enable the Company to confirm assumptions and calculations of incremental cost and payback for compliant technology for vocational vehicles in 2021, 2024 and 2027. Assuming that the calculated costs per truck (for most Low-speed/Frequent-stop Vehicles) of $1,998 in 2021, $3,332 in 2024 and $7,422 in 2027 are accurate for those vehicles, the costs are too high and would likely discourage the adoption of compliant technology. The proposed payback of 6-7 years may not be compelling to customers typically maintaining refuse and sweeper trucks in service for the 7-12 years recognized by the agencies at 80 Fed. Reg. 40286. Vocational truck buyers will view their estimated costs and payback as unfair when compared to the lower costs and shorter payback for non-vocational truck buyers. Truck owners will likely choose to defer purchases and extend the lives of old
non-compliant trucks, rather than spending more to purchase new compliant trucks, threatening or delaying the effectiveness of the GHG regulations. [EPA-HQ-OAR-2014-0827-1233-A1 p.9][This comment can also be found in section 13.2.4 of this comment summary]

The agencies’ analysis of, and reasons for, exempting small volume manufacturers of emergency vehicles also applies to small volume manufacturers of Low-speed/Frequent-stop Vehicles. Similar to the rationale the agencies provided in granting the exceptions for small manufacturers of emergency vehicle chassis, the agencies should similarly grant exceptions for small manufacturers of refuse truck, street sweeper and other Low-speed/Frequent-stop Vehicle chassis. [EPA-HQ-OAR-2014-0827-1233-A1 p.13]

Manufacturer Diversity. Custom chassis manufacturers are a diverse group, even within particular truck markets. For example, in the North American refuse truck chassis market, Autocar generally competes with two very different manufacturers. As noted in Section 1.1, Autocar has less than 300 employees, one plant and annual production of roughly 2,000 refuse trucks and 500 other trucks. Autocar’s two competitors also produce approximately 1,500-2,500 refuse trucks per year, but in contrast to Autocar, they are large, publicly-held, worldwide corporations with thousands of employees, multiple plants, multiple brands and annual production of tens of thousands of other trucks. Both of Autocar’s major competitors build and install their own engines, and at least one of them also builds and installs proprietary transmissions in its own trucks. [EPA-HQ-OAR-2014-0827-1233-A1 p.13]

4.2.2 Compliance Burden. The compliance requirements of the Proposed Regulations would impose burdens disproportionately high for a company that assembles small volumes of customized chassis and no other product lines. The ability to benefit from averaging would be limited or non-existent, as would be the ability to spread compliance costs across many vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.13]

4.2.3 Reliability Requirements. Like emergency vehicles, refuse trucks perform a public health function and therefore require a high level of reliability. Refuse trucks manage America’s solid waste stream and transport many recyclable materials. Some refuse trucks even serve double-duty as snow plows. Refuse trucks serve a critical, “24/7” function in our society, and must continue to be made available and affordable in the market. [EPA-HQ-OAR-2014-0827-1233-A1 p.13]

4.2.4 Performance Requirements. Further, the refuse industry requires a high level of performance and durability. Refuse trucks travel on residential and commercial streets, highways, dirt and gravel roads and paved and unpaved alleys. The truck must be sturdy enough to carry a widely-variable payload and to withstand the pressures exerted when the compaction unit is operating. The purpose-built features of refuse trucks, such as the high steel content (and resulting weight), high-traction tires and high PTO-running time limit the opportunities for GHG emissions reductions. These high-performance aspects present technological feasibility issues beyond other vocational vehicles, and the severe duty cycles of these vehicles (discussed above in Section 2.3) create constraints in terms of vehicle design and application of technology. [EPA-HQ-OAR-2014-0827-1233-A1 p.13-14]

4.2.5 Averaging. As discussed above in Section 2.4, certain GHG and fuel saving technologies can be applied, but Low-speed/Frequent-stop Vehicles are so different from other vocational vehicles that keeping them in the same averaging sets as other vocational vehicles is not appropriate. Accordingly, a separate standard, evaluated from a baseline specific to these vehicles, is warranted. Further, with all of the standards being predicated on averages, an assembler of just a few types of vehicles may be disproportionately impacted by its vehicles’ actual standards being at the far end of the spectrum from the averages. [EPA-HQ-OAR-2014-0827-1233-A1 p.14]
4.2.6 Low Volume → Low Impact. According to the International Council on Clean Transportation (ICCT), less than one percent of all new heavy duty trucks from 2003 to 2007 were registered to sanitation/refuse companies, and not all of those trucks were refuse vehicles (some were service trucks, freight trucks and other trucks used by sanitation companies). The annual North American market for refuse collection trucks, such as those assembled by Autocar, has averaged 6,000 new trucks over the past 10 years. The agencies recognize that an aggregate industry count 5,700 new emergency vehicles per year is too small to justify compliance with the Proposed Regulations (80 Fed. Reg. at 40,294), and should consistently extend this conclusion to the similarly-sized refuse market. Because relatively few of these vehicles exist, and they travel a relatively low number of miles, modified GHG and fuel consumption standards would not detract from the greater objectives of the rulemaking. [EPA-HQ-OAR-2014-0827-1233-A1 p.14]

4.3 The exceptions granted should be limited to 5,000 chassis per year. Autocar proposes to set a 5,000-vehicle limitation on the number of vehicles that a small chassis manufacturer may produce under this exception annually. This figure is consistent with the small-volume vehicle manufacturer exemption for NHTSA’s TREAD reporting. See 49 C.F.R. § 579.27 (reporting requirements applicable to manufacturers of fewer than 5,000 vehicles). [EPA-HQ-OAR-2014-0827-1233-A1 p.14]

The exception granted for emergency vehicles should be extended to similar Low-speed/Frequent-stop Vehicles. In the Proposed Regulations, the agencies provide a simplified compliance procedure and less stringent Phase 2 standards for emergency vehicles, and the agencies request comment on extending those flexibilities to other custom chassis manufacturers. 8 80 Fed. Reg. at 40,292-40,295. If the agencies do not grant an exemption as proposed in Sections 2 and 3 of these Comments above, Autocar proposes that small manufacturers of chassis of Low-speed/Frequent-stop Vehicles be provided a simplified compliance procedure and less stringent Phase 2 standards for their vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.12-13]

The exceptions granted should provide for a simplified compliance model. In light of the different set of feasible technologies discussed above in Section 4.4, it is appropriate to provide a simplified compliance model, as is proposed for emergency vehicles. A Phase 1-style GEM interface with a default compliant engine and transmission and a simpler set of vehicle-level standards and technologies may be appropriate, but that would not sufficiently reduce the small custom chassis manufacturer’s administrative burden of running GEM simulations for thousands of custom configurations for its customized chassis. We propose that installing certified engines should be sufficient proof of compliance. [EPA-HQ-OAR-2014-0827-1233-A1 p.16] /12/ Lacking vertical integration, a small custom chassis manufacturer has no means by which to test engines or transmissions to obtain the maps and other data needed to run GEM simulations, and in fact may be prohibited from doing so under its contracts with suppliers.

Additional lead time would not provide sufficient relief. Although Autocar appreciates the agencies’ willingness to consider providing additional lead time for compliance by small custom chassis manufacturers, the Company believes that additional lead time would not remedy the difficulties faced by such manufacturers in meeting the proposed standards or the negative consequences for the industry. For example, the manufacturers would still have limited ability to benefit from averaging and to spread compliance costs across many vehicles. We would still suffer from the shortage of technical compliance expertise, and customers would still experience disruption to their businesses due to production delays, upfront cost increases and increased continuing maintenance costs. [EPA-HQ-OAR-2014-0827-1233-A1 p.16]
2 Autocar’s Low-speed/Frequent-stop Vehicles include the following: residential and commercial refuse collection trucks, street sweepers, asphalt patchers, stripers and blasters, concrete pumpers and conveyers, aircraft deicers, refuelers and stockers and sewage suction trucks.

3 Autocar’s class 8 heavy-duty terminal tractors (referred to as “yard hostlers” in the Proposed Regulations) and Class 8 heavy-duty chassis for mobile cranes are “vocational tractors,” exempt from Phase 2 compliance under §1037.630, because terminal tractors and mobile cranes are intended for off-road operation. The agencies correctly recognize that these machines do not operate at highway speeds and would not benefit from the efficiency improvements designed for line-haul tractors. 80 Fed. Reg. at 40,654.

4 A typical average refuse vehicle payload is 10,000 pounds, and a typical maximum refuse vehicle payload is 20,000 pounds.

5 Additionally, in the Draft Regulatory Impact Analysis, Autocar observed that the testing for vocational vehicles was conducted using what is described as a “New Flyer refuse truck” with an “AT” Eaton transmission. We are not aware that New Flyer ever produced a refuse truck, and do not believe that the Eaton transmission is an AT, but rather an AMT. Autocar encourages the agencies to confirm that the baselines and standards being asserted for refuse trucks based on this testing were actually derived from a refuse truck, and not a New Flyer transit bus.

8 The agencies correctly recognize that small custom chassis manufacturers such as Autocar offer a narrow range of products, such that averaging is not of practical value as a compliance flexibility. Such companies do not have large sales volumes over which to distribute technology development costs and would bear disproportionate compliance burdens in the event that the agencies require compliance with the primary proposed Phase 2 standards. 80 Fed. Reg. at 40,294.

9 More specifically, according to recent SEC filings, one of Autocar’s main competitors in 2014 sold 69,750 Class 8 trucks in the U.S. and Canada, had plants in seven countries, had over 23,000 employees and spent $215 million on research and development. Autocar’s other main competitor, which is part of the world’s second largest truck maker, sold 57,714 trucks in North America (92% of which had proprietary engines), had plants in 19 countries, employed over 100,000 people and spent $1.96 billion on research and development.

11 As currently designed for use in refuse vehicles, hybrid technology captures normally-wasted energy from braking, converting that energy into available power to accelerate or drive the vehicle, thus reducing fuel consumption and emissions. Testing methodologies for this technology must accommodate the braking, load and terrain factors that are integral to measuring the gains derived from hybrid refuse vehicles. Dynamometer testing will not demonstrate actual improvements in GHG emissions and fuel consumption.

12 Lacking vertical integration, a small custom chassis manufacturer has no means by which to test engines or transmissions to obtain the maps and other data needed to run GEM simulations, and in fact may be prohibited from doing so under its contracts with suppliers.

Supplemental comments from Autocar:
In our October 1, 2015 comments, Autocar explained how the Proposed Regulations would adversely affect this small business that already contributes to substantial GHG emissions reduction, because it installs emissions-certified engines and transmissions and sells a high concentration of trucks with compressed natural gas engines and hybrid-drive powertrains. Yet, the EPA's Vocational Custom Chassis Memorandum (the 'Memorandum') and the underlying research set forth in documents included in the agencies' recent Notice of Data Availability (the 'NODA') propose compliance schemes that do not take into account:

• the impact of this complex compliance path on small, low-volume businesses like Autocar;

• the minimal emissions improvements achievable with the proposed technologies;

• the fact that Autocar only builds the chassis, and the body builder and vehicle owner make considerable modifications to the truck before putting it into service, over which Autocar has no control; nor

• the emissions-reduction effect Autocar already contributes by producing alternative-fuel vocational trucks.

For these reasons, Autocar submits these comments to the NODA and the Memorandum and respectfully renews its request for an exemption. [EPA-HQ-OAR-2014-0827-1885-A1 p.2]

Organization: California Air Resources Board (CARB)

CARB staff understands the unique nature and uses of emergency vehicles and supports the proposal’s provisions to allow emergency vehicles to certify to less stringent standards with reduced compliance procedures than for other vocational vehicles. California Statute and many of CARB staff’s in-use regulations similarly have special provisions for emergency vehicles. CARB staff also understands that current idle reduction technologies applicable to the Phase 2 vocational standards may not be sufficient to power all of the on-board electronics required by emergency vehicles. Therefore, CARB supports proposed emergency vehicle standards that do not require the use of specific idle reduction technologies. [EPA-HQ-OAR-2014-0827-1265-A1 p.64]

Additionally, because the proposed compliance method for emergency vehicles is simplified compared to that of other Phase 2 vocational vehicles, emergency vehicle manufacturers would not follow the otherwise applicable Phase 2 approach of entering an engine map into GEM. Instead, CARB staff supports the proposed equation-based compliance approach using a Phase 1-style GEM interface with a default engine simulated in GEM is appropriate for the emergency vehicle category. [EPA-HQ-OAR-2014-0827-1265-A1 p.64]

Organization: Daimler Trucks North America LLC

Fire/Emergency Vehicles and RVs - On 80 Fed. Reg. 40294-5, the agencies propose a scaled-down certification procedure for emergency vehicles and RVs. For applications like firetrucks and RVs, which drive little, spend little time idling, and have small volume production, a simplified compliance is indeed warranted. We recommend that the agencies use the same certification and compliance mechanisms and procedures as for all other vehicles, however, given that manufacturers cannot implement different computer systems for each type of vehicle. Rather, for vehicle applications like RVs, a GEM-based compliance mechanism that ensures compliance for vehicles built with certified engines may suffice. For emergency vehicles, which may need high torque or power or high traction
tires to react to emergencies, even if such needs result in temporarily high fuel consumption, compliance through GEM may simply mean that the vehicle has a fuel map as good as a 2014 fuel map for such emergency vehicles. [EPA-HQ-OAR-2014-0827-1164-A1 p.75]

**Possible Standards for Other Custom Chassis Manufacturers** - On providing custom chassis manufacturers with additional lead time to comply. 80 FR 40295. DTNA supports providing custom chassis manufacturers with additional lead time to comply as long as the additional lead time is given to all custom chassis manufacturers regardless of sales volumes or any other criteria which would not be in the best interest of fair market competition. [EPA-HQ-OAR-2014-0827-1164-A1 p.75]

**Lower Rolling Resistance Tires** – The agencies proposed discontinuing the option to qualify for the off-road or low speed exemption solely if the vehicle is fitted with tires that have a maximum speed rating at or below 55 mph. 80 FR 40300. DTNA agrees with EPA that the qualifying criteria related to the design and use of the vehicle should be retained. We agree that the speed rating of the tire is not as reliable a factor as the other factors listed, GAWR of 29k lbs or more, speed attainable of not more than 33 mph in two miles, or speed attainable of not more than 45 mph in two miles with unloaded vehicle weight not less than 95% of the GVWR. [EPA-HQ-OAR-2014-0827-1164-A1 p.79]

iv. RV & Custom Chassis

- **Possible Standards for Other Custom Chassis Manufacturers (Compliance Procedure)** - The agencies request comment on extending the above simplified compliance procedure and less stringent Phase 2 standards to other custom chassis manufacturer. 80 FR 40294. DTNA does not believe that it is fair or beneficial to the environment to allow simplified compliance procedures and less stringent Phase 2 standards to certain manufacturers based solely on sales volumes. If the technology exists for one manufacturer to meet the standard, then it exists for all manufacturers. [EPA-HQ-OAR-2014-0827-1164-A1 p.100]

- **Possible Standards for Other Custom Chassis Manufacturers (Stringency)** – The agencies request comment on the merits of offering less stringent standards to small volume chassis manufacturers, and seek comment as well as to other factors the agencies should consider to ensure this approach would have unintended consequences for business competing in the vocational vehicle market. 80 FR 40295. DTNA does not believe that it is fair or beneficial to the environment to allow simplified compliance procedures and less stringent Phase 2 standards to certain manufacturers based solely on sales volumes. If the technology exists for one manufacturer to meet the standard, then it exists for all manufacturers. [EPA-HQ-OAR-2014-0827-1164-A1 p.100-101]

- **Possible Standards for Other Custom Chassis Manufacturers (Sales Volume)** – The agencies request comment on an appropriate sales volume to qualify for these possible standards, and also request comment as to whether the sale volume thresholds should be different for different markets. 80 FR 40295. DTNA does not believe that it is fair or beneficial to the environment to allow simplified compliance procedures and less stringent Phase 2 standards to certain manufacturers based solely on sales volumes. If the technology exists for one manufacturer to meet the standard, then it exists for all manufacturers. [EPA-HQ-OAR-2014-0827-1164-A1 p.101]

- **Possible Standards for Other Custom Chassis Manufacturers (Competitiveness)** – The agencies request comment on whether it could adversely affect business competitiveness if custom chassis manufacturers were held to a different standard than commercial chassis manufacturers, and whether the agencies should consider allowing commercial chassis manufacturers competing in the markets to sell a limited number of chassis certified to a less stringent standard. 80 FR 40295. DTNA
believes that having different and less stringent standards would undermine fair market competition. If the technology exists for one manufacturer to meet the standard, then it exists for all manufacturers. [EPA-HQ-OAR-2014-0827-1164-A1 p.101]

· **Possible Standards for Other Custom Chassis Manufacturers (Recreational Vehicles)** - The agencies request comment on whether we should develop separate standards for different vehicle types such as recreational vehicles and buses. 80 FR 40295. DTNA would be supportive of less stringent GHG standards for recreational vehicle products. Applicable technology package considerations should be focused on 6-8 year payback periods based on typical RV duty cycles. Standard-setting technologies for the RVs should be based on a study of the technology currently used in RVs, including a study of RVs’ Crr values. All vehicle labeling standards and requirements should be consistent regardless of any specific application allowances or exemption status. The agencies should establish a pathway to certification of vehicles using engines from small manufacturers, allowing the use of a default engine fuel map without penalizing the vehicle manufacturers, until the time that small engine manufacturers have their fuel maps measured and ready for use. [EPA-HQ-OAR-2014-0827-1164-A1 p.101]

· **Possible Standards for Other Custom Chassis Manufacturers (Vehicle Exemption)** – The agencies request comment on how to design a small business vocational vehicle exemption by means of a custom chassis volume exemption and what sales volume would be an appropriate threshold. 80 FR 40295. DTNA does not believe that it is fair or beneficial to the environment to allow simplified compliance procedures and less stringent Phase 2 standards to certain manufacturers based solely on sales volumes. If the technology exists for one manufacturer to meet the standard, then it exists for all manufacturers. [EPA-HQ-OAR-2014-0827-1164-A1 p.101]

· **Custom chassis manufacturer**: what is the definition of a custom chassis manufacturer? What is the cut off in sales? [EPA-HQ-OAR-2014-0827-1164-A1 p.102]

· **Proposed Standards for Emergency Vehicles** – The agencies request comment on whether we should include any market adoption rate of idle reduction technologies for emergency vehicles, as part of the basis for the phase 2 emergency vocational vehicle standard. 80 FR 40162. In regards to adoption rate of idle technologies for emergency vehicles, we believe that the rate will be 0. We do not plan on providing any type of technology of idle reduction until it is demanded or requested by the industry as we do not want to cause any disruptions when the vehicle needs to be operating at 100% in emergency situations. If idle reduction is still necessary it should follow California's heavy duty diesel vehicle idling regulations. [EPA-HQ-OAR-2014-0827-1164-A1 p.102]

· **Proposed Standards for Emergency Vehicles** - The agencies request comment on the merits of using equation-based compliance approach for emergency vehicle manufacturers, similar to the approach proposed for trailer manufacturers. 80 FR 40293. DTNA believes the agencies should continue using GEM as the source emergency vehicle compliance. This will continue to provide a consistent methodology of compliance for all vehicles and not introduce additional complexities that could arise from using the compliance equation. [EPA-HQ-OAR-2014-0827-1164-A1 p.102]

· **Aligning HDV Emergency Vehicles (Fire Trucks) Definition** – The agencies request comment on the merits and drawbacks of aligning the definition of emergency vehicle for purposes of the Phase 2 program with the definition of emergency of the light duty GHG provisions under 40 CFR 86.1818, such as those used by law enforcement. We support the idea of aligning the definition of emergency vehicle as we have the capability of running separate reports using specific data codes to determine the amount of emergency vehicles that have been sold. The second option that we would like
to propose is that the agencies adopt the same definition as defined in 13 CCR 1956.8(a)(6). [EPA-HQ-OAR-2014-0827-1164-A1 p.102]

**Organization:** ABC Bus Companies, Inc.

Proposed Phase 2 Standards and Vocational Vehicles, states that the agencies have held dozens of meetings with manufacturers, suppliers, non-governmental organizations and other stakeholders. As there are only 4 to 6 motorcoach manufacturers that currently supply motorcoaches to the United States, it does not seem that this small group in the 'Vocational Vehicles' category was invited to provide comments related to these proposed changes. As the commodity of the Motorcoach Industry is moving people safely and comfortably, it seems that the majority of the Phase 2 text is geared to moving freight. Passenger carrying vehicles demand additional constraints that will be described further in this document. It is important to have these stakeholders' input regarding the current and past Phase 1 effects, to help determine the future effects of these Phase 2 proposals on this industry segment during the drafting process. The costs of Phase 2 compliance in the Trucking Industry can be divided up between hundreds of thousands of trucks, while there is less ability to absorb such costs for the estimated 1,000 motorcoaches produced annually. It seems that the motorcoach manufacturers will be left to deal with high compliance costs that could have an adverse effect on the Motorcoach Industry as a whole. [EPA-HQ-OAR-2014-0827-1430-A2 p.1]

There should be preemptive language in any new regulations. [EPA-HQ-OAR-2014-0827-1430-A2 p.2]

Many proposed NHTSA motorcoach 'Safety Standards', for example, coach Roll-Over Roof Structure, Passenger Window Glazing, and Fire Protection requirements, etc. are still being drafted and will not be finalized for some years to come. While motorcoach manufacturers are trying to prepare for the implementation of these 'Safety Standards' many proposed Standards in Phase 2 could conflict with the still unknown mandated 'Safety Standards'. AS NHTSA has had so much involvement in the Phase 2 proposals, we could not find where these future mandates were taken into consideration in any of the current NHTSA/EPA proposed rules, or made any allowances for them? [EPA-HQ-OAR-2014-0827-1430-A2 p.2]

ABC Bus Companies note that the Preamble gives examples of Vocational Vehicles including: urban delivery, refuse hauling, utility service, dump, concrete mixing, transit service, shuttle service, school bus, emergency, motor homes, and tow trucks, but no mention of 'over the road' or motorcoach 'line-run', or 'charter' service has been defined. [EPA-HQ-OAR-2014-0827-1430-A2 p.3]

**Organization:** GILLIG LLC

The agencies requested comment on extending the simplified compliance procedure and less stringent Phase 2 standards proposed for emergency vehicles to other custom chassis manufacturers. Many of the reasons the agencies used in support of the separate emergency vehicle standard hold true for transit buses: [EPA-HQ-OAR-2014-0827-1156-A1 p.6]

-as technologies to improve powertrain efficiencies become more complex, the compliance burden is disproportionately high for the low volume of transit buses produced. [EPA-HQ-OAR-2014-0827-1156-A1 p.6]

-with our narrow range of product offering, using averaging as a compliance flexibility is limited. [EPA-HQ-OAR-2014-0827-1156-A1 p.6]
-with approximately 1800 transit buses produced annually, GILLIG's ability to spread compliance costs across a large number of vehicles is limited. [EPA-HQ-OAR-2014-0827-1156-A1 p.6]

-transit buses are designed, built and operated very differently than other vocational vehicles such as dump trucks, tow trucks, cement mixers, refuse trucks, etc. making the proposed one size fits all vocational standard inappropriate. [EPA-HQ-OAR-2014-0827-1156-A1 p.6]

The agencies went on to suggest that a possible approach for custom chassis manufactures would be 'predicated on a simpler set of technologies.....most likely lower rolling resistance tires and idle reduction.' [EPA-HQ-OAR-2014-0827-1156-A1 p.6]

In summary, GILLIG would enthusiastically support Agency efforts for a simplified compliance procedure and less stringent Phase 2 standards for transit buses. We would propose a simplified compliance procedure for transit buses, a separate subcategory from other vocational vehicles, similar to the emergency vehicle procedure, based on lower rolling resistance tire and neutral idle technologies. We feel the neutral idle technology more so than the idle reduction technology is applicable to transit buses for reasons mentioned above. GILLIG also requests the agencies to review again the potential business impacts of the currently proposed Phase 2 rule with respect to the certification process, limited compliance flexibility, the burden of compliance and the stockpiling rule as they relate to transit buses. We believe that any one of these parts of the rule could have crippling business consequences for a transit bus manufacturer, its employees and customers. [EPA-HQ-OAR-2014-0827-1156-A1 p.6]

Organization:  Tiffin Motorhomes, Inc.

II. Summary of Comments

It is our belief and contention that the EPA and NHTSA should reconsider how the Proposed Regulations might apply to manufacturers such as Tiffin. If the regulations are adopted in their current form, the chassis division of Tiffin does not see a path to compliance for chassis it manufactures. Using Averaging, Banking and Trading provisions are not a feasible alternative for the chassis Tiffin manufactures due to the low volume, and singular purpose of use. Further, the technologies proposed by these rules do not provide a path to compliance even if all proposed technologies are applied. In order to avoid the closing of our chassis production, we respectfully request that motorhomes (1) be exempted from the proposed rules, or (2) that the EPA should establish separate regulations for motorhomes taking into account their uniqueness in both design and use, similar to what the Agency is doing with emergency vehicles. [NHTSA-2014-0132-0099-A1 p.2]

III. Impact of the economy and cost on the industry

Tiffin, like the motorhome industry as a whole, was hit hard by the recession of 2008 which saw our production drop from 13 motorhomes per day to 3 motorhomes per day. The chassis division suffered a 50% reduction in employment during this time. It was an extreme example of the volatility in the Recreational Vehicle market. As a leisure item with retail costs from $120,000.00 to $650,000.00, demand for Tiffin products drops precipitously when the overall economy significantly constricts or slows down. The chassis division returned to its pre-2008 level in 2010, but the instability in the national economy makes the motorhome market as whole somewhat uncertain. Unnecessary regulations, with a high cost of implementation and a low impact on the environment, would add an additional burden on the recovery that the company has experienced. [NHTSA-2014-0132-0099-A1 p.3]
It should also be noted that unlike commercial vehicles motorhomes do not generate income or increase in value. They are generally used only for personal recreational use and are driven less than 5000 miles per year resulting in significantly lower emissions than those produced by commercial vehicles. These factors make the increased cost imposed by these regulations difficult to absorb, and lead to extended payback periods, often beyond 20 years. [NHTSA-2014-0132-0099-A1 p.3]

IV. Compliance with the proposed regulations using ABT is not possible or feasible for Tiffin

After a studied reading of the proposed regulations, it is not possible or feasible for Tiffin to meet the proposed 2021, 2024 and 2027 standards using ABT. [NHTSA-2014-0132-0099-A1 p.3]

The ABT provisions are not a viable alternative for Tiffin for two reasons. First and foremost, Tiffin currently manufactures only two chassis models, one classified as a MHO, the other as an HHD. These chassis are produced only for motorhomes, and exclusively for Tiffin. This narrow range or products along with the low production volume provide a much lower level of compliance flexibility under the ABT provisions. The annual production volumes for these chassis are; MHO 300-500 units per year, and HHD 500-700 units per year. [NHTSA-2014-0132-0099-A1 p.3-4]

V. Technologies proposed do not provide a path to compliance for Tiffin

The technologies proposed in this rule, if available, and fully implemented, do not achieve compliance under this rule. The chart below shows the potential outcome using the proposed technologies. [NHTSA-2014-0132-0099-A1 p.4]

[Chart can be found on p.4 of docket number NHTSA-2014-0132-0099-A1]

As can be seen in this chart the proposed technologies when applied still leave a deficit to compliance of almost 6%. This assumes that these technologies are available, and provide the proposed benefit. Our low production volumes also provide less opportunity for Tiffin to spread the cost of developing these new technologies across a large number of vehicles. [NHTSA-2014-0132-0099-A1 p.4]

VI. Exemption

Tiffin acknowledges the need for new regulations in an effort to reduce GHG emissions. It is our belief that it is appropriate and acceptable for small chassis manufacturers to continue with rules similar to those in Phase 1 of Heavy Duty GHG Standards where chassis are manufacture using LRR tires and compliant engines. We respectfully request and exemption from the remaining regulations proposed in Phase 2 of these standards. [NHTSA-2014-0132-0099-A1 p.5]

VII. If not exemption then less stringent standards

If the Agency is not willing to exempt small specialty chassis manufacturers from the proposed Phase 2 regulations it is our belief that a less stringent standard is justifiable for these manufactures. We believe a standard similar to what the Agency has done for the Emergency Vehicle industry would be a viable alternative to provide a path to compliance for these manufactures. [NHTSA-2014-0132-0099-A1 p.5]

Organization: Newell Coach Corporation
Looking forward, we are very concerned that compliance with the Phase 2 HI-ID vocational vehicles standards could force us out of business since compliance with the standards do not appear to be feasible for manufacturers like Newell who have no opportunity to utilize the agency's averaging, banking and trading (ABT) provisions. In 2024, even if we were to install all the technology available in the GEM model for regional cycle vocational vehicles (e.g., start stop and weight reduction), our chassis would be far from compliant. Stop-start systems would provide very little benefit given our drive cycle at a tremendous cost.

Given the above, we respectfully request an extension of the current SBA exception for small manufacturers. In our view, a continuation of the current exemption for small businesses, if not for all small businesses then at least for motorhome chassis, would be the simplest solution for small companies like ours, and for EPA. However, if the EPA should conclude that a continuation of the SBA exemption for motorhome chassis manufacturers is not appropriate, we believe that companies who annually manufacture 500 or fewer Class 8 - HHD motorhome chassis should be provided the opportunity to certify their chassis to a less stringent standard (similar to that which has been proposed for emergency vehicles). [EPA-HQ-OAR-2014-0827-1319-A1 p.2]

Organization:  Recreational Vehicle Industry Association (RVIA)

The motorhome industry is relatively unique within the motor vehicle sector. Motorhome vehicle miles traveled (VMT) and production volumes are relatively low, and the fact that these vehicles are for non-commercial use mean there are no recoupment of costs or asset appreciation considerations available. As we will explain in more detail below, the unique nature of these vehicles merits special consideration under the Proposed Rule. [EPA-HQ-OAR-2014-0827-1261-A1 p.3-4]

RVIA’s comments also address EPA’s request for information on custom chassis manufacturers and recommend both a standard and a volume-based definition for the group, based on EPA precedent. Our response, however, in no way changes our overall view that motorhomes should be exempt as a group or at minimum subject to separate, more feasible standards. [EPA-HQ-OAR-2014-0827-1261-A1 p.4]

In order to understand the unique nature of the motorhome industry and why the Proposed Regulations inflict such disproportionate costs on the sector, it is important to provide some details on the sector.

General categories of motorhomes, prices and volumes

i. Motorhomes Types

Motorhomes are typically categorized by type of chassis as Type A, Type B or Type C. [pictures of motorhomes included][EPA-HQ-OAR-2014-0827-1261-A1 p.5]

Type A Motorhome

A Type A motorhome is built on a heavy-duty chassis with the engine located either in the rear or the front. Virtually all are built on chassis designed specifically for motorhomes. Type A’s fall into the light heavy duty (LHD), medium heavy duty (MHD) or heavy-duty (HHD) vocational vehicle categories and the average retail price is $180,000 for gasoline powered units, or $250,000 for a diesel pusher. [EPA-HQ-OAR-2014-0827-1261-A1 p.5]

Type B Motorhome
A Type B motorhome is built using a cargo van as the base. Most are built with a modified roof that is high enough to allow occupants to stand up inside. Type B motorhomes fall into the LHD vocational vehicle or work truck categories and the average retail price is $90,000. [EPA-HQ-OAR-2014-0827-1261-A1 p.5]

Type C Motorhome

Type C motorhomes usually use an extended van or pickup truck chassis with an attached cab. The Type C motorhome is known by many people as a “cab-over” motorhome, as most have an area that hangs over the cabin with a mattress for sleeping. Type C motorhomes fall into the LHD, MHD, or HHD vocational vehicle categories and have an average retail price of $89,000. [EPA-HQ-OAR-2014-0827-1261-A1 p.6]

EPA’s proposed regulations are not feasible for motorhomes and the regulations impose unreasonable costs on manufacturers and consumers with little benefit to consumers or the environment

For a number of reasons, RVIA believes that it would be inappropriate to apply the proposed vocational vehicle standards to motorhomes. [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

Compliance is not feasible for most motorhomes, especially when ABT provisions cannot be utilized. Moreover, the costs of compliance for motorhomes greatly exceed benefits to the environment and consumers. In fact, the Proposed Rules will have significant negative impacts on consumers, motorhome production, and American jobs. [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

a. Compliance is not feasible for most motorhomes

For motorhome chassis manufacturers, based on EPA's own analysis, compliance with the proposed vocational vehicle standards is not feasible in many instances. RVIA carried out a compliance assessment for all motorhome types against the proposed Alternative 3 regional vocational vehicle compliance standards for 2021, 2024, and 2027. The results of this assessment are contained in Appendix B to this submission. The table below summarizes the results of the assessment, with red shading to indicate where compliance is not feasible based on EPA's own data. It shows the following: [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

- Compliance with the proposed 2027 standards is not feasible for any category of motorhomes
- Compliance with the proposed 2024 standards is not feasible for LHD gas motorhomes, MHD diesel motorhomes, and HHD diesel motorhomes. Only LHD diesel and MHD gas motorhomes could theoretically meet the required improvements commercially or economically available to manufacturers.
- Compliance with the proposed 2021 standards is not feasible for LHD and MHD diesel motorhomes. Only LHD and MHD gas and HHD diesel motorhomes could theoretically meet the required improvements. [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

[Chart, feasible versus needed GHG reductions for motorhomes, can be found on p.16 of docket number EPA-HQ-OAR-2014-0827-1261-A1]

ABT provisions will not address the compliance feasibility problem for most motorhome chassis manufacturers. Most manufacturers will not be able to average costs and credits across their own fleets and would be forced to purchase credits corresponding to the relevant vocational vehicle weight groups
elsewhere. However, credits will be limited and expensive and may not even be available. As set forth above, the pool of chassis manufacturers is quite small and the motorhome market is very limited. There are some motorhome chassis manufacturers that serve primarily the motorhome industry and they have no opportunity to utilize the ABT provisions through averaging. There are some motorhome chassis manufacturers that serve only the motorhome industry as well as otherwise exempt segments (e.g., emergency vehicle and military segments). They also have no opportunity to utilize the averaging provisions of ABT. Both categories would have no choice but to compete for a limited pool of credits that might be available from manufacturers of larger fleets, assuming such credits are available. Significantly, EPA has made no analysis of the availability or price of such credits so cannot simply rely on the expectation that such provisions would be available and at a reasonable cost. It is EPA's burden to show its regulations impose reasonable costs. The significant cost numbers we provide below, for example, do not even begin to include the potential costs of buying credits on the market. [EPA-HQ-OAR-2014-0827-1261-A1 p.16-17]

There are also some chassis manufacturers that serve not only the motorhome industry but also multiple truck industry segments and are part of larger entities with larger fleets. These manufacturers are unlikely to utilize ABT to take care of motorhomes as doing so would increase the cost of chassis sold to more important, larger and significantly more profitable business segments. Thus, for many manufacturers of motorhome chassis, compliance with the Proposed Rules would hurt their ability to compete in the more important, larger and more profitable segments that they rely on for the bulk of their revenue. [EPA-HQ-OAR-2014-0827-1261-A1 p.17]

Moreover, it is our understanding that most vocational vehicle manufacturers will face their own difficulties meeting the standards set by EPA, at least without significant changes to EPA's GEM model for vocational vehicles. Given these circumstances, there may very well be no credits available for ABT either within the larger manufacturers' fleets or from other regulated parties. Again, EPA has provided no analysis of the availability of credits for averaging or trading within and among these manufacturers, and simply assumes, without data, that such options will be available at reasonable cost. This kind of assumption is insufficient to support the outcomes that would result with this rulemaking. [EPA-HQ-OAR-2014-0827-1261-A1 p.17]

VII. If not exempt entirely, EPA should establish separate standards for motorhomes

In the event EPA concludes that it will not exempt motorhomes entirely to maintain harmonization with the NHTSA exemption, see earlier discussion above in section IV, it is fair and reasonable that separate and more feasible standards for motorhomes be established. Proposed standards are not feasible for motorhome chassis manufacturers, as these entities are generally not in a position to utilize ABT to meet the standards and the technologies are not cost-effective. For LHD motorhomes, we support adopting only the 2021MY LHD vocational vehicle standards and maintaining those standards through 2027. For MHD and HHD motorhomes, the adoption of standards that would only require MHD and HHD motorhomes to be equipped with more efficient engines and tires could be adopted. As discussed by EPA in the Proposed Rules, standards based on improved transmissions for MHD and HHD vocational vehicles/motorhomes would not be feasible since the engine and transmission are manufactured by non-integrated manufacturers. [EPA-HQ-OAR-2014-0827-1261-A1 p.23]

Complying with standards based on the above recommendations in lieu of those proposed would reduce the incremental per vehicle cost of compliance by approximately 75% and this would reduce if not eliminate the negative economic impacts seen in the four scenario analysis discussed in the previous section. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]
VIII. Custom chassis manufacturer exemption

EPA has requested comment on whether “customs chassis manufacturers,” like emergency vehicles, should be exempt from some of the Proposed Rules and how that term should be defined. While we believe that an exemption is appropriate for all motorhomes, or at minimum, separate standards, we will provide some information in response to this request. However, RVIA strongly urges EPA not to take the position that a custom chassis manufacturer exemption will resolve all the issues RVIA has raised in this submission. While custom chassis manufacturers do deserve some special consideration, especially since they particularly cannot use ABT provisions to meet infeasible standards or the costs of the Proposed Rule, this does not mean other motorhome chassis manufacturers do not merit separate and more achievable standards. This is especially true since these other motorhome chassis manufacturers are also unlikely to be able to use ABT to solve their non-compliance problems due to the fact that most other vocational vehicles that might generate credits for motorhome chassis manufacturers are also unable to comply under the GEMS program. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

With the above qualifications in mind, RVIA would support a standard for custom chassis manufacturers that would be solely based on fitting vehicles with more efficient engines and tires. This is similar to that proposed for emergency vehicles. This would allow feasible and reasonable technologies to be applied to reduce emissions rather than fully exempting customs chassis manufacturers from all standards. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

To reduce the potential for such a provision providing some smaller manufacturers with a competitive advantage, RVIA proposes that all manufacturers, regardless of size, have the opportunity to certify a motorhome chassis to the custom chassis manufacturer standards up to a specified volume threshold. We suggest the following thresholds: [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

1,000 LHD (class 2b-5) motorhome chassis

1,000 MHD (class 6-7) motorhome chassis

2,500 HHD (class 8) motorhome chassis

We note that such a definition is consistent with prior EPA practice. EPA permits small volume test groups to be certified as if they were small volume manufacturer test groups. See 40 C.F.R. § 86.183801 (Small volume manufacturer certification procedures). [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

The same logic should apply to large, multi-vehicle manufacturers who only produce low volumes of chassis designed exclusively for use in the motorhome industry. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

EPA and NHTSA should recognize the unique nature of the motorhome sector, including its exceptional cost-sensitivity, low mileage and low production of its vehicles, and its inability to absorb significant and cumulative regulatory costs. [EPA-HQ-OAR-2014-0827-1261-A1 p.27]

Given these costs, which exceed any benefits, EPA should put motorhomes in a category separate from other vocational vehicles. If they are not exempt, they should be subject to a different and more feasible set of regulations which impose more reasonable costs. Such standards could be: [EPA-HQ-OAR-2014-0827-1261-A1 p.28]
-For LDH motorhomes, EPA should adopt only the MY 2021 LHD vocational vehicle standards and continue them through MY 2027. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

-For MHD and HHD motorhomes, EPA should require only more efficient engines and tires. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

Custom chassis manufacturers merit special recognition given their low volumes and inability to average vehicles across fleets or otherwise make economic use of the ABT provisions. These vehicles should only be required to use more efficient engines and tires. Customs chassis should be defined by volume of production set forth in section VIII to avoid unintended competitive harms, in accordance with EPA precedent. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

26 RVIA does not assert that motorhomes belong in a separate regulatory category other than vocational, but that, if regulated, it should have its own separate standards within the vocational group, just as emergency vehicles are regulated separately.

27 The analysis below only focuses on Alternative 3 as presented in the Proposed Rules. Alternative 4 would be even more problematic, but for purposes of these comments, was not modeled.

28 Clearly, if requirements under Alternative 3 are not feasible, imposition of Alternative 4 would be even less feasible.

Organization:  Recreational Vehicle Industry Association (RVIA)

The motorhome industry is relatively unique within the motor vehicle sector. Motorhome vehicle miles traveled (VMT) and production volumes are relatively low, and the fact that these vehicles are for non-commercial use mean there are no recoupment of costs or asset appreciation considerations available. As we will explain in more detail below, the unique nature of these vehicles merits special consideration under the Proposed Rule. [EPA-HQ-OAR-2014-0827-1261-A1 p.3-4]

RVIA’s comments also address EPA’s request for information on custom chassis manufacturers and recommend both a standard and a volume-based definition for the group, based on EPA precedent. Our response, however, in no way changes our overall view that motorhomes should be exempt as a group or at minimum subject to separate, more feasible standards. [EPA-HQ-OAR-2014-0827-1261-A1 p.4]

In order to understand the unique nature of the motorhome industry and why the Proposed Regulations inflict such disproportionate costs on the sector, it is important to provide some details on the sector.

General categories of motorhomes, prices and volumes

i. Motorhomes Types

Motorhomes are typically categorized by type of chassis as Type A, Type B or Type C. [pictures of motorhomes included][EPA-HQ-OAR-2014-0827-1261-A1 p.5]

Type A Motorhome
A Type A motorhome is built on a heavy-duty chassis with the engine located either in the rear or the front. Virtually all are built on chassis designed specifically for motorhomes. Type A’s fall into the light heavy duty (LHD), medium heavy duty (MHD) or heavy-duty (HHD) vocational vehicle categories and the average retail price is $180,000 for gasoline powered units, or $250,000 for a diesel pusher. [EPA-HQ-OAR-2014-0827-1261-A1 p.5]

Type B Motorhome

A Type B motorhome is built using a cargo van as the base. Most are built with a modified roof that is high enough to allow occupants to stand up inside. Type B motorhomes fall into the LHD vocational vehicle or work truck categories and the average retail price is $90,000. [EPA-HQ-OAR-2014-0827-1261-A1 p.5]

Type C Motorhome

Type C motorhomes usually use an extended van or pickup truck chassis with an attached cab. The Type C motorhome is known by many people as a “cab-over” motorhome, as most have an area that hangs over the cabin with a mattress for sleeping. Type C motorhomes fall into the LHD, MHD, or HHD vocational vehicle categories and have an average retail price of $89,000. [EPA-HQ-OAR-2014-0827-1261-A1 p.6]

EPA’s proposed regulations are not feasible for motorhomes and the regulations impose unreasonable costs on manufacturers and consumers with little benefit to consumers or the environment

For a number of reasons, RVIA believes that it would be inappropriate to apply the proposed vocational vehicle standards to motorhomes.26 [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

Compliance is not feasible for most motorhomes, especially when ABT provisions cannot be utilized. Moreover, the costs of compliance for motorhomes greatly exceed benefits to the environment and consumers. In fact, the Proposed Rules will have significant negative impacts on consumers, motorhome production, and American jobs.27 [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

a. Compliance is not feasible for most motorhomes

For motorhome chassis manufacturers, based on EPA's OWN analysis, compliance with the proposed vocational vehicle standards is not feasible in many instances. RVIA carried out a compliance assessment for all motorhome types against the proposed Alternative 3 regional vocational vehicle compliance standards for 2021, 2024, and 2027.28 The results of this assessment are contained in Appendix B to this submission. The table below summarizes the results of the assessment, with red shading to indicate where compliance is not feasible based on EPA's own data. It shows the following: [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

- Compliance with the proposed 2027 standards is not feasible for any category of motorhomes
- Compliance with the proposed 2024 standards is not feasible for LHD gas motorhomes, MHD diesel motorhomes, and HHD diesel motorhomes. Only LHD diesel and MHD gas motorhomes could theoretically meet the required improvements commercially or economically available to manufacturers.
Compliance with the proposed 2021 standards is not feasible for LHD and MHD diesel motorhomes. Only LHD and MHD gas and HHD diesel motorhomes could theoretically meet the required improvements. [EPA-HQ-OAR-2014-0827-1261-A1 p.15]

ABT provisions will not address the compliance feasibility problem for most motorhome chassis manufacturers. Most manufacturers will not be able to average costs and credits across their own fleets and would be forced to purchase credits corresponding to the relevant vocational vehicle weight groups elsewhere. However, credits will be limited and expensive and may not even be available. As set forth above, the pool of chassis manufacturers is quite small and the motorhome market is very limited. There are some motorhome chassis manufacturers that serve primarily the motorhome industry and they have no opportunity to utilize the ABT provisions through averaging. There are some motorhome chassis manufacturers that serve only the motorhome industry as well as otherwise exempt segments (e.g., emergency vehicle and military segments). They also have no opportunity to utilize the averaging provisions of ABT. Both categories would have no choice but to compete for a limited pool of credits that might be available from manufacturers of larger fleets, assuming such credits are available. Significantly, EPA has made no analysis of the availability or price of such credits so cannot simply rely on the expectation that such provisions would be available and at a reasonable cost. It is EPA's burden to show its regulations impose reasonable costs. The significant cost numbers we provide below, for example, do not even begin to include the potential costs of buying credits on the market. [EPA-HQ-OAR-2014-0827-1261-A1 p.16-17]

There are also some chassis manufacturers that serve not only the motorhome industry but also multiple truck industry segments and are part of larger entities with larger fleets. These manufacturers are unlikely to utilize ABT to take care of motorhomes as doing so would increase the cost of chassis sold to more important, larger and significantly more profitable business segments. Thus, for many manufacturers of motorhome chassis, compliance with the Proposed Rules would hurt their ability to compete in the more important, larger and more profitable segments that they rely on for the bulk of their revenue. [EPA-HQ-OAR-2014-0827-1261-A1 p.17]

Moreover, it is our understanding that most vocational vehicle manufacturers will face their own difficulties meeting the standards set by EPA, at least without significant changes to EPA's GEM model for vocational vehicles. Given these circumstances, there may very well be no credits available for ABT within the larger manufacturers' fleets or from other regulated parties. Again, EPA has provided no analysis of the availability of credits for averaging or trading within and among these manufacturers, and simply assumes, without data, that such options will be available at reasonable cost. This kind of assumption is insufficient to support the outcomes that would result with this rulemaking. [EPA-HQ-OAR-2014-0827-1261-A1 p.17]

VII. If not exempt entirely, EPA should establish separate standards for motorhomes

In the event EPA concludes that it will not exempt motorhomes entirely to maintain harmonization with the NHTSA exemption, see earlier discussion above in section IV, it is fair and reasonable that separate and more feasible standards for motorhomes be established. Proposed standards are not feasible for motorhome chassis manufacturers, as these entities are generally not in a position to utilize ABT to meet the standards and the technologies are not cost-effective. For LHD motorhomes, we support adopting only the 2021MY LHD vocational vehicle standards and maintaining those standards through 2027. For MHD and HHD motorhomes, the adoption of standards that would only require MHD and HHD
motorhomes to be equipped with more efficient engines and tires could be adopted. As discussed by EPA in the Proposed Rules, standards based on improved transmissions for MHD and HHD vocational vehicles/motorhomes would not be feasible since the engine and transmission are manufactured by non-integrated manufacturers. [EPA-HQ-OAR-2014-0827-1261-A1 p.23]

Complying with standards based on the above recommendations in lieu of those proposed would reduce the incremental per vehicle cost of compliance by approximately 75% and this would reduce if not eliminate the negative economic impacts seen in the four scenario analysis discussed in the previous section. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

VIII. Custom chassis manufacturer exemption

EPA has requested comment on whether “customs chassis manufacturers,” like emergency vehicles, should be exempt from some of the Proposed Rules and how that term should be defined. While we believe that an exemption is appropriate for all motorhomes, or at minimum, separate standards, we will provide some information in response to this request. However, RVIA strongly urges EPA not to take the position that a custom chassis manufacturer exemption will resolve all the issues RVIA has raised in this submission. While custom chassis manufacturers do deserve some special consideration, especially since they particularly cannot use ABT provisions to meet infeasible standards or the costs of the Proposed Rule, this does not mean other motorhome chassis manufacturers do not merit separate and more achievable standards. This is especially true since these other motorhome chassis manufacturers are also unlikely to be able to use ABT to solve their non-compliance problems due to the fact that most other vocational vehicles that might generate credits for motorhome chassis manufacturers are also unable to comply under the GEMS program. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

With the above qualifications in mind, RVIA would support a standard for custom chassis manufacturers that would be solely based on fitting vehicles with more efficient engines and tires. This is similar to that proposed for emergency vehicles. This would allow feasible and reasonable technologies to be applied to reduce emissions rather than fully exempting customs chassis manufacturers from all standards. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

To reduce the potential for such a provision providing some smaller manufacturers with a competitive advantage, RVIA proposes that all manufacturers, regardless of size, have the opportunity to certify a motorhome chassis to the custom chassis manufacturer standards up to a specified volume threshold. We suggest the following thresholds: [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

1,000 LHD (class 2b-5) motorhome chassis

1,000 MHD (class 6-7) motorhome chassis

2,500 HHD (class 8) motorhome chassis

We note that such a definition is consistent with prior EPA practice. EPA permits small volume test groups to be certified as if they were small volume manufacturer test groups. See 40 C.F.R. § 86.183801 (Small volume manufacturer certification procedures). [EPA-HQ-OAR-2014-0827-1261-A1 p.24]

The same logic should apply to large, multi-vehicle manufacturers who only produce low volumes of chassis designed exclusively for use in the motorhome industry. [EPA-HQ-OAR-2014-0827-1261-A1 p.24]
EPA and NHTSA should recognize the unique nature of the motorhome sector, including its exceptional cost-sensitivity, low mileage and low production of its vehicles, and its inability to absorb significant and cumulative regulatory costs. [EPA-HQ-OAR-2014-0827-1261-A1 p.27]

Given these costs, which exceed any benefits, EPA should put motorhomes in a category separate from other vocational vehicles. If they are not exempt, they should be subject to a different and more feasible set of regulations which impose more reasonable costs. Such standards could be: [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

- For LDH motorhomes, EPA should adopt only the MY 2021 LHD vocational vehicle standards and continue them through MY 2027. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

- For MHD and HHD motorhomes, EPA should require only more efficient engines and tires. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

Custom chassis manufacturers merit special recognition given their low volumes and inability to average vehicles across fleets or otherwise make economic use of the ABT provisions. These vehicles should only be required to use more efficient engines and tires. Customs chassis should be defined by volume of production set forth in section VIII to avoid unintended competitive harms, in accordance with EPA precedent. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

26 RVIA does not assert that motorhomes belong in a separate regulatory category other than vocational, but that, if regulated, it should have its own separate standards within the vocational group, just as emergency vehicles are regulated separately.

27 The analysis below only focuses on Alternative 3 as presented in the Proposed Rules. Alternative 4 would be even more problematic, but for purposes of these comments, was not modeled.

28 Clearly, if requirements under Alternative 3 are not feasible, imposition of Alternative 4 would be even less feasible.

Response:

The agencies’ responses to comments related specifically to companies meeting the definition of small business under SBA regulations are addressed in Section 15.4 of this response to comments document.

As was mentioned above in Section 6.2.3, use of simplified GEM as an optional certification tool can be justified in cases where either the typical duty cycle of the vocational application is poorly represented by any of the three final test cycles; where we find that the default GEM vehicle characteristics are so different from real world characteristics (for example engine power to vehicle weight ratio) that use of full GEM with active simulation of actual driveline parameters would not reasonably test the effectiveness of applied technologies; and where the certifying manufacturer produces small volumes of vocational chassis using a non-integrated business model where driveline optimization is not feasible and other transmission improvements would either be ineffective or not cost-effective.

Upon careful consideration of all the comments related to vocational vehicle chassis manufacturers who produce small volumes of specialized or non-diversified products, we are adopting optional standards
for seven applications of vocational vehicles that we are calling custom chassis. Although this issue has some implications for our consideration of small business concerns, the custom chassis provisions discussed in the proposal were not intended to be limited to small businesses, and are not so limited in the final rules.

Discussions with representatives on our Small Business Advocacy Review Panel included exploration of a low volume production threshold below which some manufacturers may avoid some obligations of this regulation. Consistent with the recommendations of the Panel, the agencies requested comment on how to design a small business vocational vehicle program, including comments on a possible small volume threshold below which some small business exemption may be available. Some commenters addressing this issue supported a small volume threshold for small businesses of either 200 vehicles per year, or a different threshold set based on the market share of the entity, or other low-volume thresholds ranging as high as 26,000 vehicles per year. We received adverse comment from Daimler stating it would be unfair to make less stringent standards available solely on the basis of sales volume, because if a technology exists for one manufacturer, it is available to all manufacturers. We received adverse comment from OshKosh that less stringent regulations on a limited production volume stifles a custom chassis manufacturers’ opportunity to grow their business.

Upon consideration of these comments, the agencies are not finalizing a broad sales volume threshold below which a vocational chassis manufacturer may certify under the optional standards. Instead we are adopting an optional custom chassis program that is available to businesses of all sizes and production volumes. In addition to the flexibilities described in Section 15.4, the custom chassis program includes some flexibilities for small businesses that will not be available to large manufacturers. Specifically, we are permitting small businesses to use credits generated in the primary program as part of a custom chassis compliance plan, and we are permitting small businesses that manufacture drayage tractors to certify a small number of these vehicles each year to the custom chassis standards otherwise applicable to transit buses. See Section V.C.3 of the Preamble.

In response to the comment requesting clarification on our reasons for adopting a non-GEM design standard option for motor homes, cement mixers, and emergency vehicle chassis, this is because we have determined these vehicles to have the least number of feasible technologies that can be applied in Phase 2. Emergency vehicles and concrete mixers have been determined by the agencies to essentially need only to apply low rolling resistance tires in addition to certified engines and low leakage air conditioning. Motor homes have been determined to apply these technologies as well as tire pressure systems. We generally agree with the commenters from the motor home sector that there are very few technologies likely to prove cost-effective for these vehicles, given the typically low miles traveled by these vehicles. See Section 6.3.7 above for more details on why we conclude that tire pressure systems are feasible. Where a manufacturer of these vehicles is able to apply the same technology on all of its production without averaging, we offer the non-GEM option as a compliance flexibility to avoid some of the certification burden associated with running GEM. We were unable to identify other custom chassis technology packages that we believed could be applied at 100 percent adoption rate; thus, averaging (and use of GEM) was deemed necessary for other vehicles.

In response to the comment with concerns about the custom chassis program assuming a single weight class for each vehicle type, we have concluded this simplification is valid for preventing stranded averaging sets and easing the compliance burden for low-volume manufacturers. We fully expect manufacturers to continue producing vehicles in varying weight classes as demanded by the market. The regulatory simplification does not mean that custom chassis vehicles actually must be produced at

\[195\] See proposed rules at 80 FR 40295, July 13, 2015.

\[196\] Averaging sets for custom chassis include all weight classes of a single custom chassis subcategory.
the weight corresponding to the assumed regulatory category. For example, a manufacturer may produce 100 motor homes where 90 are MHD and 10 are HHD. All of these may be simulated as MHD in GEM and comprise one averaging set, and credits for purposes of averaging will be calculated according to the actual vehicle-level regulatory useful life. The actual engines used in these vehicles will separately be certified to the applicable engine standard. See Section 6.5 for responses to comments on certification of custom chassis, and see Section V.D of the Preamble for more discussion of this process.

### 6.4.2 Off-Road/Low Speed Vehicles

**Organization:** Clarke Power Services

1031.631 Exemption of vocational vehicles intended for off-road use: The chassis of vehicles in the vocational industries in general and the off-road vehicles take a tremendous amount of load and torque (twisting). This kind of use guarantees that the chassis will be worn out prior to the modifications that were used to prepare the vehicle to be a vocational truck. The work box, crane, hydraulic lifts, etc. that are required in the vocational application are expensive and are transferred to the next chassis. When the replacement chassis is a Glider, then this commenter believes that the flexibility should be granted with regard to the engine choice. This commenter recommends that one sentence should be struck from 1031.631; that sentence being “This section does not exempt engines used in vehicles from the standards of 40 CFR part 86 or part 1036” atop of page 40655. Striking this sentence will give maximum flexibility once the agencies realize the vocational equipment being described may be older than MY 2014. [EPA-HQ-OAR-2014-0827-1005-A1 p.5]

**Organization:** Rubber Manufacturers Association (RMA)

The Agencies Should Continue to Exempt Vehicles Equipped with Tires with a Maximum Speed Rating at or Below 55 mph

In the Phase 1 rulemaking, EPA exempted a vehicle based solely on the use of tires with a maximum speed rating at or below 55 mph (“speed restricted tires”). In the Phase 2 NPRM, the agencies are proposing to eliminate this exemption because “the agencies are concerned that tires are so easily replaced that this would be an unreliable way to identify vehicles that truly need special consideration.” 80 Fed. Reg. at 40295. While RMA recognizes the concern that the agencies express in eliminating this exemption, RMA believes that the speed restricted tires merit special consideration. [EPA-HQ-OAR-2014-0827-1304-A1 p.15] [EPA-HQ-OAR-2014-0827-1933-A1 p.2]

These tires typically are designed to achieve tire performances such as high load carrying capacity and durability that are specific to the vehicles on which they are installed, which often are used in off-road applications. A tire that is appropriate for use on a vehicle used for off-road applications would not see a meaningful fuel consumption benefit due to the use of low rolling resistance tires due to its typical drive cycle at low speeds on aggressive terrain. A speed restricted tire would not be suitable for use on a vehicle that does not specify these tires. The concern that this type of tire could be installed on a vehicle that otherwise does not require these tires is not founded, since speed restricted tires would not perform appropriately on other types of vehicles. For example, if a speed restricted tire were installed on a vehicle that is used in highway applications, the integrity of the tire would be impaired at highway speeds, and the operator of the vehicle would not be satisfied with its performance. [EPA-HQ-OAR-2014-0827-1304-A1 p.15] [EPA-HQ-OAR-2014-0827-1933-A1 p.2]
OEMs specify the vehicle’s service and application and comply with the tire and wheel selection requirements of FMVSS 120, and, per FMVSS 119, such tires are marked with “Max. speed __ km/h (___ mph),” e.g., 55 mph (90 km/h), 50 mph (80 km/h), 35 mph (56 km/h). An exemption for tires speed-restricted at or below 55 mph is still appropriate, as such tires are designed for off-road applications or on-road 20%/off-road 80% applications. Such vehicles are generally governed or speed restricted by the vehicle manufacturers, e.g., OEMs. Subsequent changes to tires for higher operating vehicle speed ratings will result in generally larger tires for load capacities, and/or tire designs not appropriate for the off-road application and incidental highway transport. [EPA-HQ-OAR-2014-0827-1304-A1 p.15] [EPA-HQ-OAR-2014-0827-1933-A1 p.2]

Rather than discontinuing the exemption adopted in Phase 1 of this regulation for vocational vehicles with tires restricted to 55 mph (90 km/h), EPA/DOT should continue this exemption, as well as consider adding a GEM input option to exempt on/off road vehicles and their tires. Again, such tires are marked in accordance with the FMVSS 119 tire safety requirements. [EPA-HQ-OAR-2014-0827-1304-A1 p.16] [EPA-HQ-OAR-2014-0827-1933-A1 p.3]

Examples of such on/off road vehicles include:

Mobile Crane “DOT” vehicles with DOT tires and loads adjusted for maximum speed 55 mph that are greater than highway/vocational truck tires rated @ ≥ 62 mph (100 km/h). Low bed or high cube trailers requiring high load capacities at lower speed ratings, e.g., ≤ 55 mph. Mining and Logging “ML” tires (e.g., TRA 10.00-20 ML) @ maximum speed 50 mph (80 km/h) @ intermittent highway service (maximum 50 miles (80 km) in any 1-1/2 hour period) [EPA-HQ-OAR-2014-0827-1304-A1 p.16]

RMA appreciates the opportunity to review the GEM P2v2.1 summary. RMA continues to support the exemption of certain vocational vehicles from the subject regulations. [EPA-HQ-OAR-2014-0827-1933-A1 p.2]

**Organization:** Truck & Engine Manufacturers Association (EMA)

The agencies should restore an exemption from the Phase 1 Standards for vehicles equipped with speed-rated tires. Vehicles equipped with speed-rated tires operate more like nonroad vehicles than heavy-duty on-highway vehicles. In that regard, speed-rated tires are typically large and do not have assigned rolling resistance values. Consequently, inasmuch as those vehicles are not equipped or designed for efficient on-highway operation, they should not be regulated as if there were. [EPA-HQ-OAR-2014-0827-1269-A1 p.47]

**Organization:** Daimler Trucks North America LLC

**Off-Road and Low Speed Vocational Exemptions** – The agencies request comment on the proposed revisions to the off-road and low-speed vocational vehicle categories, including whether the rated speed of the tires should be retained, and whether vehicles intended to be covered by the provision have characteristics that are captured by the proposed criteria. 80 FR 40545. DTNA agrees with EPA that the qualifying criteria related to the design and use of the vehicle should be retained. We agree that the speed rating of the tire is not as reliable a factor as the other factors listed, GAWR of 29k lbs or more, speed attainable of not more than 33 mph in two miles, or speed attainable of not more than 45 mph in two miles with unloaded vehicle weight not less than 95% of the GVWR. [EPA-HQ-OAR-2014-0827-1164-A1 p.32-33]

**Organization:** Terex Corporation
My final comment number four is regarding page 40186. It says that six by six and eight by eight vehicle configurations are only manufactured for specialized vehicles that require extra traction for off-road applications. They are very low volume sales, and their increased fuel consumption and CO2 emissions are not significant in comparison to the overall reductions of the Phase 2 program.

Therefore, Terex suggests that vehicles with six by six and eight by eight configurations must be added to the list of exemptions under the proposed 1037.635(b) concerning glider kits. Because these vehicles operate off road, they are far more susceptible to wear and tear type frame damage that is premature compared to the engines that were designed to operate for a million miles. For this reason, gliding six by six and eight by eight vehicles is and has always been common industry practice, even before the arrival of after treatment systems on diesel engines.

Organization: Innovus Enterprise LLC

§ 1037.631 Exemption for vocational vehicles intended for off-road use.

Page 40521, Paragraph (2) Off-Road Exclusion Petition Process...outlines the spirit and intent of the Off-Road Exclusion by stating: “An exemption was warranted because these vehicles operate in a manner essentially making them incompatible with fuel saving and emission reduction technologies, such as performing work in an off-road environment, being speed restricted, or having off-road components or other features making them incompatible for roadways.” While we totally agree with this line of thinking and rational, we do not think the spirit and intent of this exemption is sufficiently captured in the proposed paragraph §1037.631(a) Qualifying criteria. [EPA-HQ-OAR-2014-0827-1116-A1 p.6]

The original wording in this section had two qualifying criteria, (a)(1) and (a)(2) either of which were qualifying factors alone. However the original (a)(1) for 55mph speed rated tires is being deleted evidently because tires can be changed out afterwards. This makes sense to us as well. However, that leaves a much narrower criteria which would now require both the new (a)(1) and new (a)(2) in order to qualify. This dismisses many other potential heavy-duty vocational vehicles designed for off-road use which meet the spirit and intent and rational for this exemption. [EPA-HQ-OAR-2014-0827-1116-A1 p.6]

Looking closer at the proposed/new (a)(1). This is good criteria and almost verbatim with the spirit and intent for this exemption. It covers the mandate for off-road environment, installed components and features making them unsuitable for normal highway operations. [EPA-HQ-OAR-2014-0827-1116-A1 p.6]

The criteria in the new proposed (a)(2) would drive this entire exemption to a vehicle with a GAWR at or above 29000; or vehicle’s speed limited to 33 mph or 45 mph. The axle rating is by no means by itself a rational criteria for this exemption other than the fact it is just an extraction from the definition of heavy duty off-road vehicle in 49 CFR 523.2 (2)(ii)(A). It appears as if the wording for this exemption was based on this same definition as the speed limitation criteria is also the same. We must also note: the definition for heavy duty off-road vehicle in 49 CFR 523.2 also contains the single criteria factor of 55 mph speed limited tires. With this, it is rational to believe the 33 mph or 45 mph specific speed limitation was never intended to be a determining factor alone for criteria in the heavy-duty off-road vehicle definition. It is also rational to believe a vehicle’s capability to employ fuel saving...
measures or emission reduction technologies was not part of the determining factor when this heavy-duty off-road vehicle definition was scripted. [EPA-HQ-OAR-2014-0827-1116-A1 p.6-7]

**Innovus Enterprise LLC Suggestion:** § 1037.631(a) Qualifying criteria. Change the sentence referring to the criteria of paragraph (a)(1) and criteria of paragraph (a)(2) to read “or” instead of “and” as defining criteria. [EPA-HQ-OAR-2014-0827-1116-A1 p.7]

**Rational:** This off-road vocational vehicle exemption makes total sense if in application the basis for having it is adequately portrayed and executable in the regulations. Continuing with the proposed criteria which includes elements of no logical affect with respect to the spirit and intent of the rule (GAWR) or limiting it to criteria originally designed for a definition of little relevance to the main arguments for this exemption (capability for fuel savings/emissions reduction) detracts from the hard work many public and private individuals have put into developing this ruling as well as those small business’ who could potentially be slighted. [EPA-HQ-OAR-2014-0827-1116-A1 p.7]

**Organization:** Autocar, LLC

Autocar’s products are of a particular vehicle type (low-speed, frequent-stop, stationary-application trucks) that will not produce the environmental benefits intended by the proposed technologies, beyond the use of an emissions-compliant engine.[EPA-HQ-OAR-2014-0827-1233-A1 p.2]

The exceptions granted should impose less stringent standards. Some of the proposed GHG and fuel saving technologies are feasible for Low-speed/Frequent-stop Vehicles, and some are not. All manufacturers should install compliant engines, so long as they are made available by engine manufacturers. Synthetic axle lubricant is also within reach currently. Also, advances can be made in reducing the leak rate of refrigerant from A/C systems. All of these technologies should be required at reasonable levels with appropriate lead times for development in connection with Low-speed/Frequent-stop Vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.14-15]

**The Types of Vehicles Autocar Assembles Should be Exempt on the Same Basis as Special Purpose Tractors and Off-Road/Low-Speed Vocational Vehicles.**

2.2 Low-speed/Frequent-stop Vehicles have a unique design and purpose. Like the exempted special purpose tractors and off-road/low-speed vocational vehicles, Low-speed/Frequent-stop Vehicles are designed to operate at low speeds, and infrequently achieve highway speeds. They operate in one or more of the following states: (A) low-speed, as in the case of street sweepers; (B) stationary, as in the case of concrete pumpers and conveyers; or (C) continuous stop-and-start, as in the case of refuse collection trucks. The chassis of these vehicles are designed to support these severe operational cycles demanding low speed, stationary power or frequent stops. [EPA-HQ-OAR-2014-0827-1233-A1 p.7-8]

2.3 Low-speed/Frequent-stop Vehicles have unique duty cycles. A refuse truck spends most of its time in collection mode, moving at low speeds from house to house or dumpster to dumpster and emptying trash receptacles into the refuse bin of the truck. It is common for a residential refuse truck to make 800-1,000 (and as many as 1,500) pick-ups in a day. A refuse truck typically only operates at highway
speeds on its way to and from its pickup route, and to and from a transfer station or landfill. The truck often has to run its PTO to activate hydraulic lifting arms to dump refuse containers into the bin, or a packer blade to compact the trash in the bin. The truck stops while waste is being loaded. Compaction can occur while the truck is stationary or moving. [EPA-HQ-OAR-2014-0827-1233-A1 p.8]

Similarly, a street sweeper spends most of its time in sweeper mode, moves at low speeds while removing debris from the street, and makes numerous turns and stops due to debris patterns, traffic and other obstructions. Again, a sweeper typically only operates at highway speeds on its way to and from its sweeping route. The operating conditions for Low-speed/Frequent-stop Vehicles necessitate the use of the lower gears of automatic transmissions and often axle ratios of 5.29 or higher. [EPA-HQ-OAR-2014-0827-1233-A1 p.8]

2.4 Some of the Agencies’ Proposed Technologies for Low-speed/Frequent-stop Vehicles are feasible, and some are not. Autocar’s comments on the feasibility and potential for penetration of the proposed technologies for reduction of GHG emissions and increased fuel efficiency for Low-speed/Frequent-Stop Vehicles are set forth at Appendix A. Some of the proposed technologies are technically possible, but many will be ineffective for Low-speed/Frequent-stop Vehicles. [EPA-HQ-OAR-2014-0827-1233-A1 p.8]

Response:

We interpret Clarke’s comment to advocate for allowing new vocational vehicles qualifying for the off-highway provisions of § 1037.631 to also be eligible for relief from engine emission standards under the provisions that apply for glider vehicles. These two sets of provisions apply independently – i.e. they are not mutually exclusive. As such, the proposed statement stating that § 1037.631 does not exempt engines from engine standards is true. If a vehicle qualifying for relief under § 1037.631 should also qualify for relief as a glider vehicle, this would be addressed under § 1037.635. Refer to Section 14.2 for details on how the agencies are responding to comments on use of gliders in vocational applications.

We interpret Terex’s comment requesting axle configuration as a criterion in eligibility for relief under our glider provisions as a comment requesting the agencies to consider axle configuration in applicability under the Phase 2 vocational vehicle regulations. We disagree that the presence of a six by six or eight by eight axle configuration is an appropriate basis to qualify vehicles as off-highway for purposes of applying less stringent standards. While this feature may be indicative that the vehicle will not experience purely highway cycles, it is not determinative regarding the feasibility of fuel saving technologies. We believe that to the extent vocational vehicles with unusual axle configurations also have features that qualify them for exemption or less stringent standards under the final Phase 2 program, we don’t need to add this as a supplemental criterion. For purposes of Phase 2 certification, vehicles with more than two drive axles will be certified as a 6x4. In Section 2.2 of this response to comments document, we address comments related to simulating unusual axle configurations in GEM.

Commenters failed to address the reasons described in the proposed rule for removing speed-limited tires from the qualifying criteria for off-highway used under § 1037.631. We are adopting these revisions because we are concerned that manufacturers would too easily be able to install tires with a low speed rating to avoid standards, even in cases where the customer or the application does not warrant those tires. Moreover, we believe that the other qualifying criteria are effective apart from considerations of tire ratings for identifying vehicles that warrant relief from greenhouse gas standards. This is especially the case, given that we are adopting less stringent optional CO₂ standards for “custom-chassis” vehicles that qualify for some but not all of the criteria identified in § 1037.631 (see Section 6.2.3).
While we continue to believe that speed-limited tires are not an appropriate basis to qualify vehicles as off-highway for purposes of applying less stringent standards, we are adopting a vehicle-based speed criterion that accomplishes this objective more reliably and more directly. In particular, the regulation allows manufacturers to qualify for off-highway consideration for vehicles with maximum speed below 55 miles per hour (see 40 CFR 1037.631(a)(2)(iv)). Such vehicles would be expected to rarely travel long distances, and are more likely to involve operations separate from transport.

It is not clear why Innovus believes an axle load rating criterion is not germane to consideration of off-highway use. Mobile cranes and mining and logging vehicles, for example, are often designed with high axle load ratings because of their off-highway functions. If a vocational vehicle is designed simply to transport heavy loads but is not speed-limited, it would then not qualify under the provisions of § 1037.631(a)(1).

Innovus and Autocar describe concerns for vehicles that meet one or the other of the criteria from § 1037.631(a)(1) and (a)(2), but not both. Since § 1037.631 exempts vehicles from all greenhouse gas requirements, we do not want vehicles to qualify for the exemption if manufacturers can apply technology to reduce CO$_2$ emissions. At the same time, we are aware that vehicles meeting one of the two conditions of § 1037.631 may not be able to apply emission control technology to the same degree as other vehicles. We are therefore creating alternate “custom-chassis” standards for such vehicles. We believe this appropriately pairs the stringency of standards with the capabilities and operating characteristics of these vehicles (see RTC 6.2.3). A few of Autocar’s specific vehicle types warrant closer attention:

- Street sweepers with a maximum speed at or above 55 mph are designed for off-highway use, but not in a way that allows us to exempt them from all CO$_2$ standards. Manufacturers of these vehicles choose to design their vehicles to operate at highway speeds, presumably to allow for substantial driving between sweeping jobs. These vehicles should be expected to apply a certain level of technology for reducing CO$_2$ emissions.
- Refuse trucks clearly spend a disproportionate amount of time operating at slow speeds; however, this only makes it more important to consider strategies such as hybrid powertrains and idle-reduction technologies. Exempting these vehicles from all CO$_2$ standards would be a missed opportunity of the first order.

### 6.5 Compliance Provisions and Flexibilities for Vocational Vehicle Standards

**Organization:** Volvo Group

Need clarification on a manufacturer’s ability to partially certify a product offer as custom chassis, while the same offer in the same application is certified to the primary standard in a separate family.

Need clarification that credits can be averaged across custom chassis types within a weight class.

**Response**

The final rules allow manufacturers to certify some vehicles to the optional custom chassis standards using simplified GEM while certifying similar vehicles in the same model year to the primary standards using full GEM. Each new application for certification is associated with a standard, and carry-over certificates would be associated with the same standard as the previous year. Any credits generated
against the custom chassis standard must remain within the narrow averaging set of that custom chassis type, and may not be traded.

6.5.1 Selection of Subcategory for Certification

Organization: Volvo Group

Vocational Vehicle Segmentation Regression Modeling

In the previously noted NREL report two regression models were put forth (see sections 3.1.1 and 3.1.2) as a means to segment vocational vehicles into regulatory sub-categories. Both models utilize multiple logistic regressions that categorize vehicles into one of two sub-categories: high-speed or low-speed. In the report NREL states misclassification errors of 25%-30% where vehicles which should fall into the high-speed cluster were classified in the low-speed cluster, while errors for low-speed vehicles being misclassified as high-speed were 6-13%. Since the agencies have stated they will rely on hybrid and engine stop-start technologies in lower speed subcategories (technologies which Volvo has commented are not currently commercially viable and technically infeasible in HHD) any error incorrectly placing more vehicles into lower speed subcategories on aggregate will result in an unintended artificial stringency increase. [EPA-HQ-OAR-2014-0827-1928-A1 p.10-11]

Without understanding proposed stringency changes from the NPRM levels, Volvo cannot sufficiently review these models in order to determine their total impact on our ability to comply with the proposed rule; however, it is inappropriate to consider a segmentation criteria that generates large errors resulting in significant compliance risk to OEMs. [EPA-HQ-OAR-2014-0827-1928-A1 p.11]

Organization: Bendix Commercial Vehicle Systems, LLC

Proposed Phase 2 Standards for Vocational Vehicles, (1) Proposed Subcategories and Test Cycles

The agencies request comment on the method for assigning vocational chassis to regulatory subcategories. Bendix supports the proposed approach to align with the objective to allow manufacturers to certify their chassis over appropriate duty cycles, while maintaining the ability of the market to offer a variety of products to meet customer demand. [EPA-HQ-OAR-2014-0827-1241-A1 p.8]

In addition to providing data on the characteristics of three overarching classes of vehicle, the Oak Ridge analysis provides a path for segmenting vocational vehicles in spite of the limited information that an incomplete chassis can provide.14 The full prediction model leads to an appropriate categorization of high- or low-speed behavior with 89 percent accuracy, with prediction of low-speed behavior 94 percent accurate. Limiting the model to engine speed at 65 mph provides less accuracy (81 percent) but may allow for more flexibility to changes to the fleet over time (such as a decreasing use of manual transmissions in all classes, or a change in fuel use for applications that were previously predominantly gasoline or diesel). [EPA-HQ-OAR-2014-0827-1896-A1 p.5]

The ability for a manufacturer to more accurately project a new vehicle’s likely duty cycle allows better assessment of both the regulatory category of the vehicle and technologies that are most applicable. Correctly identifying high-speed vehicles, particularly ones which now show even greater operation at highway cruise speeds than first proposed, would allow for greater application of aerodynamic
improvements, since there would be a clear need and payback. Similarly, the ability to more clearly define low-speed operation, which now should also include greater idle operation time, would incentivize greater application of idle reduction technologies. [EPA-HQ-OAR-2014-0827-1896-A1 p.5]

**Organization:** Eaton Vehicle Group

Also, the EPA requested comments if “all Hybrids should be tested over the urban cycle only.” We understand the EPA motivation and the underlying assumption that the market will accept Hybrids in urban applications only. However, Phase 2 spans a long interval in which HD line haul Hybrids are feasible and would not be designed for stop-and-go traffic, as shown above. The EPA should allow OEMs to certify Hybrids on the Urban cycle, but should give the option to certify over another cycle if that is more appropriate. [EPA-HQ-OAR-2014-0827-1194-A1 p.19]

**Organization:** American Automotive Policy Council

For class 2b-5 vocational vehicles, the rpm and vehicle speed based cutpoints proposed by the agencies to define the “Urban” duty cycle do not properly identify the classes of vehicles intended. This is likely due to assumptions about engine test speeds that were made based on vehicles prior to the implementation of Phase I Heavy-Duty GHG engine standards. AAPC proposes slight modifications to the cut points used to classify vehicles for these duty cycles. Additionally, AAPC believes that only the highest numerical axle ratio in a 2-spd or greater axle application should be used for classification purposes. AAPC recommends the following changes to the “Urban” duty cycle cut points: [EPA-HQ-OAR-2014-0827-1238-A1 p.32]

- For 2b-5 spark ignited gasoline vehicles, the 55mph cut point should be increased from 50% to 65% of max engine test speed [EPA-HQ-OAR-2014-0827-1238-A1 p.32]

- For 2b-5 compression ignition vehicles the 55mph cut point should be lowered from 90% to 65% of max engine test speed. [EPA-HQ-OAR-2014-0827-1238-A1 p.32]

**Organization:** Allison Transmission, Inc.

**Manufacturers Should Be Allowed To Select Appropriate Test Cycle**

EPA and NHTSA have proposed an equation for deciding how different chassis configurations will be assigned to vocational vehicle subcategories. The agencies have also requested comment on this approach and whether manufacturers should “have the freedom to select a test cycle without any need for EPA or NHTSA approval.” [EPA-HQ-OAR-2014-0827-1284-A1 p.43]

Allison is generally supportive of the vocational vehicle segmentation as proposed; however, Allison also believes that vehicle manufacturers should have the option to select the test cycle without EPA or NHTSA approval in order to better match test cycles with a vehicle’s end use. If the vehicle manufacturer could select the cycle, then there would be less opportunity for unintended consequences such as changing the number of transmission gears in order to move a vehicle from one test cycle to the next. [EPA-HQ-OAR-2014-0827-1284-A1 p.43]

As it turns out, a vocational vehicle with this 8-speed transmission would always fall into the Regional subcategory – by a large margin. This is not in-line with the expectation that most vehicles would be classified as Multi-Purpose. Allison requests that EPA and NHTSA revise the classification approach to account for ATs with 8 or more speeds. [EPA-HQ-OAR-2014-0827-1284-A1 p.41]
In order to avoid classifications that do not reflect the actual work done by such vehicles, the available calibrations for 8-speed transmissions might be restricted. Although restricting the number of gears would avoid the adverse classification, it would also result in a less fuel efficient vehicle, with greater GHG emissions, when the vehicle traveled at highway speeds. Again, such a result should be avoided in the final rule and such vehicles should be able to be classified as Multi-Purpose or Urban. [EPA-HQ-OAR-2014-0827-1284-A1 p.41]

**Maximum Engine Test Speed Is Flawed**

EPA and NHTSA are considering new vocational vehicle weightings for Urban vehicles. Under these weightings, transient operation would be at 92%, operation at 55 MPH at 7%, and 65 MPH operation at 1%. [EPA-HQ-OAR-2014-0827-1892-A1 p.9]

The applicable definition to qualify for treatment as an Urban vehicle is that the vehicle must be > 90% of max test speed at 55 MPH. But when the math is examined closely, the following result is obtained: 65/55 x 90% of maximum test speed results in the engine running at 106.4% of maximum test speed. For example, with a maximum engine test speed 2000 rpm, 90% of test speed at 55 MPH = 1800 rpm; engine speed at 65 MPH = 2124 rpm engine speed. [EPA-HQ-OAR-2014-0827-1892-A1 p.9]

Maximum engine test speed (for constant-speed engines), however, is defined as no-load governed speed (speed which yields zero torque). By definition, the engine cannot operate under power above maximum test speed. In order to correct this error, Allison recommends zero 65 MPH cycle weight be used in the Urban cycle. [EPA-HQ-OAR-2014-0827-1892-A1 p.9]

**Regional/Multipurpose Vehicle Breakpoint**

Upon closer review of the Proposed Rule, however, it appears that there are a number of configurations that are 2 points from the Regional/Multi-Purpose breakpoint. Specifically, there are construction vehicles with 7-speed transmissions classified as Regional when the majority of their use is expected to be low speed on/off road duty – a use pattern which is more in line with the Multi-Purpose duty cycle. In addition, we are currently encouraging the vehicle OEMs to configure the transmissions as 6 speeds so they will get the best possible fuel efficiency under all operating conditions. But the Proposed Rule could incentivize the configuring of transmissions at less than 6 speeds in order to change classification (which would also result in a lower stringency level). [EPA-HQ-OAR-2014-0827-1284-A1 p.40]

Therefore, Allison would recommend reducing the breakpoint between Regional and Multi-Purpose classifications from 75 to 70 to address this issue. Allison has examined data from over 8,000 vehicles using an Allison transmission. Based on this data, adjusting the breakpoint would change the classification split to be: [EPA-HQ-OAR-2014-0827-1284-A1 p.40]

Regional 3%; Multi-purpose 95%; Urban 2%

This is more in line with what we would expect to occur in the real world commercial use of vocational vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.40]

In the vocational vehicle section of the Proposed Rule and RIA, all of the assumptions regarding vocational vehicles boil down to the population splits shown below. It is very strongly influenced by assumptions about the distribution of the group that MOVES calls “short haul straight trucks.” [EPA-HQ-OAR-2014-0827-1284-A1 p.40]

[Chart, 'Cycle weightings by percent of population', can be found on p.40 of docket number EPA-HQ-OAR-2014-0827-1284-A1]
EPA indicates in the memorandum that “[a]nother simplification being considered is to assign each type of custom chassis certified with simplified GEM to a single weight class that represents the majority of vehicles of that type.” Allison believes, however, that this would result in an oversimplification of the complexities of medium heavy-duty (“MHD”) and HHD vocational vehicles. For example, emergency vehicles are found in HHD in addition to MHD. [EPA-HQ-OAR-2014-0827-1892-A1 p.5]

An unintended consequence of oversimplification would also be to deter innovation and responses to market changes over the long time period covered by the Phase 2 Rule. Specifically, vehicles that are numerous in one classification today would likely remain in this classification due to a regulatory disincentive to downsize or “right size” based on the needs of a specific intended use. [EPA-HQ-OAR-2014-0827-1892-A1 p.5]

**Organization:** California Air Resources Board (CARB)

**Comment - Assignment of vocational subcategories**

The NPRM requests comment on the assignment of vocational chassis to regulatory categories. CARB staff supports U.S. EPA and NHTSA’s assignment of regulatory subcategories for vocational vehicles. We recognize the broad range of uses in the vocational sector which dictates the use of many different test cycles to fully encompass all of the vocational duty cycles. However, there is also a need for simplicity in regulating vocational manufacturers to reduce unnecessary burden on both manufacturers and regulators. The proposal of nine subcategories for the vocational sector addresses and balances these two competing factors. The proposal to allow manufacturers to request a different duty cycle would provide necessary flexibility for those vocational vehicles that are not properly accounted for by these simplified subcategories. [EPA-HQ-OAR-2014-0827-1265-A1 p.63]

The NPRM requests comment on allowing vocational vehicle manufacturers to request a different duty cycle versus allowing them to select a test cycle without any need for U.S. EPA or NHTSA approval. CARB staff supports U.S. EPA and NHTSA’s proposal for assigning vocational vehicle test cycles through the designated formulas, while still allowing manufacturers to petition to use an alternative. CARB staff does not support allowing manufacturers complete freedom in choosing a test cycle. CARB staff believes that this freedom could lead manufacturers to test on cycles that are not applicable to the duty cycle of the vehicle in an effort to meet less stringent emission standards. The proposed mechanism of allowing manufacturers to petition for use of an alternative test method means that manufacturers must show proof that the vehicle they are certifying meets the criteria for the specific test cycle. Although slightly more burdensome for regulators, CARB staff believes the requirement of a petition to test on an alternative cycle will keep manufacturers from trying to circumvent the emission standards and is the best approach to take. [EPA-HQ-OAR-2014-0827-1265-A1 p.124]

**Organization:** Truck & Engine Manufacturers Association (EMA)

The proposed standards lack clear criteria for determining which vocational category should apply to a given vehicle configuration. The proposed criteria of maximum test speed and gear ratios do not provide the requisite definitional certainty upon which to base such fundamental aspects of the proposed standards.

**Organization:** Daimler Trucks North America LLC

**Categorization into urban, multipurpose, and regional** – The agencies propose to split vocational categories into three, based on speed. We see upsides and downsides to this approach. In particular, we
are concerned that the agencies’ definition for each of the categories does not align with the agencies’ expectations. For example, the agencies estimated that their definition of “urban” vehicles would capture 25% of the vocational market (based on calculations shared with the industry through the docket). By contrast, when we use F_n_test figures to calculate, we find that less than 3% do. In turn, this leads to an extremely troublesome error in the agencies’ use of “normalization,” which is strongly dependent on the percentage of vehicles in each subcategory—and this leads to our recommendation to drop normalization altogether. [EPA-HQ-OAR-2014-0827-1164-A1 p.31]

Almost all vehicles come out in multi-purpose, contrary to the agencies’ assumptions. One possible explanation for this disparity is the sensitivity of the categorization to minor changes in F_n_test: a slight change (100 or 200 RPM) in F_n_test can result in a large change in the percentages of vehicles in each bin. This demonstrates a problem, however: the possibility that manufacturers might adjust engine parameters to game the system, making tiny engine changes to move vehicles into other speed categories. In summary, without accurate categorization and without accurate numbers for the percentage of vehicles in each category, the normalization and equalization processes will fail; so we recommend dropping them. Moreover, because few vehicles come up in some of the categories, and because they are widely varied, we propose a weight-based vocational split (described below). [EPA-HQ-OAR-2014-0827-1164-A1 p.31]

Alternative for Categorization Proposal that Eliminates the Need for Normalization and Equalization – During discussions with the agencies this summer, the agencies floated the proposal to amend the NPRM’s categorization technique to allow manufacturers to simulate vocational vehicles in two speed categories (urban, MP, or regional) and ultimately categorize the vehicle into the category where it appears best. The idea behind this new proposal is that the agencies would assume that vehicle manufacturers design each vocational vehicle to be appropriate for its duty cycle, such that we may look after the design at the appropriate categories and match them to how we designed the vehicle. This being the case, there would no longer be a need to try to stop manufacturers from shifting vehicles from one speed category to another, which is the purpose of the normalization and equalization processes. In turn, this proposal allows us to get rid of those processes. [EPA-HQ-OAR-2014-0827-1164-A1 p.32]

In this categorization, we would subdivide MHD vehicles into Class 6 and Class 7 but keep vehicles of all speeds in one category. The top table shows that almost all of the Class 6 vehicles are of one engine type and (not shown in this table but available in a confidential setting) of one transmission type, and that most of the Class 7 vehicles are similarly homogeneous. This homogeneity of engine type and vehicle weight allows a very uniform choice of target technologies. Similarly in Class 8, splitting into narrower weight bands than simply everything over 33,000 lb. allows us to create homogeneous categories. For the sake of giving an example, we have chosen some weight ranges of 33k to 50k, in which most of the vehicles have one type of engine, 50k to 70k, in which most have two types, and 70k and above in which most have one type. Again, this simplifies the process of categorizing vehicles and choosing target technologies. Of course, this does not facilitate the agencies’ goal of assigning a penetration rate of hybrids, but as we describe elsewhere in these comments, hybrids are not an appropriate technology for the agencies’ standard setting. We understand that we sprung this idea on the agencies at the end of the comment period, and that it is a complicated idea marking a radical departure from the agencies’ proposal, so we recommend that we talk through the idea with the agencies. [EPA-HQ-OAR-2014-0827-1164-A1 p.32]

**Organization:** NAFA Fleet Management Association

Page 1306 of 2127
Fleet needs are diverse. Payback periods and fuel savings vary by use. A case in point – the duty cycle requirements for a tree trimming company may differ from the requirements of an electric utility, although both may use comparable vehicles. Some technologies will not fit in some uses. With respect to vocational vehicles, the proposal attempts to create silos. The agencies propose that a vocational chassis would be presumed to certify using the Multi–Purpose duty cycle unless some criteria is met indicating that another duty cycle would be more appropriate. The agencies acknowledge that even within certain vocational vehicle types, vehicle use varies significantly. [NHTSA-2014-0132-0111-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.180-181.]]

We are concerned with the statement in the proposal – “while intended service class may help a manufacturer decide how to classify some vehicles, we do not believe that intended service class would be a sufficient indicator by itself.” [NHTSA-2014-0132-0111-A1 p.3]

Response:

At proposal, we described a process of assigning vocational chassis to regulatory subcategories based on a calculation of the engine speed in relation to the vehicle speed. As proposed, the multipurpose subcategory was the default subcategory; however, if the vehicle’s engine speed at 55 mph was above the cut-point specified for that engine type (CI or SI) then the vehicle would be assigned to the Urban subcategory. Similarly, if the vehicle’s engine speed at 65 mph was below the cut-point specified for that engine type (CI or SI) then the vehicle would be assigned to the Regional subcategory. We also proposed some exceptions, such as specifying that hybrids would be in the Urban subcategory. Since proposal, the agencies have completed our work under the interagency agreement with DOE-NREL, and we have carefully considered all the comments related to this issue.

We note that several comments persuasively identify weaknesses in the proposed approach. Specifically, Allison explained that vehicles with two shift schedules would need clarification as to which top gear to use when calculating the applicable cut-point. Also, Daimler noted that, to the extent that downspeeding occurs in this sector over the next decade or more, cutpoints based on today’s fleet may not be valid for a future fleet. Allison noted that the presence of additional top gears could strongly influence the subcategory placement of vocational vehicles. These comments highlight the possibility of misclassification, and the potential pitfalls in a mandated classification scheme. Another weakness in the proposed approach is that even though we have obtained a great deal of data thanks to manufacturer cooperation and NREL duty cycle analysis, the only regulatory cut-point in which we have a high degree of confidence is the (proposed) cut-point between Regional and Multipurpose class 8 diesels. Any cut-points we could establish based on available data for lower weight class diesels or for gasoline powered vocational vehicles would be less robust.

These weaknesses have led the agencies to take a different approach to assigning vehicles to subcategories. The agencies are adopting final regulations that generally allow manufacturers to choose a subcategory, with a revised set of constraints relating largely to transmission type. In a regulatory structure where baselines are equal but future standards for vehicles in different subcategories have different stringencies, the agencies would typically assign subcategorization based on regulatory criteria rather than allowing the manufacturers unconstrained choice of subcategory because manufacturers could have a strong incentive to simply choose the least stringent standards. However, because the baseline performance levels of the different vocational vehicle regulatory subcategories differ widely, the agencies have determined that it is acceptable to adopt standards with unequal stringencies using the same methodology used to set all of the other standards in the Phase 2 rule: determining stringency based on the performance of the technologies in the projected compliance path, weighted by the penetration rates for those technologies. Considering the final test cycles and technology effectiveness
values, we no longer believe manufacturers will be able to easily make simple design changes and qualify for less stringent standards.

In the final weeks before promulgation of the Phase 2 rules, the agencies received significant new comments from vehicle manufacturers, which suggest there is some uncertainty with respect to the three drive cycle structure being adopted. Please see Section 6.1.4 above to read the agencies' response to these new comments and the potential implications for the framework of the vocational vehicle program.

In the final regulatory structure, although the standards for vocational vehicles in different subcategories have different stringencies, the agencies can allow the manufacturers a large degree of freedom to choose a vehicle's subcategory. We are not particularly concerned that adopting final standards with unequal percent improvements poses a danger of losing environmental benefits from this program, as long as vehicle configurations are properly classified at the time of certification. As just noted, the final standards described in Section V.C.2.d of the Preamble are derived directly from the technology packages without applying any assumptions about fleet averages. Thus, unlike at proposal, the final regulations will generally allow manufacturers to certify in the particular duty-cycle subcategory they believe to be most appropriate. Note that manufacturers may make this choice as part of the certification process and will not be allowed to change it after the vehicle has been introduced into commerce. Under this structure, the agencies expect manufacturers to normally choose a subcategory for each vehicle configuration that best represents the type of operation that vehicle will actually experience in use (presuming the manufacturer and customer would specify the technologies to reflect such operation).

The constraints discussed below and in the Preamble Section V.D.1.e are being adopted as interim provisions in response to manufacturers’ concerns that some of them could present competitive disadvantages, where different manufacturers produce very different sales mixes of vehicles equipped with different transmission types, as discussed in Section Error! Reference source not found..

The agencies are adopting final regulations that generally allow manufacturers to choose a subcategory, using good engineering judgment as set forth in 40 CFR 1068.5. We also are adopting a set of constraints on duty-cycle selection that have been revised substantially from those proposed. Because the baseline configurations against which vehicles in the Urban subcategories will measure their future performance do not include any manual transmissions, we have determined that vocational vehicles with manual transmissions may not be certified as Urban. In the real world, we do not expect any vehicles intended to be used in urban driving patterns will be specified with manual transmissions. Driver fatigue and other performance problems, especially the need for frequent shifting, make this an illogical choice of transmission. Because the drive idle cycle has a higher weight in Urban than in Regional or Multipurpose, and because manual transmissions have relatively low drive idle emissions, allowing manual transmission-equipped vehicles to be certified as Urban would inappropriately reward a technology that would not see in-use benefit, since the vehicle would not be used in urban settings for the reasons just explained. It is thus appropriate for us to adopt this constraint. In addition, as described in Chapter 2.9.2 of the RIA, both the HHD Regional and HHD Multipurpose baselines have a blend of manual transmissions, although the majority of manuals are in the HHD Regional baseline. Further, by MY 2024, our adoption rate of transmission technology reflects zero manuals in HHD Multipurpose. Thus, beginning in MY 2024, any vocational vehicle certified with a manual transmission must be classified in a Regional subcategory.

We are not adopting constraints on vehicles with automated manual transmissions certifying in either Regional or Multipurpose subcategories, because we believe this is a technology that can provide real world benefits for vehicles with those driving patterns. However, we are adopting a constraint to prevent vehicles with AMT from being certified as Urban for a reason similar to one described above...
for manuals, namely that in the real world, we do not expect any vehicles intended to be used in urban driving patterns will be specified with transmissions that do not have powershifts. Lack of smooth shifting characteristics during low speed accelerations and decelerations make AMT an illogical choice of transmission for urban vehicles, suggesting that any such classification would be inappropriate. Also, for reasons similar to those just given for manual transmissions, AMT have relatively low drive idle emissions. Thus, allowing AMT-equipped vehicles to be certified as Urban would inappropriately reward a technology that would not see in-use benefit, since the vehicle would not be used in urban settings for the reasons just explained.

Due to performance expectations we believe it is unlikely that an owner of a vehicle with a true urban driving pattern would choose an AMT or manual rather than an automatic transmission. Because both our baseline and future technology adoption rates exclude manual and AMT from consideration in the urban subcategories, we believe it is reasonable to exclude them from certification over this cycle.

Dual clutch transmissions have very recently become available for medium heavy-duty vocational vehicles and very little data are available on their design or performance. We anticipate that in the future, some designs may have features that make them perform similarly to AMT’s while others may have features that make them more similar to automatics with torque converters. Because we are not confident that we know in which duty cycle(s) they are best suited, we are adopting a partial constraint on these, namely that dual clutch transmissions without powershifting must also be constrained out of Urban. We are finalizing as proposed that any vehicle whose engine is exclusively certified over the SET must be certified in the Regional subcategory. Further, to the extent manufacturers of intercity coach buses and recreational vehicles opt these into the full program, these also must be certified as Regional vehicles. We are not finalizing the proposed constraint on hybrid configurations in the Urban test cycle.

Based on NREL drive cycle analysis of the existing fleet, we imagine that HHD vehicles with a diesel engine rpm of 1,400 and below when the vehicle is at 65 mph would be appropriately certified as Regional vehicles. However, this is illustrative only, and (unlike the proposed rules) the final rules do not include an engine speed cut-point as a criterion in subcategory selection.

6.5.2 Test Procedures

**Organization:** Edison Electric Institute

- We support the addition of test cycle procedures that include the ability to capture workday idle reduction; however, e-PTO systems are sufficiently distinct from neutral idle or stop-start technologies that they should qualify for separate off-cycle credits [EPA-HQ-OAR-2014-0827-1327-A2 p.16]
- Add a charge-depleting test cycle option to the hybrid-PTO test cycle that would better capture the fuel savings capabilities of these systems [EPA-HQ-OAR-2014-0827-1327-A2 p.16]
- Ensure that manufactures wishing to certify e-PTO systems for off-cycle credits are given proper credit for the fuel savings and greenhouse gas reduction capabilities of these systems [EPA-HQ-OAR-2014-0827-1327-A2 p.16]

**Response:**

We agree with the commenter that a charge-depleting e-PTO test cycle will better capture the fuel savings from a plug-in hybrid system. The agencies have partnered with NREL to conduct an analysis
of operational data on utility work trucks, and as a result, the final regulations include a utility factor table for use in the hybrid PTO test procedure described at 40 CFR 1037.540. Further discussion of e-PTO technologies is found above in Section 6.3.6.3.

6.6 HFC Leakage Standards for Vocational Vehicles

6.6.1 Feasibility of Applying HFC Leakage Technologies for Vocational Vehicles

Organization: ABC Bus Companies, Inc.

HVAC systems on motorcoaches are required to maintain a comfortable and healthy environment to as many as 81 passengers on a single motorcoach. Given that some of these systems are more than 10 tons, unreasonable changes to these systems could be very costly and hard to forecast many years out. [EPA-HQ-OAR-2014-0827-1430-A2 p.2]

Organization: New Flyer of America Inc.

In our discussions with other transit bus manufacturers (including Gillig LLC) and the American Public Transit Association (APTA), we share aligned concerns on other aspects of the program which are related to vocational classification, including air conditioning leakage (transit buses have significantly larger and more complex air conditioning systems than trucks), and payload. New Flyer believes the differences in vehicle systems and the operating characteristics warrant distinctive classification. [EPA-HQ-OAR-2014-0827-1306-A1 p.2]

Organization: GILLIG LLC

“EPA believes the capacity of vocational vehicle air conditioning systems are sufficiently similar to those of other HD vehicles to apply a similar leakage standard as was applied in the HD Phase 1 program for tractors and HD pickup trucks and vans.” We strongly encourage the EPA to revisit this underlying assumption and the part of the rule specifying allowable maximum refrigerant leak rates. Transit buses have appropriately sized air conditioning systems many times larger than other vocational vehicles to keep large passenger compartments supplied with conditioned air in hot and high humidity conditions. Again, this is essential for passenger comfort and safety. Additionally, system design details to allow for manufacturability in low volumes, vehicle integration/assembly, and ease of maintenance to meet the needs of this heavy duty vehicle segment are not similar to other vocational vehicles. Transit buses should be placed into their own subcategory separate from other vocational vehicles with standards more aligned with the types/sizes of air conditioning systems used. [EPA-HQ-OAR-2014-0827-1156-A1 p.3]

Organization: Environmental Defense Fund (EDF)

Finalize HFC leakage provisions for vocational vehicles

EDF fully supports EPA’s proposal to apply A/C refrigerant leakage standards to Class 2b-8 vocational vehicles. Excluded in the Phase 1 rule, vocational vehicles have air conditioning systems similar to tractors and contribute to HFC emissions through leaks. We agree that vocational A/C systems should be subject to the same A/C provisions as tractors and 2b/3 vehicles as proposed. [EPA-HQ-OAR-2014-0827-1312-A1 p.51]

Organization: Daimler Trucks North America LLC
**AC leak rate limits:** Carrying the leak rate limits from tractors to vocational vehicles is a good approach. In particular, we agree with the approach of basing compliance on the SAE J2727 calculation-based procedure rather than testing but allowing Helium testing as an option. Further, given the variety of vocational vehicles, and in turn the variety of AC configurations for those vehicles, we agree with the EPA’s approach of not tightening the AC leak rate standards at the same time as the standards are extended to vocational vehicles. We agree with the EPA’s approach of having the present standards apply only to chassis-cab AC systems, as opposed to AC systems that might be on a refrigerated van truck, as those are installed by manufacturers other than the vehicle manufacturer, and we have no familiarity with those systems. [EPA-HQ-OAR-2014-0827-1164-A1 p.110]

**Organization:** Institute for Policy Integrity at NYU School of Law

The agencies have made several changes to the Phase 2 rule that are consistent with our previous comments. Finally, the agencies have now proposed air conditioning leakage standards for vocational vehicles (though, regrettably, still no air conditioning efficiency standards or credits). For more on Policy Integrity’s views on heavy-duty vehicle regulation, see our comments on the Phase 1 rulemaking.6 [EPA-HQ-OAR-2014-0827-1195-A1 p.3] /6/ [http://policyintegrity.org/files/publications/2211_Regulatory_Report_2011_Heavy_Trucks_Rule.pdf](http://policyintegrity.org/files/publications/2211_Regulatory_Report_2011_Heavy_Trucks_Rule.pdf)

**Organization:** California Air Resources Board (CARB)

**Extension of AC leakage standard to vocational vehicles**

U.S. EPA and NHTSA are proposing to retain the AC leakage standard adopted in the Phase 1 program. U.S. EPA and NHTSA are also proposing extending the AC leakage standard to class 2b-8 vocational vehicles, which were excluded from the leakage standard in Phase 1. [EPA-HQ-OAR-2014-0827-1265-A1 p.143]

CARB staff supports the proposal to continue the AC leakage standard adopted in the Phase 1 program. CARB staff believes that the leak rate limits in the Phase 1 program are at appropriate levels that balance technical feasibility and emission reduction goals. CARB staff further supports the proposal to extend the AC leakage standard to class 2b-8 vocational vehicles, because the main obstacles (complexity in building process and potentially different entities other than chassis manufacturers involved in production and installation) identified during Phase 1 regulation development have been resolved with new information received during Phase 2 rulemaking process. CARB staff further believes that it is appropriate to set the leak rate limits for vocational vehicles at the same levels as for other tractors, heavy-duty pick-up trucks and vans, due to the substantial similarity of the AC systems for these vehicle classifications. [EPA-HQ-OAR-2014-0827-1265-A1 p.143]

**Response:**

We are adopting as proposed final regulations that apply the Phase 1 level A/C leakage standards to vocational vehicles for the reasons set out at proposal. We note that the comments essentially all supported the proposed approach. The agencies also note that the leakage standards are in terms of percent leakage (not an absolute amount of leakage) to take into account that air conditioning systems come in various sizes. We are not adopting any exemptions or exclusions to this requirement, aside from vehicles qualifying for an engine-only standard under 40 CFR 1037.631. However, in view of concerns expressed from some manufacturers about the complexity of A/C systems on large buses, we have reconsidered the compliance process for certifying leakage rates of A/C systems with refrigerant charge capacities greater than 3,000 grams. See Section 6.6.2 below for details on this process.
With respect to comments about credits for efficient A/C systems, please see Section 6.3.6.2, above, regarding electrified accessories.

### 6.6.2 HFC Compliance Provisions for Vocational Vehicles

**Organization:** Recreational Vehicle Industry Association (RVIA)

Section 1037.115(e) of the Proposed Rules is the air conditioning leakage requirement which, as drafted, would not apply to refrigeration units installed on trailers or for refrigeration units on vocational vehicles that are limited to cooling cargo. RVIA requests that EPA clarify in the final rule that the air conditioning leakage requirement also does not apply to air conditioning units in motorhomes used to cool the living space rearward of the driver. These self-contained rooftop mounted units, by design, are inherently less prone to leakage. Further, the companies that manufacture these units have no relationship with the chassis suppliers who are covered by this regulation nor are they integrated in any way with the motorhome manufacturers that purchase the chassis. Application of the air conditioning leakage standard to living-space cooling units would thus be inappropriate, impracticable, and potentially extremely difficult and costly for regulated parties. EPA should clarify that air conditioning leakage requirements do not apply to living-space cooling units in motorhomes rearward of the driver. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

**Organization:** Mobile Climate Control (MCC)

To further illustrate the difference between tractor and HD vehicle HVAC vs bus HVAC systems you can look to the SAE J2727 standard which gives a chart for calculating mobile air-conditioning system annual refrigerant emissions. This standard comes from automotive and may give good compliance when calculating the annual refrigerant emissions from a tractor or HD vehicle HVAC system. When you try to apply the same standard for calculating the emissions from a large bus HVAC system you find that the fitting types, compressor seals, and even refrigerant options are not all covered or contained at all within the standard. In the requirement, leakage rates are to be calculated in accordance with 40 CFR 86.1867-12(a). This code of federal regulations specifies refrigerant leakage rates be determined using SAE J2727, where the hose permeation rates be calculated in accordance with SAE J 2064. As an example both methods were used to estimate refrigerant leakage rate for a typical bus rearmount air conditioning unit, i.e., SAE J2727 in total, and SAEJ2727 supplemented with SAE J2064 for the hose assembly contribution. Each calculation used Aeroquip FC558 hose assemblies as the connection between the rearmount and compressor. The results are as follows: SAE J2727 — 0.56% leakage rate in g/year; SAE J2727 and SAE J2065 - 14.2% leakage rate in g/year. Using SAE J2727 alone resulted in an optimistic value for estimated refrigerant leakage rate. As previously stated above it should be noted that SAE J2727 was primarily developed to characterize automotive systems, where the size, range and type of fittings outlined in this category are not specifically applicable for bus HVAC applications and likely does not adequately represent these applications. Conversely, hose assembly refrigerant leakage rates determined by using the test methods illustrated in SAE J2064 result in conservative estimates. Although these test methods are used by hose manufacturers and subsequently integrated into their specific hose specification, the calculated permeability rate has not been observed in actual practice. Given the wide range between the two calculated values, it would seem premature to target and accept a 1.5% leakage rate without further testing and investigation.

**Response:**
We agree with commenter that the proposed regulations were unclear as to our intended applicability of air conditioning units in motor homes. In the final rule, we are adopting regulations to clarify that the low leakage standard applies for air conditioning or refrigeration units on vocational vehicles only if they draw power from engines used to propel the vehicles. See 40 CFR 1037.115(e). With this clarification, we are excluding independently powered roof units or other auxiliary powered units. We believe systems driven by propulsion engines are most likely to be within the control of the certifying manufacturer.

In response to concerns that the procedure for calculating leak rates may not be representative of leak rates of components used in very large mobile air conditioning systems, we are adopting provisions to allow manufacturers to certify using another method. The final regulations at 40 CFR 1037.115(e) include a statement that, “If air conditioning systems with capacity above 3000 grams of refrigerant are designed such that a compliance demonstration under 40 CFR 86.1867-12(a) is impossible or impractical, you may ask to use alternative means to demonstrate that your air conditioning system achieves an equivalent level of control.”

### 6.6.3 Program-Wide HFC Compliance Provisions

**Organization:** Natural Resources Defense Council (NRDC) and the Institute for Governance and Sustainable Development (IGSD)

We also encourage EPA to strengthen refrigerant leakage requirements in order to reduce leakage of high-GWP refrigerants in advance of the phase-out of those refrigerants. Specifically, we suggest that EPA require that manufacturers take steps to ensure that low leak rates are achieved over the life of the vehicles. The methods used to estimate refrigerant leakage in SAE J2727 do not appear sufficient to ensure or even predict emissions rates over these vehicles’ lifetimes of millions of driven miles, sleeper cab use (for long-haul Class 8 trucks), vibrations from independently suspended truck components, larger charge sizes, and many other conditions. [EPA-HQ-OAR-2014-0827-1305-A1 p.2]

In order to better demonstrate the efficacy of low-leak systems, EPA should require that manufacturer conduct stress testing of air conditioning components to provide an indication of their durability under road conditions. Likewise, EPA might also require that OEMs conduct road testing, which could offer a better picture of on-road wear and tear. [EPA-HQ-OAR-2014-0827-1305-A1 p.2]

**Organization:** California Air Resources Board (CARB)

The NPRM states that U.S. EPA and NHTSA are not proposing a specific in-use standard for leakage, because neither test procedures nor facilities exist to measure refrigerant leakage from a vehicle’s air conditioning system. [EPA-HQ-OAR-2014-0827-1265-A1 p.142]

While existing test procedures (SAE Standard J2763 and J2762) could be used to assess refrigerant leakage, such procedures are time consuming and costly, and thus impractical. Therefore, CARB is not opposed to U.S. EPA and NHTSA’s position of not proposing an in-use standard for leakage at this time. [EPA-HQ-OAR-2014-0827-1265-A1 p.142]

**Information required for AC leakage standard certification**

To show compliance with the AC leakage standard, U.S. EPA and NHTSA are only requiring the manufacturer to provide refrigerant leak rates, describe the type of refrigerant, and identify the refrigerant capacity of the air conditioning systems. [EPA-HQ-OAR-2014-0827-1265-A1 p.142]
CARB staff believes more information ought to be required to afford U.S. EPA and NHTSA the opportunity to verify the leakage calculation and to track technological development. CARB staff recommends that U.S. EPA and NHTSA require the following information from the manufacturer: the calculation that leads to the refrigerant leak rate estimates, and specifications of the system components with sufficient detail to allow reproduction of the calculation. This level of detail is consistent with the information that CARB staff requires light-duty manufacturers to report under the AC credit provisions in its “Advanced Clean Cars” programs for light-duty vehicles. [EPA-HQ-OAR-2014-0827-1265-A1 p.142-143]

**Emission-related warranty covers components whose failure would increase a vehicle’s emissions of air conditioning refrigerants**

U.S. EPA and NHTSA are proposing that the emission-related warranty cover components whose failure would increase a vehicle’s emissions of AC refrigerants. [EPA-HQ-OAR-2014-0827-1265-A1 p.144]

CARB staff supports this proposal. Although most refrigerant emissions occur as refrigerant gradually leaks through fittings, connection, and seals, and permeates through hoses (“regular leakage”), sudden failure of AC components may lead to the loss of the entirety or a significant portion of the refrigerant charge in a short period of time (“irregular loss”). Requiring that the emission-related warranty cover those components not only provides a venue to restore the system back to working order when component failure occurs, but also promotes the use of technologies more durable and less prone to failure, hence helping to prevent failure and reduce emissions at the design level. [EPA-HQ-OAR-2014-0827-1265-A1 p.144]

**Organization:** Honeywell Fluorine Products

SAE J2727 Does Not Properly Consider Real World Circumstances for Leakage Rates from HD, MD and VV [EPA-HQ-OAR-2014-0827-1191-A1 p.3]

In the Proposed Rule, EPA proposes to extend the application of SAE Surface Vehicle Standard J2727 scoring system as an appropriate approach to determine leakage rates from HD, MD and, now by extension, VV. [EPA-HQ-OAR-2014-0827-1191-A1 p.3]

“EPA is proposing a requirement that vocational chassis manufacturers compare the components of a vehicle’s A/C system with a set of leakage-reduction technologies and actions that is based closely on that developed through the Improved Mobile Air Conditioning program and SAE International (as SAE Surface Vehicle Standard J2727, “HFC–134a, Mobile Air Conditioning System Refrigerant Emission Chart,” August 2008 version). See generally 75 FR 25426. The SAE J2727 approach was developed from laboratory testing of a variety of A/C related components, and EPA believes that the J2727 leakage scoring system generally represents a reasonable correlation with average real-world leakage in new vehicles.” [EPA-HQ-OAR-2014-0827-1191-A1 p.3]

We believe that while SAE J2727 may be an accurate predictor of leakage rates in new light duty passenger vehicles, it has not been proven to be accurate in predicting “real-world leakage” in HD vehicles. Studies have shown that leakage rates as expressed as a percentage of the initial charges show a range of 7.3 to 11.5% (8.9 average) annually for heavy duty vehicles vs. generally 1.5 – 3% range for light duty vehicles. [EPA-HQ-OAR-2014-0827-1191-A1 p.3]
To properly account for leakage from AC units in HD vehicles, the scoring system must consider the significantly higher miles and heavier pounding these vehicles endure each year and over the life of the vehicle, as well as variation. HD vehicles often have much higher annual mileage usage, in many cases over 100,000 miles per year and 1-2 million miles over the lifetime of the vehicle. In addition, HD vehicles have different loads (engine torque on A/C compressor and engine/road vibration loads on A/C lines, fittings, and components) on its A/C components, which likely results in higher leakage rates than light duty vehicles. Finally since many HD trucks have sleeper cabs, the air conditioning systems are often run even when the vehicle is not moving, adding further to the wear and tear of the A/C system. [EPA-HQ-OAR-2014-0827-1191-A1 p.3-4]

We request EPA to consider more fully these real world realities of harder pounding over many more miles in assigning leakage rates over time for HD A/C systems. While a design based approach in estimating leakage may have applicability to new HD vehicles, we believe that real world performance based testing would reveal short comings in the application of SAE J2727 to HD, MD, and VV over the life of the vehicle. We suggest EPA gather leak rate data on older heavily used vehicles to determine if the leak rates predicted by SAE J2727 are accurate over the life of the vehicles. [EPA-HQ-OAR-2014-0827-1191-A1 p.4]

Response:

We are finalizing requirements as proposed to include A/C leakage components in the emissions-related warranty, for the reasons stated at proposal. We note further CARB’s support, which endorses the agencies’ reasoning. Similarly, in light of supportive comments from CARB, we are not adopting in-use HFC leakage requirements. We disagree that we need to collect more information from manufacturers. We are collecting a sufficient level of detail about compliance with the HFC leakage standard at the time of certification. In addition, the manufacturers are required to maintain the level of detail suggested by CARB as part of the recordkeeping requirements. EPA may audit those records at any time. The agencies also note that the study referred to in the Honeywell comments was conducted in 2007, prior to the implementation of HFC leakage standards for tractors and HD pickups in Phase 1. Thus, this study does not support the commenter’s assertion that SAE 2727 may not be an appropriate test procedure for HD vehicles. For responses to comments about our methods for estimating direct leakage emissions of HFC from A/C systems on HD vehicles, please see Section 9.2.

7 Pickups and Vans

7.1 General Comments

Response:

There are no comments in this section 7.1.

7.2 Proposed Pickup and Van Standards for CO2 and Fuel Consumption

7.2.1 Stringency of Standards

Organization: American Automotive Policy Council

Implicit and Explicit Challenges of Alternative 3 - The proposed Phase 2 Alternative 3 stringency is greater than Phase 1. Alternative 3 is aggressive and will drive technology into product. Proposals for
greater stringency than Alternative 3 are not supportable given the required early introduction of unproven technologies with their associated consumer acceptance risk, as well as the many implicit risks that impact stringency. All of these risks are detailed in our comments. [EPA-HQ-OAR-2014-0827-1238-A1 p.2]

**Phase-in of Alternative 3 Stringency** - AAPC recommends a phased-in approach to the full 2027 model year stringency rather than applying a constant 2.5% per year improvement rate to both gas and diesel vehicles standards similar to what was done by the agencies in the Phase 1 rule. [EPA-HQ-OAR-2014-0827-1238-A1 p.2]

**Need for Customer Acceptance**

AAPC strongly believes that the Phase 2 program must continue to recognize the unique functionality and utility needs of the trucking industry, and that this regulation must preserve the performance integrity and capability of these work trucks. Consumers value the payload and towing capabilities these work vehicles offer and the Phase 2 standards proposed by EPA and NHTSA should continue to align with the industry and business needs of this demographic. [EPA-HQ-OAR-2014-0827-1238-A1 p.6]

There are a couple of very important trends apparent with the customers who purchase vehicles impacted by this regulation. First, the heavy-duty customer is clearly different than the light-duty customer. This is evidenced in that the most important reason for purchase, across the segment, is capability. Research suggests that heavy-duty customers are five times more likely to cite towing requirements than any other single reason for purchase. Second, the heavy-duty customer is most likely to purchase a truck for fleet/commercial needs. Commercial customers view the vehicles as tools to get their jobs done and as pivotal to the underlying success of their business. Customers value proven and durable vehicles with powertrains that meet their capability needs with minimal down-time. The total cost of ownership is an important consideration in this segment. The significant price premium associated with advanced technologies has the potential to upset a demanding customer base. This would be exacerbated if the technologies prove to have little to no benefit on actual, real-world fuel consumption, such as those technologies whose impact is minimized under heavy loads. [EPA-HQ-OAR-2014-0827-1238-A1 p.6-7]

AAPC commends the agencies for repeatedly commenting on the need to preserve consumer choice—that is, the proposed standards should not affect consumers’ opportunity to purchase a vehicle with the performance, utility and safety features that meets their needs. AAPC agrees and supports the use of sales data, showing how customers critically balance capability with value, as highly indicative of the demanding requirements within this segment of vehicle owners and operators. [EPA-HQ-OAR-2014-0827-1238-A1 p.7]

**Implicit and Explicit Challenges of Alternative 3**

For the 2b/3 heavy-duty truck and van fleet, the Phase 2 rule’s Alternative 3 is aggressive and will challenge industry. It is concerning that there have been calls for even greater stringency beyond the aggressive standards proposed by EPA and NHTSA for Phase 2. The following factors must be addressed when evaluating stringency: [EPA-HQ-OAR-2014-0827-1238-A1 p.8]

- **Limited real data for setting standards** - Manufacturers, the agencies and all other stakeholders have a limited amount of real data under the Phase 1 program. While the light-duty vehicle fleet has been regulated under NHTSA’s CAFE program for roughly forty years, we are
still very early in the Heavy-Duty program. Effectively, we have only one full model year of industry data “under our belt.” [EPA-HQ-OAR-2014-0827-1238-A1 p.8]

- **High levels of technology in baseline fleet** - The baseline fleet has a high percentage of advanced diesel technology making additional improvements considerably more challenging. In the light-duty fleet, diesel technology accounts for 3% of fleet. In the heavy-duty fleet, diesels account for over 50% of fleet. Advanced diesel aftertreatment (i.e., SCR) presented the greatest opportunity for increased efficiency. However, it has already been applied to 100% of the Class 2b/3 diesel fleet today.

- **Customer demand for more technology** - Customer acceptance of vehicles with increasing technology could be challenging for a customer base which has continually expressed a focus on proven capability and utility. This is exacerbated by the forecast of sustained low oil prices (EIA reference) which will limit a customer’s willingness to pay for increased fuel economy. Throughout the NPRM, the agencies repeatedly reference outstanding questions regarding the relative risks in adopting alternative 4. AAPC agrees and is concerned that the required technology penetration rates for alternative 4 places too much emphasis on early introduction of advanced technology vehicles that are not yet part of this market. In addition, this risk places manufacturers in considerable jeopardy for non-compliance should a given technology not develop or make the expected fuel economy gains. [EPA-HQ-OAR-2014-0827-1238-A1 p.8]

- **Phase 2 technologies being used today** - These work trucks have a wide range of “duty-cycles” so assuming that a specific technology path will be valued by all customers equally is inappropriate. All stakeholders need to learn more about customer acceptance in this very diverse base. For example, FCA’s modern gasoline engine has robust combustion with multiple spark plugs, variable cam phasing, cylinder deactivation, and cooled EGR. These last two technologies (cylinder deactivation and cooled EGR) are suggested Phase 2 gasoline engine technologies (80 Federal Register 40351). Even with this level of gasoline engine technology, FCA is challenged by the early year Phase 1 standards and will need to look at adding even more technology for Phase 2. [EPA-HQ-OAR-2014-0827-1238-A1 p.9]

- **“Downsizing” and “boosting” could be at odds with capability needs** - Smaller displacement boosted gasoline engine technology may be applicable in some variants of commercial vans, as noted by Ford product actions. However, this technology is not suited for the pickup truck variants in this segment because of customer demands for towing capability. The graphic below illustrates fuel usage (brake specific fuel consumption vs kilowatts) effects from boosted engines while doing work. A downsized boosted gasoline engine will use more fuel compared to a larger naturally aspirated heavy-duty engine at higher loads as illustrated by the blue and black lines in the figure below. [EPA-HQ-OAR-2014-0827-1238-A1 p.9]

- **Concurrent reductions in criteria emissions** – The concurrent stringency increases in Tier 3/LEV III criteria emission requirements will negatively impact CO2 and fuel consumption. For example, there will be increased thermal loads, space velocity and NOx flux demands on aftertreatment systems during US06 testing (e.g., enrichment) that will negatively impact CO2 performance. [EPA-HQ-OAR-2014-0827-1238-A1 p.10]

- **Tier 3 emissions alignment with Phase 2 GHG stringency** - The Phase 2 GHG draft RIA and supporting technical analysis are incomplete and understate the actual stringency on chassis certified Class 2b/3 products for all alternatives. Specifically, the negative aspects of recently
released Tier 3 criteria emissions rules relative to GHG and fuel consumption are omitted from
the analysis. AAPC requests that the impact of Tier 3 criteria emissions on the Phase 2 GHG
proposal for 2019 – 2027MY be incorporated into cost, benefit, and technology projections and

AAPC estimates that the full impact of Tier 3 / LEV III requirements in 2025MY will result in an
effective stringency increase of >4% for gasoline spark ignited engines and >5% for compression
ignition engines. Furthermore the technologies and costs needed to make up the difference do not appear
to be incorporated into the existing RIA. [EPA-HQ-OAR-2014-0827-1238-A1 p.10-11]

[Table of Tier 3 and engine response and fuel consumption can be found on p.11 of docket number
EPA-HQ-OAR-2014-0827-1238-A1]

Phase-in of Alternative 3 Stringency

The class 2b/3 pickup trucks and vans regulated by the NPRM have very long product lifecycles. The
primary reason is the large amount of capital investment needed to update the vehicles and powertrains
that must be amortized over smaller annual volumes than typical light-duty vehicles. Because very few
of the components, including the powertrains, are shared with light-duty vehicles, this requires a longer
lifecycle in order to receive payback on the investment. [EPA-HQ-OAR-2014-0827-1238-A1 p.12]

In order to better align with the significant capital investments required to meet the ambitious proposed
Phase 2 greenhouse gas and fuel efficiency standards, AAPC recommends a phased-in approach to the
full 2027 model year stringency rather than applying a constant 2.5% per year improvement rate to both
gas and diesel vehicles standards similar to what was done in the Phase 1 rule. Under this
recommendation, manufacturers are still required to achieve the exact same 2027 requirement, but are
given flexibility in the stringency to better align with the long lead time required to bring advanced
technology vehicles to market. Long lead time is critical given the cumulative impact of the finalized
Phase 1 and the proposed Phase 2 standards is 32.5% CO2 improvement for diesel vehicles and 27.5%

The 14 model years covered by the finalized Phase 1 and the proposed Phase 2 standards are typically
not even two complete product lifecycles for vehicles in the Class 2b/3 market. As a result, AAPC
members will be required to rapidly innovate, invest and refine advanced technologies that are both
appreciated and embraced by American consumers. The opportunity to phase-in to full 2027 stringency
would afford manufacturers the opportunity to make the right choices for their customers while
maintaining a sustainable business model. [EPA-HQ-OAR-2014-0827-1238-A1 p.12]

A phase-in approach to full stringency is consistent with how Phase 1 standards were handled (76

[Tables, of estimated total vehicle CO2 reductions for HD Pickup Trucks and Vans, and model year
percentage reductions, can be found on p.13 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

Revising both the gas and diesel coefficients for the 2021-2026 model years to reflect the AAPC
proposal above would be consistent with the approach the agencies used in the Phase 1 regulation and
would help manufacturers manage the long lead time associated with developing the new vehicles and
powertrains that will be required in order to comply with the Phase 2 proposal. [EPA-HQ-OAR-2014-
0827-1238-A1 p.13]
Heavy-duty pickups and vans

Heavy-duty gasoline and diesel pickups and vans will reduce their fuel consumption by 16% each in 2027 relative to the 2018 standards (p. 40338). Figure 2 uses the data in the rule docket for MY 2014\textsuperscript{17} heavy-duty pickups and vans to display the distribution of models relative to the Phase 1 standards for 2014 and 2018. Two observations from the data relevant to the discussion below are: 1) work factor is a far better predictor of fuel efficiency for pickups than for vans; and 2) at present, diesel vehicles approach 2018 targets, while gasoline vehicles are approximately at 2014 target levels.

[Figure 2 can be found on p.20 of docket number EPA-HQ-OAR-2014-0827-1280-A1]

Standards for gasoline pickups and vans

The Phase 2 gasoline engine package draws primarily on research done by Southwest Research Institute (SwRI).\textsuperscript{19} SwRI evaluated a host of technologies that were deemed suitable for the Phase 2 timeframe. Engine technologies for gasoline pickups include cylinder deactivation, variable valve actuation/lift, and friction reduction. Vehicle and transmission technologies include 8-speed transmission with high efficiency gearbox, aero drag reduction, low rolling resistance tires, mass reduction, accessory improvement, low drag brakes, and hybrids. [EPA-HQ-OAR-2014-0827-1280-A1 p.21]

There is room for substantial improvement in the agencies’ gasoline package, both in technology effectiveness and in technology penetration. The agencies sometimes use lower effectiveness values than SwRI finds, without providing justification. For example, agency effectiveness numbers for cylinder deactivation, variable valve lift and turbodownsize were much lower than the SwRI estimates. The agencies assumed 22% penetration of cylinder deactivation and variable valve lift, which is conservative. Considering the expected adoption of these technologies in light-duty vehicles and considering the Phase 2 timeframe, we assume 50% penetration of these technologies in 2027. [EPA-HQ-OAR-2014-0827-1280-A1 p.21]

A major shortcoming of the agency package is the absence of turbodownsize for gasoline pickups, although they used this technology for gasoline vans. Downsize, turbocharged engines offer a major opportunity to improve gasoline vehicle fuel efficiency. SwRI compared a 6.2-liter V-8 gasoline engine to a simulated downsize 3.5-liter V-6 and found 16% fuel savings. The National Academy of Sciences (NAS) study found turbocharged downsizing benefits in the range of 10–14%. Downsize, turbocharged engines played a major role in the agencies’ compliance scenario for the light-duty fuel efficiency standards for model years 2017–25; the LD rule found 12.3% savings for 33% downsizing with turbocharging.\textsuperscript{20} A gasoline engine largely can retain its performance when downsize and turbocharged, but fuel savings benefits may be reduced or eliminated at high load operation, including towing. This technology is therefore especially suitable for vehicles not regularly employed in heavy towing. We assumed that at least 10% of pickups will adopt turbodownsize in 2027 timeframe. [EPA-HQ-OAR-2014-0827-1280-A1 p.21]

The agencies did not consider cooled exhaust gas recirculation for gasoline pickups. Cooled EGR can reduce the fuel consumption of both direct-injected and port-injected gasoline engines by reducing pumping losses, mitigating knock, cooling the exhaust, and eliminating the need for fuel enrichment.\textsuperscript{21} SwRI found 3.7% savings from cooled EGR. We assumed this technology only for pickups and vans with turbocharged, downsized engines. [EPA-HQ-OAR-2014-0827-1280-A1 p.22]
Inclusion of hybrids in the agency package (10% for pickups, 6% for vans) is a positive step. The agency estimate of 6% potential hybrid penetration for vans is likely too low, given that most of these vehicles have urban and vocational-like operation. [EPA-HQ-OAR-2014-0827-1280-A1 p.22]

In light of the above discussion, the standards for gasoline pickups and vans should reflect:

- Increased penetration of cylinder deactivation and variable valve timing. Use these technologies for at least 50% of pickups. [EPA-HQ-OAR-2014-0827-1280-A1 p.22]
- Increased the penetration of GDI and turbodownsizing to at least 10% of pickups and use cooled EGR for all downsized pickups and vans. [EPA-HQ-OAR-2014-0827-1280-A1 p.22]
- The existing hybrid assumption (10% and 6% for pickups and vans by 2027) [EPA-HQ-OAR-2014-0827-1280-A1 p.22]

Tables 4 and 5 compare technology effectiveness and penetration, respectively, for the agency package (Table VI-5, p. 40356) and in our estimate. [EPA-HQ-OAR-2014-0827-1280-A1 p.22]

The estimate of overall fuel consumption reductions needs to account for possible overlaps in benefits. For engine and transmission technologies, there is a risk of double-counting benefits when more than one technology in a package addresses the same efficiency losses. A recent ACEEE report discusses the overlapping of benefits for gasoline pickups and vans engine and transmission technologies and develops a correction factor of 23%. Using a multiplicative approach to combining technology benefits, and applying the adjustment for overlapping of benefits, we estimate that the technologies considered above, when applied at the revised penetration rates shown in table 5, provide a 22% average reduction in fuel consumption for gasoline vehicles and vans relative to Phase 1 level, as shown in table 6. [EPA-HQ-OAR-2014-0827-1280-A1 p.23]

This increment in gasoline pickups and vans will promote the integrity of the pickup market in two ways: it will reduce the fuel economy gap between these pickups and full-size light-duty pickups; and it will help reduce the efficiency gap between heavy-duty gasoline and diesel vehicles. Heavy-duty gasoline pickups, according to the Phase 2 proposal, will attain 19.5 miles per gallon (mpg), on average, in 2025 while contemporary LD pickups will average 32.5 mpg in 2025, as shown in table 7. That is, LD pickups will have more than 50% higher fuel economy than HD gasoline pickups and vans will achieve in 2025. Heavy duty pickups and full-size light duty pickups often use similar engine, vehicle, and transmission technologies and are tested on the same test cycles with same cycle weighting for certification, but at different weights. When light-duty fuel economy is corrected for the difference in test weights, the discrepancy is still 43%. Any gap between fuel economy requirements for LD and HD pickups for which there is no engineering rationale could produce distortions in the pickup market, shifting sales toward the heavier vehicles. [EPA-HQ-OAR-2014-0827-1280-A1 p.24]

The agencies’ technology package for diesel pickups and vans uses the same vehicle and transmission technologies as the gasoline package. Their engine package is not fully explained. The Phase 2 proposal...
says: “Diesel engines in the HD pickup and van segment are expected to have several improvements in their base design in the 2021–2027 timeframe. These improvements include items such as improved combustion management, optimal turbocharger design, and improved thermal management” (p. 40352). The diesel engine technology evaluation, however, estimates savings from friction reduction, turbo efficiency improvement, and engine downsizing. [EPA-HQ-OAR-2014-0827-1280-A1 p.24]

Although the agencies made a more conservative estimate of the potential for friction reduction than the estimate from SwRI, estimates of effectiveness for turbo efficiency improvement and diesel engine downsizing were the same as SwRI estimates. However, the agencies assume zero penetration of engine downsizing for pickups. While the majority of these pickups may carry substantial loads and need high towing capacities, some have low payload and towing capacities, and would be candidates for engine downsizing. In the case of diesel vans, engine downsizing is already occurring. Some manufacturers are providing this option, and its penetration is likely to increase overtime. We estimate 10% penetration of engine downsizing for pickups and 30% penetration for vans in 2027. We also assume 6% penetration of hybrids in vans, similar to gasoline vans. [EPA-HQ-OAR-2014-0827-1280-A1 p.25]

After accounting for the losses from overlapping of benefits for these vehicles, we estimate overall fuel consumption reductions of 18% reduction for diesel pickups and vans beyond Phase 1 in 2027, an additional 1.6% improvement from the agency estimate. Table 8 outlines the proposal and our estimate for Phase 2. [EPA-HQ-OAR-2014-0827-1280-A1 p.25]

Table 8 can be found on p.25 of docket number EPA-HQ-OAR-2014-0827-1280-A1

- Increase the 2027 targets for gasoline pickups and vans by 7% to reflect the adoption of advanced technologies. [EPA-HQ-OAR-2014-0827-1280-A1 p.23]
- Consider downsizing for diesel pickups with low work factor and vans, and increase the 2027 targets by 2%. [EPA-HQ-OAR-2014-0827-1280-A1 p.23]

---

The standards for gallons per 100 miles would continue to differ, due to the difference in energy content of the two fuels.

**Organization:** American Council for an Energy-Efficient Economy (ACEEE) et al.

**Heavy-Duty Pickups and Vans**

The SwRI report\(^{23}\) updated the benefits of mild and full (parallel) hybrids for heavy-duty pickups and vans. The cycle weighted effectiveness of mild hybrids at ALVW (test weight) was 40% higher than the agency estimate, while full hybrids had a small increase in benefit. The aero and tire benefits for these vehicles were also higher than the agency estimate. [EPA-HQ-OAR-2014-0827-1896-A1 p.7]

**Impact on proposal**

The agencies should strengthen the standards for heavy-duty gasoline pickups and vans to reflect a reasonable penetration of mild and full hybrids in 2027. [EPA-HQ-OAR-2014-0827-1896-A1 p.7]

**Organization:** California Air Resources Board (CARB)

**Oppose/Requested Change Comment**

**Comment - Proposed heavy-duty pickups and vans (class 2b/3) standards should be strengthened**

The NPRM solicits comment on Alternative 4 for heavy-duty pickups and vans, which would result in approximately the same Phase 2 program stringency increase of about 16 percent compared to Phase 1 but would do so two years earlier, in MY 2025 rather than in MY 2027. Alternative 4 would require CO2 reductions of 3.5 percent per year from 2021 to 2025, whereas Alternative 3 would require CO2 reductions of 2.5 percent per year from 2021 to 2027. We encourage U.S. EPA and NHTSA to accept Alternative 4 rather than Alternative 3 for heavy-duty pickups and vans. [EPA-HQ-OAR-2014-0827-1265-A1 p.64]

CARB staff believes that Alternative 4 for heavy-duty pickups and vans is technologically feasible, cost-effective, and superior to Alternative 3 for the following reasons: [EPA-HQ-OAR-2014-0827-1265-A1 p.64]

- The projected payback period for Alternative 4 is still acceptable and only a few months longer than the projected payback period for Alternative 3. Alternative 4 is projected to pay back in 34 months versus 26 months for Alternative 3 (or 34 months versus 31 months if a dynamic baseline is used), and hence adds only 3 to 8 months to the expected payback period.
Both alternatives pay back in the third year of ownership which is still expected to be well within the period vehicles are owned by the first buyer. [EPA-HQ-OAR-2014-0827-1265-A1 p.65]

- **Alternative 4 is significantly less stringent than the standards light-duty pickup trucks will be meeting in the same timeframe.** Heavy-duty pickups and vans are very similar to light-duty pickup trucks but have higher load and towing capacity requirements. Both groups of vehicles are manufactured by many of the same manufacturers (Ford, General Motors, and Fiat/Chrysler) and utilize comparable engine and vehicle technologies. For this reason, both groups would have similar routes to achieving GHG emission reductions. Furthermore, continuing availability of advanced technology credits (see page 69) would provide additional technology flexibility to manufacturers in achieving reductions beyond alternative 3. For light-duty pickups, U.S. EPA and NHTSA have set GHG emission standards that would reduce emissions by 3.5 percent per year from MYs 2017-2021 and 5 percent per year from MYs 2022-2025. For a typical light-duty pickup, the resulting CO2 standard would be 203 grams per mile (g/mi) by 2025. [EPA-HQ-OAR-2014-0827-1265-A1 p.65]

Alternative 4 would require a 3.5 percent per year improvement in CO2 emission reductions from MYs 2021-2025 and result in an average CO2 standard of 458 g/mi in 2025. Even under Alternative 4, the standard for heavy-duty pickups and vans would be more than double the allowable CO2 emissions for light-duty trucks in the same time period. [EPA-HQ-OAR-2014-0827-1265-A1 p.65]

**Alternative 4 achieves greater emission benefits and greater net societal benefits than Alternative 3.** As summarized in Table 13, Alternative 4 for heavy-duty pickups and vans would achieve an additional 21 MMT of CO2 reductions and $2.3 billion in societal benefits in the U.S. [EPA-HQ-OAR-2014-0827-1265-A1 p.64]

[Table 13 can be found on p.65 of docket number EPA-HQ-OAR-2014-0827-1265-A1]

**Organization:** Center for Biological Diversity

*Heavy-duty Pickups and Vans*

The Proposed Rule fails to apply a number of light-duty pickup/van technologies to heavy-duty pickups and vans, contrary to the technology-forcing nature of the governing statutes. Light duty pickups, along with passenger cars are subject to separate CAFE standards. The CAFE standards for model years 2017-2025 are more stringent than the proposed requirements for heavy-duty pickups: large light-duty pickups and vans must reduce emissions by approximately 41 percent between 2012 and 2025, with 32 percent of the reduction due to the most recent CAFE standards for years 2017 to 2025. In contrast, the proposed standards would require medium- and heavy-duty pickups and vans to reduce emissions by only about 24 percent over a similar span of years between 2014 and 2027, with approximately 16 percent of the reduction due to the current rulemaking for years 2017 to 2027. This amounts to only about half the fuel savings in medium- and heavy-duty pickups and vans relative to their lighter duty counterparts. Despite the differences in efficiency standards, analyses by the International Council on Clean Transportation (“ICCT”) and the American Council for an Energy-Efficient Economy have found that manufacturers could apply – and often already are applying – these same technologies to heavy-duty pickups, with the result that much greater efficiency improvements can be achieved in medium- and heavy-duty pickups and vans than currently proposed.\[32\] [EPA-HQ-OAR-2014-0827-1460-A1 p.8]

Just one example: Ford has achieved significant and rapid improvements in fuel efficiency with its F-150 through engine technological advances, weight reduction and start-stop technology to reduce
idling.\textsuperscript{33} All of these can be applied equally to medium duty pickups. [EPA-HQ-OAR-2014-0827-1460-A1 p.9]

Closing the gap between large light-duty and heavy-duty pickups and vans is crucial because the overlap in many characteristic allows manufacturers to essentially choose to classify a pickup as “heavy duty” to avoid the more stringent requirements for “light duty” pickups through minor adjustments to the vehicle. Market information is scarce, but there is some evidence that this type of regulatory avoidance is already occurring.\textsuperscript{34} This means that large light-duty standards may interact with the proposed standards for heavy-duty pickups. Due to their potential influence on manufacturers’ behavior, the large light-duty pickup standards should be treated as “fuel economy regulations by the government” under EPCA and EISA and be analyzed in the context of what constitutes the maximum feasible improvement for heavy-duty pickups and vans. Creating an incentive through rulemaking for manufacturers to avoid feasible, cost-effective, and already in-use fuel efficiency measures is arbitrary and capricious. [EPA-HQ-OAR-2014-0827-1460-A1 p.9]

The Proposed Rule simultaneously acknowledges the potential for technology migration between large light-duty and heavy-duty pickups/vans and then dismisses the importance of many of these technologies. The available data suggest that the agencies have been too quick to dismiss the potential for technology migration, even if the overall improvements in fuel efficiency are less for heavy duty than light duty pickups and vans. [EPA-HQ-OAR-2014-0827-1460-A1 p.9]

\begin{flushleft}Organization: Daimler Trucks North America LLC\end{flushleft}

\textbf{Proposed HD Pickup and Van Standard (80 FR 40334) -} The proposed Phase 2 standards can support environmental protection and reduce energy consumption. However, the proposed heavy-duty pickup and van standard, with a total stringency of about 16 percent for Phase 2 and an annual increase of approximately 2.5 percent during model years 2021 to 2027, is a challenge for automotive manufacturers. Under certain conditions, such a standard may necessitate hybridization of the affected vehicle fleet, which would require substantial development and material costs. All technologies taken into account for Class 2b/3 stringencies should reflect cost effectiveness calculations, especially alternative powertrains such as hybrids, battery, and fuel cell driven electric vehicles. Daimler recommends that EPA adopt the proposed standard over Alternative #4, as the additional two years of lead-time will be critical for automotive manufacturers in developing the necessary technologies to achieve compliance. [EPA-HQ-OAR-2014-0827-1164-A1 p.112

\begin{flushleft}Organization: FCA US, LLC\end{flushleft}

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 60-61.]
We continue to support EPA and NHTSA's attribute-based standards that recognize the utility and functionality of these work trucks. Payload and towing capacity are important to the owners of these work trucks. These work factor-based standards acknowledge the inherently higher greenhouse gas emissions and fuel consumption of higher capability vehicles.

While the light duty fleet has been regulated under NHTSA's Café Program for roughly 40 years, we are still very early in the Heavy Duty Program. We formally have one full model year of industry data under our belt. Given this limited baseline of real data, it is concerning that there have been calls for even greater stringency beyond the aggressive standards proposed by EPA and NHTSA for Phase 2. Comments regarding stringency need to address the many contributing factors, both explicit and implicit. These factors include, but are not limited to, the fact that these are work trucks, and there's a wide range of duty cycle so the values of the different technologies vary from a customer perspective.

We're challenged by year-over-year stringency increases with effectively only two products, a pickup truck and a van, to average in the 2B and 3 segment. The concurrent stringency increases, I think Ford mentioned earlier in the II and LEV III criteria emission requirements and how to manage the increased thermal loads on the after treatment systems while we continue to improve fuel economy.

The impact of changing test fuels and the test procedure adjustments that will be needed are unknowns at this point. Additional technology will be needed going forward given that some of the Phase 2 technologies are already in our fleet today. We have to take that into account, for example, FCAUS cylinder deactivation and cool EGR in today's vehicles, making these technologies unavailable for improvements in Phase 2.

Organization: General Motors

Second, the program must continue to recognize the unique functionality and utility needs of the trucking industry, and that we provide vehicles that preserve the performance integrity of these work trucks. Consumers value the payload and towing capabilities that these working vehicles offer, and the work factor-based standards set by EPA and NHTSA should continue to align with the industry and business needs of this demographic.

Organization: General Motors
The agencies' proposed Class 2B-3 standards, which are based on Alternative 3 in the Notice of Proposed Rulemaking, will continue to drive innovation, and will drive General Motors to invest in and refine new technologies that are both appreciated and optimized by American consumers. We cautiously support this path based on Alternative 3 for future emission reduction standards. This path will challenge our product plan and drive considerable technology into our heavy duty trucks and vans.

Finally, the program must attempt to minimize the potential for unintended consequences, especially for the consumer. The heavy duty fleet does not benefit from the years of data that have been collected and analyzed for the light duty fleet. Indeed, comprehensive data for this private segment is only now being accumulated and analyzed for the 2014 model year, which is the first year of Phase 1 of the medium and heavy duty truck regulations.

Year-end reports for 2014 were due to EPA by the end of March 2015, so this first year of comprehensive industry-wide data is still fairly new. This new data should be carefully evaluated and then compared to the estimates and assumptions that form the basis for both Phase 1 and the proposed Phase 2 of the heavy duty regulations.

Further, the utility provided and the duty cycle of these vehicles is completely different from the light-duty fleet. And any attempt to force more stringent regulations, such as Alternative 4, would be extremely detrimental to manufacturers, consumers, the U.S. economy, and the millions of transportation-related jobs. Indeed, comprehensive data for this product segment is only now being accumulated and analyzed for the 2014 model year, which is the first year of phase 1. The data should be carefully evaluated by the technical experts at the agencies and compared to the estimates and assumptions that form the basis for both phase 1 and the proposed phase 2 regulations.

Organization: International Council on Clean Transportation (ICCT)

- **Heavy-duty pickups and vans** – The technology availability from full-size body-on-frame light-duty pickup trucks is far greater than the efficiency technology applied in the agencies proposed 2027 pickup and van stringency determination. The agencies have applied technology improvements over 2018-2027 at about two-thirds the rate of the comparable full-size, body-on-frame light-duty pickups (i.e., 1.9% annual improvement for heavy-duty versus 2.7% for light duty). Advancing the proposed standards by three years would still keep the heavy-duty pickup and van standards well within known technologies that have already been proven out in much larger numbers in the light-duty space. More specifically regarding the applicable technologies, the major pickup and van manufacturing companies are already deploying the efficiency technologies in the heavy-duty Class 2b/3 space. For example, Ford, General Motors, Chrysler, and Daimler are applying lightweighting, downsized turbocharged engines, stop-start, cylinder deactivation, and automated manual transmission technologies in their heavy-duty products (Lutsey, 2015c, 2015d). [EPA-HQ-OAR-2014-0827-1180-A4 p.5]

**Heavy-duty pickups, vans, and vocational vehicles**

*Pickup and van technology.* Based on our extensive analysis in this area, the proposed heavy-duty pickup and van, as well as gasoline efficiency, standards appear to fall significantly short in their promotion of the full technology potential, based on the ICCT’s recent research in this area (Lutsey, 2015c,d), as well as Reinhart (2015a, b) and Khan and Langer (2015). We summarize several points from our previous work to help inform the Phase 2 rulemaking, and direct the agencies to the underlying referenced work for the full analysis. [EPA-HQ-OAR-2014-0827-1180-A4 p.11] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.40.]]
The pickup and van manufacturers are deploying the same technologies in light-duty and heavy-duty products. The light- and heavy-duty categories are a bright-line regulatory distinction; however, our assessment indicates that these two classes share many commonalities and overlap in physical attributes, engineering and design, engines, vehicle size, functionality and capacity, and efficiency technology applicability. As a result, manufacturers can and do deploy many of the same efficiency technologies in light-duty pickups as in the heavy-duty space. However, the agencies include substantially lower penetration of efficiency technology in their heavy-duty analysis. For example, cylinder deactivation, downsized turbocharged engines, advanced transmissions, low-rolling resistance tires, lightweighting each have significantly lower technology penetration and lower efficiency effectiveness in the Phase 2 rulemaking, as compared to the agencies’ light-duty rule. Reports from multiple sources suggest that leading companies are indeed increasingly planning to deploy their light-duty full-size pickup and van technology on their similar heavy-duty pickups and vans. Here are several such public examples -- [EPA-HQ-OAR-2014-0827-1180-A4 p.11]

- Ford: The Ford F250/F350 Super Duty trucks are headed toward application of F150 lightweighting technology for economies of scale gains, possibly as early as 2016 (Wernie, 2015), and this would mean downsized turbocharged engines, lightweighting, and stop-start technology would apply in the larger pickups and vans. Ford has indicated that it is indeed rolling out light-duty technologies on its heavy-duty vans and Super Duty trucks (Ford, 2014a b). [EPA-HQ-OAR-2014-0827-1180-A4 p.11]
- Fiat-Chrysler-Ram: Fiat-Chrysler is deploying its Hemi cylinder deactivation technology on its Ram 2500 and 3500 models (Williams, 2013). In addition, the Ram ProMaster commercial van offers downsized turbocharged gasoline and diesel engines, and is equipped with an automated manual transmission (Ram Commercial, 2014). [EPA-HQ-OAR-2014-0827-1180-A4 p.12]
- Daimler: Mercedes-Benz Sprinter commercial vans already utilize an advanced 7-speed automatic transmission and a downsized two-stage turbocharged diesel engine—for an 18% increase in fuel efficiency (Mercedez-Benz, 2014). Mercedes also has used start-stop technology on its Sprinter vans in Europe since 2009 (Abuelsamid, 2009). [EPA-HQ-OAR-2014-0827-1180-A4 p.12]

We recommend that the agencies establish commercial pickup and van CO2 emission and efficiency standards that are as technology-forcing as for the full-size trucks as in the light-duty vehicle standards. The proposed Phase 2 standards for heavy-duty pickups and vans will significantly increase their fuel economy and reduce their CO2 emissions, but not nearly as much as for light-duty pickups. U.S. EPA (2012) identified cost-effective technology paths to reduce the fuel consumptions and CO2 emissions of full-size body-on-frame pickups and vans by 40% in the light-duty rulemaking, before considering hybridization. However the agencies, in the case for heavy-duty Phase 2, based on our analysis of the primary NHTSA data file, appears to only be calling for a reduction of heavy-duty pickup and van CO2 emissions of 23% compared to a 2010 baseline. This demonstrates that the agencies are leaving a lot of highly cost-effective technologies, which are being deployed in large numbers in full-size light-duty pickups, out of their Phase 2 regulatory analysis. [EPA-HQ-OAR-2014-0827-1180-A4 p.12]

Another way to view the relative agency proposal versus the technology potential is to assess its annual rate of efficiency improvement. Although the agencies indicate the rules are reducing fuel consumption of pickups and vans by 2.5%/year, this neglects two facts: (1) the 2014 fleet is already beating the adopted regulations, and (2) there is a 2018–2020 period during which there is regulatory stability, with no movement in the standards. As a result the gasoline fleet appears to move at 2.2%/year, and the diesel fleet at 1.6%/year from 2014 through 2025 to meet the standards (Lutsey, 2015d). This compares with the light-duty standards that generally require a 4%/year reduction in fuel use, and almost 3%/year
Based on our analysis, we recommend that the agencies develop a more stringent progression of pickup and van standards, and advance the timing several years, to be as technology-forcing as the light-duty regulations for pickups and vans and promote all the new technologies that are available. We believe that as the agencies incorporate their full analysis and inputs from the light-duty rulemaking and recent developments from leading full-size pickup technology developers the result will be closer to a 35% (rather than 23%) 2014-2025 fuel consumption reduction and a 3%/year (rather than about 1.6%-2.2%/year) annual 2014-2025 fuel consumption reduction rate. [EPA-HQ-OAR-2014-0827-1180-A4 p.12]

**Organization:** National Automobile Dealers Association (NADA)

This vehicle group includes Class 2b and Class 3 large pickups and vans not otherwise covered by the light-duty fuel economy/GHG program. They are commonly recognized as “work trucks” principally used for a variety of commercial purposes, including heavy-trailer towing, shuttle vans, and mini-school buses. They are sold by two categories of dealerships: those primarily engaged in selling noncommercial, light-duty vehicles and those primarily engaged in selling medium- and/or heavy-duty commercial vehicles. At present, Class 2b vehicles are offered by Chrysler, Ford, General Motors, and Mercedes dealers, and Class 3 vehicles by Chrysler, Ford, General Motors, Isuzu, Mercedes, and Mitsubishi-Fuso dealers. [EPA-HQ-OAR-2014-0827-1309-A1 p.8]

Like Phase 1, the proposal targets standards using an appropriate “work factor” attribute designed to reflect consideration of vehicle payload, towing capacity, and 2 or 4 wheel drive. Standards are to phased-in between MY 2021 and MY 2027, ratcheting up by 2.5 percent each model year with the goal of achieving a 16 percent improvement over Phase 1. As under the Phase 1 rule, each OEM will have its own target based on the “work factor” of the fleet it produces for sale. [EPA-HQ-OAR-2014-0827-1309-A1 p.8]

Like vocational vehicles, “work trucks” often aren’t built by a single manufacturer, but rather are completed or altered (upfitted) by body and equipment installers or truck dealerships. This reality should be taken into consideration as the standards are finalized. OEMs who build complete vehicles or cab chassis for this vehicle group indicate that while aggressive, the proposed standards are achievable through strategies such as engine downsizing, new engine and transmission technologies, and lightweighting. [EPA-HQ-OAR-2014-0827-1309-A1 p.8]

**Organization:** Nissan North America, Inc.

As set forth below, the feasibility of the proposed Phase 2 standards for Heavy Duty Pickups and Vans (HDPV) will depend on providing significant flexibilities and credit opportunities. [EPA-HQ-OAR-2014-0827-1026-A1 p.1]

The agencies have appropriately recognized that many of the technologies used to reduce greenhouse gas emissions and fuel consumption in the light duty pickup truck and van segment are not applicable at the same adoption rate and do not have similar impacts when applied to the heavy duty segment. [EPA-HQ-OAR-2014-0827-1026-A1 p.2]
Relying on aggressive application of new technology to meet the Phase 2 standards is especially difficult for a manufacturer, such as Nissan, with limited offerings and relatively low volumes in this segment. Adding to this challenge is the fact that product life cycles tend to be longer in the heavy duty segment, making it even more difficult to make fundamental changes to the vehicle architecture that could further enhance fuel efficiency. [EPA-HQ-OAR-2014-0827-1026-A1 p.2]

The agencies’ expectations with regard to hybrid technologies are particularly aggressive. Nissan believes the widespread adoption of hybrid technology in the larger vehicle segments to be cost prohibitive and inconsistent with the utilitarian function of vehicles in the segment. Nissan does not expect hybrid technology to play a significant role during Phase 1 or during Phase 2 of the program. [EPA-HQ-OAR-2014-0827-1026-A1 p.2]

Nissan, however, continues to invest heavily and to improve its heavy duty gasoline and diesel powertrain technologies. As discussed with the agencies, Nissan already has planned substantial improvements that will dramatically increase fuel economy performance during Phase 1 of the program. These include improvements to both our V6 and V8 powertrains, and to both our gasoline and diesel engines. A significant amount of these improvements are being implemented in the short term and represent the best technological advances currently available. While Nissan and others will continue to invest in newer and yet more advanced technology, there is no certainty that the type of significant advances that are necessary to meet the stringent standards will be achieved. [EPA-HQ-OAR-2014-0827-1026-A1 p.2-3]

As Nissan has discussed with the agencies, the costs of translating light duty technology to the heavy duty market outweigh the company’s ability to recoup those costs in the competitive HDPV market. The proposed stringency level of 2.5% annual improvement is aggressive, and will require a substantial amount of technology adoption. Even with an array of credit programs and flexibilities, it may prove extremely difficult for companies with limited offerings in the segment to meet the standards, particularly in the later years. This would include each of the credit programs discussed below at the levels suggested. [EPA-HQ-OAR-2014-0827-1026-A1 p.3]

A 3.5% per stringency level is simply not feasible. The 3.5% alternative does not provide the necessary lead-time to enable manufacturers to balance competitive market constraints with the cost of applying new technologies to a limited product offering. To the extent, moreover, that the more stringent alternative is predicated on the adoption of hybrid and electric powertrain technology, Nissan -- engineering and market leader in electric vehicles -- does not believe that such technology is feasible for this market segment. [EPA-HQ-OAR-2014-0827-1026-A1 p.3]

The structure of the HDPV program is generally consistent with the Phase 1 program, and as such, provides Nissan and other manufacturers with consistency for compliance planning. In particular, the continuation of separate standards for gasoline and diesel vehicles and the work factor attribute are both critical to maintaining such consistency. Averaging and carry forward credits are essential to provide flexibility in compliance planning. [EPA-HQ-OAR-2014-0827-1026-A1 p.3]

The standards being proposed, at 2.5% annual increase in stringency, are in and of themselves at the limits of technological feasibility during the covered time frame. Alternative 4 is beyond those limits. Both levels should be supported by the array of credit opportunities described above. Should the agencies adopt the more stringent Alternative, however, these credit programs would be essential for compliance. Without them, companies with fewer product offerings, such as Nissan, will need to consider the feasibility of this market segment. With the most advanced technologies available today already being incorporated into Nissan’s offerings, the greenhouse gas reducing potential for the
medium- and heavy-duty fleets would best be achieved by accommodating lower-volume manufacturers and allowing the flexibilities to contribute to this market. [EPA-HQ-OAR-2014-0827-1026-A1 p.7]

Organization: Sierr Club

**Strengthen the proposed standards for heavy-duty pickup trucks and vans**

EPA and NHTSA should strengthen the proposed standards for heavy-duty pickups and vans. Strengthening these standards will reduce the discrepancy in standards for light and heavy-duty pickups, thereby reducing the possibility of market distortions. Many technologies are already in use in light-duty pickups, they just need a regulatory push to enter the heavy-duty pickup market. [EPA-HQ-OAR-2014-0827-1277-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.189.]]

Organization: Union of Concerned Scientists (UCS)

Class 2b-3 Heavy-Duty Pick-ups and Vans

Heavy-duty pick-ups and cargo vans form a continuum between vehicles classified under the light-duty passenger vehicle standards and the vocational vehicles and tractor-trailers that many would consider “heavy-duty” trucks. As such, the regulations of these vehicles is unique within the heavy-duty space because it is based on dynamometer testing like its light-duty counterparts, but the duty cycles can be different for these vehicles because more often they are truly used as work trucks. [EPA-HQ-OAR-2014-0827-1329-A2 p.25]

Because of the close relationship between light- and heavy-duty pick-ups, it is important that the heavy-duty and light-duty vehicle standards be harmonized as much as is reasonable to minimize environmental impacts from upsizing (customers shifting from LD to HD pick-ups)—this would also broaden deployment of technologies and help bring down costs. Below are comments related to increasing the standard of gasoline (up to a 23.6 percent improvement in 2027) and diesel (up to an 18.0 percent improvement in 2027) heavy-duty pick-ups and vans as well as the test procedures used to measure compliance. The pace of these standards would not only better represent what is feasible in this timeframe—they would also more closely align with the 3- to 4-percent annual improvement for full-size light duty pick-ups. [EPA-HQ-OAR-2014-0827-1329-A2 p.25]

**HEAVY-DUTY PICK-UP AND VAN STRINGENCY**

The technology employed in Class 2b-3 pick-ups and vans should reflect the fact that these vehicles share much in common with their light-duty counterparts. Historically, heavy-duty pick-ups were a significant increase in cost above and beyond light-duty pick-ups, where the purchaser was paying for significantly higher payload and towing capacity. However, with the increasing costs of light-duty full-size pick-ups and their increase in power, payload, and towing capacity, this segment of vehicles is more of a continuum than a step increase (Table 8). It is critical that the regulations regarding the fuel economy and greenhouse gas emissions of both light- and heavy-duty vehicles be more closely aligned given the close linkage of use and applicable technologies in these fleets. [EPA-HQ-OAR-2014-0827-1329-A2 p.25]

[Table 8, 'Cost and Performance of the Ford F-Series', can be found on p.25 of docket number EPA-HQ-OAR-2014-0827-1329-A2]
In a number of cases, manufacturers are already incorporating technologies from light-duty vehicles: Ford will be moving its 2017 F-Series Super Duty pickups to an aluminum body, just like the recently redesigned F-150; the 2014 Ram 2500 and 3500 incorporated cylinder deactivation, which had previously only been available in the 1500; and Mercedes is now offering a downsized 4-cylinder diesel engine for its Sprinter vans in addition to its 6-cylinder. The standards should reflect and encourage the further adoption of all available fuel consumption reduction technologies. [EPA-HQ-OAR-2014-0827-1329-A2 p.25]

Most of the specific engine technologies that could be applied in this space overlap with the technologies detailed in the vocational vehicles section of these comments, based on research from SwRI (Reinhart 2015a,b). For gasoline-powered vehicles, these technologies include direct injection, exhaust gas recirculation, variable valve lift and timing, cylinder deactivation, friction reduction, and turbodown sizing. For diesel-powered vehicles, more efficient turbochargers, friction reduction, downsizing, and even downsizing can further reduce fuel use from the engine. While we noted only a 10 percent application of downsizing to gasoline-powered vocational vehicles, we would expect significantly higher than that for both gasoline- and diesel-powered pick-ups and vans—Mercedes already acknowledged underestimating demand for the smaller four-cylinder diesel in its popular Sprinter (Brown 2014), and the less-demanding duty cycle for many of these vehicles, including the pick-ups, should allow for a greater opportunity in downsizing of the fleet. [EPA-HQ-OAR-2014-0827-1329-A2 p.25-26]

In terms of vehicle improvements, some of these are already happening and should be taken into consideration—for example, already mentioned was the lightweighting of the Ford F-Series Super-Duty pick-ups, which will shed hundreds of pounds thanks to the use of both an aluminum body and a high-strength steel frame (Priddle 2015). This change will already result in a 5-percent reduction in curb weight of the pick-ups, which is the maximum level of reduction assumed by the agencies by 2027. In other areas of the vehicle, the agencies have largely gotten things right: reductions in aerodynamic drag and rolling resistance, an increase in the number of gears of the transmission, and the electrification of accessories will all offer significant reductions in fuel consumption from this sector. [EPA-HQ-OAR-2014-0827-1329-A2 p.26]

Taking into account the greater adoption of downsizing and greater effectiveness of the engine technologies mentioned above, the data indicates that the agencies should be adopting a significantly higher standard for gasoline-powered pick-ups and vans. Vehicle improvements were identified from 11 to 16 percent on the regulatory cycle at 50-percent payload and 12 to 14 percent at maximum towing capability. Using the same engine packages as the vocational vehicles but with 20-percent downsizing, gasoline engine performance could improve by nearly 12 percent in the timeframe of this rule on the pick-up and van test cycles, while diesel performance could improve by slightly more than 5 percent. This would lead to gasoline pick-up standards of 23.6 percent beyond 2019 levels by 2027 and diesel standards for pick-ups and vans of 18.0 percent. [EPA-HQ-OAR-2014-0827-1329-A2 p.26]

The agencies' proposal must be 'technology-forcing' and achieve the 'maximum feasible' reductions in the timeframe of the rule. To do this, the agencies must strengthen Alternative 4 by: [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

- Ensuring that light- and heavy-duty pick-up and van standards are more closely aligned by acknowledging the full complement of applicable technologies - this would reduce consumption from gasoline-powered pick-ups and vans by 8.8 percent and diesel-powered pick-ups and vans by 2.1 percent in 2024; and [EPA-HQ-OAR-2014-0827-1329-A2 p.27]
Response:

The agencies agree that the form of the standards (work factor based) and the standard levels themselves are appropriately designed to maintain the functionality requirements of heavy duty pickups and vans while achieving emission reductions. These vehicles are purchased because of the need to perform certain jobs that cannot be performed by a light duty vehicle. By basing the standards on the working capacity by using work factor of the vehicle instead of the light duty footprint approach, these new emission standards achieve emission reductions at all the different working capacities and capabilities demanded by this segment. This approach also preserves consumer choice because consumers will seek vehicles with the necessary capabilities they require and manufacturers will design and produce vehicles for the consumer that meet new stringent emission standards solely based on the vehicle work capabilities the market demands. Consumers that need higher payload or towing or four wheel drive will purchase vehicles for that specific reason and not because of the footprint or other attribute that is not relevant to the intended use of the vehicle.

After considering the comments, EPA believes that the Phase 2 final standards that the agencies are adopting represent the most stringent standards reasonably achievable within the MY 2021-2027 period. The standards are based largely on the same technologies projected to be used in the light-duty fleet with appropriate adjustments for the heavy-duty fleet because of their specific higher load duty cycles. As described in Preamble Section VI.E.1, several technologies are projected to be used at very high adoption rates at or near 100 percent including mass reduction, 8-speed transmissions, engine friction reduction, low rolling resistance tires, improved accessories, and aerodynamic drag reductions. For gasoline engines, some commenters noted that downsizing turbo engines which are projected to be used extensively in light-duty vehicles should also be relied on in the heavy-duty analysis, including for HD pickups. As discussed in Preamble Section VLC.4.vii, the agencies agree with the comments provided by AAPC that turbo downsizing is likely to be counter-productive in heavy-duty pickups. Under heavy loads, turbo downsized engines may have higher CO₂ and fuel consumption than the engine it replaces. For this reason, EPA continues to believe that the technology can only be projected to be available for heavy-duty vans (and not pickups) and is projecting its use at 77 to 97 percent. NHTSA, in its method A analysis, likewise projects use of this technology only for heavy-duty vans.

One commenter argued for a standard predicated on a more aggressive penetration rate for cylinder deactivation, noting that in the NPRM the agencies only projected cylinder deactivation at an adoption rate of 22 percent of the overall fleet. The commenter believes that an adoption rate of 40 percent would be more appropriate. In response, cylinder deactivation is a gasoline engine technology and EPA is projecting an adoption rate of 56 percent for pickups and an adoption rate of essentially 100 percent for the gasoline engines in vans not projected to be downsized turbo engines -- a more aggressive penetration rate than urged by the commenter. With regard to some of the other technologies selected by the agencies as part of the technology basis for the standards, UCS commented that the agencies have largely gotten things right: reductions in aerodynamic drag and rolling resistance, an increase in the number of gears of the transmission, and the electrification of accessories will all offer significant reductions in fuel consumption from this sector.

AAPC commented that some of the technologies projected for Phase 2 are actually already present on some vehicles today. The agencies acknowledge that some of the same technologies are being implemented to meet the Phase 1 standards and that higher penetration levels or additional projected technologies may be required to meet the phase 2 standards. The agencies’ analysis looked at technology levels in the baseline model years of 2014 for the EPA analysis and 2015 for the NHTSA analysis, which represents the first couple of years of the Phase 1 standards where manufacturers may have already begun to add some technology. The agencies’ analyses determined that some of the projected technologies may be the same as what some manufacturers choose to adapt in order to meet the final Phase 1 standards in MY2018. However, additional technologies are available beyond those...
used to meet the Phase 1 standards and significant technology opportunities may only be available at vehicle redesign cycle occurring after Phase 1 and into Phase 2. Thus, addition of these more aggressive technologies before the Phase 2 rule takes effect is not an indication that the standards are insufficiently stringent. A specific example involves lightweighting, as already seen in some of the Ford pickup fleet. ICCT commented that the Ford F250/F350 Super Duty trucks are headed toward application of F150 lightweighting technology for economies of scale gains, possibly as early as 2016. As discussed above, the agencies believe that manufacturers are already beginning to select the key technologies they believe will allow them to meet the requirements for the Phase 1 program but also to prepare for the Phase 2 program in consideration of the limited opportunities to implement some of the technologies generally restricted to redesign cycles. Similar to the completely redesigned aluminum bodied MY2015 F150, Ford appears to be planning a similar lightweighting of the F250/350 in MY2017 due to the opportunity presented at the scheduled redesign cycle. The agencies anticipate that lightweighting technologies will be utilized by almost all manufacturers as a means to reduce emissions and fuel consumption of the next generation of pickups and vans.

EPA also remains concerned about projecting standards predicated on high levels of hybridization in the heavy-duty pickup and van fleet. Many heavy duty applications need maximum payload and cargo volume which may compete with weight increases and lost cargo volume from hybridization, directly reducing the capability and therefore work factor of the vehicle. Additionally, it is likely not feasible to size a hybridization system to be effective for any high or maximum payload or towing operation in a heavy-duty pickup or van without changing the utility of the vehicle. A manufacturer choosing to hybridize a heavy duty vehicle would likely target vans that are primarily used for cargo volumetric capacity reasons where a reasonably sized hybrid system could be incorporated and be effective under typical operation. EPA believes that the final Phase 2 standards will drive the orderly use of strong hybrid technology (the technology path under the Method B analysis includes modest penetration rates for strong hybrids) while still providing enough lead time that manufacturers could meet the standards using technology paths other than high penetration rates of strong hybrids. Thus, the gap in stringency between light-duty trucks and the Phase 2 standards for HD pickups and vans reflects constraints of the use of some technologies in the heavy-duty market resulting from the intended use of the vehicles to do more work than light-duty trucks. In addition, it is not appropriate to simply compare the change in the light-duty pickup footprint based standards to the change in the heavy-duty work factor based standards. In an apples to apples comparison, the agencies believe that the expected improvements in overall vehicle efficiency with the addition of advanced technologies to comply with the new standards for heavy-duty vehicles expressed in the form of fuel used to transport goods likely exceeds the light duty equivalent efficiency at doing work proportional to capability.

The proposed rule discussed several considerations that EPA believes remain valid. The NPRM projected that the higher rate of increase in stringency associated with Alternative 4 and the shorter lead time would necessitate the use of a different technology mix under Alternative 4 compared to the Phase 2 standards that the agencies are adopting. In EPA’s Method B analysis, the Phase 2 standards are projected to achieve the same final stringency increase as Alternative 4 at about 80 percent of the average per-vehicle cost increase, and without the expected deployment of more advanced technology at high penetration levels. In particular, under EPA’s primary analysis (Method B analysis), which does not constrain the use of strong hybrids, manufacturers are estimated to deploy strong hybrids in approximately 8 percent of new vehicles (in MY2027) under the Phase 2 standards, compared to 12 percent under Alternative 4 (in MY 2025). Less aggressive electrification technologies also appear on 33 percent of new vehicles simulated to be produced in MY2027 under Alternative 4, but are not projected to be necessary under the Phase 2 standards. Additionally, it is important to note that due to the shorter lead time of Alternative 4, there are fewer vehicle refreshes and redesigns during the phase-in period of MY 2021-2025. The longer, shallower phase-in of advanced technologies in the final standards allows for more compliance flexibility and closer matching with the vehicle redesign cycles,
which can be up to ten years for HD vans. While the Method B CAFE model’s algorithm accounts for manufacturers’ consideration of upcoming stringency changes and credit carry-forward, the steeper ramp-up of the standard in Alternative 4, coupled with the five-year credit life, results in a prediction that manufacturers would need to take less cost-effective means to comply with the standards compared with the final phase-in period of MY 2021-2027. The public comments from industry commenters generally confirmed that this is a realistic prediction.

The graphs below show the projected average per vehicle costs for the Phase 2 standards and Alternatives 4 and 5 for each manufacturer under the Method B analysis. As shown, in this Method B analysis, the Phase 2 standards are not projected to drive significant levels of technology prior to the start of the Phase 2 program in MY 2021. GM and FCA are projected to make some relatively small investments in technology prior to MY 2021 while Ford, Nissan, and Daimler are not projected to implement technologies to meet the standards until after the beginning of the program. These are the same projections presented at proposal, and the agencies did not receive comments disputing these technology projections for Phase 2 standards for years prior to MY 2021. Under Alternative 4, GM’s costs increase substantially, including costs prior to MY 2021. Ford’s costs are projected to almost double under Alternative 4 in MY 2023. Alternative 5 (even assuming, against our view that Alternative 5 is even technically feasible) drives these costs up even further with GM’s costs in MY 2021 projected to be about $3,000 per vehicle. Alternative 5 also shows significantly higher costs in MYs 2017-2018 for several manufacturers, raising additional issues of feasibility for this alternative given the lack of lead time to make substantial changes in the next few years. These graphs further illustrate that the additional lead time provided by the Phase 2 standards is projected to lower costs due to the use of less advanced technology such as hybridization, including during the early years of the program.
After several changes to the modeling inputs and logic, noted in Section VI.C(8) of the Preamble and Chapter 10.1.7 of the RIA, NHTSA’s Method A analysis shows that manufacturers could potentially meet standards with minimal reliance on strong hybrid technologies (2 percent under both Alternatives 3 and 4, and 7 percent under Alternative 5). The implementation and marketability of these technologies at this level of penetration of the market is no longer concerning in the Method A analysis. However, the same issue with lead-time still presents itself in the Method A analysis. The concern of lead-time leads NHTSA to reach the same conclusions about the maximal feasibility of Alternative 3.

The figures below show the year-by-year average per vehicle technology costs for Method A for GM, Ford, Fiat/Chrysler, and Nissan. The simulated GM progression of technology costs is similar under Alternatives 3 and 4. However: Ford, Fiat/Chrysler, and Nissan show more technology costs in early model years under Alternative 4 rather than Alternative 3. Ford’s simulated compliance strategy shows per-vehicle technology costs of $400 in MY 2017 under Alternative 3, $700 under Alternative 4, and almost $1400 under alternative 5. Alternatives 4 and 5 would put the majority of the cost burden on the
MY 2017 redesign, while Alternative 3 allows most of the cost burden to be on the MY 2025 redesign. The MY 2017 fleet will be in production at the time of publishing this rule. The next major redesign for Ford is not until MY 2025; to add an additional redesign in between the MY 2017 and MY 2025 fleet would involve much capital investment and does not seem feasible.

Similarly, FCA shows technology costs of $300 in MY 2018 under Alternative 3, $600 under Alternative 4, and $800 under Alternative 5. Nissan shows costs of $1000 in MY 2021 under Alternative 3, $1800 under Alternative 4, and $2700 under Alternative 5. The only manufacturer not shown here is Daimler; using the 2015 reference fleet Daimler does not apply additional technology in the regulatory alternatives, and incurs no additional costs. The general sequence of simulated technology costs remains the same as in the NPRM and Method B of the FRM: Alternatives 4 and 5 involve more each incurrence of technology costs than Alternative 3, even though the ending stringency curves for Alternatives 3 and 4 are the same, the additional lead time allows that manufacturers could implement technologies on during later redesigns under Alternative 3. While modeling results show that Alternative 3 could involve some early model year technology costs, they also show that Alternative 2 would forgo much of the benefits of Alternative 3. Further, the results shown here represent only one possible way that manufacturers may meet regulatory alternatives; they may avoid adding technologies in early model years, but adding more to reach over-compliance in later model years. For these reasons, NHTSA has determined that Alternative 3 represents the maximum feasible standards. Further description of the rationale behind the finalization of these standards can be found in Chapter VI.D.(9) of the Preamble and Chapter 10.2.8 of the RIA.

Per-Vehicle Technology Cost Increase for General Motors by Model Year and Alternative (Method A)
Per-Vehicle Technology Cost Increase for Ford by Model Year and Alternative (Method A)

Per-Vehicle Technology Cost Increase for Fiat/Chrysler by Model Year and Alternative (Method A)
AAPC commented in support of an alternative year-over-year phase-in that would phase-in stringency more gradually than the proposed (and now adopted) standard. AAPC recommended that rather than a 2.5 percent per year improvement, the increase should be at 1.75 percent per year through MY 2024 and then 3.5 percent per year for MY 2025 through 2027 with the MY 2027 level of stringency equally the proposed level. AAPC commented that this more gradual approach was consistent with the Phase 1 phase-in approach and would help manufacturers manage the long lead time associated with developing the new vehicles and powertrains that will be required in order to comply with the Phase 2 proposal.

The agencies are finalizing the proposed phase-in rather than adopting the approach recommended by AAPC. The more gradual phase-in recommended by AAPC would result in a loss of program benefits in each of the interim years of the program compared to the promulgated standards until the phase-in caught up with that phase-in in MY 2027. Because of the slower phase-in, the overall reduction in each interim year is lower than the phase-in being finalized. The phase-in adopted for Phase 1 with a more gradual ramp-up in standards took into consideration the shorter lead time associated with the Phase 1 standards and the uncertainty associated with implementing a new program. Phase 2 provides more lead-time than Phase 1 and the agencies believe based on their analyses of the standards that the lead-time provided is sufficient, particularly considering the flexibility also provided by credit carry-forward and carry-back provisions.

Nissan commented that the proposed stringency level of 2.5% annual improvement is aggressive, and will require a substantial amount of technology adoption. A 3.5% per stringency level -- which is what Alternative 4 would necessitate-- is simply not feasible, according to this commenter. The 3.5% alternative does not provide the necessary lead-time to enable manufacturers to balance competitive market constraints with the cost of applying new technologies to a limited product offering. To the extent, moreover, that the more stringent alternative is predicated on the adoption of hybrid and electric powertrain technology, Nissan -- engineering and market leader in electric vehicles -- does not believe that such technology is feasible for this market segment. Nissan believes the widespread adoption of hybrid technology in the larger vehicle segments to be cost prohibitive and inconsistent with the utilitarian function of vehicles in the segment. Nissan does not expect hybrid technology to play a
significant role during Phase 1 or during Phase 2 of the program. As explained above, the Method B analysis indicates that Alternative 4 would lead to more aggressive penetration rates of strong hybrids with less lead time than the standard being adopted, and EPA is rejecting Alternative 4 pull ahead standards in part for that reason. So to this extent, EPA agrees with Nissan’s comment. While Method A does not show the amount of hybrid technologies as is shown in Method B, the Method A analysis does show the highest early technology costs for Nissan of $1000 per-vehicle by MY 2021 under Alternative 3, and almost $2000 per-vehicle in MY 2021 under Alternative 4. NHTSA agrees that, based on the Method A analysis, Alternative 3 is aggressive (though feasible) and that Alternative 4 is likely not feasible.

Several commenters discussed the technology selection and effectiveness levels used by the agencies to determine the feasibility of the proposed standards had lower effectiveness levels and penetration rates than expected. The agencies worked together to determine appropriate technologies and the effectiveness of those technologies based on previous heavy duty GHG Phase 1 work, light duty GHG studies and the Southwest Research Institute (SwRI) research contract performed for the agencies. The technology effectiveness estimates were specifically adjusted for heavy duty applications subject to the conditions that these heavy duty pickups and vans are expected to experience in operation and during certification test cycles which differ from light duty. Comments from ACEEE, ICCT, Sierra Club, UCS and Center for Biological Diversity focused in on the opportunity to adapt more light duty technologies into the heavy duty segment. The agencies researched and took into consideration all light duty and heavy duty technologies currently available or believed to be available in the time frame of this rule. We determined that many light duty technologies could be used in heavy duty vehicles but at a generally reduced effectiveness and that some technologies were only appropriate for certain segments of the heavy duty fleet. Based on this understanding, we restricted certain technologies from some segments of heavy duty pickups and vans. For example, as explained above, we generally allowed specific light duty technologies, such as turbocharged downsized engines, in the van segment because of the expected loads vans experience are similar to loads experienced by the largest light duty pickups. Heavy duty pickups, on the other hand, are expected to be used much differently than vans or the light duty pickups version inasmuch as they have fewer available technology options operating at reduced effectiveness levels. Nissan, a large volume manufacturer developing vehicles with technologies for both the light duty and heavy duty applications, commented that the agencies have appropriately recognized that many of the technologies used to reduce greenhouse gas emissions and fuel consumption in the light duty pickup truck and van segment are not applicable at the same adoption rate and do not have similar impacts when applied to the heavy duty segment.

ACEEE commented that 10 percent of pick-ups in the heavy duty sector are candidates for turbocharging and downsizing if they do not require higher payloads or towing capacity. Other commenters suggested that downsizing that has occurred in light duty could also occur in heavy duty. As discussed above, the agencies evaluated turbocharging and downsizing in vehicles like vans which are not typically designed for extensive trailer towing. When we looked at pick-ups, we determined that consumers needing a pick-up without higher payload or trailer towing requirements would migrate to the lower cost light-duty versions which are typically identical in cabin size and seating as the heavy-duty versions but have less work capability. Because of this, in the agencies’ assessment, the heavy-duty pickups retained the high trailer towing and payload requirements and the corresponding larger normally aspirated gasoline engines instead of downsized turbocharged gasoline engines. Similarly, the agencies retained the larger diesel engines although there may be a segment of consumers that could use a smaller and less capable diesel engine in the heavy duty pickups. AAPC comments supported this approach as the correct combination of engine to intended use and even provided in their comments data indicating that turbocharged and downsized engines are more fuel efficient at lighter loads; however, under working conditions expected of a heavy-duty pick-up they are actually less fuel efficient than the larger engines. See the chart below supplied by AAPC in their comments.
ACEEE also commented that the agencies mistakenly did not consider cooled exhaust gas recirculation for gasoline pickups. Cooled EGR can reduce the fuel consumption of both direct-injected and port-injected gasoline engines by reducing pumping losses, mitigating knock, cooling the exhaust, and eliminating the need for fuel enrichment. ACEEE assumed this technology only for pickups and vans with turbocharged, downsized engines. The agencies determined that the basic form of EGR technology to reduce pumping losses, mitigating knock, cooling the exhaust, and eliminating the need for fuel enrichment is already present in the majority of the baseline vehicles or is added during technology implementation through the use of variable valve timing. Cooled EGR is an extension of basic EGR technology but the incremental benefit beyond basic EGR falls largely outside of areas of operation encountered during the certification test cycles. Cooled EGR is generally an incremental benefit over basic EGR in gasoline engines with elevated knock sensitivity or engines operating in areas where high exhaust temperatures require the engine to go into thermal protection. Heavily downsized and boosted engines or high compression engines are typically the applications that will see a significant benefit of cooled EGR, which is why the agencies expected high penetration of cooled EGR in light duty applications. Due to the higher load usage patterns and durability constraints, heavy duty engines will not see the same degree of downsizing and boosting or compression ratio increases in engines as projected for light duty vehicles. However, the agencies expect some manufacturers will use cooled EGR in heavy duty applications where they deem a customer benefit can be realized in the form of reduced fuel usage under the conditions described above.
UCS, Sierra Club, ICCT, CARB, and ACEEE all expressed concerns about the fact that light-duty pickup standards are much more stringent than the proposed standards for the heavy-duty fleet. UCS and ACEEE all expressed concerns that this discrepancy might create distortions between the heavy-duty and light-duty markets. It is important to note, that the heavy-duty standards are new; if distortions exist in the market they have likely existed before the new regulation. Moreover, while there are similarities between the light-duty and heavy-duty fleets, there are also differences—the redesign cycle is historically longer in the heavy-duty fleet and these vehicles are purchased for work capability, where many light-duty pickups may not be. The factors that give heavy-duty vehicles their added utility will also decrease fuel efficiency. Further, the ABT provisions in the light-duty standards allow averaging within a manufacturer’s combined car and truck fleet so that light-duty pickup stringencies can be offset by credit-generating passenger cars. In contrast, although all HD pickups and vans are a single averaging set under Phase 2 (and Phase 1), the product lines are more limited than in the light-duty fleet. Thus, there are fewer possibilities for averaging. The commenters also do not address that heavy duty pickups’ base price is typically considerably higher than the light duty pickup equivalent. A standard Google search indicates that the Ford 150 light duty pickup has a base price of $26,540; the 2016 MY F 250 base price is $32,385. The addition of fuel economy technologies on light and heavy duty pickups is unlikely to alter this basic disparity.

UCS further cited the close relationship between light-duty and heavy-duty models. NHTSA’s Method A analysis of the final rule includes some limited engine and platform sharing across these classes, as discussed in Section V.L.C(7)(d) of the Preamble and Chapter 10.1.7.1 of the RIA. Results suggest that sharing between the light-duty and heavy-duty vehicles result in a small amount of technology sharing between classes, but that amount of sharing does not result in significant additional technology applications in either class. For this reason, NHTSA further concludes that the ability to share technologies from the light-duty fleet to the heavy-duty fleet does not affect a significant proportion of the fleet. NHTSA will continue to investigate the issue of engine and platform sharing between classes in future rules.

With regard to comments on the relationship of these Phase 2 standards to the EPA’s recent Tier 3 standards, as discussed throughout the Tier 3 final rule, EPA has designed the final Tier 3 program in full recognition of the parallel implementation of the GHG standards in the same time frame as the final year for the heavy duty Phase 1 standards and the light duty 2017 to 2025 GHG rule. By aligning the implementation schedules for both sets of standards, we are facilitating the ability of manufacturers to meet one of their stated goals, the ability to develop product plans that simultaneously account for the technological challenges of both programs well into the future. We considered the feasibility of the Tier 3 standards in the context of the established GHG requirements.

The agencies recognize that these new standards will require concurrent implementation of the Tier 3/LEV III criteria emission requirements and the new heavy duty GHG and fuel consumption requirements we are finalizing. The technologies expected to be used by manufacturers to meet the Tier 3/LEV III standards do not necessarily result in negative impact to GHG emissions or fuel consumption. The majority of exhaust emission reductions from the Tier 3/LEV III programs are expected to be from reduced cold start emissions in the first couple of minutes of operation. For example, a Tier 3/LEV III strategy (see 79 FR 23461) to reduce emissions in gasoline applications may include reduced cold start enrichment to both lower engine out emissions and accelerate warm-up of the catalytic converter. This strategy should result in reduced emissions for both criteria emissions and GHG emissions. Diesel applications may require improved thermal management of the aftertreatment which should be beneficial for both programs by accelerating the warm-up and keeping the SCR system at high conversion efficiencies throughout the different areas of vehicle operation. However, due to uncertainties with these improvements regarding the extent of current optimization and future criteria emissions obligations, the agencies are not considering aftertreatment improvements in diesel.
application as a fuel-saving technology in the rulemaking analysis as discussed in Preamble section VI.C.4. In other words, while we believe that optimization of the SCR system can be considered a fuel saving technology, we did not premise the rulemaking or include technology costs on the need for this technology because of the possible future need to optimize the system for Tier 3/LEVIII emission requirements.

CARB and ACEEE also expressed concern about the dynamic baseline. ACEEE suggested that the assumption that manufacturers will apply technologies that payback within 6 months of discounted fuel savings, even if these technologies are not necessary to reach compliance is arbitrary. This assumption is based on the idea that there is a non-zero market demand for fuel economy and that this can be measured from the payback period. The assumption is that the market demand for fuel economy is small, but greater than zero. While the exact market demand for fuel economy is unknown, it is not arbitrary to assume that it is positive—ACEEE does not provide any data to suggest that the market demand for fuel economy is otherwise.

CARB cites that in their regulations they have assumed that manufacturers would comply, but not over-comply. However, it is important to note that their history is to regulate from the perspective of criteria pollutant emissions—these are typically assumed to be an externality and would not have a market value for consumers. Thus, for criteria pollutants regulation provides the only incentive for reduction, while for fuel consumption the market provides some incentive for reduction even absent regulation (the discounted value of fuel savings). It is also important to note that changing the baseline affects the benefits and costs attributed to the regulatory alternatives, but not the simulated compliance strategies themselves. For these reasons, NHTSA has continued to use the dynamic baseline in Method A for its main analysis of heavy duty pickups and vans. In other words, the same technology packages are required to meet the standards with either agency baseline approach however in the dynamic baseline used by NHTSA, less of the technologies and their costs are attributable to the new standards while in the EPA flat baseline analysis, all technologies and associated costs are included in the technology packages required to comply with the new standards.

Use of a flat baseline is also reasonable. There is a lack of empirical evidence for any specific baseline. See generally Preamble section X.A. Industry comments on payback generally refer to it as a necessary but not sufficient criteria for investment. Insofar as buyers require a positive payback within some denominated period of time, our understanding is that buyers’ considerations are informed by at least implicit judgments regarding the full range of potential risks and costs. In addition, the agencies’ analyses with different baselines is consistent with OMB guidance in Circular A-4. Finally, we note that the agencies conducted sensitivity cases for Pickups and Vans with 0, 6, 12, 18, 24 month payback periods. See Preamble Chapter 6 for details. These analyses all supported the same conclusion as to the appropriateness of the standards being adopted for heavy duty pickups and vans.

The agencies received limited comments on these different baseline approaches that dictate the costs. Some commenters expressed support for the flat baseline in the context of the need for the regulations, arguing that little improvement would occur without the regulations. Others supported the flat baseline because they believe it more fully captures the costs. Some commenters thought it reasonable that the agencies consider both baselines, given the uncertainty in this area. No commenters opposed the consideration of both baselines.

7.2.2 Work Factor

Organization: American Automotive Policy Council
**Work Factor** – AAPC supports the agencies’ attribute-based approach to medium-duty pickup and van standards that recognizes the physical demands placed on these work vehicles. These standards recognize that the various products offered have differing degrees of load carrying, trailer towing, and off-road capabilities. AAPC proposes an additional term be incorporated into the work factor for vans to account for cargo and passenger volume. [EPA-HQ-OAR-2014-0827-1238-A1 p.2]

**Work Factor Changes for Vans**

AAPC commends the agencies for continuing with a “work factor” based approach that recognizes the functional payload and towing capabilities that define vehicles in this segment. While AAPC believes that the payload, towing, and four wheel drive inputs to the work factor equation properly represent the primary intended uses of heavy-duty pickup trucks, they do not fully represent the intended uses of cargo and passenger vans, for which cargo or passenger volume are of primary importance. [EPA-HQ-OAR-2014-0827-1238-A1 p.7]

AAPC proposes that an additional volumetric term be incorporated into the work factor for vans to account for cargo and passenger volume: [EPA-HQ-OAR-2014-0827-1238-A1 p.7]

\[
WF = (0.75)* (GVWR – Curb Weight + xwd) +0.25* (GCWR – GVWR) + Max [AV / Vref, 0] \\
(GVWR – Curb Weight)
\]

Where Vref=208 cubic feet and AV = Cargo Volume - Vref

Note: Cargo volume is as determined by SAE J1100 methodology considering the total volume behind the front row of seats. [EPA-HQ-OAR-2014-0827-1238-A1 p.7]

In this scenario, vans with cargo volumes less than 208 cubic feet would receive no work factor adjustment for volume/passenger capacity. [EPA-HQ-OAR-2014-0827-1238-A1 p.8]

Separately, the agencies were seeking comment on whether inclusion of GCWR in construction of the work factor was resulting in manufacturers designing surplus towing capacity. The agencies work factor-based standards were derived using actual vehicle data (i.e., a combination of payload, towing, and 4x4 capability from actual vehicles when tested on the city highway cycle under ALVW conditions). Existing DOT Federal Motor Vehicle Safety Standards (FMVSS) and SAE J2807 requirements effectively cap the towing and GCWR in this segment. [EPA-HQ-OAR-2014-0827-1238-A1 p.8]

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)

**Work factor**

The rule defines work factor from payload and towing capacities which involves three weight parameters including gross vehicle weight rating (GVWR), gross combined weight rating (GCWR) and curb weight. Definitions of these three weight parameters, provided in the rule, involve manufacturer discretion. This leeway could weaken the standards, in effect. For example, two manufacturers recently claimed 150 to 250 lbs. additional payload in model year 2015 pickups by lowering vehicle curb weight\(^{18}\). Adding 250 lbs. to the payload would increase a vehicle’s work factor by 188 lbs. This in turn would lessen the fuel consumption/CO2 emissions reduction required in 2018 by 8.3 grams per mile, or
11 to 20%, depending on the work factor of the vehicle. Hence it is important that the agencies better define these weight parameters. [EPA-HQ-OAR-2014-0827-1280-A1 p.20]

When manufacturers can increase work factor at little cost and get benefit in fuel consumption, work-factor-based standards will incentivize such increases. This is an undesirable result that will reduce the benefits of the proposed standards. The agencies proposals to address this problem (p. 40336) are welcome. In particular, changing the shape of the standard curve for both gasoline and diesel vehicles to be flatter at higher work factors warrants further consideration. We also support the agencies’ consideration of adopting different work factor formulas for pickups and vans, especially in light of the very poor correlation between work factor and CO2 emissions for vans, as shown in figure 2. [EPA-HQ-OAR-2014-0827-1280-A1 p.21]

Recommendations: Work factor

- The agencies should better define GVWR, GCWR, and curb weights in order to reduce manufacturers’ discretion in determining these weights. [EPA-HQ-OAR-2014-0827-1280-A1 p.21]
- For the final rule, adopt a mechanism to minimize the incentive the proposed standards provide to increase work factor. [EPA-HQ-OAR-2014-0827-1280-A1 p.21]

Organization: Cummins, Inc.

Cummins supports the continued framework and metrics of Phase 1 for HD pickups and vans, which uses the work factor attribute for GHG evaluation over the same certification test cycles used for criteria emissions. The work factor term recognizes the work capacity of these vehicles to haul goods and provide services and is appropriate for HD pickups and vans. The agencies request comment on potential changes to the work factor curves and vehicle segmentation. The Phase 1 work factor was data-based using the then current US fleet sales of HD vans and pickup. Reweighting any of the terms or segmenting the fleet would require a full study, similar to that done in Phase 1, in order to ensure a feasible and fair framework for all OEMs and suppliers selling into this market. [EPA-HQ-OAR-2014-0827-1298-A1 p.32]

Organizations: Daimler Trucks North America LLC

- Work Factor Attributes (80 FR 40335 et seq.) - Daimler supports the work factor approach used in Phase 1 of the GHG regulation, as the footprint calculation does not adequately reflect Class 2b-3 vehicles and their real world purpose. Daimler also supports the approach of determining a vehicle’s fuel consumption and GHG emission reductions based on the type of work the vehicle performs in the real world. As stated in the NPRM, payload and towing are key in characterizing the difference in the
design of Class 2b-3 vehicles. Payload plays an even greater role in vehicle design than towing does. It has been noted that some Class 2b-3 vehicle manufacturers unnecessarily increase towing, particularly for diesel-powered engines, in an effort to meet the GHG regulations, with no real benefit to end users in their normal day-to-day work. [EPA-HQ-OAR-2014-0827-1164-A1 p.112]

The agencies have requested comment regarding four proposed changes related to Work Factor Attributes:

1. Although towing is an important factor, Daimler supports the agencies’ approach of weighting payload at 80% and towing at 20%. [EPA-HQ-OAR-2014-0827-1164-A1 p.112]

2. In an effort to prevent manufacturers from unnecessarily ramping up towing capacity with no real benefit to the end user, the agencies have proposed a towing cap. Although Daimler supports such a cap in principle, without knowing what the cap will be, Daimler cannot offer comment on the proposal. [EPA-HQ-OAR-2014-0827-1164-A1 p.112-113]

3. Changing the shape of the standard curve: Daimler does not offer vehicles with high towing capability. In our opinion changing of the shape seems not additionally necessary if the proposed revision of payload and towing rate weighting and the possible cap of high towing capability will be implemented [EPA-HQ-OAR-2014-0827-1164-A1 p.113]

4. With respect to applying different work factors for pickups and vans, Daimler does not currently offer pickups in the U.S. market and so does not offer comment at this point. Daimler would be interested in reviewing additional information on this proposal. [EPA-HQ-OAR-2014-0827-1164-A1 p.113]

Organization: Honeywell Transportation System (HTS)

Work Factor Should Follow Light Duty

Concerning the work factor calculation for Class 2B/3, HTS supports the current approach that recognizes professional usage of these vehicles. However, looking at the evolution of the advertised towing capacity from different manufacturers, we see that towing capacity (and therefore work factor) has increased significantly over the past five years without substantial improvement in fuel economy. HTS believes these increases in work factor are beyond the demonstrated needs of most buyers, thus there is little corresponding reduction in miles traveled or improvement in transport efficiency associated with the higher towing capacity ratings. In a 2010 survey conducted at the Texas State Fair, 90 percent of pick-up truck users expressed that they had enough capacity on their truck and 50 percent said that the older truck generation was already enough. Yet, during the period 2010-2014, the number of vehicles with more than 7500lb of work factor increased by more than 1000 percent. [EPA-HQ-OAR-2014-0827-1230-A1 p.4-5]

We believe that a knee inflection at high work factor should be proposed following the footprint principle adopted for the GHG / CAFE standard for Light Duty vehicles. This would help ensure that the rule in fact reduces GHG emissions and doesn’t merely result in vehicles with more unused capacity. HTS proposes that the inflection to the work factor begin at 7500lb. This proposed work factor “flattening” would impact less than 10 percent of all Class2B/3 vehicles sold. [EPA-HQ-OAR-2014-0827-1230-A1 p.5]

Organization: International Council on Clean Transportation (ICCT)
Pickup and van work factor. Due to the clear possibility of a shift upward in pickups’ and vans’ average work factor, we encourage that the agencies aim to prevent further market shift that would erode the regulatory program’s intended and projected benefits. Similar to the light-duty vehicle standards, a horizontal CO2 and fuel consumption kink, or cut point, as a maximum standard targets would be a necessary protection against potential runaway trends toward increased payload that undermines the program’s objectives. We recommend that the agencies set the threshold CO2 and fuel consumption standard targets at a work factor of 5,500 lbs. for gasoline trucks and 8,000 lbs. for diesel – based on these being near the 90th percentile for the model year 2014 fleet. [EPA-HQ-OAR-2014-0827-1180-A4 p.14]

Organization: Union of Concerned Scientists (UCS)

HEAVY-DUTY PICK-UP AND VAN TEST PROCEDURES

The central concern around the test procedures for heavy-duty pick-ups and vans is the way in which the work factor could provide an incentive for manufacturers to continue to add performance at the expense of fuel economy. We are already seeing very clearly that technologies such as lightweighting are being used to increase the payload of these vehicles. This has the perverse effect of reducing fuel economy targets for the vehicle, and thus a technology that could have been used to reduce fuel usage is instead being used to increase the performance of the vehicle. In order to minimize this effect, the agencies should consider an “elbow” in the work factor curve— above a specific work-factor, the fuel economy and greenhouse gas targets level off. This is similar to the features of the light-duty vehicle footprint curves, and it would eliminate the incentive more manufacturers to continue to add payload and towing capacity to game the system, regardless of whether or not it is being used by consumers. [EPA-HQ-OAR-2014-0827-1329-A2 p.26]

Response:

After considering these comments, the agencies concluded that the work factor approach established in the Phase 1 rule appropriately accounts for the different utility aspects of heavy-duty vehicles. While trucks and vans may be used differently depending on the required job, the three main attributes of payload, towing and four wheel drive remain properly accounted for at this time in the work factor equation at the current weightings. While a small portion of the fleet may be considered to have excess towing capacity relative to the actual required towing capacity by the customer, the agencies determined that the work factor design does not necessarily result in an incentive for manufacturers to build excessive towing into the vehicle design. Towing capacity increases require improvements to vehicle powertrains, cooling and brakes, generally at the expense of payload, and therefore the work factor reasonably balances an increase in towing with a reduction in payload. Additionally, increases in vehicle weight for additional towing capacity may result in an increase in the emission test weight, further penalizing unnecessary towing capacity. Moreover, as AAPC discusses, towing and payload are effectively already capped by existing DOT safety requirements in this segment. Consumers will ultimately decide on the appropriate balance of payload and towing for their applications, and the agencies therefore believe that establishing a work factor cap for the small percentage of vehicles with the highest towing capabilities is not necessary and will not result in emission increases or fuel consumption reductions under the high towing conditions for which those vehicles were purchased.

AAPC commented that the payload, towing, and 4wd inputs do not fully represent the intended uses of cargo and passenger vans, where cargo or passenger volumes are of primary importance. AAPC recommended that the agencies add a volumetric term to the work factor for vans with high (208 cubic feet or greater) cargo and passenger volumes. Vans with high volumes would have higher work factors.
and therefore less stringent targets with the AAPC recommended formula compared to the current formula. ACEEE commented that the work factor is a far better predictor of fuel efficiency for pickups than for vans and offered general support for adopting different work factor formulas for pickups and vans.

While it is likely valid that a portion of the vans are used exclusively for cargo volume and that towing is not an important attribute for these vans, the commenter failed to provide sufficient new information to support a new work factor metric specifically to address cargo focused vans. Most obviously, the suggested modification insufficiently represents the different van cargo volumes available to consumers today. A cargo volume based modification requires a complete industry van analysis of all available van cargo volumes and GHG and fuel economy performance levels from which a properly normalized adjustment would be determined, consistent with the approach used to establish the existing work factor equation for the attributes of payload, towing and four wheel drive. The agencies did not receive the level of detailed information required to determine the impact of cargo volume and establish a work factor correlation. Accordingly, the agencies are not incorporating the suggested change to the work factor for vans.

The agencies received a variety of comments on the details of the work factor approach. The agencies received comments from The American Council for an Energy-Efficient Economy (ACEEE) regarding the definition of payload and towing and manufacturer’s discretion at determining GVWR, GCWR and curb weight of the vehicle. In response, the formula for payload, GVWR minus curb weight, is specified such that it uses the same definition of the input terms as those which have always been used by the agencies for light and heavy duty vehicle regulations, including criteria pollutant emission standards and safety related designations. The agencies feel that there is no ambiguity in the definition of these terms and therefore payload calculation remains clearly defined with little or no opportunity for manipulation. The agencies have successfully used the previously established definitions of GVWR and curb weight to implement emissions and safety related programs and have not experienced any adverse issues in applying these definitions. The same is true for the definitions of terms used to calculate towing -- GCWR minus GVWR. While this definition for towing capacity does not match the method used by manufacturers in their consumer advertising, the agencies determined that the inputs of GCWR and GVWR are clearly defined in our regulations and used for many other emission and safety related determinations and therefore also remain a clear and consistent method to define towing for the purposes of calculating work factor. Again, the agencies have successfully used the previously established definitions of GCWR and have not experienced any issues that would warrant a change to the definition or use of these parameters.

ACEEE commented on recent announcements from two manufacturers that reported increases in payload capacity in their pick-ups due to a decrease in the curb weight of the vehicles from changes to light-weight materials. A reduction in vehicle weight while maintaining the same GVWR will result in a higher payload capacity which will then increase that vehicle’s calculated work factor and therefore result in a higher target GHG and fuel consumption standard. Work factor is defined as follows:

\[
\text{Work Factor} = 0.75 \times (\text{Payload} + xwd) + 0.25 \times (\text{Towing Capacity}),
\]

where:
- \(xwd=500 \text{ lbs.}, \text{ if the vehicle has 4WD}\)
- \(xwd=0 \text{ lbs.}, \text{ otherwise}\).

Similar to the light-duty (LD) footprint based approach which allows increases in GHG emissions and fuel consumption with increasing footprints, the work factor is designed to allow increases in GHG emissions and fuel consumption with increases in capability to do work, primarily hauling payload and towing. The HD pickup and van fleet has a different purpose than the light-duty vehicle fleet. These HD
vehicles are largely used for their towing and carrying capacity. Because consumers value the utility aspect of these vehicles more than footprint or some other attribute, the agencies set the standards based on work factor. While it does create a potential incentive for manufacturers to game the attribute-based standards, this could be a trade-off for creating standards that will preserve the utility of the heavy-duty fleet. The agencies partially addressed these concerns in the Phase 1 rule, by defining payload capacity as GVWR minus curb weight. Id. at 57162.

More generally, it is important to consider how these standards were developed. As alluded to above, payload, towing capacity, and drive type (all characteristics that are uniquely utilized in the heavy-duty fleet) are correlated with fuel efficiency. The work factor based targets were developed with this in mind. Since work factor and fuel efficiency can work in opposite directions, in order to game the standards manufacturers would have to decrease their fuel consumption target by more than they increase the achieved fuel consumption of a vehicle model by changing any component which influences work factor.

Further, by reducing curb weight, these manufacturers increase the work capability of their trucks specifically purchased by consumers to transport payload and (sometimes) to tow. Additional payload capacity is not always needed, but will sometimes allow the user to transport more goods and could result in fewer trips. Additionally, the reduction in curb weight will be beneficial in all other situations of unloaded and partially loaded transport of goods because a reduction in curb weight of the vehicle results in less energy wasted simply to move the vehicle regardless of payload. For this reason, the agencies included mass reduction as among the technologies on which the stringency of the final standards (as well as the Phase 1 standards) is based.

As established above, in most cases increases in work factor would be accompanied by an increase in fuel consumption. However, NHTSA has identified one case where this is not true. By applying mass reduction manufacturers can increase payload (and thereby work factor) and also decrease fuel consumption. The current version of the CAFE model includes both the decreases in the target of individual vehicle models, which occur from increased payload, and the decreases in fuel consumption when mass reduction is applied. These decreases in the standards are included in the projected average required fuel consumption levels of manufacturers, and associated decreases in average fuel consumption of the fleet due to mass reduction is included in the average achieved fuel consumption levels of manufacturers.

In summary, we have considered the possibility for manufacturers to game attribute-based standards. However, since most means by which a manufacturer might increase work factor would be accompanied by an increase in fuel consumption, we do not think the opportunities for manufacturers to game the standards are many. In the case of mass reduction application, where manufacturers could increase work factor and decrease fuel consumption to improve the position of individual vehicle models, we have included this in the model. We are open to suggestions on how we could further minimize the perverse incentives of the attribute-based standards, or to better capture them within the modelling results for future rule-making. We will continue to monitor the possibility for manufacturers to game standards and re-evaluate how we might set future standards differently if the need arises.

7.2.3 Separate Gasoline and Diesel Vehicle Standards

Organization: American Automotive Policy Council
Maintain Separate Gas and Diesel Standards - AAPC supports the agencies’ proposal to continue maintaining separate, but comparably stringent, CO2 and fuel consumption standards for compression ignition and spark ignition engines. [EPA-HQ-OAR-2014-0827-1238-A1 p.2]

Maintaining Separate Gas and Diesel Standards

AAPC supports the agencies’ proposal to maintain separate, but comparably stringent, CO2 standards for compression ignition and spark ignition engines. This approach insures that manufacturers of either engine type will implement the latest CO2 reducing technologies. As the agencies observed when the Phase 1 Heavy-Duty GHG rule was promulgated, significant technological and market-based differences exist between heavy-duty gasoline and heavy-duty diesel engines (76 Federal Register 51765). This will remain the case for the Phase 2 program (2019-2027), making a single standard commercially and technically impractical for both combustion technologies. [EPA-HQ-OAR-2014-0827-1238-A1 p.7]

Maintaining separate but comparably stringent spark ignition and compression ignition standards will allow customers for specific applications to take advantage of the combustion technology that best meets their specific application requirements while assuring that their particular engine is equipped with the latest fuel efficient technology regardless of combustion type. Maintaining a viable heavy-duty spark ignition market is critical for customers considering total cost of ownership including utility, maintenance, and serviceability. [EPA-HQ-OAR-2014-0827-1238-A1 p.7]

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Reducing the gap between gasoline and diesel efficiency requirements would also be a step forward for the heavy-duty pickup and van standards. Given that the work factor parameter has been specifically designed to capture the utility of these vehicles as it relates to fuel efficiency, gasoline and diesel vehicles should in principle be subject to the same, performance-based standard for CO2. As shown in Figure 2, there is a substantial difference at present in the performance of gasoline and diesel vehicles, which presents challenges for the adoption of a fuel-neutral standard at this time. However, reducing the gap between the diesel and gasoline standards by strengthening the gasoline standard, would help to address this problem. [EPA-HQ-OAR-2014-0827-1280-A1 p.24]

Organization: Cummins, Inc.

Cummins does not support different standards between gasoline- and diesel-fueled HD pickups and vans [EPA-HQ-OAR-2014-0827-1298-A1 p.34]

In Phase 1, the agencies set separate standards for gasoline- and diesel-fueled HD pickups and vans, with less stringency for gasoline vehicles. This offset in stringency was attributed to the short lead-time to implement Phase 1 versus the required time to develop and certify vehicles. Despite sufficient lead-time for Phase 2, the agencies have maintained the offset in stringency between gasoline and diesel vehicles (see Figure 13) through MY2027. As mentioned earlier, SwRI studies have demonstrated technologies that could be applied to both gasoline and diesel pickups and vans that achieve CO2 reductions that exceed the proposed standards for these vehicles. With ample time to develop and validate these technologies for the start of Phase 2, it is plausible for the agencies to establish a path of converging stringency for all HD pickups and vans. Such a pathway would create fuel neutral standards and eliminate any competitive advantage or preference to a particular GHG/FE technology and maintain the environmental benefits envisioned by the regulation, regardless of operating fuel. [EPA-HQ-OAR-2014-0827-1298-A1 p.34-35]
In Phase 1 and in the proposed Phase 2 regulations, there are large differences between the stringencies of the diesel and the gasoline standards, resulting in stricter requirements for diesel engines. This results in a significant disadvantage for the more efficient diesel technology. Today, diesel engines meet the most stringent emission standards and are therefore as clean as gasoline engines. Moreover, diesel technology is more efficient than gasoline technology with regard to fuel consumption. With respect to GHG emissions, gasoline vehicles should not be treated in a less stringent way than diesel vehicles. Instead, the stringency of both standards should be harmonized in the Phase 2 regulation. [EPA-HQ-OAR-2014-0827-1164-A1 p.113]

A level playing field is required for gasoline and diesel vehicles

Under Phase 1, EPA and NHTSA finalized weaker standards for gasoline pickups and vans than their diesel counterparts. As a result, the efficiency gap between gas and diesel trucks will grow over the timeframe of the Phase 1 rule (2014-2018). For Phase 2, the agencies have proposed standards for heavy-duty pickups and vans that require a 16% improvement beyond 2018 for both diesel and gasoline engines. These standards fail to close the efficiency gap between the different engine types and will instead perpetuate and increase the gap. [EPA-HQ-OAR-2014-0827-1312-A1 p.38]

The proposed standards are inconsistent with EPA’s long-standing precedent of setting standards that are fuel neutral and based on the capabilities of the technological leader. By setting a weaker standard for gasoline vehicles, the agencies have not established a level playing field and are creating incentives to shift from lower CO2 diesel vehicles to higher CO2 gasoline vehicles. Recent sales data for this vehicle class suggests that this shift is already occurring under the Phase 1 program and it will only be exacerbated under the Phase 2 program. This shift will put at risk the ability of the overall program to deliver the environmental results expected from the Phase 2 program. We recommend that the agencies set strong performance-based fuel neutral standards based on the technological leader. At the very least, this final rule should begin to close the efficiency gap between gasoline and diesel pickups and vans. [EPA-HQ-OAR-2014-0827-1312-A1 p.38]

The proposed rule strives for lower GHG emissions and improved fuel economy in Class 2B/3. This could be done through advanced diesel engines, advanced gasoline engines (including electrification or hybrid technology), or through some combination of these. Establishing technology/fuel neutral regulations allows industry to develop the most cost effective solution that meets consumer expectations. Instead of setting separate gasoline and diesel vehicle standards, we suggest that the baseline overall fleet CO2 emissions be calculated from the projected 2018 share of gasoline and diesel truck models, and that future emissions reductions are calculated from this baseline for the entire fleet independent of fuel type. [EPA-HQ-OAR-2014-0827-1230-A1 p.3-4]

Indeed, the EPA itself stated in the Phase 1 standard that “the agencies agree that standards that do not distinguish between fuel types are preferable where technological or market-based reasons do not argue otherwise,” and “expect to reexamine the need for separate gasoline/diesel standards in the next
rulemaking.” Based on the review of the proposal, HTS does not see evidence that such a reexamination has occurred, and therefore we recommend that the standard not distinguish between fuel types. This would ensure that the goal of an overall reduction of GHGs and improved fuel efficiency are met without creating the unintended consequences that could occur from favoring one fuel type over another. For example, if a particular powertrain has a less stringent GHG target and is lower cost, the market could shift in that direction resulting in higher overall GHG for the industry – the exact opposite intention of the proposed rule. [EPA-HQ-OAR-2014-0827-1230-A1 p.4]

**Organization:** International Council on Clean Transportation (ICCT)

**Fuel neutrality**

We note that the agencies appear to violate their own generally preferable principle of establishing fuel-neutral standards with their separate gasoline and diesel engine standards, pickup and van standards, and vocational standards (See, e.g., Lutsey, 2015c). In each case, the spark-ignited gasoline-related standards are set at less stringent levels than compression-ignition diesel. The gasoline standards miss opportunities to promote cost-effective efficiency technologies, and the standards are providing an incentive to shift the market from higher functionality, lower CO2 diesel products to lower functionality, higher CO2 gasoline products over time. This proposed approach would provide a sizeable incentive to manufacturers and consumers alike to shift to gasoline products, which often have lower CO2 characteristics for the same or sometimes lesser utility. The standards ideally would be set based on environmental performance, without special protection for spark-ignited gasoline products. We recommend that the agencies consider greater technology penetration in all spark-ignited gasoline products to finalize standards that are more truly emissions and efficiency performance based standards. [EPA-HQ-OAR-2014-0827-1180-A4 p.16-17]

**Organization:** Motor & Equipment Manufacturers Association (MEMA)

**Ensure Technology-Neutral, Performance-Based Standards** [EPA-HQ-OAR-2014-0827-1274-A1 p.3]

With respect to the heavy-duty pickups and vans category, while MEMA supports the continued use of the work factor attribute that takes into account both payload and towing capacities, MEMA does not favor the continuation of separate targets for gasoline and diesel vehicles. Rather than have different standards under Phase 2 that depend on the fuel/engine type, the agencies should mirror the regulatory approach used for light-duty trucks under the light-duty vehicle National Program, as well as for light-duty trucks and complete Class 2b-3 vehicles under Tier 3, and put in place a uniform performance standard that does not differentiate between gasoline and diesel. An alternative to the proposed rule would be to simply require a 16 percent fleet average CO2 emissions reduction.\(^3\) Consequently, the industry and customers pick the fuel and technology combination that offers the best value while also meeting the requirement. [EPA-HQ-OAR-2014-0827-1274-A1 p.4] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.194.]]

---

\(^3\) Using MY2018 baseline

**Organization:** Robert Bosch LLC
Although not a “heavy-duty” (HD) engine or vehicle manufacturer, Bosch has a keen interest in the Phase 2 proposed rule. [EPA-HQ-OAR-2014-0827-1466-A2 p.2]

Bosch has long advocated for policies that allow all technologies to compete on a level playing field in order to most effectively and fairly achieve societal objectives. We are puzzled with the lack of fuel neutrality in the proposed Phase 2 standards for HD pickup trucks and vans. By way of example, we observe that a model year (MY) 2021 diesel pickup truck with a work factor (WF) of 5,000 pounds would have a CO2 target value that is 30.5 g/mile lower (i.e., more stringent) than the target value for an identical gasoline pickup (515 g/mile vs. 545.5 g/mile). We further observe that while the compression-ignition (CI) – spark-ignition (SI) gap would narrow slightly over time, in MY 2027 and all later model years there would still be a 26.5 g/mile difference between the more stringent CI/diesel standard and the less stringent SI/gasoline standard for a HD pickup with a 5,000 pound WF (442 g/mile vs. 468.5 g/mile). In Bosch’s view, a sustained – from MY 2014, the start of Phase 1, through MY 2027 and all later years – preference for one technology over another via the imposition of differential performance standards prevents industry from investing in and developing the best available technologies. It also appears unfair and unwarranted. [EPA-HQ-OAR-2014-0827-1466-A2 p.2-3]

EPA and NHTSA established the separate CI/SI standards in Phase 1, but emphasized in the 2011 final rule “that they are not committed to perpetuating separate GHG standards for gasoline and diesel heavy-duty vehicles and engines, and expect to reexamine the need for separate gasoline/diesel standards in the next rulemaking.” 3 A perpetuation of separate standards, however, is precisely what the agencies have proposed for Phase 2 HD pickups and vans, with the apparently only cursory reexamination having yielded a justification that is no different from the one proffered by the agencies in Phase 1 – the existence of technological distinctions between SI engines and CI engines. Not “until advanced research evolves the gasoline fueled engine to diesel-like efficiencies,” the agencies now posit, will the HD pickup truck and van sector be suited for fuel-neutral GHG emissions and fuel consumption standards. [EPA-HQ-OAR-2014-0827-1466-A2 p.3]

Bosch strongly disagrees with the proposed continuation of separate target values for gasoline and diesel, and notes that the agencies preface the proposed Phase 2 HD pickup and van standards by acknowledging that these particular vehicles “share both substantive elements and a regulatory structure much more in common with light-duty trucks than with the other heavy-duty vehicles.” EPA and NHTSA proceed to explain that: (i) “[o]ver 95 percent of the HD pickups and vans sold in the United States” are manufactured “by companies with major light-duty [pickup truck and van] markets” in the U.S.; (ii) “these companies typically base their HD pickup and van designs on higher sales volume light-duty truck platforms and technologies, often incorporating new light-duty truck features into HD pickups and vans at their next design cycle”; and (iii) the same chassis dynamometer test procedure applies to both HD and light-duty pickups and vans. Given all of these factors, as well as the agencies’ intent “to develop an overall analysis fleet spanning both the light-duty and HD pickup and van fleets,” Bosch strongly maintains that HD pickups and vans should be regulated under Phase 2 in the very same manner that their light-duty brethren are regulated – through performance standards that do not differentiate between SI/gasoline and CI/diesel. [EPA-HQ-OAR-2014-0827-1466-A2 p.4]

The GHG emissions and corporate average fuel economy standards for light trucks do not distinguish, and have never distinguished between gasoline and diesel. Rather, the same CO2 target value applies to all types of light trucks manufactured in the same model year. 9 Similarly, EPA regulates light-duty trucks – and also complete Class 2b and 3 vehicles – under Tier 3 equally; the same exhaust emission standards apply to all vehicles regardless of the engine type. 10 Such an even-handed, fuel-neutral approach should be adopted for HD pickup trucks and vans under Phase 2, all the more so because it was not the approach taken under Phase 1, which represented the very first time HD vehicle GHG
emissions and fuel efficiency were regulated by the agencies. [EPA-HQ-OAR-2014-0827-1466-A2 p.4-5]

As in the Phase 1 proposed rule, EPA and NHTSA state that they “are not basing the proposed standards on a targeted switch in the mix of diesel and gasoline vehicles,” and “the proposed program is not intended to force, nor discourage, changes in a manufacturer’s fleet mix between gasoline and diesel vehicles.” This intent notwithstanding, Bosch believes that a market shift towards spark-ignited vehicles and away from HD pickups and vans powered by “fundamentally more efficient” CI engines would be a very real possibility under Phase 2 if the separate gasoline and diesel targets are finalized as proposed. Equally if not more important, any such shift would signify not only a move towards less efficient internal combustion engines, but would be counterproductive from a programmatic/environmental and energy standpoint in that the corollary necessarily would be an increase rather than a reduction in CO2 emissions from (and fuel consumption for) the HD pickup truck and van sector. [EPA-HQ-OAR-2014-0827-1466-A2 p.5-6]

In response to the agencies’ belief that “similar levels of technology development and cost” would be required for both types of vehicles, Bosch stresses that diesel engines, from a criteria pollutant (especially NOx) emissions perspective, have made far greater strides over the years than gasoline engines, and for that reason have incurred greater technological development costs than the latter. While equivalent CO2 target values may be more expensive, comparatively speaking, for SI engines to achieve (based on the agencies’ cost analysis), the additional cost imposed on these engines likely would not rise to the level of, much less overtake CI engines’ historically higher technological development and system costs (e.g., diesel particulate filters and selective catalytic reduction systems), which only figure to increase under Tier 3. [EPA-HQ-OAR-2014-0827-1466-A2 p.6]

For all of these reasons, Bosch calls on the agencies to apply to all Phase 2 HD pickup trucks and vans the same CO2 target values regardless of the engine technology (SI or CI). To the extent the agencies believe subjecting all vehicles to the same targets is unjustified due to “the potential disruption” from a market shift, Bosch maintains that it is equally unjustified, for precisely the same reason, to subject diesel vehicles to target values that are lower than those for gasoline vehicles. Bosch notes, too, that by setting uniform performance standards, all potential future technology packages compete on a level playing field in order to achieve the desired CO2 reduction in the most economical way possible for consumer acceptance. The preservation of a certain price differential between CI and SI engines must not become a target itself. [EPA-HQ-OAR-2014-0827-1466-A2 p.6-7]

Ultimately, then, Bosch urges the agencies to issue a Phase 2 final rule that establishes, once and for all, GHG and fuel efficiency parity among all HD pickups and vans, i.e., a fair and level playing field for these vehicles irrespective of their technology (CI or SI), as is the case for light trucks under the light-duty National Program and Tier 3 (as well as the California Air Resources Board’s LEV III Program), and as EPA expressly indicated in the Phase 1 proposed rule it wanted to do. [EPA-HQ-OAR-2014-0827-1466-A2 p.7]

2 Throughout these comments, we use the term “heavy-duty” to apply to the same engines and vehicles referenced by EPA and NHTSA in the proposed rule. See 80 FR at 40145.

3 76 FR 57106, 57165 (Sept. 15, 2011); see also EPA, EPA Response to Comments Document for Joint Rulemaking, at 6-182 – 6-183 (Aug. 2011), available at http://www.epa.gov/otaq/climate/documents/420r11004.pdf. The agencies added in the comment response document that Phase 1 “differs from other recent rulemakings in this regard in that we are
regulating GHGs and fuel consumption for the heavy-duty sector for the first time, and so believe the goal of fuel-neutrality is best met by setting standards based on the market/technology situation as it exists today.” Id. (emphasis added).

9 See 40 CFR §§ 86.1818-12(c)(3).

10 See 40 CFR §§ 86.1811-17, 86.1816-18; 79 FR 23414, 23425 (Apr. 28, 2014) (Tier 3 emission standards “are fuel-neutral”). Notwithstanding technological differences (not to mention significantly higher compliance costs for CI (vs. SI) engines), fuel neutrality is, of course, also a key feature of the HD engine emission standards for NOx, non-methane hydrocarbons, and particulate matter under 40 CFR 86.007.11 and 86.008-10.

15 In this regard, Bosch emphasizes that while HD gasoline pickups and vans “are generally . . . less expensive than diesels” in terms of the upfront cost, 80 FR at 40514, a recent University of Michigan Transportation Research Institute (UMTRI) study underwritten by Bosch shows that from a total cost of ownership (TCO) perspective, one that takes into account not only the initial purchase price but also such factors as the costs of fuel, insurance, repairs, and maintenance and also resale value and depreciation, most HD diesel pickup trucks have a lower TCO than their gasoline counterparts. UMTRI, Total Cost of Ownership: A Diesel Versus Gasoline Comparison (2012-2013) (June 2015), available at http://www.umtri.umich.edu/sites/default/files/Belzowski.Total_.Cost_.%20of.Ownership.Paper_.2015.Final2 .pdf.

16 75 FR at 74213 (stating EPA’s desire “to revise the heavy-duty vehicle and engine regulations to make them consistent with the light-duty vehicle approach, applying standards for all regulated criteria pollutants and GHGs regardless of fuel type”) (emphasis added).

Response:

The agencies requested comment on both the level of stringency of the standards and the continued separate targets for gasoline and diesel HD pickups and vans. AAPC supported the agencies’ proposal to maintain separate targets noting that the approach ensures that manufacturers of either engine type will implement the latest CO2 reducing technologies. AAPC further commented that significant technological and market-based differences exist between heavy-duty gasoline and heavy-duty diesel engines. According to the commenter, maintaining separate but comparably stringent spark ignition and compression ignition targets will allow customers for specific applications to take advantage of the combustion technology that best meets their specific application requirements.

Several commenters did not support the proposed approach but instead supported setting a single fuel-neutral set of targets. Cummins commented that there is sufficient lead-time and technology to create a pathway to fuel-neutral targets, and that fuel neutral targets would eliminate any competitive advantage or preference to a particular GHG/FE technology and maintain the environmental benefits envisioned for the program. Daimler, Honeywell, and MEMA similarly commented in support of fuel-neutral standards. Honeywell and Motor and Equipment Manufacturers Association (MEMA) suggested basing the standards on a 16 percent improvement from the projected MY 2018 gasoline/diesel combined baseline. ACEEE and ICCT commented in support of a single set of standards set at or close to the capabilities of diesel technology. These commenters suggested that gasoline engines should be subject to more stringent standards than proposed and that gasoline and diesel engines should be held to the same performance-based standards.
Bosch disagreed with maintaining separate targets for gasoline and diesel HD pickups and vans. Bosch recommended that targets be fuel neutral, as they are in the light-duty vehicle programs. Bosch commented that it “believes that a market shift towards spark-ignited vehicles and away from HD pickups and vans powered by ‘fundamentally more efficient’ CI engines would be a very real possibility under Phase 2 if the separate gasoline and diesel targets are finalized as proposed.” Bosch continues that “any such shift would signify not only a move towards less efficient internal combustion engines, but would be counterproductive from a programmatic/environmental and energy standpoint. Bosch further commented that “diesels from a criteria pollutant (especially NOx) emissions perspective, have made far greater strides over the years than gasoline engines, and for that reason have incurred greater technological development costs than the latter. While equivalent CO₂ target values may be more expensive, comparatively speaking, for SI engines to achieve (based on the agencies’ cost analysis), the additional cost imposed on these engines likely would not rise to the level of, much less overtake CI engines’ historically higher technological development and system costs.”

The agencies generally prefer to set standards that do not distinguish between fuel types where technological or market-based reasons do not strongly argue otherwise. However, as with Phase 1, we continue to believe that fundamental differences between spark ignition and compression ignition engines warrant unique fuel standards, which is also important in ensuring that our program maintains product choices available to vehicle buyers. In fact, gasoline and diesel fuel behave so differently in the internal combustion engine that they have historically required unique test procedures, emission control technologies and emission standards. These technological differences between gasoline and diesel engines for GHGs and fuel consumption exist presently and will continue to exist after Phase 1 and through Phase 2 until advanced research evolves the gasoline fueled engine to diesel-like efficiencies. This will require significant technological breakthroughs currently in early stages of research such as homogeneous charge compression ignition (HCCI) or similar concepts. Because these technologies are still in the early research stages, we believe the separate fuel type standards are appropriate in the timeframe of this rule to protect for the availability of both gasoline and diesel engines and will result in roughly equivalent redesign burdens for engines of both fuel types as evidenced by feasibility and cost analysis in RIA Chapter 10. For the same reasons, the agencies are adopting separate standards for diesel and SI vocational engines.

In order to maintain the same overall level of stringency as proposed for the program, a fuel neutral standard would result in an increase in stringency for gasoline or spark ignition vehicles with a matching relaxation of stringency for diesel or compression ignition vehicles relative to the separate numerical levels established in the proposal for gasoline and diesel vehicles. Based on the analysis of available technologies for both types of vehicles, the agencies do not feel it is appropriate to adopt such a change for either gasoline or diesel vehicles. This change could lead to an undesirable reduction in penetration of fuel efficient technologies in diesels, particularly from manufacturers who produce predominately diesel vehicles, while requiring a higher penetration of advanced technologies like strong hybridization in gasoline vehicles, distorting consumer choice. Additionally, the agencies do not agree with the comment stating that maintaining separate gasoline and diesel targets of equal increases in stringency of 2.5 percent per year from the Phase 1 final standards will result in a shift to less efficient gasoline vehicles. The agencies determined that manufacturers have similar technology challenges and corresponding costs regardless of fuel type and therefore manufacturers do not have an easier or lower cost long term path to compliance by simply shifting production from one fuel type to the other.

Note further that a manufacturer’s fleet average standard is the production weighted average of all its targets, both gasoline and diesel. Thus, there is no separate gasoline vehicle standard, or separate diesel standard. Commenters may have been confused on this point (several of the commenters referred to gasoline ‘standards’, or diesel ‘standards’). This averaging feature of the standard further increases incentives to add advanced technologies to either gasoline or diesel vehicles if manufacturers perceive it
advantageous to do so, since the benefit is experienced fleet wide, not just for the gasoline or diesel segment of a manufacturer’s production line.

The agencies also received comments that the standards should be based exclusively on the GHG capabilities of diesel vehicles. The commenters viewed the separate gasoline and diesel standards as preferential treatment of gasoline-powered vehicles which have inherently higher GHG and fuel consumption. As discussed in Preamble Section VI.B.1, the agencies are maintaining the separate gasoline and diesel standards for heavy duty pickups and vans. As discussed earlier, diesel engines are fundamentally more efficient than gasoline engines providing the same power (even gasoline engines with the technologies discussed above) while using less fuel. However, dieselization is not a technology path the agencies included in the analysis for the Phase 1 rule or the Phase 2 rules. Gasoline-powered vehicles account for nearly half of the heavy-duty pickup and van market and are used in applications where a diesel may not make sense from a cost or consumer choice standpoint. Commenters did not address the costs of extensive dieselization.

More stringent standards, including Alternative 4, could result in manufacturers switching from gasoline engines to diesel engines in certain challenging segments. EPA remains concerned that this pathway could cause a distortion in consumer choices and significantly increase the cost of those vehicles, particularly considering that more stringent standards are projected in the Method B analysis to require penetration of some form of hybridization. Also, the agencies did not consider the impact dieselization would have on lead-time, as shifting nearly half the market from gasoline to diesel engines would require substantial retooling of production. Commenters did not account for the costs or address the feasibility of such retooling in the lead time available under either Phase 2 or Alternative 4. In addition, if dieselization occurs by manufacturers equipping vehicles with larger diesel engines designed for broad coverage of applications typical of this sector rather than “right-sized” engines, the towing capability of the vehicles could increase, resulting in higher work factors for the vehicles, higher targets, and reduced program benefits. Bosch commented that holding gasoline vehicles to the same GHG standards as diesels would bring the costs of compliance with all emissions standards, including criteria pollutant standards, for gasoline vehicles more in line with diesels, considering the costs of complying with criteria pollutant standards are much higher for diesels compared to gasoline vehicles. In response, EPA’s Method B analysis shows that significantly more stringent gasoline vehicle GHG standards may require high levels of hybridization which, as discussed above, may not be acceptable for this market segment. This, in turn, could lead to dieselization, as manufacturers would opt to phase out gasoline-fueled vehicles rather than opt for widespread hybridization of their product offerings. EPA continues to believe that it is reasonable to adopt Phase 2 standards that continue to preserve the opportunity for manufacturers to produce and consumers to choose gasoline-powered vehicles in this market segment.

7.2.4 Test Procedures

Organization: American Automotive Policy Council

Test fuel changes and needed Agency adjustments – Moving to Tier 3 E10 test fuel has impacts on octane and energy content of the test fuel. The agencies need to make test procedure adjustments to avoid unintended increases in greenhouse gas and fuel consumption standard stringency. Industry is so concerned about this adjustment that they have initiated a test program to quantify these effects in the light-duty arena. The AAPC recommends a similar program for the heavy-duty segment. [EPA-HQ-OAR-2014-0827-1238-A1 p.11]

Class 2b/3 Truck and Van Test Weights
The current methodology for Class 2b/3 CO2 testing limits the Equivalent Test Weights (ETW) to 500 pound increments. While this is appropriate in terms of defining a reasonable number of sub-configurations, it provides no incentive for implementing weight reductions less than amounts that would result in a change to the next lowest 500 pound ETW bin. For example, a manufacturer with a 7,200 lb. ALVW truck would be in the 7,000 lb. ETW class. Implementing an 800 lb. weight reduction would result in a 400 lb. change to the vehicle’s ALVW (assuming that the full 800 lbs. is added to the vehicle’s payload). This would lower the ALVW to 6,800 lbs., resulting in the same 7,000 lb. ETW class as the heavier vehicle. [EPA-HQ-OAR-2014-0827-1238-A1 p.25]

While work factor targets are calculated to individual pounds, test weights are limited to 500 lb. increments. [EPA-HQ-OAR-2014-0827-1238-A1 p.26]

As a matter of public policy, the regulations should be designed to encourage incremental weight reductions by manufacturers whenever possible, not just large-scale weight reductions requiring huge investments of resources. AAPC recommends that a credit mechanism be defined that allows manufacturers to use the ADC formula found in § 86.1819–14 (g)(1) to account for weight reductions within an ALVW test weight class (actual ALVWs within 50 lb. increments). [EPA-HQ-OAR-2014-0827-1238-A1 p.26]

Organization: California Air Resources Board (CARB)

Comment - The test weight bins should be changed in order to allow for more realistic testing of heavy-duty pickups and vans due to mass reduction

CARB staff believes weight reduction can be a cost-effective technology that can achieve significant CO2 reductions. A prime example of the effectiveness of this technology is the recently redesigned F150 which makes extensive use of aluminum. In fact, all manufacturers are expected to incorporate vehicle weight reduction across their light-duty fleet (where emission test weight (ETW) bins are significantly smaller) in response to the 2017-2025 GHG requirements. As currently structured, the ETW bins for class 2b and 3 vehicles (500 lbs) tend to discourage the use of this technology since significant weight reduction is required before any benefit can be demonstrated over the applicable emission test cycles. Narrowing the ETW bins could encourage early implementation of vehicle weight reduction across a vehicle product line as well as providing manufacturers with increased flexibility in using weight reduction as part of their technology portfolio. Another benefit of reducing ETW bins is that the test results would more accurately reflect vehicle GHG emissions. Accordingly, CARB staff recommends restructuring the compliance process to encourage vehicle weight reduction by reducing the applicable ETW bins to 125 pound increments. [EPA-HQ-OAR-2014-0827-1265-A1 p.66]

Organization: Daimler Trucks North America LLC

HD Pickup and Van Test Procedures (80 FR 40341) - Daimler supports the agencies’ approach of keeping the test procedures fundamentally the same and continuing regulations that create as level of a playing field as possible. Daimler also supports the agencies’ proposals to change how vehicles are categorized into test bins. Creating smaller ranges decreases the chances of one manufacturer having an unfair advantage over another within a test bin. However, the potential increase in the number of bins as a result of this effort is cause for some concern. The agencies should promote opportunities for manufacturers to generate additional credits. At this time, Daimler does not offer comment as to
appropriate methods allowing for analytical adjustments of CO2 levels and fuel consumption within vehicle weight class. [EPA-HQ-OAR-2014-0827-1164-A1 p.113]

Response:

The test procedures for HD pickups and vans currently specify using a fuel with properties established under the light-duty (LD) vehicle Tier 2 program. EPA recently finalized new emission standards under the Tier 3 program for both LD vehicles and HD pickups and vans which will begin to phase-in in MY2017 for LD vehicles and MY2018 for vehicles over 6000 pounds GVWR, including HD pickups and vans. As part of the Tier 3 program, new test procedures require the use of a new test fuel containing 10 percent ethanol which is more representative of in-use fuel that the vehicles will encounter. The agencies are investigating any potential impact of changes to the fuel properties on GHG emissions and fuel consumption and have committed to providing appropriate adjustment to the test procedures if necessary to ensure no change in stringency of the Phase 1 or the Phase 2 standards. Additionally, any potential regulatory action as a result of the findings from this investigation would also address provisions allowing for an appropriate phase-out of data generated on the current GHG emissions and fuel consumption certification fuel as to avoid an unnecessary disruption in manufacturer’s long term planning and testing requirements.

AAPC commented that the current methodology of grouping vehicles by the Equivalent Test Weight (ETW) in increments of 500 pounds for determining their GHG and FE performance is too large to capture weight reductions that may occur within a 500 pound grouping. Under the current test procedures, vehicles are tested at 500 lb. increments of inertial weight classes when testing at or above 5500 lbs. test weight. For example, the commenter stated that all vehicles having a calculated test weight basis of 11,251 to 11,750 lbs. are tested at 11,500 lbs. (i.e., the midpoint of the range). However, for some vehicles, the existence of these bins and the large intervals between bins may reduce or eliminate the incentive for mass reduction for some vehicles, as a vehicle may require significant mass reduction before it could switch from one test weight bin to the next lower bin. For other vehicles, these bins may unduly reward relatively small reductions of vehicle mass, as a vehicle’s mass may be only slightly greater than that needed to be assigned a 500-pound lighter inertia weight class. For example, for a vehicle with a calculated test weight basis of 11,700 lbs., a manufacturer would receive no regulatory benefit for reducing the vehicle weight by 400 lbs., because the vehicle would stay within the same weight bracket.

The agencies believe this (and similar comments) have some merit. In response, the agencies are finalizing an option allowing manufacturers to divide vehicle models into 50 pound increment groupings of vehicles for the different Adjusted Loaded Vehicle Weights (ALVW) for purposes of more precise calculation of CO2 emissions performance within the 500 pound increment test weight classes. ALVW will vary within a single ETW largely depending on the varying models curb weights from customer option selection and other production variations. The calculation of CO2 emissions performance for the 50 pound increment groupings is performed as described in 40 CFR 86.1819-14(g)) for analytically adjusting CO2 (ADCO2) emissions. The test results at the existing 500 pound increment ETWs will be used to determine the CO2 emissions performance level of the new groupings using the analytically derived equation. This new ADCO2 emissions level is only used for this new grouping and cannot be used to extend determination of other ALVW groupings emission performance levels. The vehicle specific values used to determine the change in ETW in the ADCO2 emissions calculation to estimate the performance of the smaller grouping should be consistent with value used to calculate the single work factor of that same grouping. This change does not impact the ETW of a group of vehicle models that are contained in the 500 pound increment of ETW when performing testing nor does it eliminate any vehicle in that grouping from being responsible for emission performance at
the 500 pound increment test weight classes. As described, this change only allows for more precise
CO$_2$ emissions estimation for the potentially different curb weights of vehicles grouped in a single ETW
class for purposes of fleet average calculation. If a manufacturer chooses to use the 50 pound increment
approach, they are required to use this option for all of their HD vehicles that are chassis certified
(including loose engines).

7.3 Projected Pickup and Van Technologies, Effectiveness, and Cost

Organization: American Chemistry Council (ACC)

A Lightweighting vehicle is one of the strategies to achieve reduced greenhouse gas (GHG) emissions
and fuel consumption. This is an area where lightweight plastic polymer composites can play a
significant role in designing new medium and heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1147-A2 p.2]

Composites are a combination of tough plastic resins, reinforced with glass, carbon fibers and other
materials. These plastic composites are lighter weight than traditional automobile materials, yet
maintain high levels of strength and a high resistance to corrosion. Plastic and composite materials
provide a way to lighten vehicles while maintaining passenger safety and the integrity of the vehicle.
Additional properties of plastics and composites, including strength to weight ratio, energy absorption
and flexible design, make these materials ideal for use in the manufacturing of medium and heavy-duty
vehicles. [EPA-HQ-OAR-2014-0827-1147-A2 p.2]

The chart labeled “Figure 1” below provides data regarding the tensile strength and density of filled
plastics, polymer composites, metals, and alloys. As shown in the chart, there are many plastics and
polymer composites that are significantly less dense than most metals and alloys while offering similar
tensile strengths. These data illustrate the fundamental physical advantage that many plastics and
polymer composites can offer over metallic automotive materials: higher strength-to-weight ratios that
can enable automakers to lightweight vehicles while maintaining safety and performance. As vehicles
across the board begin reducing weight to comply with the new GHG emissions standards and fuel
efficiency standards proposed by this rulemaking, new lightweight vehicle architectures will emerge.
Lightweight plastic and polymer composites have the characteristics needed to help deliver energy
saving results while supporting innovative designs that satisfy consumer preference. [EPA-HQ-OAR-
2014-0827-1147-A2 p.2]

Recent model year cars and trucks have greatly benefited from plastic and composite materials as well.
In the last 47 years, the use of lightweight plastics in U.S. automobiles grew from an average of 60
pounds (27 kilograms) per vehicle to approximately 330 pounds (150 kilograms) per vehicle in 2014.
More than 50% of a typical vehicle’s volume is composed of plastics and polymer composites, but these
materials only account for approximately 10% of total vehicle weight. It is evident that medium and
heavy-duty vehicles can reap the same benefits as the lightweight vehicle sector by embracing cutting
edge plastic and composite technology which reduce weight and allow manufacturers to consolidate
components. A timely example on a 2010 vehicle is illustrated by an all new plastic two-shot window
lift carrier plate that replaces a metal-intensive assembly comprising 21 components produced with 16+
processing and assembly steps with a plastics-intensive, 10-component unit produced in 10 assembly
steps. [EPA-HQ-OAR-2014-0827-1147-A2 p.3]
The proposed rulemaking recognizes the use of lightweight plastic and polymer technologies, such as thermoplastics. ACC applauds this recognition, particularly considering the fact that the increasing interest in plastic and composites within the global automotive industry follows well-documented trends of composite usage to increase efficiency in the civilian and military aerospace industries. Choosing plastic and polymer composites to lightweight medium and heavy-duty vehicles is a decision supported by science that can pay immediate and long term dividends. [EPA-HQ-OAR-2014-0827-1147-A2 p.3-4]

Aerodynamic Benefits

Aerodynamic enhancement features on trucks often utilize lightweight plastics that add very little weight while providing large aerodynamic gains. Lightweight plastic and polymer composites also have excellent durability with damage and corrosion resistance compared to the traditional steel and aluminum alternatives. Those characteristics, along with the benefit of low tooling manufacturing, makes plastic and polymer composites a viable material for aerodynamic technologies like side skirts and trailer end fairings. The function of aerodynamic technologies and lightweight plastic and composites go hand in hand for they both have the ability to reduce GHG emissions and fuel consumption. [EPA-HQ-OAR-2014-0827-1147-A2 p.4]

In 2014, ACC’s Plastics Division published a detailed report titled “Plastics and Polymer Composites for Automotive Markets Technology Roadmap.” This road mapping process engaged technical experts and leaders from the automotive and plastics and polymer composites industries, including perspectives from original equipment manufacturers, tier suppliers, material developers, researchers, federal agencies, and consultants, to discuss the current limitations to the increased use of plastics and polymer composites and to identify industry-wide actions that can accelerate the increased widespread use of these materials in future vehicles. The roadmap synthesizes the findings from this effort through 2014 and sets a path forward for the plastics and polymer composites and automotive industries through 2030. This roadmap is designed to help the automotive and plastics and polymer composites industries maintain a strong foundation upon which to build partnerships and initiate collaborative programs that address changing market needs. Implementing this roadmap will require significant resources to accomplish both shorter-term priorities and the long-term vision for 2030 and beyond. We would be pleased to meet with the agencies to further discuss our roadmap implementation efforts so that the information can be effectively leveraged to meet the objectives of this Proposed Rule. [EPA-HQ-OAR-2014-0827-1147-A2 p.5]

Organization: National Automobile Dealers Association (NADA)

NHTSA and EPA estimate that the per vehicle average costs to comply with these new heavy-duty pickup and van standards will, due to potential fuel savings, result in a 3 year average payback period. However, many customers could face significantly higher actual costs and thus longer pay back periods. While not mandatory, the Phase 2 proposal clearly contemplates that compliance for this vehicle group will be achieved in part by engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop start engine stop and powertrain hybridization. [EPA-HQ-OAR-2014-0827-1309-A1 p.8]
Organization: XL Hybrids

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 242.]

the projected incremental cost for the heavy-duty pickup and vans, strong and mild hybrids, seem a little bit low. The heavy-duty pickup and van strong and mild hybrid cost projected in RIA tables 2-179 and 2-183 are based on weight scaling from the light-duty sector that do not adequately account for production volume differences between light-duty and heavy-duty sectors.

Organization: California Air Resources Board (CARB)

Comment – The heavy-duty pickups and vans technology list should include battery electric or fuel cell electric technology, hybridization of diesel engines and dieselization

CARB staff has significant concerns regarding the following assertion: [EPA-HQ-OAR-2014-0827-1265-A1 p.66]

As discussed in Section I, the agencies request comment on the proposed approach for the advanced technology multipliers for heavy-duty pickups and vans as well as the other heavy-duty sectors, including comments on whether or not the credits should be extended to later model years for more advanced technologies such as EVs and fuel cell vehicles. These technologies are not projected to be part of the technology path used by manufacturers to meet the proposed Phase 2 standards for heavy-duty pickups and vans. (page 40389 of the NPRM) [EPA-HQ-OAR-2014-0827-1265-A1 p.66-67]

A large population of heavy-duty pickups and vans are used as last-mile delivery vehicles that return to a yard or terminal on a daily basis. Last-mile delivery vehicles will be ideal candidates for zero-emission technologies, especially fuel cell electric technology. With this understanding, CARB staff is considering regulations that will incentivize and/or mandate zero-emission technologies in the heavy-duty sector within the Phase 2 timeframe. Specifically heavy-duty pickups and vans, especially in last-mile delivery applications, is an area that CARB staff considers fertile for greater adoption of zero-emission technologies in the near-term. CARB staff believes that the federal Phase 2 standard is important to incentivize early adoption and deployment of zero-emission technologies in this category. [EPA-HQ-OAR-2014-0827-1265-A1 p.67]

The NPRM requests comment on the proposed technology list that would be used by manufacturers to comply with the heavy-duty pickup and van standard. CARB staff recommends that the list include battery electric and fuel cell electric technologies. [EPA-HQ-OAR-2014-0827-1265-A1 p.67]

The list of technologies should also include hybrid diesel technologies as CARB staff believes strong hybrids in the heavy-duty pickup and van sector will be widely available in the 2025 timeframe. Currently, XL Hybrids and Crosspoint Kinetics have commercially-available hybrid systems for both new purchases and existing vehicle conversions. [EPA-HQ-OAR-2014-0827-1265-A1 p.67]

XL Hybrids currently has hybrid systems for box trucks (Ford E-350/E-450 cutaway, Ford E-450 strip chassis), Reach walk-in commercial vans (Isuzu/Utilimaster), cargo vans and passenger wagons (Chevy Express 2500/3500, GMC Savana 2500/3500, Ford E-150/E-250/E-350, Ford Transit), shuttle buses (Ford E-350/E-450 cutaway, Ford E-450 strip chassis, GM 3500/4500 cutaway (available September
Crosspoint Kinetics currently has hybrid systems for a variety of new class 3-7 trucks and buses, including a retrofit option for existing vehicles. Their systems have been tested and approved at Altoona and have been certified by the Federal Transit Administration. [EPA-HQ-OAR-2014-0827-1265-A1 p.67-68]

CARB staff believes that if there is a projected demand created by regulatory Phase 2 (Alternative 4) requirements, these two companies, and likely other companies, would make additional hybrid systems available for the targeted heavy-duty truck and van sector. Since the basic hybrid system designs from XL Hybrids and Crosspoint Kinetics have been proven in actual fleet operations, additional demands for their products would lower the price of hybrid technologies due to increased production. The technology could also be more economically designed for other vehicle platforms, creating additional growth and development for hybrids in general. [EPA-HQ-OAR-2014-0827-1265-A1 p.68]

Furthermore, U.S. EPA and NHTSA's own modeling on the projected level of hybridization penetration necessary by 2030 to comply with the different regulatory alternatives showed that for two companies (Daimler and Nissan), no hybridization is necessary to comply with Alternative 4 (Tables VI-25, page 40378 of the NPRM, and VI-26, page 40378-40379 of the NPRM, respectively). Another company, Fiat/Chrysler needs only 3 percent hybridization penetration to comply with Alternative 4 (Table VI-24, page 40376-40377 of the NPRM) and Ford needs to have 14 percent hybridization penetration to meet Alternative 4 requirements (Table VI-23, page 40375-40376 of the NPRM). Of the major manufacturers, only GM would need to have a significant level of hybridization penetration at 79 percent to comply with Alternative 4 (Table VI-22, page 40375 of the NPRM). This lends further support for the feasibility for Alternative 4, which CARB staff recommends. [EPA-HQ-OAR-2014-0827-1265-A1 p.68]

Response:

The agencies recognize there is a range of diversity and complexity for mass reduction and material substitution technologies and there are many techniques that automotive suppliers and manufacturers are using to achieve the levels of this technology that the agencies have modeled in our analysis for this program. We agree that there is an area where lightweight plastic polymer composites can play a significant role in designing new medium and heavy-duty vehicles. In our analysis, we discuss an overall vehicle mass reduction not specific to one part of the vehicle with cost estimates that are also not specific to any component or material that would be substituted.
The agencies also identified aerodynamic drag reduction as a technology that could be implemented to reduce the GHG emissions and fuel consumption. We agree that materials made from lightweight plastics could help provide aerodynamic reductions and in fact are already seeing significant use of these materials in the light-duty fleet. Many of the similar approaches to reduce aerodynamic drag in light duty, particularly in trucks and MDPVs are also applicable to the heavy-duty segment.

With regard to the comment regarding projected incremental cost for the heavy-duty pickup and vans, strong and mild hybrids, as discussed in the NPRM, the agencies utilized cost and technology estimates that originated from light duty vehicle MY 2017-2025 GHG rule cost analysis but were then adjusted upward for the heavy duty vehicles based on the increase in GVW between the light duty and heavy duty segment. The effectiveness of hybrid systems was reduced relative to the light duty levels because of the duty cycles of heavy duty vehicles tend to result in more loaded operation and reduced opportunity for hybrid system energy recovery. The hybrid systems in light duty have been evolving dramatically in the past few years and as such costs have been fluctuating with different designs, but there has been a general trend of reduction in cost, particularly in the batteries, with each new generation of hybrid system. It is difficult to precisely predict what the cost of a heavy duty hybrid system will cost when this rule begins to take place in MY2021 and phases in the years that follow as manufacturers determine what applicable level of hybridization they can incorporate into their heavy duty vehicle designs. For these reasons, the agencies feel that our estimates of the various hybrid systems discussed in the NPRM and FRM are appropriate estimates based on our research of light duty systems and then scaled for heavy duty vehicles.

During the development of the NPRM, the agencies worked closely with and communicated with CARB regarding our determination of technologies that were appropriate at this time for a Phase 2 national program and that would be included in the agencies’ modeling in support of the final standards. In their comments, CARB discusses battery electric or fuel cell electric technology for heavy duty pickups and vans as a technology that could be included in the agencies’ list of available technologies. These technologies are not projected to be part of the technology path used by manufacturers to meet the Phase 2 standards for heavy-duty pickups and vans. The agencies determined that while battery electric or fuel cell electric technology may be a viable technology option at some point in the future for this sector, insufficient information exist regarding the cost and effectiveness of these technologies in the heavy duty pickup truck and van sector in the time frame of this rule. They agencies instead chose to offer advanced technology multipliers for use of these technologies on all Phase 2 vehicles to incentivize the adoption of these technologies.

In their comments, CARB staff believes strong hybrids in the heavy-duty pickup and van sector will be widely available in the 2025 timeframe. According to CARB staff, XL Hybrids and Crosspoint Kinetics currently have commercially-available hybrid systems. The agencies included both mild and strong levels of hybridization in the modeling for the NPRM and the FRM. The Method B model predicted that some level of both mild and strong hybridization was appropriate and cost effective in the heavy duty pickup and van segment for the finalized standards, but that these levels would rise sharply if the standards were pulled ahead. As discussed above, EPA determined that Alternative 4 was inappropriate largely for these reasons, especially considering the adequacy of lead time to require higher levels of penetration of these advanced technologies by 2025 rather than 2027. In addition, as explained in response 7.2.1 above and Preamble section VI.E, the method B analysis indicates that the Phase 2 standards are projected to achieve the same final stringency increase as Alternative 4 at about 80 percent of the average per-vehicle cost increase, without necessitating the high penetration rates and short lead times for mild hybrids.
7.4 Flexibilities and Compliance Provisions for HD Pickup and Van Standards

7.4.1 Averaging, Banking, and Trading Credits Provisions

Organization: American Automotive Policy Council

Given the limited historical data available for medium- and heavy-duty engines and vehicles, we support the flexibilities noted as a means to address the inherent program uncertainties and ensure the program’s continued success. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

Credit Carry Forward and Transfers - AAPC supports extending the carry-forward of banked, surplus credits by both Agencies until they are fully used to offset future debits and separately remove the restrictions for credit trading between the differing regulatory categories. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

Credit Carry Forward and Transfers

Carry Forward

The limited five year carry-forward mechanism for CAFE and GHG credits was apparently chosen because it mimics the current light-duty CAFE program, but this approach is neither optimal nor required for the heavy-duty program. Heavy-duty credits should have a longer life to better align the program with the realities of the heavy-duty fleet. The heavy-duty fleet differs fundamentally from the light-duty fleet for the following reasons: [EPA-HQ-OAR-2014-0827-1238-A1 p.13]

- Industry heavy-duty volumes are much smaller (only 5% of light-duty fleet volumes) [EPA-HQ-OAR-2014-0827-1238-A1 p.13]
- Individual manufacturers have fewer models to average for compliance (essentially a pickup and van with many variants) in the heavy-duty versus light-duty fleet. [EPA-HQ-OAR-2014-0827-1238-A1 p.13]
- With fewer models and longer renewal times for heavy-duty vehicles and powertrains, manufacturers have less frequent opportunities to implement significant fuel consumption / CO2 improvements. [EPA-HQ-OAR-2014-0827-1238-A1 p.14]
- The heavy-duty fleet has multiple “regulatory buckets” (2b/3 fleet, engine dyno, GEM, etc.) that further constrain a manufacturer’s ability to balance credits and debits. [EPA-HQ-OAR-2014-0827-1238-A1 p.14]

AAPC supports extending the carry-forward of banked, surplus credits by both Agencies until they are fully used to offset future debits. While adopting an extended carry-forward time period provides greater flexibility in how manufacturers use credits they have generated, it does not change the overall effectiveness of the program. There are multiple reasons why adopting this policy would benefit stakeholders: [EPA-HQ-OAR-2014-0827-1238-A1 p.14]

- Motivates Early Action - Extending the life of credits provides greater flexibility for manufacturers in using the credits they have generated. As the agencies themselves have noted in the Light-Duty regulation (77 Federal Register 62666), carrying forward of credits beyond 5 years provides manufacturers a significant incentive to over-comply to present regulation in order to generate credits for future use. This rewards early investment and encourages adoption of additional CO2 reducing technologies that manufacturers would otherwise not be
incentivized to deploy. These credits would also help manufacturers resolve lead-time issues and manage uncertainties, such as future NOx reduction, while facing aggressively increasing standards from Phase 1 to Phase 2. [EPA-HQ-OAR-2014-0827-1238-A1 p.14]

- Consistent with Product - A long credit life is more consistent with how the vehicles and powertrains under this regulation are viewed by both manufacturers and customers. Manufacturers refresh these vehicles less often as smaller annual volumes drive longer investment amortization and customers view vehicles as functional tools that are oftentimes used by the first owner for a full vehicle lifetime. [EPA-HQ-OAR-2014-0827-1238-A1 p.14]

- Follows Precedent - There is precedent within the EPA regulations for extending the life of GHG credits. The EPA in the 2017-2025 Light-Duty GHG regulations established an extended carry-forward provision. The rationale given (76 Federal Register 74968) was that extended carry-forward “provisions are not expected to change the emissions reductions achieved by the standards, but should significantly reduce the cost of achieving those reductions.” This assessment is even more compelling in the context of the Heavy-Duty rule, as extended carry-forward would enable manufacturers to comply with the requirements of the Phase 2 proposal at an overall lower cost. EPA also notes (77 Federal Register 62789) that compliance features, such as extended carry-forward, are particularly valuable because, in contrast to the Light-Duty CAFE program, no option to pay fines in lieu of compliance exists under the Clean Air Act. In addition, the increasing stringency of Phase 2 program under Alternative 3 merits more flexibility. EPA’s action in the light-duty program establishes a precedent for providing this type of flexibility. As EPA noted in their EPA Fact Sheet – August 2012: “To facilitate the transition to the increasingly more stringent MYs 2017-2025 standards, EPA is finalizing under its Clean Air Act authority a one-time CO2 credit carry-forward provision beyond 5 years, allowing credits generated from MYs 2010 through 2016 to be used through MY 2021.” [EPA-HQ-OAR-2014-0827-1238-A1 p.14]

- Allowed by Statute – The agencies are allowed to make this change and are not constrained by the CAFE statute. The CAFE statute provides, in 49 USC 32902(k), that the Secretary of Transportation is to regulate commercial medium-duty and heavy duty on-highway vehicles, and work trucks, by developing test methods, measurement metrics, fuel economy standards, and compliance and enforcement protocols, that are: appropriate, cost-effective, and technologically feasible. This language leaves the design of the program to the Secretary’s discretion, and imposes no specific limitations on the life or usage of credits under the program. [EPA-HQ-OAR-2014-0827-1238-A1 p.15]

All of the other CAFE provisions that address fuel economy and associated requirements are found in sections 32902(a)-(d). Sections 32903(a) and 32903(e) set forth CAFE’s 5-year carry-forward/3-year carry-back provision for passenger automobiles and non-passenger automobiles subject to the light-duty CAFE program. These provisions do not apply to the heavy-duty program promulgated by the Secretary pursuant to section 32902(k). Thus, the heavy-duty CAFE program is not subject to any statutory restrictions pertaining to credit life requirements. [EPA-HQ-OAR-2014-0827-1238-A1 p.15]

NHTSA can, under the statute, establish any credit mechanism that is consistent with the overall directive to promulgate an “appropriate, cost-effective and technologically feasible” set of regulations for heavy-duty vehicles. For the reasons outlined above, our proposal to carry-forward credits until they are fully used to offset debits is consistent with these statutory directives. [EPA-HQ-OAR-2014-0827-1238-A1 p.15]

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)
The UAW strongly supports an Averaging, Banking and Trading and Off-Cycle Technology credit program that “plays an important role in making the proposed technology-advanced standards feasible, by helping to address many issues of technology challenges in the context of lead time and costs.” [EPA-HQ-OAR-2014-0827-1248-A2 p.10]

The credit system works well and is essential in the heavy-duty pickup and van sector because the year-over-year stringency requirements do not reflect the reality of product cycle and the small number of platforms in the segment. Extended carry-forward time in light duty regulation, encourage manufacturers to make greater improvements sooner because surplus credits will not expire. This model should also be applied to the medium and heavy duty segments. We urge EPA and NHTSA to examine ways to enhance the existing credit program to account for the realities of the market. [EPA-HQ-OAR-2014-0827-1248-A2 p.10]

**Organization:** Nissan North America, Inc.

**One Time Credit Carry Forward Through Model Year 2027**

Nissan strongly supports allowing a longer, one-time carry forward from Phase 1 of the program to Phase 2. Similar provisions were made in the light duty program and the same reasoning applies to the HDPV program as well. Since companies such as Nissan are investing heavily in the near term and using the best and most advanced technology, the credits earned by adopting such advanced technologies now is essential to meeting the more stringent standards later. Credits earned during Model Years 2014 through 2020 should be allowed to be carried forward during the pendency of the Phase 2 program, through to Model Year 2027. Allowing such use of credits encourages companies to deploy investment in more advanced and costly technology earlier, obtaining significant greenhouse gas benefits, rather than simply meeting compliance and adding new technology later. [EPA-HQ-OAR-2014-0827-1026-A1 p.4]

**Response:**

As discussed in Chapter 1.4.7, the agencies received general comments regarding credit carry-forward in addition to the HD pickup and van specific comments shown above. The agencies received comments from CARB that the agencies should not allow Phase 1 credits to be carried forward into Phase 2. CARB commented that Phase 1 credits should be limited to a three year carry-forward or MY 2020 whichever is sooner. CARB is concerned that Phase 1 credits may reduce the efficacy of the Phase 2 program and delay technology development progress.

The agencies are retaining the 5 year credit carry-forward provisions for HD pickups and vans as proposed. As discussed in Section VI.C of the Preamble, the agencies believe that the standards for HD pickups and vans are feasible without extending the credit carry-forward provisions. The agencies continue to believe that credit carry-forward provides important flexibility to manufacturers especially in transitioning to more stringent standards and restricting the provision could be disruptive to manufacturer product plans. However, the agencies understand CARB’s concerns regarding Phase 1 credits being used to postpone technology progress if some manufacturers were to accumulate large credit banks under Phase 1. Large banks of Phase 1 credits combined with unlimited credit-forward could have the unintended effect of allowing some manufacturers to delay the application of Phase 2 technologies. CARB suggested that the agencies had not considered the Phase 1 credits, but the agencies’ modeling included credit carry-forward and credits that are expected to be banked from the Phase 1 standards. The modeling did not indicate that a 5 year credit carry-forward would result in a significant delay in the application of technology, but would provide flexibility to manufacturers in
implementing the Phase 2 standards which become more stringent year-over-year in MYs 2021-2027. Although some commenters supported longer credit carry-forward, the agencies did not receive comments that the proposed standards which are being finalized would not feasible with only five year credit carry-forward. The 5 year credit carry-forward preserves needed flexibility for transitioning to more stringent Phase 2 standards by allowing manufacturers to mesh the phase-in with their product redesign cycles. The limit also helps to address concerns regarding delaying the introduction of technology in Phase 2 or market disruptions that could occur is a manufacturer saved credits over many years and achieving a cost advantage by using those credits in a single year.197

Further, Daimler and AAPC argue that credits be transferable between the light-duty and heavy-duty classes. However, EPCA and EISA does not allow for the transfer of credits between the light-duty and heavy-duty classes. Further, the agencies do not have enough data to conclude that allowing credit transfers between vocational vehicles, tractor trailers, and heavy-duty pickups and vans will not compromise the benefits of the program. These three classes are vastly different, and it may be easier to comply in one class and not to advance technologies in the other classes. Until more information is available the agencies have concluded that the credits generated in one vehicle class are not transferable with those generated in another class.

### 7.4.2 Air Conditioning System Credits

**Organization:** American Automotive Policy Council

**Acknowledge Mobile Air Conditioning Improvements** - AAPC recommends adopting a credit approach that acknowledges the greenhouse gas and fuel consumption benefits of direct and indirect A/C system improvements. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

**Acknowledge Mobile Air Conditioning (MAC) Improvements**

**Light-Duty MAC Efficiency**

During the creation of the 2012-2016 Light-Duty vehicle greenhouse gas regulation, EPA created a list of efficiency technologies (75 Federal Register 25428) which could earn a pre-defined and pre-approved credit in grams per mile of CO2. These credits could be applied to every vehicle that used the defined technologies. These were termed “indirect” mobile air conditioner credits since the emissions reduction did not result within the air conditioner system itself, but rather from the savings in fuel ultimately used to power the MAC system. This has proven itself to be a highly successful approach for gaining rapid implementation of air conditioner efficiency technologies. The following table shows the growth in MAC credits: [EPA-HQ-OAR-2014-0827-1238-A1 p.17]

[Table of credits in million sof megagrams of CO2 can be found on p.17 of docket number EPA-HQ-OAR-2014-0827-1238-A1]

The table above shows that air conditioner efficiency technologies were not heavily used among vehicles sold in the U.S. at the beginning of the greenhouse gas regulatory period, with the total industry

---

197 Note that the agencies have accounted for potential windfall credits from Phase 1 in other areas of the Phase 2 program, in particular, increasing the stringency of the vocational engine standard (and other engines certified exclusively under the transient cycle). See Section II.D.5 of the FRM Preamble.
claiming only 2.1 million megagrams (i.e., metric tons) in CO2 credits in 2009. (See Appendix A for detailed history of Light-Duty MAC Credits 2009-2013). [EPA-HQ-OAR-2014-0827-1238-A1 p.17]

As the Alliance of Automobile Manufacturers noted in their comments on the 2012-2016 and 2017-2025 Light-Duty vehicle greenhouse gas and fuel economy rulemakings (EPA-HQ-OAR-2009-0472-6952 and EPA-HQ-OAR-2010-0799-9487, respectively), EPA based its MAC efficiency credits on estimates of each technology’s percentage impact on the total fuel usage by vehicle air conditioner systems in the United States. However, EPA’s estimate of baseline total air conditioner usage was well below the estimates of others, such as researchers from the National Renewable Energy Laboratory and Oak Ridge National Laboratory, as well as longstanding benchmarks used by industry. We continue to believe that this low baseline used by EPA, which was less than half the baseline MAC energy usage estimated by the other major sources, resulted in MAC efficiency credits which are far below the actual real-world fuel savings and CO2 reductions that are resulting from these technologies. [EPA-HQ-OAR-2014-0827-1238-A1 p.17]

MAC improvements in the light-duty fleet have been acknowledged by EPA as a significant source of real-world benefits, leading EPA to state in its 2012 MY report: [EPA-HQ-OAR-2014-0827-1238-A1 p.17]

“About 40 percent of these [credits] were accrued through the use of the optional credit programs for air conditioning systems, indicating a significant, real-world benefit as a result of the introduction of the technologies underlying these optional credit programs.” (EPA Manufacturer Performance Report for the 2012 Model Year, p. 11) [EPA-HQ-OAR-2014-0827-1238-A1 p.17]

MAC Efficiency in Class 7, Class 8, and Vocational Truck Regulations

EPA included fuel savings from improved air conditioner credits in setting the standards for Class 7 and Class 8 heavy trucks, as well as vocational vehicles: “Compared to 2017MY air conditioners, air conditioners with improved efficiency compressors will reduce CO2 emissions by 0.5 percent.” (80 Federal Register 40221). The difficulty of the standards was increased over time due to the forecast phase-in of these improved MAC systems (80 Federal Register 40228). [EPA-HQ-OAR-2014-0827-1238-A1 p.18]

For regulatory compliance, an improvement factor of 0.5% is given to vehicles with “high-efficiency” air conditioner compressors, defined as either electric compressors or improved mechanical compressors. High-efficiency compressors are an input variable in the GEM model which results in a 0.5% fuel consumption reduction, thereby de facto giving Class 7, Class 8 and vocational trucks the benefit of a pre-defined and pre-approved off-cycle fuel consumption credit for these compressors (80 Federal Register 40631). (Note: reference to 86.1868-12(h)(5) in the NPRM appears to be incorrect since that section covers improved evaporators and condensers whereas the correct reference would be to compressors with reduced reheat 86.1868-12(h)(1).) [EPA-HQ-OAR-2014-0827-1238-A1 p.18]

Clearly, the agencies recognize the environmental benefits that can be achieved from vehicle air conditioner efficiency improvements, and has included incentives within this NPRM for Class 7, Class 8 and vocational truck regulations to achieve these benefits through a simple pre-defined credit. To not acknowledge the potential environmental benefits and give credit for these same technologies on Class 2b/3 vehicles, with their significantly higher volumes, is inconsistent and counter-productive. [EPA-HQ-OAR-2014-0827-1238-A1 p.18]

Class 2b/3 MAC Efficiency Pre-Approved Credit List
The proposed regulation also explicitly applies the pre-defined light-duty MAC and off-cycle credit pick lists to MDPV's (Medium Duty Passenger Vehicles). The result would be that all light-duty vehicles, MDPV's, Class 7, Class 8 and vocational trucks would have pre-defined credit lists for MAC and off-cycle technologies. Class 2b/3 trucks (non-MDPV's) would be the only remaining vehicles that would not have access to pre-defined credit lists for MAC and off-cycle technologies. [EPA-HQ-OAR-2014-0827-1238-A1 p.18]

All the technologies from the light-duty vehicle MAC and off-cycle credits lists are applicable to Class 2b/3 vehicles, as are the additional technologies from the Class 7, 8 and vocational truck credit lists (e.g., automatic tire inflation, adaptive cruise control, electric steering and cooling, stop-start, neutral idle and extended idle). The advantages from a pre-defined credit list have already been thoroughly established with the rapid implementation of improved air conditioner technologies on light-duty vehicles, leading to the creation of the expanded light-duty pre-defined off-cycle credit list for 2014 (77 Federal Register 62737). The same successful template should be applied to all of the Class 2b/3 trucks, from the start of the Phase 1 program, in order to expand the options for cost-effective technologies with which to comply with this regulation. The result will be better environmental results, achieved quicker, and at lower cost. [EPA-HQ-OAR-2014-0827-1238-A1 p.18]

While light-duty and heavy-duty vehicles have similar air conditioning systems, the AC17 test has not yet confirmed its ability to usefully function in this regulatory role, and we would urge that it not be included in the MAC efficiency crediting provisions for heavy-duty vehicles until all inaccuracies are addressed via the ongoing collaborative agency/OEM development work. AC17 A-to-B testing in this segment would be very difficult and impractical given the magnitude of the AC17 differential relative to the test-to-test variability in large fuel consumption vehicles. [EPA-HQ-OAR-2014-0827-1238-A1 p.18-19]

If the AC17 test is adopted, manufacturers should be permitted to use AC17 test results from light-duty versions of the same AC systems when similar. Given the proliferation of low-volume designs in the vocational vehicle category, AC17 testing requirements would be impractical for these vehicles and should not be required. [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

Light-Duty MAC Refrigerant/Leakage

The table above documents the rapid reduction in refrigerant leakage resulting from the direct MAC credit program. Leakage reduction improvements increased 69% to 10.3 million megagrams in only three years, from 2009 to 2012. The increase on a per vehicle basis was from approximately 3.5 grams per mile of CO2 per vehicle in 2009 to approximately 4.0 grams per mile in 2012 (EPA Manufacturer Performance Report for the 2012 Model Year, p. 29). [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

Although industry-wide statistics have not yet been published beyond 2012, production capacity for the new low-global-warming refrigerant R-1234yf has increased. Following its introduction on a few models in 2013, R-1234yf has been implemented on many important vehicle platforms totaling millions of vehicles. The incentive created by pre-defined MAC credits has accelerated the U.S. HFC reduction program into a leading position worldwide, laying the groundwork for eventual phase-out or dramatic phase-down of high GWP automotive refrigerants. [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

Light-Duty SNAP Program

Based on the early start and clear incentives provided by the MAC provisions in the Light-Duty greenhouse gas regulation, EPA recently published a final rule (80 Federal Register 42870) under its
Significant New Alternatives Program (SNAP) which will remove high-GWP R-134a entirely from use as an air conditioner refrigerant in new light-duty vehicles by the 2021 model year. AAPC recommends that EPA approve R-1234yf and other low GWP refrigerants for use in heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

Class 2b/3 Pre-Defined Refrigerant Credit List

The experience from the Light-Duty vehicle program shows that a pre-defined list of credits for refrigerant improvements on heavy-duty vehicles would accelerate these improvements. Credits for low leak air conditioner systems and credits for low-global-warming refrigerants should both play a role, laying the basis for eventual industry-wide refrigerant replacements in systems with high refrigerant containment integrity. By using an incentive approach, rather than mandates, companies move as quickly as they can, according to their various constraints and capabilities, with the result that the most eager early actors break down barriers and reduce costs to smooth the path for an eventual industrywide switchover. [EPA-HQ-OAR-2014-0827-1238-A1 p.19]

The current rulemaking is an appropriate time to create this incentive structure in heavy-duty vehicles. At a minimum, given the similarities in the air conditioning systems between Class 2b/3 trucks and many light-duty trucks, as well as the experience of the light-duty vehicle manufacturers with these provisions of the Light-Duty regulation, a pre-defined credit list for refrigerants should be created for Class 2b/3 trucks. The credit levels and other provisions should be identical to the credit provisions for light-duty trucks in the same time period, through 2025 model year, including acknowledging further improving leakage and moving R-134a systems to low-GWP refrigerants. [EPA-HQ-OAR-2014-0827-1238-A1 p.20]

[Table of MAC credits can be found on p.20 of EPA-HQ-OAR-2014-0827-1238-A1]

Organization: FCA US, LLC

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 62.]

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 134.]

As far as A/C system improvements, we believe there is value in recognize the greenhouse gas and fuel consumption contributions from reducing the energy demand of the A/C systems. We also believe there's additional opportunity to further harmonize with the Light Duty Program and recognize the added greenhouse gas emission benefit beyond leak reduction. That's switching to a lower global warming potential a refrigerant can provide.

Organization: General Motors

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 102-103.]

For example, the pre-defined and pre-approved list of mobile air conditioner greenhouse gas credits has incentivized a rapid improvement in the efficiency and leak integrity of light duty vehicle air conditioners. These incentives are now paving the way for an early transition to lower global warming
air conditioner refrigerants as millions of new vehicles are being produced with the new refrigerants, many years in advance of any mandate to make the switch.

Organization: Nissan North America, Inc.

Air Conditioning Credits

As in the light duty program, air conditioning improvements can assist in reducing greenhouse gas emissions and fuel consumption. Although the agencies did not provide air conditioning efficiency credits in Phase 1 and continued that approach in the proposal, the agencies should reconsider that position. [EPA-HQ-OAR-2014-0827-1026-A1 p.4]

The decision not to include such credits in the proposal was based on a conclusion that the CO2 emissions in heavy duty vehicles due to air conditioning systems is likely minimal compared to their overall emission of CO2. While that comparison may be valid, air conditioning systems nonetheless represent an area where substantial CO2 reductions can be had. The final rule should account for these opportunities and apply air conditioning efficiency credits as set forth below. [EPA-HQ-OAR-2014-0827-1026-A1 p.4]

The following figure reflects the CO2 reducing potential of improving the efficiency of air conditioning systems in this market segment: [EPA-HQ-OAR-2014-0827-1026-A1 p.4]

[The figure, AC Impact (%) vs. SC03 CO2 w/ AC On (g/mi), can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1026-A1]

In the light duty rule for Model Years 2017-2025, the agencies estimated the greenhouse gas reductions associated with small (5.6%) passenger car, medium (4.8%) passenger car, large (4.5%) passenger car, and light duty truck (3.5%). Based on SC03 emissions testing on Nissan light duty truck Model A with the air conditioning running, the impact of air conditioning efficiency improvements for a comparable 2b class heavy duty model is estimated to be 3.3%. The results and comparison with the light duty program are shown below: [EPA-HQ-OAR-2014-0827-1026-A1 p.5]

[The table, summarizing various SC03 cycle values for various car sizes, can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1026-A1]

Based on this analysis, the maximum air conditioning credit value would be 9.7 g/mile. Accordingly, the air conditioning system menu, and the associated credits, should be as follows: [EPA-HQ-OAR-2014-0827-1026-A1 p.5]

[The table, summarizing estimated CO2 reduction for several technological advances, can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1026-A1]

As shown, there are in fact significant benefits that can be gained through improving the efficiency of air conditioning systems. Recognizing and encouraging the translation of air conditioning efficiency improvements from the light duty segment to this HDPV segments provides additional consistency in the technology to be deployed. The credits would provide a necessary tool towards compliance with the aggressive Phase 2 standards and would help achieve further reductions in GHG emissions. [EPA-HQ-OAR-2014-0827-1026-A1 p.6]
Response:

The agencies did not propose and are not adopting A/C efficiency credits for heavy-duty pickups and vans. AAPC suggests that the agencies could allow the same credits as are available in the light-duty vehicle program but no data is provided regarding the appropriateness of the credits. The EPA would need to resolve a number of open issues relating to environmental implications of A/C efficiency credits for these vehicles (among them, potential credit generation rate, whether credits would be windfall, implications for the standard stringency) before considering adopting an A/C efficiency credit regime. Also, the AC17 test is an integral part of the light-duty vehicle program serving as a confirmation that the credits are based on actual performance improvements. The agencies do not believe that it would be appropriate to provide credits based only on the presumption that systems similar to those used in light-duty trucks will provide the same improvements in heavy-duty pickups and vans with no confirmation through testing. AAPC suggested simply using the light truck list of A/C efficiency credits without providing any data. Nissan suggested revising the credits upward from the light truck level, based on limited light truck data and without any HD vehicle data to support its analysis. With regard to AAPC comments regarding credits provided in the other vehicle sectors, EPA notes that for other sectors any available A/C technologies and associated credits are considered as part of the feasibility analysis for setting the standards for the other sectors and not simply additional credits available to the manufacturers. A/C credits were not considered in the standard setting for HD pickups and vans.

AAPC also recommended that EPA provide credits for reduced refrigerant leakage and alternative refrigerant usage similar to the light-duty vehicle program. In response, EPA has already established standards in Phase 1 for refrigerant leakage. EPA does not believe that it would be appropriate to provide credits for items that are essentially required. Providing such credits without an increase in total program stringency similar to the light-duty approach to A/C efficiency and refrigerant leakage would result in an unwarranted loss of program benefits. See Section I.F of the Preamble and Chapter 1.7 of this Response to Comments document for how the Phase 2 program handles the use of alternative refrigerants.

7.4.3 Off-cycle Credits for HD Pickups and Vans

Organization: American Automotive Policy Council

Acknowledge Off-Cycle Improvements - AAPC recommends adopting a credit approach that acknowledges the greenhouse gas and fuel consumption benefits of off cycle technologies that are not completely captured on the current test cycles. [EPA-HQ-OAR-2014-0827-1238-A1 p.3]

Acknowledge Off-Cycle Improvements

Off-cycle and Innovative Credits

In Phase 1 of the Light-Duty greenhouse gas regulation for 2012-2016, EPA used a “menu” of pre-defined and pre-approved credits for mobile air conditioners, but required individual approvals for each off-cycle credit. Off-cycle technologies were required to be “new and innovative” and “not in widespread use,” and could not also generate significant on-cycle benefits. Industry responded with rapid implementation of air conditioner technologies, but only two small off-cycle credit requests were approved for other technologies, each taking approximately six months for reviews and approvals. [EPA-HQ-OAR-2014-0827-1238-A1 p.21]

EPA later stated that:
“These criteria have interfered with the goal of providing an incentive for the development and use of off-cycle technology that reduces CO2 emissions.” (77 Federal Register 62835) [EPA-HQ-OAR-2014-0827-1238-A1 p.21]

For Phase 2 Light-Duty, EPA created an off-cycle technology “menu” or “pick list” of credits. EPA also eliminated the criteria that technologies be “new and innovative,” “not in widespread use,” and could not also generate on-cycle benefits. In order to encourage investment in these technologies, EPA also made clear that the credits would not expire, stating: [EPA-HQ-OAR-2014-0827-1238-A1 p.21]

“EPA is also making clear that once approved, EPA does not intend to sunset a technology’s credit eligibility or to deny credits to other vehicle applications using the technology.” (77 Federal Register 62836) [EPA-HQ-OAR-2014-0827-1238-A1 p.21]

Model Year 2014 was the first year for the new light-duty off-cycle credit menu. While 2014 reporting is only recently completed, there has been extensive industry interest in the new off-cycle program, and the provisions can be expected to be heavily used, resulting in rapid acceleration in implementation of these real-world fuel saving technologies. [EPA-HQ-OAR-2014-0827-1238-A1 p.21]

With respect to off-cycle credits, Phase 1 of the Heavy-Duty vehicle rule resembled Phase 1 of the Light-Duty rule. Manufacturers could apply for credits for innovative technologies on a case-by-case basis using extensive documentation. To our knowledge, no innovative technology credits have been granted during Phase 1 under this regulatory template (for Class 2b/3 trucks). [EPA-HQ-OAR-2014-0827-1238-A1 p.21]

**Off-Cycle Credits in Class 7, Class 8 and Vocational Vehicle Regulations**

As with MAC high-efficiency compressors, the proposed Heavy-Duty vehicle regulation for Class 7, Class 8 and vocational trucks establishes de facto pre-defined and pre-approved off-cycle credits for a variety of technologies. This NPRM proposes that these technologies be included in the GEM simulation tool with pre-defined fuel efficiency values, with the result that vehicles including the technologies have lower fuel consumption. Some of the improvement might partially be experienced in conditions that would be on-cycle in the standard FTP test, but some of these improvements are clearly experienced in off-cycle conditions. Several examples are discussed on page 1063 of the NPRM: [EPA-HQ-OAR-2014-0827-1238-A1 p.21-22]

“(4) GEM applies a 2 % emission reduction for tractors with predictive cruise control. This includes any cruise control system that incorporates satellite-based global-positioning data for controlling operator demand. [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(5) GEM applies a 0.5 % emission reduction for tractors with a high-efficiency air conditioning compressor. This includes mechanically powered compressors meeting the specifications described in 40 CFR 86.1868-12(h)(5), and all electrically powered compressors. [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(6) GEM applies a 1 % emission reduction for tractors with electrically powered pumps for steering and engine cooling. [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(7) GEM applies a 1 % emission reduction for tractors with automatic tire inflation systems. [EPA-HQ-OAR-2014-0827-1238-A1 p.22]
(8) GEM accounts for emission reductions for reduced idle for the following technologies: [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(i) Stop-start technology for vocational vehicles. Phase 2 vocational vehicles qualify for reduced emissions in GEM modeling if the engine shuts down no more than 30 seconds after the onset of any of the following conditions: [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(A) The vehicle’s brake is depressed at a zero-speed condition. [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(B) A vehicle with automatic transmission goes into “Park.” [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(ii) Neutral-idle technology for vocational vehicles. A Phase 2 vocational vehicle with an automatic transmission qualifies for reduced emissions in GEM modeling if the vehicle goes into neutral (or reduces torque equivalent to being in neutral) at a zero-speed condition. [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

(iii) Extended-idle reduction. If your sleeper cab is equipped with idle reduction technology meeting the requirements of § 1037.660 that will automatically shut off the main engine after 300 seconds or less, GEM applies a 5 percent emission reduction for Phase 2 vehicles. For Phase 1, enter 5.0 g/ton-mile as the input (or a lesser value specified in § 1037.660); otherwise leave this field blank.” [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

Class 2b/3 Pre-Approved Off-Cycle Credit List

As discussed previously with respect to MAC efficiency credits, the proposed regulation applies the pre-defined light-duty off-cycle credit pick list to MDPVs (Medium Duty Passenger Vehicles). The result would be that all light-duty vehicles, MDPVs, Class 7, Class 8 and vocational trucks would have pre-defined credit lists for off-cycle technologies. Class 2b/3 trucks (non-MDPVs) would be the only remaining vehicles that would not benefit from pre-defined off-cycle credit lists. [EPA-HQ-OAR-2014-0827-1238-A1 p.22]

All the technologies from the light-duty vehicle off-cycle credits lists are potentially applicable to Class 2b/3 vehicles, as are the additional technologies from the Class 7, 8 and vocational truck credit lists (e.g., automatic tire inflation, adaptive cruise control, electric steering and cooling, stop-start, neutral idle and extended idle), as well as additional technologies that are not yet on any of the lists. The advantages from a pre-defined credit list have already been thoroughly established with the rapid implementation of improved air conditioner technologies on light-duty vehicles, leading to the creation of the expanded light-duty pre-defined off-cycle credit list for 2014 (77 Federal Register 62737). [EPA-HQ-OAR-2014-0827-1238-A1 p.22-23]

AAPC recommends the same successful template be applied to all of the Class 2b/3 trucks, from the start of the Phase 1 program, in order to expand the options for cost-effective technologies with which to comply with this regulation. This will incentivize the early introduction of technology that will result in improved environmental results, achieved quicker, and at lower cost. [EPA-HQ-OAR-2014-0827-1238-A1 p.23]

Light-Duty Off-Cycle Technologies
All of the technologies on the light-duty off-cycle technology pick list can be expected to generate real-world emissions reductions for each heavy-duty truck at levels equal to or exceeding the light-duty truck credit values (i.e., this is a conservative starting point). In general, this would be expected based on the higher fuel consumption of heavy-duty engines. For perspective, note that in the EPA analysis for light-duty off-cycle credits, the light truck pick list credit is larger than the passenger car credit for all the technologies except lighting, engine heat recovery to generate electricity, and solar panels. These technologies where the credits are equal deal directly with vehicle electricity supply and usage, and are not closely tied to conventional engine operation. For the technologies more directly tied to conventional engine operation, the larger engines used in light trucks compared to passenger cars resulted in pick list off-cycle credits ranging from 25% to 133% larger. Comparing Class 2 and Class 3b trucks to the total light truck category would be expected to result in similar credit growth, since the light truck category includes many vehicles in the minivan, crossover or small SUV classes with smaller engines and more carlike design and performance. [EPA-HQ-OAR-2014-0827-1238-A1 p.23]

Implement an Off-Cycle Credit Pick List

For the reasons cited above, off-cycle credit opportunities similar to the light-duty fleet should be adopted for the medium and heavy-duty fleets. AAPC also recommends adding additional technologies to the pre-defined list of off-cycle technologies. These technologies are summarized immediately below. See Appendix B for a full explanation of these additional technologies and the methodology used to calculate credits. Constraining additions to technology list could have the unintended consequence of slowing innovation for technologies that save fuel in real-world driving and are of high importance to the powertrain/vehicle system. [EPA-HQ-OAR-2014-0827-1238-A1 p.24]
give real-world benefits on these vehicles beyond the benefits on the standard fuel economy tests. We also request that these off-cycle credit provisions be kept simple and accessible, without extensive requirements for additional testing or for meeting other criteria, caps or thresholds, in order to encourage rapid innovation and experimentation in this promising area. [EPA-HQ-OAR-2014-0827-1238-A1 p.25]

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Available credit for solar control for heavy-duty pickups and vans**

For heavy-duty pickups and vans (class 2b/3), the NPRM requests comment on establishing a pre-defined technology menu list for off-cycle emissions, including solar control (see table VI-33, page 40390 of the NPRM). U.S. EPA and NHTSA consider these vehicles to be analogous to light-duty vehicles, since they use the same chassis test procedure. To determine the appropriate default level of credits for these heavier vehicles, the NPRM requests comments with supporting heavy-duty pickup-and van-specific data and analysis that would provide a substantive basis for appropriate adjustments to the credits levels. As with the light-duty vehicle program, U.S. EPA and NHTSA would also consider including a cap on credits generated under the pre-defined list. Such a cap addresses issues of uncertainty regarding the level of credits automatically assigned to each technology. [EPA-HQ-OAR-2014-0827-1265-A1 p.152]

CARB staff believes it is appropriate to include solar control in the pre-defined technology menu list for heavy-duty pickups and vans along with a preapproved credit. Credits for solar control are largely about reducing the heat build-up in parked vehicles, reducing the need to idle to stay comfortable, and reducing the load on the engine from operating the AC, since AC use generally reduces fuel economy. Class 2b/3 vehicles likely spend less of the workday parked than do light-duty vehicles although they probably do spend part of the work day parked with the engine off. They likely spend more time idling than light-duty vehicles, some of which time could be reduced if there was less need for comfort idling. The balance of the workday is spent in motion. Solar control has a benefit during driving operations as well, although the fuel economy of vehicles with larger engines are less affected by the use of an AC than are light-duty vehicles with smaller engines. The value established for light-duty trucks of 3.9 g CO2/mile could be used. However, CARB staff believes it would be appropriate to reduce this value by the assumed contribution from the backlite, since work vehicles often do not have substantial if any backlites. CARB staff assumed, based on an overview of the literature for its Cool Car proposal,\(^8\) that 30 percent of the solar energy enters the vehicle through the backlite. Therefore, CARB suggests a pre-approved credit of 2.7 g CO2/mile for the 2b-3 sector. Manufacturers who believed that this underestimates the value that solar controls provide to their vehicle model could provide appropriate test data to substantiate a request for a greater off-cycle credit. [EPA-HQ-OAR-2014-0827-1265-A1 p.152-153]

**Organization:** Ford Motor Company
Ford supports expansion of the Phase 1 allowance to generate emission credits for CO2 improvements for technologies providing on road fuel consumption benefits that are not captured by the emissions test cycles or models.

Organization: General Motors

The success of these air conditioner provisions led to the expansion of this approach in 2014 for the light duty fleet with the introduction of an expanded off cycle list of pre-assigned and pre-approved credits for other technologies that reduce fuel usage and conditions not comprehended in the standard fuel economy test, such as colder weather, higher speeds, or extended idle times.

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

Implementation of an Off Cycle Credit Pick-List

We support American Automotive Policy Council’s proposal to implement an Off Cycle Credit Pick List. A “pick list” or “menu” would give Class 2b and Class 3 vehicles regulatory credit for greenhouse gas emissions reductions that result from the use of various “off cycle technologies.” A pick list exists for light duty vehicles, and this proposal contains pre-assigned credits for the real world benefits of various technologies used in Class 7 and 8 tractors and vocational vehicles. A Class 2b/3 pick list give real world benefits on these vehicles beyond the benefits on the standard fuel economy tests. Finally, the off cycle credit provisions should avoid extensive requirements for additional testing or for meeting other criteria, caps or thresholds, in order to encourage further innovation. [EPA-HQ-OAR-2014-0827-1248-A2 p.10]

Organization: Nissan North America, Inc.

Off-Cycle Credits

The availability of off-cycle credits is critical. The agencies should include the same pre-defined pick-list that is used in the light duty program, and should also include a mechanism to add new technologies to the list. Again, off-cycle technologies on the light duty credit menu can be translated to the heavy duty and adjusted for use in that segment. Nissan calculated the benefits for Active Transmission Warm Up and Active Engine Warm Up. Using a 0.58% greenhouse gas reduction rate (at U.S. average temperature of 580 F) applied in the light duty rulemaking and Nissan Model B classified as Class 2b Heavy Duty, Nissan calculated the benefit from those technologies to be 3.2 g/mile. [EPA-HQ-OAR-2014-0827-1026-A1 p.6]

[The table, which displays the CO2 emission, impact and benefit of the Nissan Model B, can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1026-A1]
These technologies have the proven potential to reduce greenhouse gas emissions, and should be included in an off-cycle credit program which recognizes this benefit and assists towards compliance with the standards. [EPA-HQ-OAR-2014-0827-1026-A1 p.7]

Response:

Several commenters supported allowing manufacturers to use the light-duty vehicle off-cycle credit menu for HD pickups and vans. In their comments, AAPC referred to the two tables below. The tables provide the off-cycle credits available for light-duty trucks.

**Light-duty Truck Off-cycle Pre-approved List:**

AAPC commented that at minimum, the light truck list (i.e. the off cycle technology menu providing default values for enumerated off-cycle technologies from the light-duty vehicle GHG rules) should be made available for HD pickups and vans. AAPC comments that for thermal control technologies credits could be left unchanged, or are at least a lower priority for re-analysis. AAPC further commented that the credits for active aerodynamic features, stop-start and active engine and transmission warm-up...
should be reassessed for a specific heavy-duty vehicle analysis, and pre-approved credits should be established for these technologies at a greater level than for light-duty trucks. We note, however, that AAPC provided no data supporting why the light truck default level would be appropriate for HD pickups and vans, or data on which to establish an appropriate level of credits for HD pickups and vans. AAPC suggests that EPA perform an analysis to adjust the credit levels for HD pickups and vans, but again, provided no data to support such an analysis. EPA believes off-cycle credits must be supported adequately by data for the applicable vehicles to ensure that the credits realistically reflect actual technology performance. EPA’s request for comments in the NPRM on the topic of off-cycle credits emphasized the need for data in support of any recommended credits. Therefore, EPA is not extending the light truck menu credits to HD pickups and vans as requested by AAPC. Manufacturers may generate off-cycle credits for these technologies through the off-cycle credit provisions established in Phase 1.

AAPC further provided a list of technologies in addition to the light truck list above and requested associated off-cycle credits for the technologies, shown below. AAPC provided a further description of these technologies and recommended credits in Appendix B of their comments.

For the technologies listed in the table above, there are three primary reasons that the agencies are not adopting credit levels recommended by commenters. In many cases, the analysis provided by commenters did not include sufficient real-world heavy-duty vehicle data on which to base the recommended menu credit value. Thus, in several cases, the analysis provided by commenters was based on light-duty vehicle data or on simulations with little detail provided, which analysis is not directly applicable to heavy duty pickups and vans for purposes of technology performance.
quantification. Second, in several cases, the technologies recommended for off-cycle credits for HD pickups and vans provide significant on-cycle benefit. Such technologies are considered to be adequately captured by the test procedures (within the meaning of section 86.1819-14 (d)(13)) and are therefore not considered to be eligible for off-cycle credits. Examples of adequately captured technologies that commenters recommended for off-cycle credits include cylinder deactivation and cooled EGR. Moreover, these are technologies the agencies expect to be in the mix of technologies used to meet the standards (and are projected to be used in the respective analyses of compliance paths on which the stringency of the final standards are predicated). EPA has already indicated that off-cycle credits are not available for technologies that form part of the technology basis for the greenhouse gas standards because these technologies’ benefits would already be reflected in the standard’s stringencies (and costs), since the technologies would not even be under consideration unless their benefits were “adequately captured” in two-cycle space. 77 FR 62835 (Oct. 12, 2012). Likewise, many of these technologies are inherent to vehicle design and so are similarly ineligible. Id. at 62732, 62836. Finally, a few other recommended technologies are considered safety-related technologies not eligible for credits because they could reasonably be expected to fall under vehicle safety standards in the future and so would be adopted in any case. Granting off-cycle credits for these technologies for HD pickups and vans consequently would amount to an unwarranted windfall. Adaptive cruise control and forward collision warning systems are examples of these technologies.

Each technology and the reason EPA is not providing credits is provided below:

- High Efficiency Alternator – AAPC provides only data from light-duty vehicle applications in their credit analysis, many of which are passenger cars. The EU approach referred by AAPC is also based on light-duty vehicle applications (AAPC only suggests part of the EU approach as appropriate while rejecting other aspects of the program that they view as problematic) and it is unclear if it would be appropriate for HD vehicles. While AAPC provides one simulation of a HD vehicle which is supportive of the recommended credit, EPA believes more data is needed upon which to establish the appropriate credit level. EPA rejected establishing menu credits for high efficiency alternators in the light-duty vehicle program. See 77 FR 62730. AAPC acknowledges this noting “We agree that the situation may be complicated since real-world efficiencies can be very vehicle specific and alternator specific, and average vehicle real-world electrical loads are not well documented, and probably vary considerably between vehicles.” EPA continues to view the assessment of off-cycle credits for high efficiency alternators as complex and requiring data to support the off-cycle credit level. This technology may be eligible for credits under the off-cycle credits provisions established for Phase 1 which would require a model-specific demonstration of the credit level requested.

- Cylinder Deactivation – As noted above, EPA views cylinder deactivation to be adequately captured by the test procedures (within the meaning of section 86.1819-14 (d)(13)) and therefore ineligible for off-cycle credits. EPA also questions AAPC’s rationale that cylinder deactivation should be eligible for an off-cycle credit based on the amount of time the vehicle is driven in an unloaded condition without also acknowledging times when the vehicle is driven in a highly loaded condition which would make cylinder deactivation relatively less effective than over the 2-cycle test. Also, the suggested credit is based on simulation data only.

- Cooled Exhaust Gas Recovery –EPA views cooled EGR to be adequately captured by the test procedures (within the meaning of section 86.1819-14 (d)(13)) and thus ineligible for off-cycle credits because the technologies recommended for off-cycle credits must be for a technology that is “not adequately captured on the Federal Test procedure (FTP) and/or the highway Fuel Economy Test (HFET).”

---

198 This provision states that an off-cycle credit must be for a technology that is “not adequately captured on the Federal Test procedure (FTP) and/or the highway Fuel Economy Test (HFET).”
credits. As with cylinder deactivation, EPA questions AAPC’s rationale supporting the recommended credit. With cylinder deactivation, AAPC argued that off-cycle credits are appropriate to capture benefits when the vehicle is driven in lightly loaded conditions without discussing what happens in highly loaded conditions. For cooled EGR, AAPC argues the opposite, that vehicles are “frequently used” in highly loaded conditions where cooled EGR is more effective compared to the 2-cycle test, without discussing the technology’s performance under lightly loaded conditions. AAPC only provides that their estimated credit is based on simulations performed by FCA on its heavy-duty pickup.

- Transmission Bypass Valve – This credit is not supported by HD vehicle test data and it is not clear that the credit is derived in a way that is applicable to HD vehicles or is reflective of the performance of the technology in real world operation. Also, this technology has been used for several years in HD vehicles and would not likely be considered innovative under the HD off-cycle regulatory provisions found at 40 CFR 86.1819-14 (d)(13) (previously 40 CFR 1037.104 (d)(13)).

- Neutral Drive Idle – AAPC does not provide data for HD pickups and vans supporting their effectiveness estimate, on-cycle benefit, or real-word idle. More data, including model specific data would be need to support the requested 10.7 g/mile credit.

- Automatic Tire Inflation – AAPC does not provide HD pickup and van specific data to support the significant (~ 5 g/mile) requested credit.

- Adaptive cruise control – As noted above, adaptive cruise control is not eligible for credits because it could reasonably be expected to fall under vehicle safety standards in the future and so would be adopted in any case. Granting off-cycle credits for these technologies consequently would amount to an unwarranted windfall.

- Electric Accessory Systems – Electric accessory improvements provide on-cycle benefits and are included in the technologies that the agencies expect to be used to meet the standards. Since these standards are part of the basis for the standards, they would not be eligible for off-cycle credits. Moreover, the credit level suggested by AAPC of 3 percent of a vehicle model CO₂ level would result in a relatively large credit (e.g., in the range of about 12 to 16 g/mile for a MY 2027 gasoline-fueled vehicle), and data would be needed on HD pickups and vans if EPA was going to consider the credit further. Also, the credit would need to be considered as part of the standard setting process since, as noted above, electric accessories are among the technologies the agencies expect to be used to meet the standards. For Class 7 and 8, these technologies and their effectiveness values are built into the GEM model and are therefore considered in the feasibility analysis for establishing the level of the standards.

- Vacuum, DEF, engine oil, transmission oil, fuel and coolant pumps – AAPC notes only that the credit values requested for all pumps listed were calculated using the VMT difference between MOVES and the weighted metro highway cycle using the Alpha model to compute the benefit. No data or further explanation is provided and EPA does not believe the credit request was adequately supported for these technologies.

- Air Conditioning Compressor with Variable Crank Case Suction Valve Technology – AAPC discusses EPA’s approval of off-cycle credits for this technology in the light-duty vehicle program for certain GM vehicles and requests the same level of credits as provided for some of GM’s light-duty vehicles for all HD pickups and vans. No data on HD pickups and vans is provided to support the credit request. EPA believes that HD vehicle data and perhaps model-specific data would be
needed to support the credit request. EPA notes that manufacturers could apply for credits for this technology for HD vehicles under the off-cycle credits program established in the Phase 1 rule.

EPA also notes that taken as a whole, AAPC requested off-cycle credits that could total in the range of 40 to 50 g/mile. This represents a significant fraction of the overall reductions expected for the Phase 2 program for this vehicle class and would need to be supported by substantial data. Further, with respect to those technologies which are not already part of the basis of the Phase 2 standards for HD pickups and vans, if EPA had sufficient data on which to base such credits and were to provide the credits, the off-cycle credits could then potentially be considered in the feasibility assessment that is integral to the standard setting process, as they were for the other sectors. This could lead to an assessment that more stringent standards are feasible for the HD pickup and van sector. It is unlikely that the credits would simply be available for use by manufacturers in lieu of making other changes to the vehicles that are projected to be made to meet the standards. Also, because off-cycle credits have not been considered in the feasibility assessment of the final standards, EPA does not view the credits as critical or essential in meeting the standards being finalized.

Nissan also commented in support of providing the same menu of off-cycle comments for HD pickups and vans as is provided for light-duty vehicles. Nissan suggested that the credits from the light-duty program could be adjusted for use in the HD segment. Nissan provides an example for active engine and active transmission warm-up where the credits from the light-duty program are increased by assuming the technology will reduce HD CO\textsubscript{2} emissions by the same percentage and applying that percentage improvement to an example Nissan heavy-duty vehicle CO\textsubscript{2} level. No HD effectiveness or other data is provided. As noted above, EPA is not extending the use of the light-duty vehicle off-cycle credits menu to HD pickups and vans. EPA believes off-cycle credits need to be sufficiently supported by real-world data and Nissan does not provide data necessary to establish a general credit for all HD pickups and vans. System design and effectiveness could vary significantly from vehicle model to vehicle model. Manufacturers may generate off-cycle credits for these technologies through the off-cycle credit provisions established in Phase 1.

CARB staff commented in support of including off-cycle credits for solar thermal controls in particular. CARB notes that there are some differences in vehicle operation and design between light-duty vehicles and HD vehicles and suggests a credit adjustment for those differences. EPA agrees with CARB staff that solar thermal controls are likely to provide a benefit for HD vehicles as well as light-duty vehicles. EPA is not establishing a menu credit for solar thermal control or other credits due to the lack of HD vehicle specific data on which to base the credit levels. Indeed, CARB staff comments point out that adjustments to credit levels would be needed to account for vehicle operation and design differences. CARB suggests an adjustment but does not provided HD vehicle data to support the adjustment. As previously noted for other technologies on the light-duty vehicle off-cycle credit menu, manufacturers may generate off-cycle credits for these technologies through the off-cycle credit provisions established in Phase 1.

### 7.4.4 Compliance Provisions

**Organization:** Cummins, Inc.

*Cummins supports alignment of GHG useful life with LEVIII/Tier 3 criteria emissions useful life [EPA-HQ-OAR-2014-0827-1298-A1 p.35]*

Cummins supports alignment of the GHG useful life with the criteria emissions useful life promulgated in the LEVIII/Tier 3 rules. Cummins also supports adjusting Phase 1 credits used in Phase 2 to account
for the differences between the useful life definitions for each phase. [EPA-HQ-OAR-2014-0827-1298-A1 p.35]

**Organization:** Daimler Trucks North America LLC

**In-Use Standards (80 FR 40342)** - Daimler has no comment regarding the proposed change in the current useful life of 11 years and 120,000 miles to reflect EPA’s useful life of 15 years and 150,000 miles. Daimler encourages the agencies to ensure that there will be a fair credit exchange process from Phase 1 to Phase 2. [EPA-HQ-OAR-2014-0827-1164-A1 p.113]

**Organization:** Nissan North America, Inc.

EPA’s proposal, moreover, to adjust the credits from Phase 1 to Phase 2 to account for the changes in the Useful Life of the vehicles is appropriate, and will ameliorate any asserted diminution in benefits arising from the extension of Phase 1 credits through the pendency of the Phase 2 program. [EPA-HQ-OAR-2014-0827-1026-A1 p.4]

**Response:**

EPA is finalizing the adjustment to credits to account for the change in useful life from Phase 1 to Phase 2 so that credits are not devalued due to the credit calculation equation which includes a useful life factor. This issue is discussed above in Chapter 1.4.7.

7.5 Proposed Non-CO2 GHG Standards for Pickups and Vans

**Response:**

EPA did not receive any comments specific to HD pickups and vans regarding N₂O and CH₄ standards. Comments regarding air conditioning system credits for HD pickups and vans are discussed above in Chapter 7.4.2.

7.6 DOT HD CAFE Model

**Organization:** General Motors

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 104.]

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, pp. 122-123.]

Finally, the program must attempt to minimize the potential for unintended consequences, especially for the consumer. The heavy duty fleet does not benefit from the years of data that have been collected and analyzed for the light duty fleet. Indeed, comprehensive data for this private segment is only now being accumulated and analyzed for the 2014 model year, which is the first year of Phase 1 of the medium and heavy duty truck regulations.

Year-end reports for 2014 were due to EPA by the end of March 2015, so this first year of comprehensive industry-wide data is still fairly new. This new data should be carefully evaluated and
then compared to the estimates and assumptions that form the basis for both Phase 1 and the proposed Phase 2 of the heavy duty regulations.

Further, the utility provided and the duty cycle of these vehicles is completely different from the light-duty fleet. And any attempt to force more stringent regulations, such as alternative 4, would be extremely detrimental to manufacturers, consumers, the U.S. economy, and the millions of transportation-related jobs. Indeed, comprehensive data for this product segment is only now being accumulated and analyzed for the 2014 model year, which is the first year of phase 1. The data should be carefully evaluated by the technical experts at the agencies and compared to the estimates and assumptions that form the basis for both phase 1 and the proposed phase 2 regulations.1386

Response:

GM expresses concern about the utility difference between the light-duty and medium-/heavy-duty fleets. The agencies have noted the difference between these fleets and have designed the standards to take into consideration the difference in utility. Where the light-duty fleet has varying vehicle targets by footprint, the heavy-duty pickup and van fleet has targets that vary by work-factor (determined by payload, towing capacity, and drive type). The agencies believe that constructing the vehicle targets from work factor ensures that consumer choice will be maintained.

GM further express concerns about using the most current data available in considerations of phase II standards. Method A uses the MY 2015 fleet as its reference fleet. Section 6.C(2) of the Preamble and Chapter 10.2.2 compare the distribution of the 2014 work factor to the distribution of the 2015 work factor. GM, Daimler, and Ford show some shifts of the distribution towards higher work factors, while Nissan and Fiat/Chrysler have very similar work factor distributions for the two MY fleets. While this data is preliminary, it seems to suggest that there have not been significant changes in the distribution of work factor for each OEM which would eliminate consumer choice of high-utility vehicles. While the standards have not adversely affected the utility of heavy-duty pickups and vans, preliminary evidence might suggest the possibility that manufacturers may “game” the standards and create vehicles that are more powerful than consumers may otherwise demand. This is an issue we will continue to investigate in future rulemakings as more data from the Phase I and Phase II rulemakings become available. As it stands, the agencies believe that the work factor based standards maintain the utility of vehicles, which we agree with GM, is a priority for the heavy-duty vehicle class. See response 7.2.2 above.

GM also suggests that alternatives more stringent than Alternative 4 could have negative impacts on the economy, consumers and manufacturers. We have considered these and other concerns about the stringency of standards. As discussed in other comment responses and in both documents, we have determined that the lead-time under Alternatives 4 and 5 would be such that it may require manufacturers to add additional redesigns. Since this would be a costly endeavor, the regulations on this class of vehicles are relatively new, and manufacturers will have to split available capital to respond to these regulations between all regulatory classes, the agencies have determined that Alternative 3 is the maximally feasible alternative, and the appropriate standard under the Clean Air Act, and are adopting this alternative as the final standard for heavy duty pickups and vans. See response 7.2.1 above.
8 Regulatory Alternatives and General Stringency

8.1 General Comments 1387

Organization: Allison Transmission, Inc.

In deciding how stringent the Phase 2 rule should be, EPA and NHTSA should be mindful that their authority to regulate MD/HD vehicles is not unbounded; costs and the feasibility of new standards are key statutory considerations. EPA and NHTSA must also take into account the complex medium- and heavy-duty (“MD/HD”) marketplace; the agencies must allow sufficient time for new technology to be integrated into commercial fleets which require high reliability and continuous vehicle availability. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]

EPA and NHTSA Should Rely on Market Forces to Drive Improvements in Greenhouse Gas Emissions and Fuel Efficiency; Alternative 3 Is Most Appropriate

EPA and NHTSA Must Take Into Account Structure of Commercial Truck Market

Since the Phase 1 rule was promulgated in 2011, Allison has supported efforts by EPA and NHTSA to increase the agencies’ knowledge of the MD/HD commercial truck sector and the effect of transmission systems on GHG and FE. During multiple meetings and presentations, we have emphasized the importance of aligning regulatory standards with real world operating conditions of commercial vehicles. Allison has participated in the testing of different transmission systems and fully supported the agencies’ efforts to make the Greenhouse Gas Emission Model (“GEM”) more accurate and aligned with the various work requirements and road conditions experienced by MD/HD vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.8]

The Phase 1 rulemaking is projected to conserve 530 million barrels of oil and avoid 270 million metric tons of GHG emissions. In the current rulemaking, EPA and NHTSA seek to make additional gains in GHG and FE extending well into the next decade. Allison believes that additional improvements are possible; Allison is a leader in the development of advanced transmission systems, including hybrid systems, and believes that standards can be strengthened to “account for ongoing technical advancements.” We also believe that it is possible to build upon the regulatory structure established in the Phase 1 rule and that the GEM can serve as the primary certification methodology, helping to alleviate the burden of testing literally hundreds of different vehicle variants. But EPA and NHTSA must recognize that there are limits to how fast the commercial truck market can incorporate new technology, or perhaps more importantly, maybe willing to pay for such technology. [EPA-HQ-OAR-2014-0827-1284-A1 p.8]

EPA and NHTSA indicate that the Phase 2 standards are intended to “represent a more technology-forcing approach than the Phase 1 standards.” The agencies state that the proposed standards “will effectively require manufacturers to develop new technologies (or significantly improve technologies).” That is assuredly so, but there are realistic limits to how the purchasers of commercial vehicles will react. For this and other reasons, Allison believes that adoption of Alternative 3 is most appropriate and that advancing technology requirements by 2-3 years as accomplished by Alternative 4 is not appropriate or supported in the record of this rulemaking. [EPA-HQ-OAR-2014-0827-1284-A1 p.8]
With regard to projecting the adoption of new technology, EPA and NHTSA cannot rely on any precedent, whether regulatory or judicial, that may have been established with respect to regulations that may have been applied to the light duty vehicle (“LDV”) sector. The MD/HD market shares little in common with the LDV market. Combination tractors and vocational vehicles are almost exclusively used for commercial purposes and there is no incentive to operate inefficiently or waste fuel; there is little or no “leisure use” of commercial vehicles aside from the discrete market for motor homes. In addition, the MD/HD market operates to closely match engines and vehicles with intended use; purchasers specify combinations of engine and vehicle technologies which will accommodate the work to be done by the vehicles at lowest operational cost. Finally, as the agencies acknowledge, the MD/HD manufacturing sector is extremely diverse consisting of various engine, vehicle and component manufacturers, body builders, trailer manufacturers and other suppliers. Thus, attempts to “drive” technological innovation must take this structure into account when promulgating standards. [EPA-HQ-OAR-2014-0827-1284-A1 p.8-9]

EPA and NHTSA project that Phase 1 standards would result in emission reductions of 9 to 23% as compared with 2010 standards for combination trucks and 6 to 9% in emission reductions for vocational vehicles. The Phase 2 rulemaking projects an 18 to 24% reduction as compared with MY 2017 standards, which would yield roughly 24 to 47% emission reductions from vehicles subject to this regulation through MY 2027. Thus, simply on a basis of relative stringency, these reductions could theoretically exceed the 2030 projected reductions for electric power plants under the recently promulgated Clean Power Plan by 32%. [EPA-HQ-OAR-2014-0827-1284-A1 p.9]

In determining stringency, EPA and NHTSA must assess how costs will be imposed on various entities affected by this rulemaking. The agencies propose regulatory flexibility with respect to emergency vehicles and low-volume chassis manufacturers to address the concerns of small businesses. Certain banking and trading opportunities may be available to larger manufacturers, allowing for flexibility in phasing in new technology. But the broader assessment of stringency (and the resulting costs borne by manufacturers and consumers) relies on the projected adoption of numerous technologies resulting in a projected per vehicle cost impact of $11,680 for tractors and $3,380 for vocational vehicles in MY 2027. The agencies then rely on the market to respond by valuing the “payback” of future decreases in fuel cost to the upfront cost of purchasing the new technology (an assumption which may be especially challenging in the vocational vehicle market since such “payback” would not occur for six years). [EPA-HQ-OAR-2014-0827-1284-A1 p.9]

Alternative 3 therefore must be viewed as an aggressive program to decrease GHGs and increase fuel economy in MD/HD vehicles, especially given that meeting the standards is only possible through continuous technological improvement, an assumption which the agencies concede is itself uncertain. Alternative 3 is comparable in stringency to EPA’s efforts to control GHGs from electric generating units under CAA section 111(d) but could be viewed as more aggressive since costs in the MD/HD sector cannot be embedded into the product in the same manner as electricity. [EPA-HQ-OAR-2014-0827-1284-A1 p.9]

EPA must therefore read its authority under CAA section 202 in the context of the commercial truck market and commercial and economic restraints that are operative in this market. NHTSA must similarly recognize that its EISA authority is separate and apart from its authority with respect to LDVs and that it is to be guided specific language incorporated into the Energy Independence and Security Act of 2007, as noted below in Section I.D. [EPA-HQ-OAR-2014-0827-1284-A1 p.9-10]
There are other unmandated alternatives to achieve good fuel economy. My pre-emissions truck worked more efficiently, partly due to my driving skills. If those driving skills were taught to others, fuel economy would improve. Highway congestion is another unaddressed proven waste of fuel every year. I estimate that in one day of a recent trip, I burned an extra ten gallons of fuel due to congestion, the point being those two suggestions do not involve concerns of unproven technology or unknown costs of the new technology.

Organization: Daimler Trucks North America LLC

Further, the analyses presented within the Alternatives section of the Preamble should separate the costs and benefits of tractors and trailers as lumping those two categories together does not allow for comparison to these unique and different sectors between alternatives. Without being able to look at the costs and benefits of the alternatives for just tractors or just trailers, we are not given enough information to be able to comment on the alternatives. [EPA-HQ-OAR-2014-0827-1164-A1 p.73]

Organization: National Automobile Dealers Association (NADA)

In fact, for all the reasons discussed above, serious concerns exist as to whether Alternative 3 is appropriate, cost-effective, and technologically feasible. Given the proposal’s long lead time and with an eye toward avoiding untoward market disruptions, NADA/ATD suggests that the final rule include a formal review process to reassess key assumptions and variables (e.g., new technology feasibility and cost, uptake rates, freight demand, fuel prices, and interest rates, customer creditworthiness) in order to verify whether the structure and stringency of Alternative 3 still makes sense for MYs 2024 and beyond. [EPA-HQ-OAR-2014-0827-1309-A1 p.11]

Organization: Odyne Systems LLC

While Scenario Three, which results in full compliance by 2027 for all truck classes would represent a positive guidepost for the industry, Odyne believes that cost effective technologies exist to meet timelines and technology adoption scenarios laid out in Scenario Four, or a new Scenario with increased stringency using the Scenario Three timeline. [EPA-HQ-OAR-2014-0827-1239-A1 p.3] [[This comment can also be found in EPA-HQ-OAR-2014-08267-1372, p.229.]]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

The agencies preferred alternative, Alternative 3, proposes a ten year lead time for manufacturers to meet the Phase II standards by MY 2027, “which the agencies believe is adequate to implement the technologies…to meet the proposed standards. For some of the more advanced technologies production
prototype parts are not yet available.” Again, the livelihood of millions of truck drivers and thousands of small business owners should not be predicated on the agencies belief that Alternative 3 and its ten year lead time is adequate to meet the Phase II standards. No matter how great the hoped for benefits of any technology may be, if it’s not ready for prime time, it can be a business killer for owner-operators and small fleets which make up the vast majority of the US truck fleet. [EPA-HQ-OAR-2014-0827-1244-A1 p.10]

The objective for this rulemaking is to provide more fuel efficient trucks while also reducing both GHG and non-GHG emissions. Nevertheless, this goal will be ruined, along with the careers of those employed throughout the trucking industry, if the agencies do not heed the concerns of the drivers concerning appropriate lead time, stringency, and testing. Although agencies have stated that they desire to avoid disrupting the market, such as the infamous “pre-buys” in 2007, it appears as if the warnings of drivers, and original engine manufacturers (OEMs) have again fallen on deaf ears. [EPA-HQ-OAR-2014-0827-1244-A1 p.10]

As noted by the agencies in their proposed rule, they received warnings from a number of industry stakeholders that owner-operators, as well as large fleets, often plan to purchase their trucks more than a year in advance. Therefore, if they fear a reduction in reliability, increased operating costs, reduced residual value, or large increases in purchase prices, they will adjust their purchase plans to avoid these business killing aggravations. The agencies stated, “The proposed Phase 2 standards would represent a more technology-forcing approach than the Phase 1 approach, predicated on use of both off-the-shelf technologies and emerging technologies that are not yet in widespread use. The agencies are proposing standards for MY 2027 that would likely require manufacturers to make extensive use of these technologies. For existing technologies and technologies in the final stages of development, we project that manufacturers would likely apply them to nearly all vehicles.” (Emphasis added). The agencies are approaching Phase II with the belief various technologies will experience high market penetration rates. However, an overestimation of adoption rates will negatively affect the cost and benefit analysis. For example, Alternative 3 assumes that 90% of the market will adopt auxiliary power units (APUs) by MY 2024, which is simply not realistic, as many trucking operations have absolutely no need for an APU. Moreover, the agencies have assumed that waste heat recovery (WHR) technology, which is still in prototype stage, will have a market penetration of 15% by MY 2027 under Alternative 3. The OEMs have stated very clearly that WHR has numerous technical challenges for which no solutions have been discovered as yet, therefore the technology is still unproven. The complexity and the cost for such a technology would create positive conditions for a pre-buy situation, as owner-operators will not risk their livelihood on unproven technologies. [EPA-HQ-OAR-2014-0827-1244-A1 p.10-11]

The agencies have proposed an overall level of fuel economy stringency labeled as Alternatives 3 for all engines, vehicles, and most categories of trailers. Unlike in Phase I where the agencies projected that manufacturers could meet the Phase I standards with off-the-shelf technologies only, the agencies project that Alternative 3 standards could be met through a combination of off-the-shelf technologies applied at higher market penetration rates and new technologies that are still in various stages of development and not yet in production. However, as previously mentioned in the comments above, the agencies cost and benefit analysis of Alternative 3 is founded upon unrealistic and inappropriate adoption rates, which have effectively skewed the benefits proposed as part of NPRM and RIA. While the agencies do “recognize that there is some uncertainty in projecting costs and effectiveness, especially for those technologies not yet widely available, but believe that the thresholds proposed for consideration account for realistic projections” (emphasis added), the livelihood of hundreds of thousands of small business owners depends on affordable and reliable equipment to compete and survive in a highly competitive industry. [EPA-HQ-OAR-2014-0827-1244-A1 p.34-35]
While the proposal does not mandate any specific technologies, the proposed performance standards of Alternative 3, which require a 10.4 percent fuel and CO2 emission reduction by MY 2027 for long-haul tractor-trailers, along with a 17.9 percent reduction in tire rolling resistance, a 26.9 percent reduction in aerodynamic drag, and a 304 lbs. reduction in weight, require the adoption of unproven and unreliable technologies, such as WHR. Though the agencies seem to be congratulating themselves for allowing 10 years of lead time in order for OEMs to comply with Alternative 3, the manufacturers have clearly stated in their comments that such stringency is not conducive to producing affordable and reliable tractors and trailers. [EPA-HQ-OAR-2014-0827-1244-A1 p.35]

According to OOIDA President and CEO Jim Johnston, as well as OOIDA Board Members, who have made their living by driving a truck, “We know that it’s the manufacturers’ responsibility to make the equipment to accomplish that [the fuel efficiency and GHG standards], but it is the EPA that sets the rules. And it’s setting them at a pace that does not allow for enough time to road test the equipment. This results in expensive repairs and time-consuming breakdowns that are wrecking profit margins and interfering with operations. There’s no time to figure out the standards, to see what works, and how to fix it before the government is putting out new rules...When you are a one-truck business, being down for repair is a real problem. And failures with this technology can keep a truck in the shop all the time. Fleets on the other hand, aren’t running all their trucks at the same time and they have the ability to simply pull another truck out while one truck is down...When you [EPA] are developing these rules, you must keep in mind that most of the freight is moved by small-business trucking operations, not the big companies.” [EPA-HQ-OAR-2014-0827-1244-A1 p.35-36]

OOIDA strongly believes that the market should drive fuel efficient technologies instead of expensive mandates. The agencies stated in their proposed rule that “both public and confidential historical information shows that tractor trailer fuel efficiency improved steadily through improvements in engine efficiency and vehicle aerodynamics over the past 40 years.” In fact, since 1949 and even earlier, truck manufacturers have sought to increase the fuel efficiency and performance of heavy-duty diesel engines and trucks, and these improvements have been driven by fleet owners and owner-operators seeking fuel efficient trucks, as fuel is the number one expense of every trucking operation. [EPA-HQ-OAR-2014-0827-1244-A1 p.36]

OOIDA proposes that agencies’ preferred alternative, Alternative 3, as well as Alternatives 4 and 5, are unrealistic and if adopted as part of this rulemaking process, will severely compromise the agencies’ praiseworthy objectives to increase the fuel efficiency of medium-and heavy-duty trucks and reduce GHG emissions. Truck drivers certainly desire fuel efficient trucks and appreciate cleaner air to breathe. While various governmental agencies and environmental groups tend to paint owner-operators as individuals who do not care about the environment, nothing could be further from the truth. It is crucial to understand that owner-operators are not only hardworking Americans who help to move our economy, but that they also spend a majority of their life around tractor-trailers. Therefore, it is in their best interest, as well as in the interest of the public, to operate clean and efficient trucks. [EPA-HQ-OAR-2014-0827-1244-A1 p.36-37]

Ultimately however, OOIDA believes that Alternative 1 would be the best alternative to reach the agencies goals, as this will allow for the healthy development of technologies without the possible risk of a pre-buy or a no-buy situation. Additionally, this will help prevent the forcing of unreliable and costly technologies that could easily put an owner-operator out of business. According to FMCSA, 96 percent of motor carriers operate 20 trucks or less, while 90 percent of carriers operate 6 trucks or less. The owner-operator represents approximately half of all motor carriers. [EPA-HQ-OAR-2014-0827-1244-A1 p.38]
Alternatives 3 or 4 very well could put many owner-operators out of business, and thus would have a major unintended consequence on the nation’s economy, as 70 percent of all freight is moved by a truck. [EPA-HQ-OAR-2014-0827-1244-A1 p.38]

Finally, OOIDA proposes that the agencies also include as part of their Alternatives an option which contains driver training. According to the NAS:

- Driver training offers potential savings for the trucking industry that rival the savings available from technology. [EPA-HQ-OAR-2014-0827-1244-A1 p.38]

- Indications are that this could be one of the most cost-effective and best ways to reduce fuel consumption and increase fuel productivity of the trucking sector [EPA-HQ-OAR-2014-0827-1244-A1 p.39]

- Establish a curriculum and process for certifying fuel-saving driving techniques as part of commercial driver certification and to regularly evaluate the effects of such curriculum [EPA-HQ-OAR-2014-0827-1244-A1 p.39]

The agencies failed to address truck driver training as a possible Alternative, which could realize greater benefits at a significantly lower cost. A study done by SmartDrive, an innovative solutions company, conducted a study of 695 Class 8 truck drivers to determine the effect of fuel efficiency training. The study results showed that 80% of fuel waste involves acceleration, deceleration, speeding and turning. Furthermore, the study found that by following eco-driving best practices, drivers could improve fuel economy on average up to 22%. That average reduction in fuel consumption could save fleet operators as much as $12,553 per vehicle in fuel cost annually. [EPA-HQ-OAR-2014-0827-1244-A1 p.39]

In fact, by simply changing the driving habits to improve smooth driving performance, driving at appropriate speeds and reduce unnecessary idling, fleets affirmed that eco-driving can realize significant improvement in fuel mileage and reduce operating expenses, and reduce emissions. Within two months of driver training, the fuel economy increased to an average of 6.73 mpg from a baseline of 5.92 mpg, which is a 14 percent increase. The top 25 percent performing drivers improved their fuel economy to 7.98 mpg after two months of training. [EPA-HQ-OAR-2014-0827-1244-A1 p.39]

35 Sandi Soendker, “EPA takes notes on OOIDA concerns,” Landline Magazine (April 2014)

39 Technologies and Approaches to Reducing the Fuel Consumption of Medium- and Heavy-Duty Vehicles

40 Fuel Efficiency Study: Commercial Transportation, SmartDrive (May 2011).

Organization: Truck Renting and Leasing Association

Other unintended, adverse impacts may arise if the mandated technologies are not mature and reliable. Based on our discussions with OEMs and others, we understand that it is unclear if the proposed Alternative 3 targets – which include a number of unrealistic technology penetration rates – can be achieved. Pushing even faster, as would be the case with Alternative 4, or revising the stringencies -- especially on engines -- would most certainly create downstream issues for the purchasers or lessees of
the vehicles. Our understanding is that the OEMs believe that the time required to develop and test the technologies that will be needed to meet the Proposed Standards is already limited, suggesting that even shorter deadlines may be impossible to satisfy. [EPA-HQ-OAR-2014-0827-1140-A1 p.5-6]

Response:

The agencies address the technical basis for each of the standards in the respective Preamble sections, and in Chapter 2 of the RIA. With respect to pulling ahead those standards by two years (Alternative 4 at proposal), or pulling them ahead with additional stringency (Alternative 5 at proposal), the agencies are distinctly conscious of OOIDA’s point that new technologies must be proven reliable in-use before they are widely deployed, and also that small businesses can be disproportionately harmed if controls are unreliable and lead to vehicle downtime. It is for this reason that the final standards are carefully phased in, that application rates of most technologies are less than 100%, that application rates are carefully geared to appropriate vehicle drive cycles to best assure that the standards will result in in-use reductions, and that the rules contain various exemptions and flexibilities for small businesses. The agencies are revising certain of the proposed standards based on comments which persuasively indicated that further stringencies were feasible at reasonable cost, but are largely rejecting Alternative 4 largely due to inadequate lead time which could result in the harms mentioned in OOIDA’s comment. Alternative 5 not only lacks sufficient lead time, but is for the most part simply not feasible.

At the same time, the agencies reject the comment that no further regulatory action (Alternative 1) is appropriate (or even legal). The record here shows that there are substantial available, cost-effective emission reductions available for each of the categories covered by the phase 2 rule which would not occur but for the rule. Section IX.A of the Preamble to the final rule and RTC Section 11.2.2 also discuss the various reasons such substantial emission reductions remain possible even though the target industry is commercial with an incentive to reduce fuel-related operating costs

8.2 General Comments on Stringency

Organization: Advanced Engine System Institute (AESI)

AESI strongly supports setting a final Phase 2 greenhouse gas standard that will strongly encourage innovative companies to develop new technologies and systems that can help medium- and heavy-duty vehicle and engine makers to quickly, cost-effectively, and reliably reduce or eliminate carbon pollution and still over perform on criteria pollutants. We appreciate the delicate balance that the agencies must consider between setting an engine standard that appears feasible using technology available now or in the very near term and under current fuel price conditions versus setting a slightly more stringent technology driving standard that will prompt even faster evolution and greater consumer savings in the long run. [EPA-HQ-OAR-2014-0827-1152-A1 p.1-2]

Organization: Allison Transmission, Inc.

EPA and NHTSA should not finalize standards that are more stringent than those contained in Alternative 3. The Proposed Rule lacks sufficient rationale and a demonstrated technical basis for the levels of stringency contained in Alternative 4. [EPA-HQ-OAR-2014-0827-1284-A1 p.2]

Organization: American Council for an Energy-Efficient Economy (ACEEE)
ACEEE strongly supports EPA and NHTSA’s work to establish Phase 2 greenhouse gas and fuel efficiency standards for heavy-duty vehicles and engines. The proposed rule, built on the success of the first phase, represents another important step toward major reductions in fuel consumption and greenhouse gas emissions of the heavy-duty sector. We recommend that the agencies strengthen the proposed rule in several areas to ensure that the Phase 2 program achieves maximum economic and environmental benefits. [EPA-HQ-OAR-2014-0827-1280-A1 p.31]

Organization: American Lung Association

We believe that the joint proposal provides an important first step in the process toward protecting the public from harmful pollutants in this vehicle sector, but that the proposal must be strengthened to address greater pollution reductions needed in Southern and Central California. [NHTSA-2014-0132-0087-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.142.]

In closing, the American Lung Association urges you to strengthen the final rule and clean air protections by: [NHTSA-2014-0132-0087-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.146.]

- implementing a stronger standard more rapidly; [NHTSA-2014-0132-0087-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.146.]
- beginning immediately the process to set a national low-NOx standard; [NHTSA-2014-0132-0087-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.146]
- maintaining a greater focus on advanced technologies; [NHTSA-2014-0132-0087-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.146.]

Therefore, the American Lung Association supports the strongest possible greenhouse gas and other emission standards on the nation’s trucks, buses and other polluting sources. We support EPA’s efforts to update all standards to match the scientific understanding of the harms we face from the widespread air pollutants, toxics and climate change. For these reasons, we believe that greater protections and stronger emission reductions are needed in the final Phase 2 rules for medium and heavy-duty engines and vehicles. [NHTSA-2014-0132-0087-A1 p.2]

Organization: Business for Innovative Climate & Energy Policy

As major U.S. businesses representing nearly two million American jobs and nearly $400 billion in annual revenue, we are writing to urge EPA and NHTSA to strengthen the proposed Phase 2 Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles. BICEP supports the adoption of stronger standards that require a 40% reduction in truck fuel consumption by 2025. Strict standards will save businesses money, catalyze investment in high efficiency truck technologies, and reduce climate risk. Most of our companies depend on trucks to transport our products, and an efficient trucking industry will be critical to our future success. [NHTSA-2014-0132-0095-A1 p.1]

The environmental imperative for action is clear. Freight trucks already account for over 450 million tons of global warming emissions each year. As trucks represent the fastest growing single source of GHG emissions, it is critical that we adopt the strongest possible standards in order to check that growth
and ensure the availability of fuel efficient trucks. Strong GHG standards for heavy trucks will provide a level playing field for companies seeking to reduce their carbon footprint and help avoid the significant costs associated with climate change. [NHTSA-2014-0132-0095-A1 p.2]

As successful American businesses, we know the importance of recognizing and seizing opportunities. This rulemaking is a rare opportunity to strengthen our economy, save businesses and consumers money, create jobs, and mitigate climate risk. Thus, we urge the agencies to adopt stronger Phase 2 fuel efficiency and GHG standards, and call for regulations requiring a 40% reduction in truck fuel consumption by 2025. [NHTSA-2014-0132-0095-A1 p.2]

**Oppose/Requested Change Comment**

**Comment – GHG emissions reductions of proposed regulation in California**

CARB staff consulted with both U.S. EPA and NHTSA throughout the development of the proposed federal Phase 2 Heavy-Duty Program and fully recognizes the potential benefits that would result should CARB harmonize California’s future Phase 2 GHG regulation with the proposed Phase 2 rulemaking, namely, nationwide consistency for engine and vehicle manufacturers. [EPA-HQ-OAR-2014-0827-1265-A1 p.20]

However, as explained in further detail below, CARB staff believes that U.S. EPA and NHTSA’s proposed adoption of emission standards corresponding to “Alternative 3” does not adequately serve California’s needs to reduce both greenhouse gas emissions and petroleum usage from heavy-duty vehicles, and therefore urges its federal partners to adopt the emission standards corresponding to the “Alternative 4” option. [EPA-HQ-OAR-2014-0827-1265-A1 p.20]

We recommend Alternative 4 be the preferred standard across all vehicle categories – tractors, (see comment on page 30), vocational vehicles (see comment on page 36), pickups and heavy-duty vehicles (see comment on page 52) and trailers (see comment on page 57), and in fact in several instances recommend tightening the final stringency also. We recommend tighter standards for tractor and vocational engines as well. In general, CARB staff believes that the NPRM is overly pessimistic about the outlook for the implementation of advanced technologies such as BEVs and FCEVs, as well as the ability of engine and truck manufacturers to engineer solutions that are needed to meet global GHG goals. Generally, CARB staff believes that U.S. EPA and NHTSA should be more willing to push the technology envelope, and have confidence in the ability of industry to meet far reaching environmental goals. As discussed at length in other comments, we believe that more stringent standards for both compression ignition and spark-ignited engines and vehicles are appropriate and could be met in a cost-effective manner. Our recommended reinstitution of Advanced Technology Credits would make Alternative 4 even more attractive and attainable. The projected balances of Phase 1 credits, discussed further below, supports our belief that the engine and truck industry can and will do its part to curb global GHG emissions if more stringent standards are set. [EPA-HQ-OAR-2014-0827-1265-A1 p.20-21]

The benefits of adopting the Alternative 4 standards across all vehicle categories are critical to California for meeting our GHG and petroleum reduction targets for 2030 and 2050. Alternative 4 standards would result in an additional 4 MMT carbon dioxide (CO2) benefit by 2030 in California which is equivalent to removing about 3,300 class 8 long-haul tractor-trailers off the road. This reduction would be a critical first step towards California meeting its goal of reducing petroleum use by 50 percent in 2030. [EPA-HQ-OAR-2014-0827-1265-A1 p.21]
Organization: California Interfaith Power and Light

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p.104.]

The EPA and NHTSA clean truck standards would be a huge step in addressing all of the above. And the standards can be even stronger. The draft rule, as it stands, 36 percent reduction of fuel consumption in trucks by 2027 is a good start. However, we urge EPA and NHTSA to adopt standards that will achieve a 40 percent target by 2025.

With existing technologies and future innovation in the works, especially here in California, we can surely reach much better than an average of six miles per gallon for most heavy-duty vehicles.

Organization: California State Senator Ricardo Lara

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 57.]

In order to meet our reduction goals, we must invest in cleaner transportation technologies with a technology-neutral approach that incentivizes improvements in air quality along with reductions in greenhouse gases. We have made that commitment in California, investing millions of cap and trade dollars to the development of clean truck technology. However, we need an ambitious federal standard that complements and supports these efforts with stringent rules that will be implemented as soon as possible.

Organization: CALSTART

We are concerned the current proposed stringency is unlikely to drive advanced technology important for future needs and the plans of key regions [EPA-HQ-OAR-2014-0827-1190-A1 p.1]

We offer some possible approaches to consider: [EPA-HQ-OAR-2014-0827-1190-A1 p.2]

– Increase stringency AND add more flexibility to achieve it [EPA-HQ-OAR-2014-0827-1190-A1 p.2]

Organization: Center for Biological Diversity

We strongly support a significant increase in the stringency of the greenhouse gas and fuel standards for medium- and heavy-duty trucks, in particular: the addition of trailers to the regulated sectors; the inclusion of powertrain and driveline efficiency improvements for vocational vehicles; and the closure of the “glider” loophole. The proposed standards would require greater reductions than imposed by Phase 1 standards, with about 40 percent more greenhouse gases avoided in 2030 than would otherwise be achieved through Phase 1 standards alone. While there is no question that enhanced fuel and greenhouse gas regulations are an important step, the Proposed Rule fails to capture significant, additional savings and leaves open a significant loophole for natural gas engines. [EPA-HQ-OAR-2014-0827-1460-A1 p.1-2]

The agencies intentionally set “soft” standards during Phase 1, indicating that the first set of standards was intended to be achievable with available technologies and that greater technology innovation would
be required in Phase 2. As we previously commented, this tepid Phase 1 requirement left many reduction opportunities on the table. Specifically, the Center strenuously urged the agencies to promulgate more stringent standards; to improve the cost-benefit analysis to better reflect the actual costs of climate change; and to remove a number of the credits, averaging and banking provisions that would have weakened the actual emissions reductions and fuel savings resulting from the Phase 1 standards.

Now it is time for the agencies to prescribe the stringent, maximal reductions that were neglected during Phase 1. The currently-proposed standards are an improvement, but still fall far short of what is maximally feasible and necessary to best protect against climate change and ensure energy security.

---

**Organization:** Center for Neighborhood Technology

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 125.]

We'd like to speak in support of the previous recommendation from the Union of Concerned Scientists that would recommend going to a standard that would reach 40 percent reduction, improvement in fuel efficiency by 2024.

**Organization:** Climate 911

Our concern is that the proposed standards fall short of what is achievable and that the difference between what is proposed and what is possible will be counted in human lives and suffering and the permanent loss of a habitable planet. [EPA-HQ-OAR-2014-0827-1179-A1 p.1]

The need to lower diesel consumption is urgent, the cost of failure unthinkably high and there is no justification for delay or half measures. We strongly urge you to tighten the proposed standards and shorten the implementation timetable. [EPA-HQ-OAR-2014-0827-1179-A1 p.1]

**Organization:** Climate Resolve

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 231.]
And we urge you to strengthen these standards to ensure the greatest reductions in oil use and global warming emissions.

**Organization:** Coalition for Clean Air/California Cleaner Freight Coalition

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 215.]

While the proposed standards are a good first step, I urge you to strengthen these...
to be technically feasible and economically practicable. The regulatory analysis and technical support documents raise the constraint that NHTSA faces in terms of practicability. The cost estimates note that they do not include potential costs of accelerating technology and the regulatory discussion explicitly says that there is concern that a higher standard which requires a more rapid incorporation of untested technology may not be feasible. [EPA-HQ-OAR-2014-0827-1336-A1 p.59]

Figure VI-4 shows the external analysis. It plots the Phase I and Phase II standards energy savings and costs in the same axes as the third party studies discussed in Section IV. The graph highlights the anomaly. To make the cost curves comparable, we have included both Phase I and Phase II and have stated all costs in 2009$, which would be equivalent to the third party analyses. [EPA-HQ-OAR-2014-0827-1336-A1 p.59-60]

EPA/NHTSA have developed cost curves that show relatively low costs for the smaller increases in efficiency. The graph also shows a clear shift in cost as one moves to higher levels. This would be consistent with the EPA/NHTSA concern about feasibility. [EPA-HQ-OAR-2014-0827-1336-A1 p.60]

Figure VII-2 also puts a recent analysis by the ICCT in perspective. Responding to some claims by members of the industry that the proposed standards exceed even the super truck projects, the ICCT analysis shows that the super combining all the elements of the super truck program (engine, aerodynamics and tires), the improvement in fuel economy would be 2.4 times larger. They do not give costs, however. Moreover, that includes every truck maxing out on each technology, not something regulatory agencies generally require. If we consider two bundles, better engines or aerodynamics plus tires, the improvement would be 1.7 times as large. The ICCT is certainly correct in concluding that “if the US standards are going to require technology-forcing SuperTruck-like standards for tractors, it is more likely this would be in some future Phase 3 rulemaking for perhaps 2030 and beyond.” The issue for regulatory analysis comes down to what would the much more aggressive standards cost? And how hard can the agencies push the industries under the statute? That is not a question that can be answered by simply identifying the technological frontier. [EPA-HQ-OAR-2014-0827-1336-A1 p.60-61]

Organization: Daimler Trucks North America LLC

The agencies must allow for reasonable lead-time and stability. In particular, the agencies must recognize that Alternative 4 is too stringent and accelerating an already very stringent proposal is unworkable. [EPA-HQ-OAR-2014-0827-1164-A1 p.6]

The agencies must correct unrealistic technology Fuel Consumption Reduction (FCR) values and penetration rates for technologies used in standard setting. [EPA-HQ-OAR-2014-0827-1164-A1 p.6]

1. Stringency and Standards

**DTNA is interested in Getting the FCR Values Correct** – As we noted in our Vehicle Stringency section above, we think the agencies took the correct approach of trying to determine the FCR benefits of technologies and the reasonable penetration rate of each. We do, however, have concerns with the FCRs that the agencies assumed. We want to make sure those numbers are correct, as errors could lead to regulations crediting or penalizing technologies differently than should happen, based on real-world FE benefits. To that end, we have a lot of data that we wish to share with the agencies. Below is a
summary, but we wish to have further discussions in a confidential setting. [EPA-HQ-OAR-2014-0827-1164-A1 p.80]

**Organization:** Daimler Trucks North America LLC

The result is that we need to make a dozen assumptions, any one of which could be wrong, before we even see a path to 2027 compliance. In turn, we think that the 2027 standards are overly aggressive. [EPA-HQ-OAR-2014-0827-1164-A1 p.69]

**Organization:** Dignity Health

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 203.]

We strongly support the adoption of regulations requiring a 40 percent decrease in fuel consumption by 2025.

**Organization:** East Yard Communities for Environmental Justice (EYCEJ)

The proposed standards are a step in the right direction in increasing efficiency and reducing oil use, but they can be further strengthened. We support the analysis from the Union of Concerned Scientists and urge the EPA to finalize stronger standards that reduce trucks’ fuel use by 40% by 2025. [EPA-HQ-OAR-2014-0827-0843 p.1]

There is an opportunity here to go beyond the bare minimum. From benefiting the economy by reducing business costs, to saving thousands of barrels of oil per day, to reducing global warming emissions by millions of metric tons. We implore you to go above and beyond your call of duty for the sake of this nation and its myriad of communities - finalize standards that reduce trucks’ fuel use by 40% by 2025. Thank you. [EPA-HQ-OAR-2014-0827-0843 p.2]

**Organization:** Environment America and other local citizens across America

However, we can accomplish more. According to analysis by experts, by 2025 we have the potential to cut fuel consumption of new trucks by at least 40 percent compared to 2010 levels. Standards that extend beyond 2025 could achieve even larger savings.[4] [EPA-HQ-OAR-2014-0827-1295-A1 p.1]

**Organization:** Environment California Research and Policy Center, Environment America Research and Policy Center

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 161-163.]

We applaud the Obama administration for proposing standards that will over the lifetime of trucks affected by the rule avoid one billion metric tons of global warming emissions. While this is a strong
step in the right direction, we urge you to strengthen these standards to ensure the greatest reductions in oil use and global warming emissions

This stronger proposal would mean a triple win for clean air, the climate, and consumers. And I urge you to go the extra mile and finalize stronger standards to reduce trucks’ fuel use by 40 percent by 2025.

Organization: Environment California Research and Policy Center, Environment America Research and Policy Center

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 162.]

Specifically, Environment California and Environment America support strengthening the standards to achieve 40 percent fuel savings by 2025, which would save an additional 200,000 barrels of oil per day in 2035 and avoid an additional 40 million metric tons of global warming emissions annually according to analysis by our colleagues at the Union of Concerned Scientists. That is the equivalent of shutting down not 1, not 2, but 12 coal-fired power plants. And it would save the average big rig driver $30,000 in annual fuel costs in 2025. It is new technology that pays for itself in just over a year.

Organization: Fuller, Tony

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 148-149.]

However, these standards need to be strengthened to achieve at least a 40 percent reduction by 2025. The science shows that the technology exists to do this. Strong 40 percent reduction standards are what I call really a no-brainer decision.

Organization: General Motors

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 122.]

While we are cautiously supportive of this plan for future emissions reduction standards, it is important to note that alternative 3 increases the effective stringency far beyond what is a cursory analysis at 2.5 percent per year would suggest. A combination of procedural, modeling, and fuel changes results in a more stringent regulation.

Organization: Genthem, Inc.

In our view current regulation does not sufficiently encourage application of new technologies which would improve fuel efficiency at the engine level. The proposed rule, in its current form, requires only modest improvements from engine manufacturers and it does not have a mechanism which would promote implementation of new technologies such as electrification of accessories, improving alternator efficiency and installation of other devices for direct generation of electricity such as waste heat recovery devices. [EPA-HQ-OAR-2014-0827-1133-A1 p.1]

Organization: Gilroy, JD
With all these positive aspects to the standards, I can only think of two sorts of reservations I have. One is the inevitable one with any proposed standards that some might think them not progressive enough. While I am certainly no expert to make that case, I can at least convey the claim of the UCS that more stringent standards could achieve greater reductions in fuel consumptions—40% versus 36%—and do so two years earlier—by 2027 instead of 2029, if the standards, for example, were to apply not only to combination tractors but to the trailers they haul. [EPA-HQ-OAR-2014-0827-0751 p.2]

On balance then, I am extremely in favor of the proposed standards, wishing only that even stronger standards be considered, if technologically feasible, along with similar new pollution reduction standards for air and rail vehicles. [EPA-HQ-OAR-2014-0827-0751 p.2]

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

Medium and heavy truck manufacturers have overcome challenges meeting Phase 1 stringency requirements that were developed assuming market adoption of existing off the shelf technology. Phase 2, in contrast is technology forcing. [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

The UAW supports developing and bringing new technology to the fleet as long as the technology is reliable, cost effective and manufacturers have more than one technology path to comply with stringency requirements. [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

We strongly agree with the EPA and NHTSA’s warning that poorly crafted regulations forcing unproven technology can lead to: [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

**Organization:** Investor Network on Climate Risk

As long-term investors representing over $86 billion in assets, and as members of the Investor Network on Climate Risk (INCR), we are writing to urge EPA and NHTSA to strengthen the proposed Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2. We support strong standards that go beyond EPA and NHTSA’s proposed rule, and require a 40% reduction in heavy truck fuel consumption by 2025. Strong standards are feasible, cost effective, and represent a significant opportunity to drive economic growth by shielding us from oil price volatility, catalyzing investment in advanced truck technologies, and reducing climate risk. [NHTSA-2014-0132-0113-A1 p.1]

In sum, strong standards will strengthen our economy, spur innovation, and reduce both our dependence on oil and climate risk. Accordingly, we urge the agencies to adopt strong Phase 2 fuel efficiency and GHG standards requiring a 40% reduction in truck fuel consumption by 2025. [NHTSA-2014-0132-0113-A1 p.2]

**Organization:** MacLaughlin, Douglas

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 225.]

Administration's proposals are a good first step, but the UCS and other organizations, as I have heard today, have shown that they can be strengthened. They have analyzed this issue in detail and made specific additional proposals. They and other organizations have shown that new technology and new
trucks can reduce fuel consumption by a number we have heard quite a bit, 40 percent, by 2025. That is more and faster than the administration’s proposed goal to date, at any rate, of 36 percent reduction by 2027.

**Organization:** Manufacturers of Emission Controls Association (MECA)

Technology development has a 15-20 year cycle from the lab to commercialization. This is why stringent standards are a critical signal to industry to make investments today for technologies that will be needed in the future. MECA members are engaged in developing a large portfolio of efficiency technologies that will directly or indirectly impact CO2 emissions. These technologies include advanced SCR catalysts, passive NOx adsorbers (PNA) and substrates, waste heat recovery, turbochargers, turbo-compounding, EGR coolers, EGR valves and other air management technologies, thermal management strategies including insulated dual wall manifolds and exhaust systems, active thermal management approaches, advanced fuel injection and ignition systems. Technologies, like turbo-compounding and advanced air management strategies are already being commercialized in Europe whereas others such as Rankine cycle systems and advanced high pressure injection, are under demonstration and technologies with still longer term horizons, such as thermoelectric generators are still in the laboratory. MECA members estimate that using the proposed Alternative 3, 2027 engine efficiency standards, some of these technologies, such as waste heat recovery, will fall significantly short of the penetration rates forecasted in the proposal. [EPA-HQ-OAR-2014-0827-1210-A3 p.2]

**Organization:** Mass Comment Campaign sponsored by anonymous 1 (email) - (23)

But these vital emissions reductions don’t go far enough. They must be strengthened to better protect our communities and families. [EPA-HQ-OAR-2014-0827-1341-A1 p.1]

**Organization:** Mass Comment Campaign sponsored by anonymous 3 (email) - (308)

From aerodynamic trailers to automated manual transmissions and advanced engines, the technology exists to cost-effectively meet stronger standards. Analysis shows that we can reduce new truck fuel consumption 40 percent by 2025, compared to 2010 trucks. It is critical that the agencies strengthen these standards, particularly the engine standard, to ensure efficiency improvements throughout freight trucks. [EPA-HQ-OAR-2014-0827-1477-A1 p.1]

**Organization:** Mass Comment Campaign sponsored by Center for Biological Diversity (web) - (4,429)

I am writing to urge you to strengthen your proposed emissions standards for medium- and heavy-duty trucks with a rule that will take us confidently into the future. The current proposal addresses our needs but doesn’t do nearly enough. We need serious cuts to avoid the worst effects of climate change and increase energy security and protect public health, especially among vulnerable communities who are disproportionately located near highways and industrialized zones. [EPA-HQ-OAR-2014-0827-1167-A1 p.1]

Please -- do everything in your power to see that our climate and health are protected with a rule that requires serious emissions cuts and strong standards for big trucks. [EPA-HQ-OAR-2014-0827-1167-A1 p.1]
Organization: Mass Comment Campaign sponsored by CREDO Action (web) - (56,914)

“The EPA’s proposed heavy truck fuel efficiency standards are a strong step toward cutting carbon emission from trucks and addressing climate change. But they must be made even stronger. I urge you to set a standard that achieves a 40 percent reduction in fuel consumption by 2025.” [EPA-HQ-OAR-2014-0827-1117 p.1]

Organization: Mass Comment Campaign sponsored by Sierra Club (email) - (26,917)

While the proposed standards are a good first step, I urge you to strengthen these standards to ensure the greatest reductions in oil use and carbon pollution. [EPA-HQ-OAR-2014-0827-0814-A1 p.1]

From aerodynamic trailers to automated manual transmissions and advanced engines, the technology exists to cost-effectively meet stronger standards. [EPA-HQ-OAR-2014-0827-0814-A1 p.1]

I urge you to strengthen these standards as you move forward. [EPA-HQ-OAR-2014-0827-0814-A1 p.1]

Organization: Mass Comment Campaign sponsored by the Environmental Defense Fund (email) - (60,831)

But these vital emissions reductions must be strengthened to reflect the safeguards that available technology can provide for our communities and families. [EPA-HQ-OAR-2014-0827-1229-A1 p.1]

Medium- and heavy-duty vehicles currently account for about 20 percent of greenhouse gas emissions and oil use in the U.S. transportation sector, but only comprise about five percent of vehicles on the road. These trucks are also the fast-growing single source of climate pollution in the U.S. Improving fuel efficiency and emissions standards on these vehicles is achievable with proven technology options and highly cost effective and will provide significant savings to truck drivers and consumers. In fact, a leading technical evaluation found these trucks can reduce fuel consumption 40% by 2025, compared to 2010 levels. [EPA-HQ-OAR-2014-0827-1229-A1 p.1]

And it has wide public support. According to the Consumer Federation of America (CFA), a large majority of Americans (71 percent) favor requiring manufacturers to increase the fuel efficiency of heavy-duty trucks. [EPA-HQ-OAR-2014-0827-1229-A1 p.1]

Please finalize stronger standards that take effect no later than model year 2024 to protect our communities from the harmful emissions discharged by big freight trucks and buses. Our communities, our families and our children are counting on your leadership. [EPA-HQ-OAR-2014-0827-1229-A1 p.1]

Organization: Mass Comment Campaign sponsored by The League of Conservation Voters (LCV) (web) - (6,603)

Please implement the strongest possible fuel efficiency standards for heavy duty trucks [EPA-HQ-OAR-2014-0827-1228-A1 p.1]
Thank you for proposing new standards to significantly improve freight truck fuel efficiency. These standards are a strong first step, but EPA and DOT must strengthen these standards to ensure the greatest reductions in oil use and carbon pollution. [EPA-HQ-OAR-2014-0827-1228-A1 p.1]

Organization: Mass Comment Campaign sponsored by Union of Concerned Scientists (email) - (28,135)

The technology exists to cost-effectively meet stronger standards sooner than you have proposed. It is critical that the proposal be expanded to capture the full suite of cost-effective solutions available for each type of heavy-duty vehicle, including improved aerodynamics on trailers, more efficient engines in tractor-trailers, and new technologies such as hybrid and electric drive trains. [EPA-HQ-OAR-2014-0827-0913-A1 p.1]

Organization: Moms Clean Air Force

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 63.]

But while the proposed standards are a good first step, I urge you to strengthen these standards to ensure the greatest reductions in oil use and global warming emissions.

Organization: Motor & Equipment Manufacturers Association (MEMA)

Provide More Flexibilities to Ensure Engine Technologies are Utilized [EPA-HQ-OAR-2014-0827-1274-A1 p.4]

Overall, the engines and engine technologies available in the near-term and in the pipeline are feasible. The proposed stringencies are achievable and going in the right direction, but there are opportunities to further utilize feasible engine technologies. Programs like the Department of Energy’s “SuperTruck” have shown there are efficiency improvement possibilities – but there is still a long leap between what is possible and what is feasible. If the agency desires to push performance – which, in turn pushes technologies, then the answers reside somewhere in between what is possible and what is feasible. To be clear, MEMA is not prescribing a specific or different stringency. We only note that there might be some opportunities for the agencies to add more flexibilities to ensure that engine technologies are utilized and adopted. Some examples are: friction reduction, parasitic loss reduction (including on-demand oil and coolant flow control), improved thermal management, higher efficiency after treatment, electrification of auxiliaries and application of on-demand approaches and engine breathing improvements (such as higher efficiency turbochargers and variable valve actuation). MEMA members will address their product lines and technologies in their individual company comments. [EPA-HQ-OAR-2014-0827-1274-A1 p.4-5] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.193.]]

Organization: Moving Forward Network

Our Network is deeply concerned that both agencies put forward the strongest regulation possible since this regulation address harmful climate pollution. [EPA-HQ-OAR-2014-0827-1130-A2 p.1]

Organization: National Association of Clean Air Agencies (NACAA)
With respect to aspects of the proposal NACAA believes should be improved, we offer the following comments. [EPA-HQ-OAR-2014-0827-1157-A1 p.2]

In a March 18, 2015 letter to your respective agencies, NACAA provided our recommendations for essential components of a Phase 2 rule. In those recommendations, we urged for a rule that would reduce GHG emissions and fuel consumption across the entire fleet by at least 40 percent, on average, compared to 2010. Unfortunately, we find the overall effectiveness of the Phase 2 proposal to fall short of our recommendation and, more importantly, significantly short of what can and should be achieved. Accordingly, we believe the overall stringency of the proposal should be enhanced to take advantage of missed opportunities that, if incorporated into the final rule, would drive technology and ensure that maximum emission reductions and reduced fuel consumption are achieved. [EPA-HQ-OAR-2014-0827-1157-A1 p.2-3] [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.52-53.]

Organization: Natural Resources Defense Council (NRDC)

In finalizing the rule, we urge the agencies to incorporate our recommendations to strengthen the program beyond what the agencies have proposed. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

Increase the Standard Stringency throughout the Phase-in Period

NRDC believes that stringency of the overall standards should be strengthened beyond the proposed levels. The proposed Phase 2 standards (described as Alternative 3) reduce fuel consumption and carbon dioxide (CO2) emissions by 24 percent relative to the Phase 1 standards by 2027. The agencies have described cost-effective standards in Alternative 4 that achieve the same reductions in 2024. Prior to the proposal, analysis by the American Council for an Energy Efficiency Economy (ACEEE), the Union of Concerned Scientists (UCS) and NRDC showed that overall medium- and heavy-duty fuel consumption could be reduced by at least 40 percent from 2010 levels and approximately 28 percent from 2017 levels by 2025 – a level and timeframe that is more consistent with Alternative 4 than Alternative 3. Upon further evaluation, NRDC believes standards that achieve fuel consumption and emissions reductions of at least 24 percent by 2024 and at least 31 percent by 2027 would meet the agency obligations for setting standards that are maximum feasible (for NHTSA) and appropriate (for EPA). [EPA-HQ-OAR-2014-0827-1220-A1 p.3-4]

Achieving standards stronger than those proposed by the agencies will clearly result in larger and sooner reductions in petroleum consumption and carbon pollution. The agencies analysis shows that Alternative 4 reduces oil consumption and carbon pollution by 13 percent and increases net benefits by over $24 billion compared to the proposed Alternative 3. In this comparison, the Alternative 4 standards ended in 2024. By extending more stringent, technology-forcing standards beyond 2024 the agencies can provide valuable market certainty for manufacturers that will encourage companies to make ongoing investments in fuel-saving innovations that will further reduce carbon pollution. [EPA-HQ-OAR-2014-0827-1220-A1 p.4]
While the 2027 proposed standards provide a long timeframe, they are too modest to spur all cost-effective technology deployment. Significant improvements can be made to the proposal stringency, particularly in the areas of tractor engines and vocational vehicles. [EPA-HQ-OAR-2014-0827-1220-A1 p.4]

Organization: Navistar, Inc.

The Proposed Rule is not economically practicable as it is currently written. In addition, the standards are not the maximum feasible, but exceed the maximum feasible standards in stringency. We urge both agencies to address the concerns in these comments as well as those filed in EPA's docket. [NHTSA-2014-0132-0094-A1 p.3]

Organization: Nelson, Dennis

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 93-94.]

Secondly, I will offer my constructive criticism for improvement. The heavy duty vehicle fuel economy and carbon emissions standards should be made even stronger in order to achieve about 40 percent in fuel savings by 2025. This would use cost-effective technologies that are now being deployed or demonstrated. An additional 40 million metric tons of climate disrupting pollution would be avoided each year by 2035, which would be the equivalent of closing down around 12 coal-fired stations.

Organization: North American Die Casting Association (NADCA)

However, should the Administration move forward with the Phase II standards, we encourage regulators to adopt a nationwide ceiling with achievable standards rejecting Alternative 4. [EPA-HQ-OAR-2014-0827-1283-A1 p.3]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

The rule as proposed, however, does not take full advantage of available and proven technologies and should be made stronger in several areas. [EPA-HQ-OAR-2014-0827-1221-A1 p.1]

Organization: Orange EV

We support the efforts by EPA and NHTSA to address greenhouse gas emissions and fuel efficiency in this proposed rule, but encourage the agencies to adopt stronger standards and full implementation as soon as possible. [EPA-HQ-OAR-2014-0827-1135-A1 p.1]

Stricter emission standards can be achieved with existing technologies that have been proven to meet operational demands while making financial sense. To speed adoption we encourage the offering of
incentives that defray the cost of initial purchase and implementation to at or below the cost of current alternatives. [EPA-HQ-OAR-2014-0827-1135-A1 p.1]

**Organization:** PACCAR

Although some engine manufacturers may support a greater improvement in fuel efficiency/GHG emissions under Alternative 4, the full benefit of the technologies needed to achieve that reduction appears only in certain applications. Even if it were possible to reduce fuel consumption and GHG emissions by greater amounts in all applications and duty cycles, that level of improvement will require the use of technologies that are not familiar to customers and may be undesirable to them. In a number of cases, these technologies do not exist in the marketplace and may not have even reached the stage of prototype with some OEMs. Vehicle Stop-Start systems, dual clutch transmissions, and waste heat recovery are three examples of technologies that customers have no experience with today. If customers do not purchase engines and vehicles with newer technologies, then the overall emission reduction goal may not be achieved and is unlikely to be cost effective. The accelerated timeline of Alternative 4 also does not allow for technology reliability demonstrations and may result in technologies being rushed to market. For commercial vehicles, it is imperative that new technologies are sufficiently robust and reliable across the broad range of applications for this market to allow the vehicles to operate throughout their work day. Downtime due to product unreliability negatively impacts the viability of companies and the economy. PACCAR therefore strongly supports the adoption of Alternative 3, taking into account the revisions suggested in these comments. [EPA-HQ-OAR-2014-0827-1204-A1 p.4]

**Organization:** Proterra

Proterra is already exceeding these desired results for heavy duty public transportation buses and would encourage EPA and NHTSA to be even more aggressive in setting GHG and Fuel Efficiency targets by adopting more stringent standards, as proposed in the Alternative 4 standards. Among other benefits of the proposed Phase 2 Program, including reducing carbon pollution and improving energy security, these higher standards will save transit operators money. Proterra customers have already saved close to $1M in fuel and maintenance costs. [EPA-HQ-OAR-2014-0827-1160-A1 p.2]

**Organization:** Quealy, Kevin

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 172-174.]

However, I do believe that significant progress will not be made in a timely manner if the EPA does not implement a full-fledged attack on carbon pollution released by the truck fleets that fill our Nation's roadways.

Strong standards to reduce trucks' fuel use by 40 percent by the year 2025 should be a top priority of the Agency.

**Organization:** Respiratory Health Association

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p.131.]
Every barrel of oil burned means more carbon dioxide in the atmosphere, further increasing global warming. Reducing fuel consumption through greater efficiencies and through the development of non-fossil fuel technologies that eliminate carbon emissions are needed to address these health threats. For those reasons, we believe strong EPA greenhouse gas tailpipe standards are necessary. And while we strongly support the direction of proposed EPA climate rules for new trucks, we also believe the proposed standards should be strengthened, and that EPA should increase its goal to achieve a 40 percent fuel savings by 2025.

The ability to gain additional reductions is there. The agency should go beyond its very conservative approach to capture additional fuel reductions, a strategy we believe will benefit public health for many years to come.

**Organization:** Sierra Club

Our organizations urge the agencies to strengthen the proposed standards to ensure the greatest possible reductions in oil use and carbon pollution and to finalize the standards as soon as possible. [EPA-HQ-OAR-2014-0827-1277-A1 p.3]

**Organization:** Transportation Power

[We] encourage the agencies to adopt stronger standards and full implementation by 2024. [EPA-HQ-OAR-2014-0827-1149-A1 p.1]

The rule, as is, would lock in the status quo for technology until 2030. Please consider strengthening the proposed standards and revising the timeline for full implementation to 2024. [EPA-HQ-OAR-2014-0827-1149-A1 p.1]

**Organization:** Truck Renting and Leasing Association

However, TRALA has several concerns about the Proposed Standards, which we have set forth below: (3) the agencies’ technology assumptions are overly optimistic [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

**Organization:** Union of Concerned Scientists (UCS)

However, with a projected increase in freight miles from this sector more must be done to curb growth in emissions and fuel usage, and we believe there are a number of ways in which the proposal can be strengthened to ensure that EPA and NHTSA are meeting their statutory obligations. [EPA-HQ-OAR-2014-0827-1329-A2 p.1]

The analysis noted above highlights the simple fact that while the agencies have put forward a comprehensive proposal, the regulation can be strengthened significantly. Improving this regulation will help maximize the feasible reductions in the timeframe of this rule and set the industry on a more sustainable path for decades to come. [EPA-HQ-OAR-2014-0827-1329-A2 p.27]

**Organization:** Volvo Group
As currently drafted the proposal grossly underestimates the actual efficiency improvements required to meet the proposed targets for several reasons. First, the baseline efficiency from Phase 1 vehicles is significantly overestimated. Second, the lack of margins for aerodynamic and engine map audits would force us to understate our certified efficiency inputs to ensure passing a subsequent audit. Third, the aerodynamic measurement procedure overstates the aerodynamic drag and the targets fail to account for the impact of a non-aerodynamic test trailer. Collectively, these issues amount to an increase in stringency by approximately 17%, e.g. from 32% to 49% for high-rise sleeper tractor-trailer combinations, based on the MY 2027 targets, as shown in the chart below. [EPA-HQ-OAR-2014-0827-1290-A1 p.10]

Excessive stringency results in uncertainty that the proposal can be implemented, excessive cost, unreliable products, delays in new vehicle purchases, production disruption, lay-offs, and delays in achieving benefits. Volvo supports comments by EMA relative to stringencies and we elaborate on our concerns below. [EPA-HQ-OAR-2014-0827-1290-A1 p.18]

For reasons set forth below, due to numerous errors in setting stringency levels in the rule, there is substantial uncertainty that manufacturers can even comply with the agencies’ proposal. Unless these errors are corrected, there is substantial uncertainty that, among other things, the proposal would accomplish its intended purpose. Furthermore, as a result of these errors, the proposal lacks an adequate factual basis. In addition, the excessive stringency resulting from these errors will result in excessive cost, unreliable products, delays in new vehicle purchases, product disruption, lay-offs, and delays in achieving benefits, if such are even achievable under the proposal as drafted. For these reasons Volvo believes EPA must revisit and correct its assumptions before proceeding with the proposed rule. [EPA-HQ-OAR-2014-0827-1290-A1 p.18]

Stringency and Technology Penetration Summary

As noted above, the significant errors in assumptions made for purposes of setting stringency levels renders these levels highly suspect and likely unachievable. The agencies have failed to provide adequate explanation or evidence to demonstrate that the stringency levels are achievable and justified. Moreover, the assumptions (penetration levels and feasibility) relied on to set the established stringency levels do not support those levels. Finally, due to these errors, there is substantial uncertainty that the rule, if adopted as proposed, would even achieve its intended purpose. As a result, the proposal is not the product of reasoned decision making, and should be revisited and revised to address these errors. [EPA-HQ-OAR-2014-0827-1290-A1 p.29]

Organization: XL Hybrids

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 240.]

We are very appreciative of the efforts of the federal government team in developing the phase 2 draft rules and agree with the basic principles and structures that have been proposed. And, as currently proposed, we support the preferred alternative.]

Response:

The agencies considered all of the general comments associated with the proposed Alternative 3 and Alternative 4 standards, as well as other comments on overall stringency. We believe there is merit in many of the detailed comments received regarding technologies. These are discussed in detail in
Sections II through VI of the FRM Preamble and Chapter 2 of the RIA. Instead of merely choosing from among the proposed alternatives, the agencies have developed a set of final standards that reflect our reevaluation of the ability to pull ahead certain technologies, the limitations in adoption rates and/or effectiveness of other technologies, and consideration of additional technologies.

As can be seen from the comments, there is uncertainty and a wide range of opinions regarding the extent to which these technologies can be applied. Vehicle manufacturers tended to take the conservative position for each technology and argue that the agencies should not project effectiveness or adoption rates beyond that which is certain. Many other commenters took a more optimistic view. Some merely cited the 40 percent reduction supported by a wide variety of NGOs. Whether explicitly or implicitly, these commenters argued for the agencies to assume that each potential technology will be highly effective in most applications. However, the agencies believe the most likely outcome will be that some technologies will work out better than expected while others will be slightly more challenging than projected. Thus, the agencies have tended to make balanced projections for the various technologies, although some may be slightly optimistic while others are somewhat conservative. We believe the overall effect of this approach will be standards that achieve large reductions with minimal risks to the industry of unreliable or under-performing technology.

Comments on the engines standards are addressed in Section 3 of this RTC. However, since many of the commenters highlighted the engine standards, it is also worth addressing them briefly here to highlight the changes from the proposal. On the vocational side, we changed the baseline engine to reflect the most recent certification data, which significantly strengthens them relative to the NPRM. The detailed analysis of vocational engine stringency and the baseline engine standards is addressed in Chapter 2.7.4 of the RIA. We also made changes to the tractor engine standards. We decreased the dis-synergy assumed in the analysis from 15 percent to 10 percent, and significantly increased the projected market penetration for WHR Rankine cycle technology. As a result of these and other updates, the projected improvements over the baseline for the 2027 tractor engine standards increased from 4.2% estimated at proposal to 5.1%. Chapters 2.3 and 2.7 of the RIA provide detailed justification of these changes from proposal.

Comments on the need for compliance margins are addressed in Section 1.4 of this RTC.

8.2.1 **General Comments on Phase-in 1411**

**Organization:** California Air Resources Board (CARB)

In this NPRM, U.S. EPA and NHTSA have set forth a broad range of compliance strategies and technologies that they anticipate engine and vehicle manufacturers will utilize in order to comply with the emission standards associated with both Alternatives 3 and 4. Such compliance strategies and technologies vary from well-established control technologies that are currently widely available (essentially “off-the-shelf” technologies) to control technologies that are only utilized in certain industry segments or that will likely require substantial development before they will be commercially available on a widespread basis throughout the industry (e.g., Rankine-cycle engines and strong hybrid pickups and vans). [EPA-HQ-OAR-2014-0827-1265-A1 p.25]

As demonstrated below, CARB staff believes that for each regulated category of engines and vehicles, U.S. EPA and NHTSA have identified specific technologies that will be commercially available and that will enable manufacturers to comply with the proposed emission standards within the time frames associated with Alternative 4. [EPA-HQ-OAR-2014-0827-1265-A1 p.25]

“Given this time frame, we feel there is substantial room for deference to the EPA’s expertise in projecting the likely course of development. The essential question in this case is the pace of that development, and absent a revolution in the study of industry, defense of such a projection can never possess the inescapable logic of a mathematical deduction.” [EPA-HQ-OAR-2014-0827-1265-A1 p.25]

Organization: California Air Resources Board (CARB)

The benefits of adopting the Alternative 4 standards across all vehicle categories are critical to California for meeting our GHG and petroleum reduction targets for 2030 and 2050.6 Alternative 4 standards would result in an additional 4 MMT carbon dioxide (CO2) benefit by 2030 in California which is equivalent to removing about 3,300 class 8 long-haul tractor-trailers off the road.7 This reduction would be a critical first step towards California meeting its goal of reducing petroleum use by 50 percent in 2030. [EPA-HQ-OAR-2014-0827-1265-A1 p.21]

Adopting Alternative 4 standards across all vehicle categories would also result in the Phase 2 program being fully phased in by 2024 (by 2025 for pickups and vans), three years earlier than if Alternative 3 standards are adopted. This would allow manufacturers to take action on reducing NOx emissions from the heavy-duty vehicles addressed in this rulemaking in a timelier manner. This is especially important since heavy-duty vehicles are responsible today for one-third of California’s NOx emissions. The South Coast Air Basin will need nearly a 90 percent reduction in heavy-duty vehicle NOx emissions by 2031 from 2010 levels to attain the 2008 National Ambient Air Quality Standards (NAAQS) for ozone. Additionally, on November 25, 2014, U.S. EPA issued a proposal to strengthen the ozone NAAQS. If a change to the ozone NAAQS is finalized, California and other areas of the country will need to identify and implement measures to reduce NOx as needed to complement federal emission reduction measures. [EPA-HQ-OAR-2014-0827-1265-A1 p.21]

Organization: CALSTART

We are concerned the current proposed stringency is unlikely to drive advanced technology important for future needs and the plans of key regions [EPA-HQ-OAR-2014-0827-1190-A1 p.1]

We offer some possible approaches to consider: [EPA-HQ-OAR-2014-0827-1190-A1 p.2]

– Increase stringency AND add more flexibility to achieve it [EPA-HQ-OAR-2014-0827-1190-A1 p.2]

Therefore, we strongly support increasing the stringency requirements of these vocational segments, with a minimum target of 20% (though varied by different segment). In terms of the rule timeline, we remain sensitive to both OEM and fleet desires for a longer investment horizon and a more measured, stair-step regulatory approach to ensure quality product delivery. However, we believe any longer regulatory timeline (2027) would only make sense in the context of increased stringency, with some commensurate added flexibility. We will discuss flexibility in a following section. [EPA-HQ-OAR-2014-0827-1190-A1 p.4]

Organization: Environmental Law and Policy Center
[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 218.]

Regulations should be fully implemented by 2024 rather than 2027 as proposed. My understanding is that EPA's own analysis shows that this deadline is achievable.

Delaying the final phase-in of today's rule to 2027 means we won't be able to respond to any of these changes until at least 2030. Faster implementation of today's rule means flexibility to respond sooner to tomorrow's opportunities.

**Organization:** National Automobile Dealers Association (NADA)

The Phase 2 proposal largely phases-in beginning with MY 2021, culminating in standards for MY 2027. Regulated truck trailer manufacturers must begin compliance in 2018 for EPA and 2021 for NHTSA. Such a long lead time benefits OEMs by allowing them to plan their compliance strategies well ahead of time. On the other hand, setting rules up to 12 years into the future necessarily raises questions on the assumptions involving for critical variables like fuel price, interest rates, and freight demand. [EPA-HQ-OAR-2014-0827-1309-A1 p.5]

10 NADA/ATD will not comment on the proposed trailer standards.

**Organization:** Navistar, Inc.

Finally, the cost estimate in the NPRM significantly underestimates the vehicle program costs for Alternative 3, which is only made worse by the acceleration of the standard proposed in Alternative 4. The cost/benefit analysis estimates that vehicle program costs will be approximately $113 million per year between 2018 and 2020. Alternative 4 would drive significant additional stringency into the 2024 MY, which would require greater investment over the same time period. This would further undermine the cost estimate in the NPRM and would drive significant price increases in MY2021 and MY 2024 as manufacturers struggled to meet the accelerated time table. [EPA-HQ-OAR-2014-0827-1199-A1 p.18]

**Organization:** Navistar, Inc.

The NPRM proposes three tiers of emission standards in 2021, 2024 and 2027. However, as we note, the engines actually need to be developed over a year before to the vehicle. As a result, the rule envisions a near constant state of development for nine years in order to meet the regulatory requirements. That is if only GHG rules apply. If future NOx, OBD or other rules also come into play, the complexity increases well beyond even that in this Proposed Rule. Notwithstanding, given the aggressive nature of the standards, we think the three tier approach is the minimal lead time that will be required. At the very least, the agencies also must consider the cumulative impact of potential regulations on feasibility and costs. However, we see little indication that this has been considered in the NPRM. [EPA-HQ-OAR-2014-0827-1199-A1 p.9]

As a result of the Proposed Rule, then, there is a significant risk that the industry will be in nearly continuous development from 2019 through 2027. The result of this complexity will be added costs, including as a result of aggressive timeframes and constricted validation periods between product launches. From a customer’s perspective, there may be additional costs and also potentially additional
down time as new technologies come on continuously for a 17 year period. [EPA-HQ-OAR-2014-0827-1199-A1 p.9]

We also like to point out that phase 1 is not fully even mature, having only become mandatory beginning in MY2014. That is only about 21 months ago and there is over a year until the final tier of Phase 1 in MY2017. Therefore, this represents a very aggressive regulatory pace, with new Proposed Rule adding a tremendous amount of added complexity. Also, as a result, the Proposed Rule has had little chance to learn from the experience that will be gained from full implementation of Phase 1. [EPA-HQ-OAR-2014-0827-1199-A1 p.9]

The new emission standards adopted by Phase 1 should not be changed in this rule prior to the date the new emission standards go fully into effect. Not only is this an imperative of the Clean Air Act and the need for adequate notice, it is also key to feasibility and simple fairness. The proposal includes a modification to the wind-average drag calculation for model year 2018 (calendar 2017) and later vehicles. This would impact the current Phase 1 certifications and adjust the aero bin down for many vehicle configurations. This reduction in the aero bin effectively lowers the Phase 1 emission standard. This would be inappropriate, arbitrary and capricious and should be stricken or modified to take effect in alignment with the MY2021 standard. We also fully agree with EMA comments on this issue. [EPA-HQ-OAR-2014-0827-1199-A1 p.9]

12 40 C.F.R. Eq. 1037.525-6. This is a new equation applicable after MY2017, thus it will be used while Phase 1 is still in effect.

Organization: Triple Decker Transport Ltd.

Based on our first hand experiences with the 2004-10 diesel engine emission regulations I would URGE PATIENCE!!!!! [EPA-HQ-OAR-2014-0827-0908-A1 p.1]

In ending I would PLEAD FOR PATIENCE!!! We cannot go thru an expedited acceleration of regulations (as in the 2004-2010 diesel engine emission regulations) WITHOUT proper testing of the new technologies. So please choose Alternative 3. [EPA-HQ-OAR-2014-0827-0908-A1 p.3]

Organization: Walsh, Michael and Charlton, Stephen

1. Retain the current phase-in schedule, while increasing stringency in 2021 and 2024 proportional with the final step proposed in bullet 1 above:

[NHTSA-2014-0132-0102-A1 p.10]

Response:

The agencies noted in the proposal that the Phase 2 standards represent a more technology-forcing approach than the Phase 1 approach, predicated on use of both off-the-shelf technologies and emerging technologies that are not yet in widespread use. 80 FR 40154. As such, we recognized that assuring
proper lead time would be very important and requested comment on this issue. Many commenters, including most non-governmental organizations, supported more stringent standards with less lead time. Vehicle manufacturers did not support more stringent standards and emphasized the importance of lead time. Although some technology and component suppliers supported more stringent standards, they also supported the proposed lead time. To the extent these commenters provided technical information to support their comments on stringency and lead time, it is discussed in Sections II through VI of the Preamble, and in Chapter 2 of the RIA. However, the vast majority of the comments summarized here addressed the issue of lead time from a broader view. This issue is addressed in more detail in Section 1.5 of this RTC.

8.3 Comments on the Baselines

Organization: American Council for an Energy-Efficient Economy (ACEEE)

Greenhouse Gas and Fuel Consumption Impacts

Baseline

The agencies request comment on their choice of baseline scenario (p.40166). To analyze the benefits of the proposed standards, the agencies compare the expected outcomes of the standards to those of two distinct baseline scenarios: the less dynamic baseline and the more dynamic baseline. The less dynamic baseline represents a reasonable attempt to incorporate the effects of existing policies (California Air Resources Board’s Tractor-Trailer Greenhouse Gas regulation and EPA’s SmartWay Transport Partnership) on box trailers’ adoption of aerodynamic technologies and low rolling resistance tires (RIA p.5-12). However, the more dynamic baseline relies on the assumption that pickups and vans and tractor technologies that pay back within the first six months of ownership will be taken up in the market (p.40492 and RIA p.5-12). This is an arbitrary assumption. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]

In general, assumptions regarding the trajectory of fuel efficiency in the absence of standards are necessarily highly speculative, given the many complex factors that can produce rising or falling fuel efficiency over time. The agencies’ assumption in earlier fuel efficiency rulemakings of constant fuel efficiency in the baseline scenario best maintains the transparency of the analysis. [EPA-HQ-OAR-2014-0827-1280-A1 p.26]

Recommendation: Baseline

- Assume flat fuel efficiency in the baseline scenario unless there is strong evidence that another assumption is more plausible. Alternative baseline assumptions are appropriate for a sensitivity analysis. [EPA-HQ-OAR-2014-0827-1280-A1 p.27]

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Flat vs. dynamic baseline scenario

The NPRM requests comment regarding which alternative baseline scenario is most appropriate (flat baseline scenario vs. dynamic baseline scenario). Historically, for modeling and emission projection purposes, CARB staff assumes manufacturers would not go beyond regulations’ requirements except
where we have data that shows otherwise. CARB staff does not have data that suggests that manufacturers, in the absence of further, stricter standards, would make vehicles more fuel efficient than required by the Phase 1 standards. As a result, our EMFAC 2014 emissions inventory database does not project fuel economy improvements or CO2 emission rate reductions beyond what is required by Phase 1, and CARB staff has been using a flat baseline for our Phase 2 emissions analysis. In the absence of certainty regarding how manufacturers would behave if no Phase 2 program were adopted, CARB staff believes the approach taken in the NPRM and RIA to examine both a less dynamic and more dynamic baseline is valid and reasonable. [EPA-HQ-OAR-2014-0827-1265-A1 p.132]

**Organization:** Center for Biological Diversity

The Proposed Rule omits any comparison with emission levels in 1990, the internationally agreed-upon emission baseline year. That omission must be corrected, as the effect of the rulemaking on the climate problem would otherwise remain opaque rather than transparent. Reductions from business as usual are meaningful only in context, and that context has not been supplied. Crucially, CO2 emissions from heavy-duty vehicles increased 71 percent between 1990 and 2013 and constituted over 7 percent of all US greenhouse gas emissions,

\[3\] highlighting the importance of reducing greenhouse gas emissions from this sector to the maximal extent possible. The goal of the rulemaking must be not only to do better than Phase I, but to also actually drive down overall emissions as quickly as possible. [EPA-HQ-OAR-2014-0827-1460-A1 p.2]

---

**Organization:** Daimler Trucks North America LLC

**Real-World Adoption Rate of Technologies** – The agencies request comment on their hypotheses about the causes of slow adoption of readily available and apparently cost-effective technologies for improving fuel efficiency. HDV owners have limited capital to spend on new vehicles, plus they need reliable equipment so that they do not suffer breakdowns while trying to operate. These owners typically decide whether to buy a new technology based on the change in price of a truck, change in fuel economy, payback, current economic cycle and outlook, profitability, used equipment values, credit availability, and regulatory awareness. Only some of these concerns are captured in the agencies’ conceptual framework. Many of the factors to slow adoption of new technologies discussed in the reference cited by EPA. See Klemick, Heather, Elizabeth Kopits, Keith Sargent, and Ann Wolverton (2014). “Heavy-Duty Trucking and the Energy Efficiency Paradox.” US EPA NCEE Working Paper Series, Working Paper 1402. Slow adoption can be traced back to customers’ experiences with the rollout of EPA 2004/2007/2010 emission standards which created many issues including: reliability issues, downtime, increased maintenance – all of which caused missed and late loads and driver dissatisfaction. Customers’ experiences taught them to be cautious, especially smaller operators. EPA needs to carefully research customer experiences from these earlier regulations to understand the motivation of customers and the consequences of mandating new standards that could have the same effects. [EPA-HQ-OAR-2014-0827-1164-A1 p.87]

**Ref. Case against which Costs and Benefits are calculated** – The agencies request comment on which alternative baseline scenarios would be most appropriate for analysis in the final rule. 80 FR 40166. While DTNA appreciates that EPA attempted to take a thorough and comprehensive look at analyzing the baseline, in order to more easily understand the multiple approaches to “No Action” for tractors, a
table summarizing the details of the assumptions would be appropriate and helpful. Regarding the assumptions made in developing the different baseline scenarios, first of all, DTNA appreciates that the agencies’ recognition of how we have focused on fuel economy improvements in the past. However, judging our industry’s success based on pre-Phase 1 market conditions is not the appropriate baseline by which to measure due to the extraordinary increase in the price of trucks around that time due to other EPA regulations. In 2011, when the agencies were promulgating Phase 1, trucks had just finished undergoing a [redacted]% increase in price due largely to emissions regulations. In addition, having undergone earlier experiences with downtime and increased maintenance due to similar emissions regulations in 2004 and 2007, customers were on “high alert” with regards to new technology likely contributing to their “slow” process to assess technologies and adopt them. In addition, during this time truckers were experiencing poor profitability, weak freight, and limited access to credit made worse by the recent end of a major recession, limiting their ability to spend more on fuel efficiency technologies given the three year [redacted]% increase in the price of criteria emission technologies required to meet emission standards. EPA2010 emissions standards, which essentially forced the use of SCR, resulted in recovering some of the fuel efficiency gains lost due to earlier EPA NOx rules. So SCR could be viewed as one of the most expensive fuel efficiency technologies adopted by customers. While fuel efficiency gains from SCR were not enough to get similar efficiency to pre-2004 model year vehicles, the gains were an improvement over 2007 performance (DTNA can provide information about this in a confidential setting). Given the complexities surrounding customer decisions, it does not seem appropriate to simply use a 6-month payback period as a proxy for all of these considerations. Rather, the agencies should investigate the effects of the high costs of criteria pollutant standards on customer decisions within this industry and within this timeframe to determine a more accurate picture of customer behavior absent regulation, to better understand whether or not customers truly were just not rejecting fuel efficient technologies, and to better estimate the baseline technology market penetration assumptions. [EPA-HQ-OAR-2014-0827-1164-A1 p.130]

Further, DTNA does not agree that while the agencies estimated the cost and efficacy of fuel efficiency technologies that performance and utility should have been held constant, and that payload should have been modeled as being preserved. If low rolling resistance tires were required to be on vehicles that, for example, go off-road a majority of the time, utility will be lost. If heavy technologies, such as battery APUs are required as a result of stringency, payload will likely be lost. The agencies seem to rely heavily on the concept that absent regulation, fuel efficiency will remain stagnant as manufacturers simply trade ever cheaper fuel efficiency technologies to maintain a certain level of efficiency and work to reduce cost. While there is an economic efficiency in reducing cost by choosing or not choosing certain technologies, and replacing certain technologies (e.g. predictive cruise control capturing some the benefit that hybrid technology would have, as discussed with our Super Truck comments in the Hybrid and ePTO section of our Technology Penetration Rate discussion, above) this does change the historic demand of our customers to continually improve their total cost of operations. [EPA-HQ-OAR-2014-0827-1164-A1 p.130-131]

Organization: Gilroy, JD

A second reservation is about future extensions of these standards. Should there be any declarations now in the standards of longer-term goals in fuel efficiency? These standards may well succeed in reducing fuel usage and corresponding pollution to near 2010 levels, but we emitted a huge amount of pollution in 2010. [EPA-HQ-OAR-2014-0827-0751 p.2]

Organization: He, Leard, McConnell
Heavy-duty trucks are an increasingly important source of greenhouse gas emissions in the transportation sector. In 2011, U.S. Environmental Protection Agency (EPA) and National Highway Traffic Safety Administration (NHTSA) announced the final rule of Phase 1 fuel economy standards for medium and heavy-duty vehicles with model year from 2014 to 2018. The second phase of the regulations call for reduction in fuel consumption (gallons of fuel/1,000 ton payload mile) by 24% for combination tractors and 16% for vocational vehicles from 2018 to 2027. This is equivalent to about 3.09% and 1.96% per year improvement in fuel economy for combination trucks and vocational vehicles respectively. How challenging will such fuel economy improvements be? There is little information about fuel economy from trucks – it is not reported at the time of truck sale or during operation. One important source of data, the Vehicle Inventory and Use Survey (VIUS), a random sample of the truck fleet in the U.S., provides valuable evidence about fuel economy of different types of trucks and how fuel economy has changed over time. This study looks at the evidence about fuel economy and other truck attributes from this survey, and provides implications for a dynamic baseline of improvements in fuel economy. [NHTSA-2014-0132-0115-A1 p.1-2]

We find that the annual rate of technological progress from 1973 to 2002 is about 0.93% for combination trucks, and 0.83% for vocational vehicles. That is to say, absent of regulations, we can expect a business-as-usual improvement in fuel economy by 8.71% for combination trucks and 7.70% for vocational vehicles in 10 years. [NHTSA-2014-0132-0115-A1 p.2]

Additional improvements in truck fuel economy may be made through vehicle design changes. Most forms of aerodynamic designs are used to reduce drag, minimize noise emission and prevent undesired lift forces. Tires with less rolling resistance, such as radial tires, can also improve fuel efficiency. Various onboard idle reduction equipment help shorten idle time at truck stops, terminals and delivery sites, and therefore reduce energy loss. Other technologies include (but are not limited to) electrification of accessories, reducing frictions in bearings, valve trains, and the piston-to-liner interface. [NHTSA-2014-0132-0115-A1 p.2-3]

Theoretically, the trade-off relationship between MPG and truck attributes, can be illustrated as follows (take MPG and weight for example). As Figure 1 shows, the tradeoff between MPG and vehicle weight is a downward sloping curve. The exogenous technological advances introduced in section 2.1 push the production curve upward. If vehicle weight remains the same, fuel economy is improved as technological progress occurs. [NHTSA-2014-0132-0115-A1 p.3-4]

[Figure 1, 'Theoretical illustration: trade-off between MPG and vehicle weight', can be found on p.4 of docket number NHTSA-2014-0132-0115-A1]

3 Data and Graphical Evidence

The Vehicle Inventory and Use Survey was conducted by the Census Bureau from 1963 to 2002. We use data collected every five years from 1982 to 2002. Random samples are generated for every state, with surveys asking for detailed information about trucks’ physical and operational characteristics. [NHTSA-2014-0132-0115-A1 p.4]

The trade-off relationship between MPG and vehicle weight (including cargo), as well as between MPG and engine displacement, for combination trucks can be illustrated in the two graphs below. [NHTSA-2014-0132-0115-A1 p.4]
[Figure 2, 'Trade-off between MPG and vehicle weight for class 7, 8 combination trucks', and 3, 'Trade-off between MPG and engine displacement for class 7, 8 combination trucks', can be found on p.5 of docket number NHTSA-2014-0132-0115-A1]

5 Policy Implication and Conclusion

In this study, we examine the trade-off relationship between fuel economy and vehicle attributes (weight and engine displacement, in particular). We also explore a dynamic baseline in fuel economy improvements by estimating the technological progress in the absence of regulations. We find that technological progress in MPG for combination trucks is about 30.87% from 1973 to 2002. It can be translated to 23.59% reduction in fuel consumption (gallons/1,000 ton payload mile). The annual rate is about 0.92%. If the progress of business-as-usual stays the same, from 2018 to 2027, approximately 8.01% reduction in fuel consumption can be expected, even without regulation. While the proposed rule calls for a 20% reduction, the remaining 11.99% will have to come from either more technological advances or changes in trade-o attributes, such as vehicle weight and engine power. For vocational vehicles, the technological progress in MPG is about 27% within 30 years, equating to a 21.26% reduction in fuel consumption. If technological advances remain the same from 2018 to 2027, fuel consumption will be reduced by 7.15%, just under half of the target.

Our findings suggest that it is important to count for the business-as-usual technological progress in improving fuel economy as analyzing the impacts of the new fuel efficiency standards for heavy-duty trucks. We recommend the agencies to consider such dynamic baseline in the final rule of phase 2 standards, as ignoring it may result in an overestimation of both the cost of the regulation, as well as the fuel consumption savings and greenhouse gas emissions reductions due to the new rules.

**Organization:** International Council on Clean Transportation (ICCT)

**Market factors**

Available data and historical trends indicate the agencies include a flat reference truck efficiency baseline, with the sole exception of improvements in trailers that are linked to California’s regulations that affect trailers. The agencies’ continued consideration of fleet-wide vehicle efficiency improvements in the absence of new regulatory standards is unwarranted. The ICCT has supported many governments around the world in collecting and analyzing data. Based on our work to date, although technology improves and fleet-level efficiency improvements occur, there is no evidence to support the assumption of a new sales-fleet-averaged heavy-duty vehicle fleet CO2 or fuel consumption reduction in the absence of regulations. In the case of analyzing the impact of the Phase 2 standards, including reference trailer improvements that are linked to the California regulations on trailer efficiency devices is warranted; however, otherwise retaining flat efficiency characteristics for all engines, trucks, and tractors for scenarios would best reflect the evidence on historical trends in the U.S. [EPA-HQ-OAR-2014-0827-1180-A4 p.17]

There are pervasive market barriers in the market, that have long prevented the uptake of even technologies with very attractive payback periods—for example, 6 months up to 2 years (see, e.g., Vernon and Meier, 2012; Roeth et al, 2013). Routinely, just small fractions of the fleet – a handful of technology-leading companies, representing a small fraction of the fleet, adopt technologies. The agencies consideration of technology adoption based on precise payback periods in the absence of regulation does not appear to be based on any empirical analysis of fleet-wide shifts. [EPA-HQ-OAR-2014-0827-1180-A4 p.17-18]
Technology and Cost Analyses Should Use Less Dynamic Baseline

The agencies should compare the costs and benefits of new standards to a baseline of new vehicles that show little or no fuel efficiency or emissions improvements in the absence of the new standards. A more dynamic baseline should not be used as a basis for setting standards. NRDC believes that it is the existence of fuel consumption and carbon pollution standards that will cause manufacturers to invest and deploy significant amounts of fuel efficiency and low emissions technology. The Energy Information Administration shows that the heavy truck fleet showed almost no fuel efficiency improvements during years without efficiency standards. From 1966 to 2006 the average year-over-year improvement for heavy trucks was 0.2 percent and from 2007 to 2013 the improvement rate was 0.0 percent. [EPA-HQ-OAR-2014-0827-1220-A1 p.9]

In the Executive Summary of the proposal, the agencies summarize the proposed rule impacts on fuel consumption, GHG emissions, benefits and costs as a range defined by the less and more dynamic baselines. The Executive Summary presentation leaves the impression that the two baselines are equally probable. NRDC disagrees; the Executive Summary and main analysis should utilize the less dynamic baseline. The more dynamic baseline should be constrained to a sensitivity analysis. [EPA-HQ-OAR-2014-0827-1220-A1 p.10]

Accurately consider market forces

We urge the agencies not to consider fleet-wide efficiency improvements in the absence of new standards. Although small segments of the fleet do adopt fuel saving technologies, there are entrenched market barriers that have prevented the adoption of many fuel saving technologies, even those that have quick payback periods. According to organizations such as the International Council on Clean Transportation, evidence does not support the assumption that fleet oil consumption and carbon pollution would decrease without regulations. [EPA-HQ-OAR-2014-0827-1277-A1 p.3]

Response:

The No Action Alternatives for today’s analysis, alternatively referred to as the “baselines” or “reference cases,” assume that the agencies did not issue new rules regarding MD/HD fuel efficiency and GHG emissions. These are the baselines against which costs and benefits for these standards are calculated. The reference cases assume that model year 2018 engine, tractor, vocational vehicle, and HD pickup and van standards will be extended indefinitely and without change. They also assume that no new standards would be adopted for trailers.

NHTSA considered its primary analysis to be based on the dynamic baseline, where certain cost-effective technologies are assumed to be applied by manufacturers to improve fuel efficiency beyond
the Phase 1 requirements in the absence of new Phase 2 standards. EPA considered both reference cases. The results for all of the regulatory alternatives relative to both reference cases, derived via the same methodologies discussed in this section, are presented in Section X of the FRM.

Some commenters expressed support for a flat baseline in the context of the need for the regulations, arguing that little improvement would occur without the regulations. Others supported the less dynamic baseline because they believe it more fully captures the costs. Some commenters thought it reasonable that the agencies consider both baselines given the uncertainty in this area. No commenters opposed the consideration of both baselines, although some argued that assuming a dynamic baseline is unrealistic or should be limited to a sensitivity analysis.

Although commenters were more supportive of using a flat baseline, the agencies have continued to analyze two different baselines for the final rules because we recognize that there are a number of factors that create uncertainty in projecting a baseline against which to compare the future effects of this action and the remaining alternatives. The composition of the future fleet—such as the relative position of individual manufacturers and the mix of products they each offer—cannot be predicted with certainty at this time. Having parallel baselines from which to analyze is one reasonable way to account for this unavoidable uncertainty.

Significantly, we note that the both reference cases lead us to the same conclusions, although using a dynamic reference cases results in somewhat lower values for both cost and benefits. This is because costs, benefits, and cost-effectiveness were not significantly limiting factors in determining the stringency of the standards for this rulemaking. Rather, we found that actual technological feasibility and lead time to be the more limiting factors.

While we understand the Center for Biological Diversity comment regarding comparison with emission levels in 1990, we do not believe that is the appropriate baseline for this rulemaking context.

8.4 Comments on Alternative 2

**Organization:** Association for the Work Truck Industry (NTEA)

**Fuel Efficiency Payback**

The NTEA requests that standards similar to those described as “Alternative 2” be considered for the vocational truck segment. [EPA-HQ-OAR-2014-0827-1187-A1 p.3]

With regard to Alternative 3, in 2027 when the standard is fully phased in, heavy-duty vehicles across all classes would achieve up to the following CO2 emissions and fuel use reductions.

- 24 percent for combination tractors designed to pull trailers and move freight when compared to Phase 1 standards
- 8 percent for trailers when compared to an average model year 2017 trailers
- 16 percent for pick-up trucks and light vans when compared to Phase 1 standards [EPA-HQ-OAR-2014-0827-1187-A1 p.3]

Further, the proposal calculates figures for expected payback periods based on the additional costs associated with the proposed standards and the economic savings based on the increased fuel efficiency
expected with Alternative 3. The proposal estimates “Reasonable Payback Periods for the Trucking Industry In model year 2027,” for the buyer of a new vehicle. The notice states that the buyer would recoup the extra cost of technology used to achieve the standard (Alternative 3) within:

- 2 years for a tractor/trailer combo
- 3 years for pick-ups and vans

The expected payback periods for tractor/trailer combinations and pick-ups/vans seems reasonable. Most companies would look towards a 2-3 year payback period for moderate fuel efficiency gains. [EPA-HQ-OAR-2014-0827-1187-A1 p.4]

Regulatory Burden Equity

According to the proposal, the overall transportation sector is responsible for 70% of oil consumption and 28% of GHG emissions. By 2010 all medium and heavy duty vehicles were responsible for 23% of the total transportation sector fuel consumption and GHG emissions. [EPA-HQ-OAR-2014-0827-1187-A1 p.4]

Of these transportation sector totals, combination tractors were responsible for two-thirds of the overall MDV and HDV fuel consumption and GHG emissions. Vocational trucks were responsible for only 20%. Yet, the proposed rules would set standards such that combination tractor owners would see a payback on the additional regulatory costs of 2-3 years. Owners of vocational trucks would be burdened with a 6 year payback. [EPA-HQ-OAR-2014-0827-1187-A1 p.4]

The NTEA respectfully suggests that the agencies consider standards more in line with Alternative 2 for the vocational truck segment. The proposed standards (Alternative 3) place an unfair burden on this segment of the vehicle population in relation to the other regulated segments (tractor/trailer combinations and pickups and vans). [EPA-HQ-OAR-2014-0827-1187-A1 p.4]

Per the notice, Alternative 2 represents a stringency level which is approximately half as stringent overall as the “preferred” alternative (3). The agencies developed Alternative 2 to reflect a continuation of the Phase 1 approach of applying off-the-shelf technologies rather than requiring the development of new technologies or fundamental improvements to existing technologies. [EPA-HQ-OAR-2014-0827-1187-A1 p.4-5]

The agencies project that the Alternative 2 vocational vehicle standard could be met with lower adoption rates of the other technologies that could be used to meet Alternative 3. [EPA-HQ-OAR-2014-0827-1187-A1 p.5]

Organization: Daimler Trucks North America LLC

Regarding Alternative 2, while the agencies immediately dismiss it as being faulty as both a matter of policy and of law, given the number of factors currently in the preferred approach that actually make the rule nearly twice as stringent as designed, Alternative 2 should be reconsidered if these other technical issues are not corrected. For example, it is estimated that due to baseline errors, elimination of compliance margins, and regulatory trailer specifications, that the reduction required from linehaul approaches 50% - in which case Alternative 2 would actually provide the agencies with the reductions claimed by the rule for linehaul. In addition, Alternative 2 should be adopted in part for vocational
vehicles as the current program for vocational vehicles under the preferred approach is not tenable. As the agencies mention – Alternative 2 could be met without the use of strong hybrids, a technology that is extremely expensive and highly likely to create market disruptions. A more realistic approach is to adopt Alternative 2, in particular for vocational vehicles and include an ‘advanced credit’ similar to that under Phase 1 to encourage the hybrid market to recover as currently there is no hybrid market (see our discussion of hybrids in the “Vocational Vehicle Stringency” section of this document). [EPA-HQ-OAR-2014-0827-1164-A1 p.73]

Further, we do not understand why it is estimated that technology effectiveness would be lower under Alternative 2 than Alternative 3. We request that the agencies provide an explanation. It is not readily apparent why technologies in use today and under develop would erode in efficiency gains due to adoption of Alternative 2 as opposed to the preferred approach. In addition, the agencies have assumed that Alternative 2 would involve less integrated optimization for linehaul vehicles and engines. There has been a fundamental shift by truck manufacturers to optimize fuel efficiency to focus not on discreet components but instead look at the complete vehicle and operations, as this is where remaining gains are available. Based on what data and information is this assumption made? Please provide details. [EPA-HQ-OAR-2014-0827-1164-A1 p.74]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

OOIDA recommends that the agencies do not so easily disregard Alternative 2. According to the NPRM, Alternative 2 represents a stringency level which is approximately half as stringent overall as the preferred alternative. The agencies developed Alternative 2 to consider a continuation of the Phase 1 approach of applying off-the-shelf technologies rather than requiring the development of new technologies or fundamental improvements to existing technologies. For tractors and vocational vehicles, this also involved less integrated optimization of the vehicles and engines. Put another way, Alternative 2 is not technology-forcing. The agencies’ decisions regarding which technologies could be applied to comply with Alternative 2 considered not only the use of off-the shelf technologies, but also considered other factors as well, such as how broadly certain technologies fit in-use applications and regulatory structure. The resulting Alternative 2 could be met with most of the same technologies the agencies project could be used to meet the proposed standards, although at lower application rates. Alternative 2 is estimated to be achievable without the application of some technologies, at any level. [EPA-HQ-OAR-2014-0827-1244-A1 p.37]

Nevertheless, the agencies stated that they are not proposing Alternative 2 because they do not believe that it represents the “maximum feasible improvement” within the meaning of 49 U.S.C. 32902(k)(2). However, OOIDA would argue that Alternative 2 is the “maximum feasible improvement” because it does not force technologies that could be harmful to consumers or to the market. In addition, while the some of the adoption rates for the various technologies are still too high, such as for the APU estimate, overall this Alternative is far more realistic. [EPA-HQ-OAR-2014-0827-1244-A1 p.38]

Response:

As noted in Section X of the FRM Preamble, the agencies are not adopting standards reflecting Alternative 2 for reasons of both policy and law. Technically feasible alternate standards are available that provide for greater emission reductions and reduced fuel consumption than provided under Alternative 2. These more stringent standards, which are being adopted, are feasible at reasonable cost, considering both per-vehicle and per-engine cost, cost-effectiveness, direct benefits to consumers in the form of fuel savings, and lead time. Consequently, the agencies do not believe that the modest
improvements in Alternative 2 would be appropriate or otherwise reasonable under section 202 (a) (1) and (2) of the Clean Air Act, or represent the “maximum feasible improvement” within the meaning of 49 U.S.C. 32902(k)(2).

Central to this conclusion is the conclusion that the final standards are feasible and appropriate. Comments related to this conclusion are addressed in Sections 3 through 7 of this RTC and Chapter 2 of the RIA.

8.5 Comments on Alternative 5 1424

Organization: Daimler Trucks North America LLC

Regarding Alternative 5, DTNA agrees that this is too stringent to be feasible. [EPA-HQ-OAR-2014-0827-1164-A1 p.74]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

OOIDA proposes that agencies’ preferred alternative, Alternative 3, as well as Alternatives 4 and 5, are unrealistic and if adopted as part of this rulemaking process, will severely compromise the agencies’ praiseworthy objectives to increase the fuel efficiency of medium-and heavy-duty trucks and reduce GHG emissions. Truck drivers certainly desire fuel efficient trucks and appreciate cleaner air to breathe. While various governmental agencies and environmental groups tend to paint owner-operators as individuals who do not care about the environment, nothing could be further from the truth. It is crucial to understand that owner-operators are not only hardworking Americans who help to move our economy, but that they also spend a majority of their life around tractor-trailers. Therefore, it is in their best interest, as well as in the interest of the public, to operate clean and efficient trucks. [EPA-HQ-OAR-2014-0827-1244-A1 p.36-37]

Response:

We agree that Alternative 5 is not feasible. We are not adopting Alternative 5 because we cannot project that manufacturers can develop and introduce in sufficient quantities the technologies that could be used to meet Alternative 5 standards. Some examples of technology adoption rates that were used in Alternative 5 for MY 2024 that the agencies do not believe are feasible include the following:

- Up to 66% adoption rate of strong hybrids for gasoline HD pickups
- 40% adoption rate of strong hybrids in tractors
- Up to 3% electric vehicles plus 36% adoption rate of strong hybrids in some vocational vehicle subcategories
9 Aggregate GHG, Fuel Consumption, and Climate Impacts

9.1 General Comments
9.1.1 1425MOVES Model 1425

Organization: Recreational Vehicle Industry Association (RVIA)

c. Motorhome VMT

In assessing the impact of this rule, RVIA commissioned Statistical Surveys, Inc. to collect vehicle miles travelled (VMT) data for motorhomes. In carrying out this analysis, Statistical Surveys, Inc. used data from IHS Inc., a well-known source of information on the automotive industry, to review odometer readings of three year old motorhomes sold in calendar years, 2012-2014. Using readings from 987 motorhomes, Statistical Surveys found that the average VMT for motorhomes was 4,290 and that the median VMT was 3,042. Thus, for the current analysis, EPA should use the more accurate figure of an annual 4,290 VMT for motorhomes, but, given the lower median, even that number is likely conservative. For additional details on the motorhome VMT work carried out by Statistical Surveys, Inc. see Appendix A. [EPA-HQ-OAR-2014-0827-1261-A1 p.8][This comment can also be found in section 6.3 of this comment summary]

Because motorhomes are used primarily for camping and recreation purposes, they are relatively under-driven compared to other vehicles. They are typically driven from Point A to Point B (e.g., a family residence to a campground or event) via interstate highways and other rural roads. Average motorhome use is 27.5 days per year. Many use days are spent in the stationary mode at a campground. [EPA-HQ-OAR-2014-0827-1261-A1 p.9]

EPA should use a more accurate though still very conservative VMT figure of 4,290 miles in its calculations and determine more accurate and specific payback periods for motorhomes under the Proposed Rules, using more accurate ICMs and scenarios (i.e., Scenario 4 as set forth VI.b). Doing so will demonstrate the payback periods are significantly longer than for other vocational and regulated vehicles under the Proposed Rules -- even longer than average years of ownership in nearly all circumstances -- and thereby do not provide consumers with a significant benefit. [EPA-HQ-OAR-2014-0827-1261-A1 p.27]

EPA should also recognize that the more realistic low-level production and low VMT, as well as episodic use of motorhomes, would result in fewer emission reductions relative to other vocational and other regulated vehicles. [EPA-HQ-OAR-2014-0827-1261-A1 p.28]

Response:

The commenter suggested using an average annual VMT of 4,920 for motorhomes. Also, the analysis by the commenter based on the IHS data suggested that the actual VMT might even be lower. The modified version of MOVES2014a used in the final rulemaking projects that the annual mileage traveled by new motorhomes is less than 2,200 miles in calendar year 2011. The annual mileage tends to decrease for all motor homes in future years, especially for older motorhomes. Therefore, we believe the assumptions of annual motorhome VMT in MOVES is consistent with the finding by Statistical Surveys, Inc.
The decision-making regarding the final standards for each vehicle category were based on the need to
decrease GHG emissions and fuel consumption, along with the projected maximum feasible technology –
considering technology costs and requisite lead time consistent with the requirements of the CAA and
EISA. Metrics related to cost effectiveness were not limiting the agencies from determining the
standards. We note that this rule is not being finalized with the motivation to provide operators with a
specific payback period. We present paybacks estimates in order to provide information regarding one
aspect of the potential effect of the standards on the user community.

Organization: Vehicle Industry Association (RVIA)

EPA’s motorhome MOVES model forecast for motorhomes in unrealistic

In the Proposed Rule, it is stated that, according to the MOVES model forecast, there will be
approximately 90,000 recreational vehicles manufactured for MY 2018. For motorhome sales to reach
90,000 by MY2018, shipments would need to increase 20% per year. Although sales have increased
significantly over the past five years, this was largely a function of post-recession recovery. The annual
growth rates since the recession have not been representative of historic shipment trends. When
examining historic sales trends for the 20 years preceding the recession, shipments averaged slightly
under 60,000 units per year. From 1991 to 1999, a period of steady growth, shipments went from 41,948
to 71,514, an annual average increase of 6.9%. A second growth period occurred from 2001 to 2004
when shipments went from 49,207 to 71,633, an average growth rate of 13.3%. Based on this history,
the idea that the industry will go from 44,000 shipments in 2014 to 90,000 shipments in 2018 is
unsupported and unlikely. EPA's conclusion is further unrealistic in view of the projected decrease in

Even if a rather optimistic annual 10% motorhome shipment growth rate for the next four years were to
be presumed, shipments would not exceed 65,000 units. Though also optimistic, this is a far more
realistic estimate than the 90,000 figure used in the Proposed Rules. It is also conservative since it
would still not account for production lowered by application of the Proposed Rules. In modeling
motorhome emissions, EPA should at maximum project motorhome shipments to not exceed 65,000 for

We note that by using the more appropriate shipment estimates discussed above, GHG emissions
projected by EPA for motorhomes will be only 2/3 of that projected by EPA, and therefore, the
corresponding emission decreases from the Proposed Rule will be significantly less than predicted by
EPA, further showing that the Proposed Rules are not reasonable for the motorhome sector. [EPA-HQ-
OAR-2014-0827-1261-A1 p.25-26]

EPA should use a more accurate estimate of annual production volume of motorhomes for use in its
MOVES model forecast. The 90,000 figure used is overly optimistic and is not consistent with recent
data. 65,000 vehicles is a more accurate though still optimistic estimate. [EPA-HQ-OAR-2014-0827-
1261-A1 p.28]

Response:

In the version of MOVES used for the notice of proposed rulemaking analysis, MOVES2014, the
vehicle population in 2011 is considered a base year population. MOVES2014 estimates motorhome
population of slightly less than 1.5 million in 2011. A study by the Survey Research Center estimated that there were over 2.1 million motorhomes in 2011. The National Household Transportation Survey in 2009 estimated that there were just under 1.1 million motorhomes in 2009. Therefore, we believe the base year population of motorhomes in MOVES falls within the range of estimates obtained from third-party data. MOVES then forecasts the sales and future year populations by applying the year-to-year growth rates of VMT from U.S. Energy Information Administration’s Annual Energy Outlook (AEO) to the base year population – AEO2014 was used for the NPRM and AEO2015 was used for the FRM.

We agree that the MOVES estimates for population growth and sales of motorhomes may be considered aggressive compared to the motorhome sales data provided by RVIA. However, given the lack of available data to update MOVES, we believe relying on AEO projections for assumptions of sales and growth projections for motorhomes is justified. Furthermore, we believe the impacts of different sales projections on GHG reductions from the rule are minimal since it is estimated that the difference in model year lifetime GHG reductions of Phase 2 projected by MOVES and the one projected by using the motorhome shipment estimates suggested by RVIA above is less than 1 million metric tons of CO$_2$-eq, 0.1% of the reductions from the heavy-duty sector.

9.2 Projected Reductions in Fuel Consumption and GHG Emissions

Organization: California Air Resources Board (CARB)

Alternative 4 vs. Alternative 3 Emission Benefits

This comment provides an overview of the emissions benefits from the proposed regulation in California. Trucking operations in California differ substantially from the national average. Trucks that are operated primarily in California are retained by fleets longer than the national average. In addition, the California trucking market is segmented, with national, regional and local fleets all competing in different segments of the goods movement economy; and hence it has a lower fraction of long-haul freight truck traffic as compared to national truck activity. This leads to a different vehicle fleet mix, vehicle age, and vehicle miles traveled (VMT) profiles than the national average. California’s emissions model, EMFAC2014 (v1.0.7), reflects these California-specific factors, and is used to estimate the GHG emissions impact of the proposed rule as applied to medium and heavy-duty vehicles operating in California. [EPA-HQ-OAR-2014-0827-1265-A1 p.21-22]

Using the model year (MY) specific percent reductions in CO2 emission rates, staff assessed the emissions impact of the proposed regulation under both alternative 3 and 4 scenarios. Figure 1 shows

---

201 U.S. Department of Transportation, Federal Highway Administration, 2009 National Household Travel Survey. URL: http://nhts.ornl.gov.
the impact of the Phase 1 and Phase 2 (Alternative 3) regulations on GHG emissions from affected vehicles. Results show a combined reduction of ~31 percent in GHG emissions by 2050. Furthermore, staff analysis shows that as compared to alternative 3, alternative 4 would achieve an additional 4 MMT cumulative benefit in CO2 emissions by 2030 (Figure 2). If Alternative 4 is adopted, Phase 1 and 2 together would achieve approximately a 22 percent reduction in petroleum use from the medium- and heavy-duty sector in 2030. This reduction would be a first step towards reaching the California Governor's goal of up to a 50 percent reduction in petroleum use by 2030. As shown in Figure 1, due to the relatively fast growth of freight activity in California and at California ports (which handle roughly 40 percent of the nation’s freight flow), GHG emissions from the regulated trucks will start increasing in 2035. Therefore, achieving California’s mid- and long-term climate change targets will require additional steps such as broader use of renewable fuels, increasing use of zero-emission technologies, and increasing operational efficiencies.

[Figure 2, 'Statewide Cumulative On-Road CO2 Emissions Benefit from the Alternative 3 and Alternative 4 of Phase 2 Regulation', can be found on p.23 of EPA-HQ-OAR-2014-0827-1265-A1]

Response:

Thank you for the comment. As shown in RIA Chapter 5, in terms of year-by-year GHG reductions, the final program is expected to reduce more GHGs over the long run than both the proposed program and Alternative 4. In general, the greater reductions can be attributed to increased market penetration and effectiveness of key technologies, based on new data and comments, leading to increases in stringency such as with the diesel engine standards.

Organization: California Air Resources Board (CARB)

Neutral Comment to Provide Additional Information

Comment – GHG emissions reductions

According to Table VII-13 of the NPRM, the annual downstream GHG emissions impact of the proposed regulation (preferred Alternative 3 vs. Alternative 1a baseline using Analysis Method A) in year 2050 is reported as ~134.9 MMT CO2eq (at the national level). In order to compare these federal emissions reductions estimates to a California-specific analysis, it is necessary to have estimates of the baseline emissions (baseline Alternatives 1a and 1b). However, the NPRM does not provide baseline information. [EPA-HQ-OAR-2014-0827-1265-A1 p.173]

Therefore, CARB staff encourages U.S. EPA and NHTSA to either provide estimates of GHG emissions (in MMT CO2eq) for baseline scenarios (Alternatives 1a and 1b), or report the benefits as a percent reduction from the baseline emissions similar to those provided in Section VIII of the NPRM for non-GHG emissions (e.g. Table VIII-7). [EPA-HQ-OAR-2014-0827-1265-A1 p.173]

Response:

Thank you for the comment. In the FRM, the annual greenhouse gas reductions from downstream and upstream are presented both in absolute tons and in percent reductions relative to the baselines.
6 Assembly Bill 32: Reduce GHG emissions to 1990 levels by 2020.; Executive order B-32-15: Reduce GHG Emissions to 40 percent below 1990 levels by 2030; Executive order S-21-09: Reduce GHG emissions to 80 percent below 1990 levels by 2050; Governor Brown’s inaugural address: Reduce petroleum use in cars and trucks in California by up to 50 percent by 2030.

7 Assuming tractor meets baseline emission level of 88 g CO2/ton-mile; payload of 38,000 lbs; travels 120,000 miles/year over 6 year period (2024 to 2030).

9 Id.

10 The affected EMFAC vehicle categories by Phase 1 and 2 regulations are heavy-duty trucks and buses exceeding 8,500 pounds GVWR.

**Organization:** California Air Resources Board (CARB)

**Calculation of HFC emissions**

U.S. EPA and NHTSA are proposing to estimate refrigerant emissions from heavy-duty vehicles using the same emission rates for light-duty vehicles assumed in the Vintaging Model, consistent with the methodology in U.S. EPA and NHTSA’s heavy-duty Phase 1 GHG regulation. [EPA-HQ-OAR-2014-0827-1265-A1 p.146]

Heavy-duty vehicles are primarily used for commercial or industrial purposes, as opposed to light-duty vehicles, typically used for commuting or pleasure. For this reason, heavy-duty vehicles, and hence, their AC systems, operate much longer than light-duty vehicles. Longer operation of the AC systems leads to higher annual refrigerant leakage and may accelerate aging-related deterioration of refrigerant containment. Therefore, CARB staff encourages U.S. EPA and NHTSA to continue to evaluate refrigerant emission rates for heavy-duty vehicles, in order to improve the understanding of refrigerant emissions for this sector. CARB staff is willing to provide assistance in this regard. [EPA-HQ-OAR-2014-0827-1265-A1 p.146]

**Response:**

Thank you for your comment. As suggested, we plan to continue to evaluate the HFC emission inventories from heavy-duty vehicles and look forward to coordinating with CARB on these efforts.

**Organization:** Honeywell Fluorine Products
Studies have shown that leakage rates as expressed as a percentage of the initial charges show a range of 7.3 to 11.5% (8.9 average) annually for heavy duty vehicles vs. generally 1.5 – 3% range for light duty vehicles.\[EPA-HQ-OAR-2014-0827-1191-A1 p.3\]

To properly account for leakage from AC units in HD vehicles, the scoring system must consider the significantly higher miles and heavier pounding these vehicles endure each year and over the life of the vehicle, as well as variation.\[EPA-HQ-OAR-2014-0827-1191-A1 p.3\] HD vehicles often have much higher annual mileage usage, in many cases over 100,000 miles per year and 1-2 million miles over the lifetime of the vehicle. In addition, HD vehicles have different loads (engine torque on A/C compressor and engine/road vibration loads on A/C lines, fittings, and components) on its A/C components, which likely results in higher leakage rates than light duty vehicles. Finally since many HD trucks have sleeper cabs, the air conditioning systems are often run even when the vehicle is not moving, adding further to the wear and tear of the A/C system.\[EPA-HQ-OAR-2014-0827-1191-A1 p.3-4\]

We request EPA to consider more fully these real world realities of harder pounding over many more miles in assigning leakage rates over time for HD A/C systems. While a design based approach in estimating leakage may have applicability to new HD vehicles, we believe that real world performance based testing would reveal short comings in the application of SAE J2727 to HD, MD, and VV over the life of the vehicle. We suggest EPA gather leak rate data on older heavily used vehicles to determine if the leak rates predicted by SAE J2727 are accurate over the life of the vehicles. [EPA-HQ-OAR-2014-0827-1191-A1 p.4]

**Response:**

Please see RTC Section 6.6.3 for responses to the use of SAE J2727 as a certification procedure. We will continue to evaluate direct leakage emission inventories of HFC from A/C systems on HD vehicles in the future.

### 9.3 Climate Impacts and Indicators 1430

**Organization:** American Automotive Policy Council

**Global Warming Potential (GWP) change for non-CO2 GHGs** - EPA should refrain from having different GWP based on vehicle classifications. If EPA chooses to lower the N2O GWP from 298 to 268 and increase CH4 from 25 to 36 based on latest IPCC report, the cost-benefit analysis needs to be clearly outlined in the final RIA inclusive of the impact on flex fuel vehicle and CNG products. In addition, the effective impact on greenhouse gas stringency associated with offsetting exceedances of the N2O and CH4 cap standards must be evaluated. Furthermore, the draft RIA should also include a detailed analysis of the merits of using Global Temperature Potential (GTP) values in lieu of GWP for both N2O and CH4. As stated above, this change should be consistent across all vehicle classes, as well as, all regulations under EPA and NHTSA authority. [EPA-HQ-OAR-2014-0827-1238-A1 p.11]

**Response:**

As noted in the Preamble of the final rule, the GWPs being used in this action are consistent with the IPCC 4th Assessment Report unless stated otherwise. One key exception is that the CO2 Credit trading program will use GWPs from the Fifth Assessment Report (see 40 CFR 1036.705). The reasoning and details are discussed in Section VII.D.2.a of the Preamble of the final rule. See also Response to Comment Section 12.1.1.
The cost-benefit analysis itself is done using the Social Cost of CO₂, the Social Cost of CH₄, and the Social Cost of N₂O. These are the appropriate metrics to use in order to determine the monetized impacts of a marginal change in greenhouse gas emissions.

EPA recognizes that there are potential merits of using the Global Temperature Potential in some applications; some research suggests that this metric is well adapted for use with non-well-mixed substances. However, for a rule that is targeted towards long-lived greenhouse gases, the most appropriate metrics are the GWP-100 and the Social Cost metrics and EPA does not consider an analysis of the GTP in this rule to be necessary.

Organization: American Lung Association

The American Lung Association shares the Administration’s view that climate change first and foremost represents a public health crisis and a public health opportunity. In recognition of that, the American Lung Association has enlisted health and medical organizations in support of the Obama Administration’s Clean Power Plan and other measures to fight climate change. Earlier this year, the American Lung Association in California launched a public awareness campaign, Doctors for Climate Health, to bring this point home. Throughout the United States, medical voices are speaking up – including Surgeon General Vivek Murthy – that climate change is the public health challenge of our time. [NHTSA-2014-0132-0087-A1 p.1][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.142.]

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards protecting public health.

Organization: Center for Biological Diversity

A group of leading climate scientists has calculated that developed countries like the United States must reduce their greenhouse gas emissions by 35-65 percent below 1990 levels by 2030 in order to preserve a likely chance of limiting global temperature rise to 2°C this century. On an economy-wide basis, moreover, current United States climate policy, which includes heavy-duty vehicle standards, will result in emissions 5 percent above 1990 levels by 2030. [EPA-HQ-OAR-2014-0827-1460-A1 p.2]

The urgency of addressing greenhouse gas pollution is becoming more evident every day. The National Climate Assessment released in May 2014 by the U.S. Global Change Research Program states that “reduc[ing] the risks of some of the worst impacts of climate change” will require “aggressive and sustained greenhouse gas emission reductions” over the course of this century. Humanity is rapidly consuming the remaining “carbon budget” necessary to preserve a likely chance of holding the average global temperature increase to only 2°C above pre-industrial levels. According to the IPCC, if non-CO₂ forcings are taken into account, total cumulative future anthropogenic emissions of CO₂ must remain below about 1,000 gigatonnes (Gt) to achieve this goal. Another recent scientific report found that “[i]n all of the studies consistent with limiting warming below 2°C the energy sector needs to decarbonise rapidly and reduce to zero emissions as early as 2040 but no later than 2070.” Even more recently, the International Energy Agency projected that in its central scenario, the entire remaining 1,000 GtCO₂ carbon budget will be consumed by 2040. Some leading scientists – characterizing the effects of even a 2°C increase in average global temperature as “disastrous” – have prescribed a far more stringent carbon
budget for coming decades.10 The agencies must consider the present rulemaking within the context of the global carbon budget, especially through the lens of achieving accelerated and deep cuts to U.S. fossil fuel usage. [EPA-HQ-OAR-2014-0827-1460-A1 p.2-3]

4 Bill Hare et al., Below 2°C or 1.5°C Depends on Rapid Action from Both Annex I and Non-Annex I Countries, Climate Action Tracker Policy Brief at 12 (June 4, 2014) (“Hare et al. 2014”) (calculating “from the IPCC AR5 scenarios that reductions for the Annex I countries in 2025 and 2030 are 25-55% and 35-65% below 1990 levels respectively for an equity scenario based on relative capability to mitigate”).

5 Hare et al. 2014, supra note 4 at 12. The Proposed Rule also is insufficient to achieve either the United States’ international pledge to reduce emissions 17% below 2005 levels by 2020 or its longer-term stated goal of reducing emissions 83% below 2005 levels by 2050. Id.

7 Intergovernmental Panel on Climate Change, Climate Change 2013 Synthesis Report: Approved Summary for Policymakers at SPM-8 (Nov. 1, 2014) (“IPCC AR5 SYR SPM”) (“Multi-model results show that limiting total human-induced warming to less than 2°C relative to the period 1861-1880 with a probability of >66% would require cumulative CO2 emissions from all anthropogenic sources since 1870 to remain below about 2900 GtCO2 (with a range of 2550-3150 GtCO2 depending on non-CO2 drivers). About 1900 GtCO228 had already been emitted by 2011.”); see also see also Intergovernmental Panel on Climate Change, Climate Change 2013: The Physical Science Basis. Contribution of Working Group I to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change; Summary for Policymakers at 14 (2013) (“IPCC AR5 WGI SPM”) at 25-26 (“Limiting the warming caused by anthropogenic CO2 emissions alone with a probability of >33%, >50%, and >66% to less than 2°C since the period 1861–1880, will require cumulative CO2 emissions from all anthropogenic sources to stay between 0 and about 1570 GtC (5760 GtCO2), 0 and about 1210 GtC (4440 GtCO2), and 0 and about 1000 GtC (3670 GtCO2) since that period, respectively. These upper amounts are reduced to about 900 GtC (3300 GtCO2), 820 GtC (3010 GtCO2), and 790 GtC (2900 GtCO2), respectively, when accounting for non-CO2 forcings as in RCP2.6. An amount of 515 [445 to 585] GtC (1890 [1630 to 2150] GtCO2), was already emitted by 2011.”). United Nations Environment Programme, The Emissions Gap Report at 13-22 (2013) (describing emissions “pathways” consistent with meeting 2°C and 1.5°C targets).

8 Hare et al. 2014, supra note 4 at 2.

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

Organization: Climate 911

According to the most recent Fifth Assessment Report of the IPCC, global greenhouse gas emissions must peak by 2020 and decline rapidly thereafter to avoid irreversible catastrophic climate change. At this time we are facing a very large gap between the emissions reductions required to accomplish this and the sum of the commitments offered by the international community. 2020 is only five years away. As the largest historical contributor to the atmospheric GHGs and world’s current second largest emitter, the US must cut our GHG emissions as steeply and deeply as possible if we want other countries to do the same. [EPA-HQ-OAR-2014-0827-1179-A1 p.1]

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

Organization: Competitive Enterprise Institute et al.

Although the ostensible purpose of the rule is to reduce greenhouse gas (GHG) emissions and oil imports, the climate and energy-security benefits of the rule are entirely speculative and vanishingly small at best. [EPA-HQ-OAR-2014-0827-1251-A2 p.2][This comment can also be found in section 11.10 of this comment summary]

II. The rule’s climate and energy security benefits are vanishingly small at best and completely unverifiable.

The proposed standards, which phase in during model-years 2021–2027, apply to four types of HDVs: (1) combination tractors (semi-trucks), (2) trailers pulled by combination tractors, (2) heavy-duty pickups and vans, and (4) vocational trucks (a wide-ranging assortment of trucks and buses). The agencies estimate that the technologies needed to comply with the proposed standards will cost $25 billion but that the rule will generate $230 billion in net benefits over the lifetime of vehicles sold in the regulatory timeframe, including $170 billion in fuel savings. [EPA-HQ-OAR-2014-0827-1251-A2 p.5-6][This comment can also be found in section 11.10 of this comment summary]

Although the ostensible objectives of the rule are to reduce GHG emissions and oil consumption, the climate and energy-security benefits, if any, are speculative and no one will actually experience them. [EPA-HQ-OAR-2014-0827-1251-A2 p.6][This comment can also be found in section 11.10 of this comment summary]

Climate Change Impact

Based on the unverifiable assumption that each ton of carbon dioxide-equivalent (CO2e) GHGs emitted imposes a “social cost” of $37-$77 during 2012-2050 (assuming a 3% discount rate), the agencies
project $34 billion in cumulative climate benefits from emission reductions over the lifetimes of the covered vehicles.11 [EPA-HQ-OAR-2014-0827-1251-A2 p.6]

Yet the agencies also estimate that by 2100, the rule will decrease atmospheric CO2 concentration “approximately 1.1 to 1.2 parts per million by volume (ppmv).” That miniscule change would, in turn, reduce global mean temperature by “approximately 0.0026 to 0.0065°C” and global mean sea level rise by “approximately 0.023 to 0.057 cm” (depending on whether climate sensitivity is as low as 1.5°C or as high as 6°C). It would also reduce ocean acidification by 0.0006 pH.12 [EPA-HQ-OAR-2014-0827-1251-A2 p.7]

Such tiny decreases in global warming and sea-level rise cannot be distinguished from the noise of interannual variability.13 Similarly, the tiny projected decrease in ocean acidification is orders of magnitude smaller than natural inter-seasonal and inter-regional variations.14 Such changes would have no detectable effect on heat-related mortality, weather patterns, coral calcification rates, or any other climate-related indicator people care about. Hypothetical climate benefits during the lifetimes of vehicles subject to the rule would be even more microscopic. In short, the rule’s multi-billion-dollar climate benefits exist only in the virtual world of integrated assessment models (IAMs) – computer models that combine speculative climatology with speculative economics.15 [EPA-HQ-OAR-2014-0827-1251-A2 p.7]

13 According to the Climatic Research Unit of the UK Met Office, the margin of error in estimating global surface temperature is 0.1°C – 15 to 38 times larger than the projected decrease in global mean temperature. UK Met Office, “2014 one of the warmest years on record globally,” January 26, 2015, http://www.metoffice.gov.uk/news/release/archive/2015/2014-global-temperature

14 In coastal waters, month-long ocean pH varies from 0.024 to 1.430 pH units. Even “Open water areas [in the Southern Ocean] experience a strong seasonal shift in seawater pH (~0.3-0.5 units) between austral summer and winter.” Hofmann et al. 2011. High-Frequency Dynamics of Ocean pH: A Multi-Ecosystem Comparison. PLOS/one, http://journals.plos.org/plosone/article?id=10.1371/journal.pone.0028983

Response:

See Response to Comments Section 11.8 for responses to critiques of the Social Cost of Carbon methodology.

The commenter’s claims that the benefits are unverifiable and speculative are incorrect. The science behind the impact of greenhouse gas emissions on global temperatures and subsequent impacts is extensive, well-documented, and robust, as can be verified in the assessments of the IPCC, the NRC, and the USGCRP. 202

The commenter has highlighted what they see as a disconnect between billions of dollars of cumulative carbon benefits as calculated by the Social Cost methodology, and the changes of fractions of a degree and millimeters of sea level rise. However, this apparent disconnect is resolved by understanding the spatial and temporal scales of climate change. The key insight is to recognize that any benefit, even a marginal one, to any individual or in any one location aggregated over billions of individuals, hundreds of thousands of miles of coastline, and so forth can yield sizeable numbers, and that the Social Cost methodology is the right tool to do this kind of aggregation. That is, it appropriately monetizes impacts by aggregating over space and time and types of impacts. Aggregation is not only important for a single impact (such as sea level rise and damage to coastal properties), but because there are such a wide range of impacts from heat waves to allergens to flooding to droughts. Furthermore, because of the lifetime of greenhouse gases, these impacts can occur over decades and centuries. Additionally, global average temperature changes also need to be understood in the context of history, where a few degrees of global temperature change was enough to go from ice sheets covering much of high latitude land areas to today’s climate.

---

202 For a complete list of core references from IPCC, USGCRP/CCSP, NRC and others relied upon for development of the TSD for EPA’s Endangerment and Cause or Contribute Findings see Section 1(b), specifically, Table 1.1 of the TSD. (Docket EPA-HQ-OAR-2010-0799).
Climate change will not be halted by any individual action. It is a global, long-term issue and solving the problem will require many actions in aggregate. Reducing global greenhouse gas emissions, including those from the U.S., will reduce impacts in the U.S. and around the globe.

**Organization:** Dignity Health

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 204.]

Strong phase 2 standards offer a rare opportunity to address serious health concerns associated with climate change and cut freight costs.

Freight trucks currently account for about half a billion tons of climate-forcing GHG emissions per year and are the fastest growing single source of GHG emissions in the United States.

**Response:**

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards protecting public health.

**Organization:** Environmental Defense Fund (EDF)

**Harms Associated with Climate Change**

As EPA has properly concluded, the scientific record demonstrating that “elevated concentrations of greenhouse gases in the atmosphere may reasonably be anticipated to endanger the public health and welfare of current and future U.S. generations is robust, voluminous, and compelling.”

The transportation sector is the second largest source of domestic greenhouse gas emissions and heavy-duty trucks and buses are responsible for nearly a quarter of the sector’s GHG emissions. Significantly reducing these emissions from new heavy-duty vehicles is necessary to mitigate the serious harms associated with climate change in the United States. [EPA-HQ-OAR-2014-0827-1312-A1 p.6]

The proposal’s Regulatory Impact Analysis (“RIA”) provides an overview of the pressing threats posed by greenhouse gas emissions and a summary of EPA’s 2009 Endangerment Finding. It also incorporates major assessments by the U.S. Global Change Research Program (USGCRP), the Intergovernmental Panel on Climate Change (“IPCC”), the National Academies’ National Research Council (NRC), and more recent assessments that support the endangerment finding. Climate research and assessment reports published since 2009 (and cited in the heavy-duty RIA) further emphasize the urgency of climate change and the need to mitigate greenhouse gas emissions. The climate science that forms the basis of the Endangerment Finding provides a legally sufficient and scientifically compelling justification for curbing greenhouse gas emissions from heavy-duty vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.6]

**A. Direct threats to public health and welfare from climate change**

Climate change is threatening, and will continue to threaten, public health in many regards. It is expected to increase the incidence and severity of heat waves, for instance, which are particularly dangerous to the elderly, the very young, and the infirm. Warmer days lead to enhanced ozone (or
smog) formation, which can exacerbate respiratory illnesses, contribute to asthma attacks and hospitalizations, and heighten the risk of premature death among affected populations. Because a warmer atmosphere retains more moisture, climate change will produce heavier precipitation events, stronger tropical cyclones, and associated flooding, spreading toxins and diseases and causing severe infrastructure damage, social upheaval, and widespread injury and death. Pathogens and pests are expected to disseminate among susceptible populations due to changes in those species’ survival, persistence, habitat range, and transmission under changing climate conditions, further endangering the public.

As EPA has attested at length, climate change also threatens public welfare. Sea level rise is well documented and is very likely to accelerate over the coming decades. Rising seas, amplified by storm surges and stronger tropical cyclones, will threaten our coastal homes, cities, and infrastructure, forcing expensive efforts to protect or relocate critical resources. Millions of U.S. citizens will be affected and many will be displaced. Further inland, shrinking snowpack and early spring melts will increase flood risks early in the melt season and will cause water shortages throughout much of the western United States, which now depends on snowpack as a reliable water source. Droughts, especially in the western and southern United States, are expected to occur more frequently, and the extent of drought-limited ecosystems is projected to grow by 11 percent for every degree Celsius of warming. This phenomenon will exacerbate the water scarcity already affecting numerous regions of the country. Furthermore, the combination of changing atmospheric chemistry and shifting, more violent weather patterns will likely cause crop damage and crop failure, with corresponding increases in food prices and declines in availability. On forested lands, the same changes will instigate more severe fires, as seen in California this summer, pest outbreaks, and higher tree mortality, which will likely disrupt timber production.

B. Climate change threatens the ecosystems upon which society depends

Natural environments and biodiversity provide humans with a wide range of benefits, or “ecosystem services,” including fresh water supplies, fertile soil for agriculture, fisheries, climate regulation, and aesthetic, cultural, and recreational benefits. However, climate change will have major implications for wildlife, biodiversity, and the fundamental ecosystem services upon which we depend. Observed changes in our climate are already shifting habitat ranges, altering migration patterns, and affecting reproductive timing and behavior. At anticipated levels of increased global temperature, many terrestrial, freshwater, and marine species are at far greater risk of extinction than in the past. The situation is particularly dire for Arctic wildlife, as climate change causes significant loss of sea ice and a dramatic reduction in marine habitat for polar bears, ice-inhabiting seals, and other animals. And the resilience of many ecosystems is likely to be exceeded this century by an unprecedented combination of climate change, associated disturbances (e.g., flooding, drought, wildfire, insects, ocean acidification), and other global change drivers (e.g., land use change, pollution, fragmentation of natural systems, overexploitation of resources).

The footprint of humans on the planet is now straining ecosystems more than at any time in history. Terrestrial, freshwater, and marine environments have already undergone extensive transformation and deterioration. More than 75 percent of Earth’s ice-free land has been altered by human activity. Nine of the world’s fourteen biomes (each of which designates a broad ecological land category) have been converted into cropland at factors ranging from 20 to 50 percent. Over 40 percent of the world’s oceans, including two-thirds of the ocean waters within the United States Exclusive Economic Zone, are designated as having an anthropogenic impact rating of at least “medium high.”
Together with these stressors, climate change is having a major effect on ecosystems. For example, research indicates that climate change and other anthropogenic factors are causing the sixth mass extinction of global biodiversity in the last 600 million years of life on Earth, with current extinction rates 100 to 1,000 times greater than historical rates. In 2007, the IPCC concluded that by the mid-21st century, 15 to 37 percent of plant and animal species worldwide would be committed to extinction if temperatures increase 1.6 to 1.8 °C above late 20th century levels. “Specialist” species—those with a narrow tolerance for changes in habitat, diet, or other environmental conditions—are particularly vulnerable to the threat of extinction due to climate change.

Even species that do not go extinct will have to contend with ecological conditions they have not previously faced. Many terrestrial species are shifting their geographical ranges in response to a changing climate. Plants and animals have moved to higher elevations at a median rate of 0.011 kilometers per decade and to higher latitudes at a median rate of 16.9 kilometers per decade, two to three times faster than previously reported. For example, of the 305 bird species tracked in annual Christmas bird counts during the last four decades, 177 species (58 percent) had significant northward range shifts, with more than 60 species moving 100 miles or farther. These range shifts are likely to cause unprecedented interactions among species.

Shifts in seasons, especially in the duration and intensity of winter, are also having significant impacts on ecosystems. One consequence of shifting seasons is the increased likelihood of mismatches between interdependent species (e.g., predator and prey, insects and flowers). A striking example is found in western forests, where warmer winters and longer growing seasons have triggered more intense and extensive forest fires, promoting mountain pine beetle outbreaks that kill millions of trees across millions of hectares of forest. In turn, the decreased availability of whitebark pine nuts as a food source for grizzly bears has been tied to lower cub birth rates, lower over-winter survival rates, and increased conflicts between bears and humans.

In the coming decades, climate-related disturbances (such as altered precipitation regimes and extremes in weather and temperature) will continue to have marked impacts on ecosystems. In some cases, these phenomena will cause ecosystems to transition to significantly different community types. For example, more arid ecosystems and river habitat areas will likely be particularly sensitive to changes in precipitation and water supply caused by climate change. Reduced river flow and longer droughts in these regions are projected to diminish native cottonwood and willow populations and render them more susceptible to livestock grazing and encroachment from upland species and invasive weeds. Such changes in ecosystem composition and function will pose critical adaptation challenges for affected human communities.

In short, greenhouse gas emissions are fundamentally destabilizing global ecosystems. Because human society depends upon the goods and services these ecosystems provide, this ecological crisis is a pressing threat to public welfare.

C. Harm associated with ocean acidification

Some of the carbon dioxide emitted by fossil fuel combustion is subsequently absorbed by the world’s oceans. Because carbonic acid forms when carbon dioxide dissolves in water, rising CO2 emissions are causing the seas to become more acidic. Independent of climate change, ocean acidification alone demonstrates that greenhouse gases endanger public welfare. The National Research Council has reported that ocean acidity has increased approximately 30 percent since pre-industrial times, and could intensify by three to four times this amount by the end of the century if carbon emissions remain
uncurbed. Furthermore, increasing rates of ocean acidification may hamper the oceans’ ability to absorb more CO2, resulting in more atmospheric carbon and, in turn, intensified climate change. Increased acidification poses a significant threat to the ocean’s critical food webs. For instance, it will sharply reduce the underwater area suitable for coral reefs, which function as fish nurseries. Similarly, planktonic animals, which are an important food supply for many underwater species, may be unable to tolerate more acidic waters. By disrupting the delicate balance of oceanic ecosystems, acidification could have devastating impacts on coastal communities that rely heavily on the sustained health of their fisheries.

Ocean acidification is taking place with extraordinary rapidity. According to a 2012 study that surveyed hundreds of millions of years of ocean chemistry, the current rate of CO2 release into the oceans (and hence the rate of acidification) “stands out as capable of driving a combination and magnitude of ocean geochemical changes potentially unparalleled in at least the last ~300 [million years] of Earth history.” Based on future projections of atmospheric carbon concentration, ocean acidity can be expected to increase by 100 to 150 percent by the end of this century. Troublingly, this upward shift in acidity will be accompanied by increasing surface stratification of the ocean on account of warmer surface waters. As a result, phytoplankton will experience both heightened acidity and more intense exposure to light. Together, these two phenomena have been shown to dramatically reduce the photosynthesis and growth of diatoms, currently responsible for approximately 40 percent of total primary production in the oceans. Accordingly, the combination of heightened acidification and ocean stratification may result in a “widespread decline in marine primary production,” doing great damage to the base of the oceanic food chain with potentially devastating effects on the food supply for many regions around the globe.

D. New research, reports, and assessments show increasing severity of harm

Greenhouse gas emissions and atmospheric carbon concentrations have continued to rise in the years since EPA made its Endangerment Finding. As EPA moves forward with the truck standards, the evidence of an intensifying threat reflects the importance of selecting the most protective standards possible in this rule, as well as the need for continued efforts to control emissions from other sectors.

Global greenhouse gas emissions are now rising faster than the IPCC’s highest emissions scenario from 2007, as illustrated in the figure below, compiled by the European Environment Agency.

The graph shows six IPCC emissions scenarios (labeled A1B to B2), compared with actual atmospheric carbon measurements from two sources. The highest scenario, A1F1, which assumes a “world of very rapid economic growth” with “fossil-intensive” energy systems, is the most aggressive scenario generally modeled. The graph demonstrates that, in the last decade, global emissions have rapidly increased to match, or even slightly outpace, the A1F1 scenario. Hence, in the absence of swift emissions reductions, we can expect harms even greater than those projected under the IPCC’s highest emissions scenarios in the Fourth Assessment Report (AR4).
Recent modeling results project that by mid-century, warming may be significantly greater than scientists had previously forecast. According to this research, by 2050, average global temperatures could warm by 1.4 to 3°C relative to the 1961-1990 period, even under mid-range emissions scenarios (which current emissions figures significantly exceed). Numerous large-scale reports and assessments further attest that threats to public health and welfare from carbon emissions are even more pressing than anticipated just a few years ago. For instance, it is now clear that the IPCC’s sea level rise projections in AR4 were overly conservative. A recent IPCC report notes that “satellite-measured sea levels continue to rise at a rate closer to that of the upper range of [earlier] projections” and that “the contribution to sea level due to [ice] mass loss from Greenland and Antarctica is accelerating.” Similarly, in the Fifth Assessment Report (AR5), the IPCC’s Working Group 1 predicts that sea levels could increase by as much as 0.82 meters by the late 21st century and 0.98 meters by 2100. By contrast, the AR4’s upper bound estimate for sea level rise was just 0.59 meters by the late 21st century. [EPA-HQ-OAR-2014-0827-1312-A1 p.12-13]

More broadly, Working Group 1 emphasizes that “[s]ubstantial advancements in the availability, acquisition, quality and analysis of observational data sets in atmosphere, land surface, ocean, and cryosphere have occurred since the AR4.” These advancements point primarily toward increased estimates of the severity of the harm that will result from climate change. The report for AR5, for instance, asserts that “[m]easurements of glacier change have increased substantially in number since AR4,” and that, with regard to the Greenland Ice Sheet, “large rates of mass loss have spread to wider regions than reported in AR4.” The report also increases AR4’s estimates of the radiative forcing (or heat-trapping) potential of current and predicted atmospheric greenhouse gas concentrations, and expresses increased confidence since AR4 in its determinations regarding upper-ocean warming, the link between climate change and precipitation patterns, and the human influence on global surface temperature increases, water cycle variations, daily temperature maxima, extreme precipitation events, and droughts, to name just a few examples. [EPA-HQ-OAR-2014-0827-1312-A1 p.13]

The USGCRP’s Third Climate Assessment reflects a similar pattern. Describing changes from the Second Climate Assessment, the authors explain that “[c]ontinued warming and an increased understanding of the U.S. temperature record, as well as multiple other sources of evidence, have strengthened our confidence in the conclusions that the warming trend is clear and primarily the result of human activities.” For example, the authors emphasize that “[h]eavy precipitation and extreme heat events are increasing in a manner consistent with model projections; the risks of such extreme events will rise in the future,” and that “[a] longer and better-quality history of sea level rise has increased confidence that recent trends are unusual and human-induced. Limited knowledge of ice sheet dynamics leads to a broad range of potential increases over this century.” [EPA-HQ-OAR-2014-0827-1312-A1 p.13-14]

Finally, in May 2013, the Interagency Working Group on the Social Cost of Carbon (IWG) published an updated assessment that increases the predicted threat that climate change poses and will continue to pose into the future. The IWG’s original estimate in 2010 provided four potential values to represent the cost that each metric ton of CO2 emissions will impose on society for the year 2020: $7, $26, $42, and $81. The 2013 estimate increases those values to $12, $43, $65, and $129, respectively. While the Joint Environmental Commenters believe that these updated figures fundamentally underestimate the true cost of carbon emissions, they nonetheless reflect the same trend as seen in the scientific literature: not only does the potential harm from carbon emissions increase with each additional ton released into the atmosphere, but the severity of the predicted harm increases as our understanding of climate change grows. [EPA-HQ-OAR-2014-0827-1312-A1 p.14] [This section can also be found in section 11.8 of this comment summary]
These new studies, reports, and assessments indicate that the urgency of acting to curb greenhouse gas emissions has, if anything, grown since the 2009 Endangerment Finding. Emission trajectories are already at or beyond what was anticipated in the 2007 IPCC reports, and are causing severe effects on an accelerated timeline. In the absence of substantial emissions reductions, the harms to public health and welfare from climate change may well prove catastrophic. While robust actions are needed in every sector of our economy to mitigate the greenhouse gas emissions that contribute to public health and environmental harms, improving the efficiency of the heavy-duty fleet is one of the most impactful things we can do to stem climate pollution in the United States. Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards protecting public health.

Organization: Fuller, Tony

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 149-150.]

The U.S. EPA and the DOT also have a moral obligation to future generations to adopt strong standards. We are in a race to prevent a global temperature rise of two degrees above pre-industrial times, to limit
the impacts that climate change would have on this planet. Unfortunately, current plans don't go far enough. According to Climate Action Tracker, a group of research organizations dedicated to analyzing the world’s progress, U.S. action plans are short of what's needed.

By increasing these second phase standards to a 40 percent reduction, we could take one step towards limiting the impacts of climate change.

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

Organization: Gilroy, JD

A second thing I like very much about the proposed standards is that all the information I've seen about them indicate that their impact on the environment will be enormous in a favorable direction. A Union of Concerned Scientists (UCS) website stated that their impact could be as great as a reduction of a million barrels of oil per day by 2035, or more than the Keystone XL pipeline could ever provide. Another source indicated that the standards could ultimately cut global warming emissions by 1 billion metric tons or be the equivalent of eliminating all greenhouse gas emissions from electricity and power usage by all US residents for a year. If these estimates are anywhere near correct, the standards will play a major role in diminishing our greatest global danger. [EPA-HQ-OAR-2014-0827-0751 p.2]

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

Organization: Investor Network on Climate Risk

In addition, climate change presents significant long-term risks to the global economy, and to investors across all asset classes. Strong standards will serve to mitigate that risk by providing significant GHG reductions; the standards we propose have the potential to save 270 million metric tons of GHG emissions annually by 2030. [NHTSA-2014-0132-0113-A1 p.2][This comment can also be found in section 11.10 of this comment summary]

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

Organization: Manufacturers of Emission Controls Association (MECA)

The Manufacturers of Emission Controls Association (MECA) is pleased to provide comments in support of the U.S. EPA’s proposed rulemaking to establish medium- and heavy-duty greenhouse gas emission standards and corporate average fuel economy standards for model years 2018 and beyond. We believe an important opportunity exists to continue to reduce greenhouse gas emissions and improve fuel economy from medium- and heavy-duty engines and vehicles by applying the fundamental regulatory structure that has been effective under the first phase of the medium and heavy-duty standards. [EPA-HQ-OAR-2014-0827-1210-A3 p.1] [This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p.95.] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.211.]]

Anthropogenic activities, particularly the burning of fossil fuels, have changed the composition of the atmosphere in ways that threaten dramatic changes to the global climate. Signs of climate change are evident worldwide and additional changes will have serious impacts on our nation’s future. Although transportation is a vital part of the economy and is crucial for everyday activities, it is also a significant source of greenhouse gas (GHG) emissions. Some of the important greenhouse gas emissions from fossil fuel combustion from mobile sources include: carbon dioxide (CO2), nitrous oxide (N2O), methane (CH4), and black carbon. Climate change is also impacted negatively by higher ground-level ozone emissions. Ozone levels are in turn linked to hydrocarbon and NOx emissions from mobile and stationary sources. The adverse health effects of ozone is compounded by rising temperatures caused by climate change. These complex relationships support the need to continue to reduce emissions of criteria pollutants and climate forcing compounds and we commend the agency for making further progress in this effort. [EPA-HQ-OAR-2014-0827-1210-A3 p.1-2]

In conclusion, MECA commends EPA for taking important steps to continue to reduce greenhouse gas emissions and improve fuel economy from medium- and heavy-duty vehicles. MECA believes that a variety of advanced powertrain options are available for reducing carbon dioxide emissions from these vehicles and engines. MECA believes that the proposed reductions for greenhouse gas emissions from heavy-duty vehicles proposed by EPA are technically and economically feasible under a 2024 implementation timeframe. Our industry is prepared to do its part and deliver cost-effective advanced emission control and efficiency technologies to the heavy-duty sector to assist in achieving lower greenhouse gas emissions, while also meeting future reductions in NOx and other criteria pollutants. [EPA-HQ-OAR-2014-0827-1210-A3 p.15]

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

Organization: Mass Comment Campaign sponsored by anonymous 1 (email) - (23)
I am concerned about the impact of climate change and air pollution on the health of my family. Climate change threatens the health of our children through increased heat, air pollution, fires, storms, drought, airborne allergens, and other serious effects. That's why I strongly support improved fuel efficiency standards that would reduce dangerous climate pollution from medium and heavy duty trucks. [EPA-HQ-OAR-2014-0827-1341-A1 p.1]

The proposed standards will help protect our families from harmful climate change and from unhealthy air pollution. They will significantly reduce our national fuel consumption, and will save money for both truckers and consumers. [EPA-HQ-OAR-2014-0827-1341-A1 p.1]

Response:

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

Organization: Michaels and Knappenberger

The Environmental Protection Agency’s (EPA) proposed regulation Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2 results in no demonstrable or verifiable mitigation of future climate change—the primary justification for the regulation. The reported reductions in the rate of rise of atmospheric carbon dioxide concentrations, average global temperature and global average sea level are so small as to be statistically indistinguishable from the evolution of these measures absent this regulation. As such, it is scientifically improper for the EPA to claim this regulation results in a “meaningful” impact on future climate change. Further, the EPA did not investigate any impact beyond the grossest of global-scale measures. [EPA-HQ-OAR-2014-0827-1206-A1 p.1]

Specific Comments on Climate Change

We list below a few of the glaring faults, logical flaws, and inconsistencies, primarily found in Section D (“Climate Impact and Indicators”) of these proposed regulations. This is by no means an exhaustive list. [EPA-HQ-OAR-2014-0827-1206-A1 p.2]

Federal Register, Vol. 80, No. 133, pg 40148:

“Finally, it should be noted that the concentration of carbon dioxide in the atmosphere continues to rise dramatically. In 2009, the year of the Endangerment Finding, the average concentration of carbon dioxide as measured on top of Mauna Loa was 387 parts per million. The average concentration in 2013 was 396 parts per million. And the monthly concentration in April of 2014 was 401 parts per million, the first time a monthly average has exceeded 400 parts per million since record keeping began at Mauna Loa in 1958, and for at least the past 800,000 years according to ice core records.” [EPA-HQ-OAR-2014-0827-1206-A1 p.2]

According to the Draft Environmental Impact Statement EIS accompanying this NOPR, this regulation is determined to reduce the atmospheric burden of CO2 by the year 2100 by approximately 1ppm (e.g., Page S-21 of the draft EIS). This means that the CO2 reduction achieved by this proposed regulation 85 years hence is 14 times less than the atmospheric increase (as described in the quote above) that took place during in the 5 years following 2009—the year of the Endangerment Finding. This fact alone
should make obvious the overall ineffectiveness of this regulation in mitigating future climate change—the intended outcome of the rule. [EPA-HQ-OAR-2014-0827-1206-A1 p.2]

*Federal Register*, Vol. 80, No. 133, pg 40407:

“Once emitted, GHGs that are the subject of this proposed regulation can remain in the atmosphere for decades to millennia” [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

Similar text is repeated on page 40408.

This is completely wrong. The turnover time for atmospheric carbon dioxide is about 3-5 years. So the actual CO2 molecules that are emitted and the “subject of this proposed regulation” do not remain in the atmosphere for decades to millennia, but instead, remain less than a decade. Your simplified explanation of the concept you are attempting to explain does an injustice to the underlying science and casts doubt as to the rigor of the scientific explanations throughout the body of the report. [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

See the Intergovernmental Panel on Climate Change’s Fourth Assessment Report, Glossary (term: “Turnover”) for a more accurate and complete scientific description. [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

*Federal Register*, Vol. 80, No. 133, pg 40408:

“Based on modeling analysis performed by the agencies, reductions in CO2 and other GHG emissions associated with these proposed rules will affect future climate change.” [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

This is a statement completely devoid of meaning as it now stands. Please include a defensible definition of the term “will affect.” Just because a climate model can produce an output to four significant digits (in this case, thousandths of degrees) does not mean that it is precise at that level. The measurement error for global temperature as well as the accruing round-off errors in the model clearly render such specifications useless, which means the term “will effect” is devoid of meaning. [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

Is “affect” measurable? Detectable? Significant (in any sense of the word)? [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

The draft EIS noted that (page 5-75, footnote 37): [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

“[T]he projected reductions in global climate effects for each of the alternatives are too small to incorporate into a regional/local-scale analysis, which would likely introduce uncertainties at the same magnitude or more than the projected change itself (i.e., the projected change would be within the noise of the model).” [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

In other words, EPAs own analysis concedes that the model noise is greater than the model signal. This is indisputable proof that the impacts are statistically insignificant. Further, if the model noise represents real world noise, then this is also indisputable proof that the “affect” will be undetectable and thus unverifiable. And further still, no one could argue that averting 0.003°C of a projected 3.48°C of global
warming (as described in the draft EIS, e.g., pg. S-21) would have any ecologically significant impacts in the real world. [EPA-HQ-OAR-2014-0827-1206-A1 p.3]

We also note that a formal estimate of the full range of uncertainties around the estimated impacts (e.g., global average temperature, sea level rise) from these regulations was not performed. While sensitivity to a range of climate sensitivity values was examined, the draft Regulatory Impact Analysis (RIA) (pg.6-44) notes: “Other uncertainties, such as uncertainties regarding the carbon cycle, ocean heat uptake, or aerosol forcing, were not addressed.” [EPA-HQ-OAR-2014-0827-1206-A1 p.4]

These types of uncertainties can be addressed had the EPA used the newest version of Model for the Assessment of Greenhouse Gas-Induced Climate Change, or MAGICC (v6, http://live.magicc.org/) which now can be run in a probabilistic mode incorporating a range of carbon cycles estimates and other model parameter estimates. Had this been done, the overlap between the baseline runs and the perturbed runs (to reflect this regulation) would have been so great that no statistical difference could ever exist between them. [EPA-HQ-OAR-2014-0827-1206-A1 p.4]

In summation, in no way will the carbon dioxide reductions compelled by this regulation “affect” future climate change in a scientifically meaningful fashion. As it stands, EPAs statement is incorrect, misleading and should be removed. [EPA-HQ-OAR-2014-0827-1206-A1 p.4]

Federal Register, Vol. 80, No. 133, pg 40408:

“EPA determines that the projected reductions in atmospheric CO2, global mean temperature, sea level rise, and ocean pH are meaningful in the context of this action.” [EPA-HQ-OAR-2014-0827-1206-A1 p.4]

This is gross a mischaracterization and an affront to sound science. The EPA did not “determine” anything scientifically. It simply stipulates that the “projected reductions” are “meaningful.” In fact, EPAs own analysis shows that they are not. [EPA-HQ-OAR-2014-0827-1206-A1 p.4]

As mentioned previously, the draft EIS (footnote 37) finds that the noise in the model output is greater than the signal—prima facie evidence that the impacts of this regulation are undetectable. An undetectable impact cannot be a “meaningful” one. [EPA-HQ-OAR-2014-0827-1206-A1 p.4]

Further, the “global mean temperature” although a metric of climate change, is not a measure of specific impacts of the local climate that may occur in association with a change in the global temperature. An analysis of the resulting changes to the local/regional weather/climate that may result from these regulations (i.e., those changes which may result in “meaningful” impacts) was not conducted for this regulation. It is specifically stated in the draft EIS (pg. 5-75) that: [EPA-HQ-OAR-2014-0827-1206-A1 p.4]

NHTSA’s [and EPA’s] assumption is that reductions in climate effects relating to temperature, precipitation, and sea level rise would reduce impacts on affected resources. However, the magnitude of the changes in climate effects that the alternatives would produce (see Section 5.4) are too small to address quantitatively in terms of their impacts on the specific resources discussed below. Consequently, the discussion of resource impacts in this section does not distinguish among the alternatives; rather it provides a qualitative review of projected impacts (where the potential benefits of reducing GHG emissions would result in reducing these potential impacts) and the magnitude of the risks involved in climate change. [EPA-HQ-OAR-2014-0827-1206-A1 p.4-5]
Cleary the EPA (and the NHTSA) are merely assuming that the admittedly meager reductions resulting from this regulation will reduce the potential environmental impacts in a “meaningful” way. No quantitative analysis or proof of such an outcome is demonstrated. [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

In fact, the only example offered by the EPA is risible (Federal Register, Vol. 80, No. 133, pg 40409): [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

“These effects are occurring everywhere around the globe, so benefits that appear to be marginal for any one location, such as a reduction in seal level [sic] rise of half a millimeter, can be sizable when the effects are summed along thousands of miles of coastline.” [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

Summing an inconsequential rise (half a millimeter) over large area does NOT result in large impacts. This is a ludicrous assertion and one without any backing. What editor or GS-15 in charge of this proposal could be so simple? [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

We ask EPA to consider a simple question: Does it have a threshold below which the impacts of CO2 reductions from a proposed action would be too small to be of any consequence and therefore the regulation would not stand as an action producing “meaningful” impacts on future climate change? [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

If so, what is it?

To us, and we would presume many others, a climate change regulation that shows (Federal Register, Vol. 80, No. 133, pg 40409): [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

“that relative to the reference case, by 2100 projected atmospheric CO2 concentrations are estimated to be reduced by 1.1 to 1.2 part per million by volume (ppmv), global mean temperature is estimated to be reduced by 0.0026 to 0.0065 °C, and sea-level rise is projected to be reduced by approximately 0.023 to 0.057 cm” would fall far beneath such a threshold. [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

If such a threshold does not exist, then the EPA has not only thrown science out of the window but has also helped itself to limitless executive power. Such a situation cannot stand, but it is a sad hallmark of the Obama Administrations manifold activities on climate change. [EPA-HQ-OAR-2014-0827-1206-A1 p.5]

“Though the magnitude of the avoided climate change projected here in isolation is small in comparison to the total projected changes, these reductions represent a reduction in the adverse risks associated with climate change (though these risks were not formally estimated for this action) across a range of equilibrium climate sensitivities.” [EPA-HQ-OAR-2014-0827-1206-A1 p.6]

We applaud the EPA for this time doing what it is typically not wont to do—that is, make a direct determination of the impact that this proposed regulation will have on the course of future climate change. The EPA’s findings that the resulting impacts on future climate change are so small comports with our own findings using a similar set of tools—that the impact of the these and other federal actions on the future evolution of the earth’s climate at global, regional, or local scales, is, by any normative scientific evaluation measure, inconsequential and undetectable. [EPA-HQ-OAR-2014-0827-1206-A1 p.6]
Yet, somehow the EPA considers that these demonstrably undetectable changes (by the EPA’s own reckoning (see footnote 37 of the draft EIS)) will “contribute to reducing the risks associated with climate change.” Perhaps more remarkably, this finding was made despite the fact that “these risks were not formally estimated for this action.” [EPA-HQ-OAR-2014-0827-1206-A1 p.6]

**Sea Level Rise**

The sea level rise module in the DICE model used by the IWG2013/2015 produces future sea level rise values that far exceed mainstream projections and are unsupported by the best available science. The sea level rise projections from more than half of the scenarios (IMAGE, MERGE, MiniCAM) exceed even the highest end of the projected sea level rise by the year 2300 as reported in the Fifth Assessment Report (AR5) of the Intergovernmental Panel on Climate Change (see figure). [EPA-HQ-OAR-2014-0827-1206-A1 p.23][This comment can also be found in section 11.8 of this comment summary]

[Figure, 'Sea Level Rise (DICE)', can be found on p.23 of docket number EPA-HQ-OAR-2014-0827-1206-A1]

How the sea level rise module in DICE was constructed is inaccurately characterized by the IWG2013 (and misleads the reader). The IWG2013 report describes the development of the DICE sea level rise scenario as: [EPA-HQ-OAR-2014-0827-1206-A1 p.23][This comment can also be found in section 11.8 of this comment summary]

“The parameters of the four components of the SLR module are calibrated to match consensus results from the IPCC’s Fourth Assessment Report (AR4).” [EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]

However, in IWG2013 footnote “6” the methodology is described this way (Nordhaus, 2010): [EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]

“The methodology of the modeling is to use the estimates in the IPCC Fourth Assessment Report (AR4).” [EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]

“Using estimates” and “calibrating” are two completely different things. Calibration implies that the sea level rise estimates produced by the DICE sea level module behave similarly to the IPCC sea level rise projections and instills a sense of confidence in the casual reader that the DICE projections are in accordance with IPCC projections. However this is not the case. Consequently, the reader is misled. [EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]

In fact, the DICE estimates are much higher than the IPCC estimates. This is even recognized by the DICE developers. From the same reference as above: [EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]

“The RICE [DICE] model projection is in the middle of the pack of alternative specifications of the different Rahmstorf specifications. Table 1 shows the RICE, base Rahmstorf, and average Rahmstorf. **Note that in all cases, these are significantly above the IPCC projections in AR4.**” [emphasis added][EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]
That the DICE sea level rise projections are far above the mainstream estimated can be further evidenced by comparing them with the results produced by the IWG-accepted MAGICC modelling tool (in part developed by the EPA and available from http://www.cgd.ucar.edu/cas/wigley/magicc/). [EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]

Using the MESSAGE scenario as an example, the sea level rise estimate produced by MAGICC for the year 2300 is 1.28 meters—a value that is less than 40% of the average value of 3.32 meters produced by the DICE model when running the same scenario (see figure below). [EPA-HQ-OAR-2014-0827-1206-A1 p.24][This comment can also be found in section 11.8 of this comment summary]

[Figure, 'Projected Sea Level Rise (MESSAGE)', can be found on p.25 of docket number EPA-HQ-OAR-2014-0827-1206-A1]

The justification given for the high sea level rise projections in the DICE model (Nordhaus, 2010) is that they well-match the results of a “semi-empirical” methodology employed by Rahmstorf (2007) and Vermeer and Rahmstorf (2009). [EPA-HQ-OAR-2014-0827-1206-A1 p.25][This comment can also be found in section 11.8 of this comment summary]

However, subsequent science has proven the “semi-empirical” approach to projecting future sea level rise unreliable. For example, Gregory et al. (2012) examined the assumption used in the “semi-empirical” methods and found them to be unsubstantiated. Gregory et al (2012) specifically refer to the results of Rahmstorf (2007) and Vermeer and Rahmstorf (2009): [EPA-HQ-OAR-2014-0827-1206-A1 p.25][This comment can also be found in section 11.8 of this comment summary]

The implication of our closure of the [global mean sea level rise, GMSLR] budget is that a relationship between global climate change and the rate of GMSLR is weak or absent in the past. The lack of a strong relationship is consistent with the evidence from the tide-gauge datasets, whose authors find acceleration of GMSLR during the 20th century to be either insignificant or small. It also calls into question the basis of the semi-empirical methods for projecting GMSLR, which depend on calibrating a relationship between global climate change or radiative forcing and the rate of GMSLR from observational data (Rahmstorf, 2007; Vermeer and Rahmstorf, 2009; Jevrejeva et al., 2010). [EPA-HQ-OAR-2014-0827-1206-A1 p.25][This comment can also be found in section 11.8 of this comment summary]

In light of these findings, the justification for the very high sea level rise projections (generally exceeding those of the IPCC AR5 and far greater than the IWG-accepted MAGICC results) produced by the DICE model is called into question and can no longer be substantiated. [EPA-HQ-OAR-2014-0827-1206-A1 p.25][This comment can also be found in section 11.8 of this comment summary]

Given the strong relationship between sea level rise and future damage built into the DICE model, there can be no doubt that the SCC estimates from the DICE model are higher than the best science would allow and consequently, should not be accepted by the IWG as a reliable estimate of the social cost of carbon. [EPA-HQ-OAR-2014-0827-1206-A1 p.25-26][This comment can also be found in section 11.8 of this comment summary]

And here again, the IWG (2015) admits that these sea level rise estimates are an outlier on the high end, yet retains them in their analysis by claiming that they were interested in representing a “range” of possible outcomes. But, even the IWG (2015) admits that the IPCC AR5 assigned “a low confidence in projections based on such [semi-empirical] methods.” It is internally inconsistent to claim the IPCC as
an authority for limiting the range of possibilities explored by the IAMs (which it did in the case of equilibrium climate sensitivity) and then go outside the IPCC to justify including a wildly high estimate of sea level rise. Such inconsistencies characterize the IWG response to comments and weaken confidence in them. We thereby suggest that our comments should be considered independently from the IWG (2015) response. [EPA-HQ-OAR-2014-0827-1206-A1 p.26][This comment can also be found in section 11.8 of this comment summary]

We did not investigate the sea level rise projections from the FUND or the PAGE model, but suggest that such an analysis must be carried out prior to extending any confidence in the values of the SCC resulting from those models—confidence that we demonstrate cannot be assigned to the DICE SCC determinations. [EPA-HQ-OAR-2014-0827-1206-A1 p.26][This comment can also be found in section 11.8 of this comment summary]

Response:

EPA has reviewed this comment and has determined that the Preamble and RIA have appropriately characterized climate impacts despite the commenter’s critiques. EPA responds to the various points that the commenter makes as follows.

The commenter compares the benefits of the rule (a reduction of 1.2-1.3 ppm of CO₂ in 2100) to the historical change in CO₂ concentrations since 2009 (12 ppm, based on an annual average of 387 ppm in 2009, compared to an annual average 399 ppm in 2014). While the commenter appears to think that this
comparison (e.g., that the carbon dioxide concentration reductions resulting from the rule are about \(1/10\)th of the increase in concentrations observed over a 5 year period) shows that the rule has little effect, the EPA considers that eliminating 6 months of concentration increase based on a single rule addressing a single sector in a single country is a meaningful reduction in the rate of rise of concentrations. This is especially true due to the lifetime of carbon dioxide perturbations.

The commenter also objects to the sentence stating that GHGs can remain in the atmosphere for decades to millennia, noting that the turnover time for carbon dioxide molecules is about 3-5 years. However, the perturbation lifetime of carbon dioxide is indeed on the order of thousands of years. In Chapter 6 of the IPCC Fifth Assessment Report, the persistence of carbon dioxide is characterized in the following fashion:

“The removal of human-emitted CO2 from the atmosphere by natural processes will take a few hundred thousand years (high confidence). Depending on the RCP scenario considered, about 15 to 40% of emitted CO2 will remain in the atmosphere longer than 1,000 years. This very long time required by sinks to remove anthropogenic CO2 makes climate change caused by elevated CO2 irreversible on human time scale”

EPA understands that any individual molecule of carbon dioxide emitted by the combustion of fossil fuels will likely be absorbed by the ocean or the biosphere on a timescale of years. However, it is well understood that this timescale is not the relevant one for understanding the climate impacts of carbon dioxide, and for the impact, it is the increase in concentrations resulting from emissions of carbon dioxide and the perturbation of the carbon cycle that matters, and this increase in concentration lasts for thousands of years, as the IPCC quote makes clear.

The commenter then makes a series of critiques about the significance of the action in terms of avoided warming, comparing the projected reduction to the total projected warming. The range of projected temperature reductions is 0.0027 to 0.0065 degrees, compared to total projected warming of 1.8 to 4.8 degrees. This is a reduction of more than 0.1%. Because this reduction is due to one action, for one sector, for one nation, it is not a meaningful percentage. Climate change is not expected to be solved by any single action, but rather a large number of them. As discussed in the response to EPA-HQ-OAR-2014-0827-1251-A2 above, the challenge of understanding a problem of the geographic, temporal and encompassing nature of climate change can be best addressed using the Social Cost methodology for cost-benefit analysis, as it appropriately integrates over time and space and across numerous impacts.

The commenter also makes an error regarding the interpretation of the probabilistic mode of MAGICC 6.0. Comparison of any given perturbation run to the baseline should use the same set of uncertain parameters. If the appropriate procedure is followed, then in every case, there will be a reduction in warming and other impacts when comparing the future with emissions reductions to a future without. Whether the uncertainty span of the baseline runs and the perturbed runs might overlap has no relevance: in fact, the uncertainty spans do overlap in the analysis presented in the RIA, based on the uncertainty range of climate sensitivity, but noting that a perturbation run done with a climate sensitivity of 4.5 might be warmer than a baseline run with a sensitivity of 1.5 is not a useful comparison.

The commenter also critiques the discussion of considering the impacts of half a millimeter of sea level rise over thousands of miles of coastline as “ludicrous.” However, there are already existing damages from storm surges, nuisance flooding, and other events. Every additional millimeter of sea level rise will make these damages worse. This incremental damage over a single mile of coastline will be small, but there is a non-zero chance that this additional millimeter will be the last straw needed to flood a basement or subway system, overtop a levee, or short out a power line. Sea-level rise damages are non-
linear which makes the following comparison limited, but as a first order approximation, a millimeter of sea level rise that impacts 40,000 miles of coastline (e.g., the shoreline mileage of the continental US) will cause damage of the same order of magnitude as a rise in local sea level of 10 cm across 400 miles of coastline (e.g., the coast of Delaware). Such an analysis could also be done for global coastlines. Add to this the marginal increase in risk of more intense heatwaves due to a fraction of a degree of warming aggregated across the population of the U.S. or the world, and the increase in risk due to drought and floods and ocean acidification and the other myriad impacts of climate change, and there are billions of dollars of impact – exactly as calculated by the Social Cost methodology.

For the response to critiques of the sea level rise approach used in the Social Cost of Carbon, see Response to Comments Section 11.8.

**Organization:** Moving Forward Network

Importantly, Network members include individuals who live in and work directly with environmental justice communities. Moreover, many of these communities will be the hardest hit by climate change. Consequently, the Network has a personal stake in how EPA and NHSTA address harmful climate pollution from large equipment. [EPA-HQ-OAR-2014-0827-1130-A2 p.1]

**Response:**

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change.

**Organization:** Operation Free

Additionally, the use of fossil fuels increases the likelihood of more troops sent into harm's way. As the Department of Defense's recent Report on National Security Implications of Climate-Related Risks and a Changing Climate affirms, climate change is widely recognized as a 'threat-multiplier.' Frequent and severe weather events destabilize some of the world's most dangerous regions. This exacerbates existing national security threats by pushing already unstable states to near constant crisis. The United States is requested to respond to disasters every two weeks a number likely to increase as the impacts of climate change become more acute. [EPA-HQ-OAR-2014-0827-1175 p.2] [[These comments can also be found in EPA-HQ-OAR-2014-0827-1372, pp.194-195.]]

**Response:**

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change as well as reducing the use of fossil fuels.

**Organization:** Respiratory Health Association

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p.129-131.]
It's become increasingly clear that global warming is a health threat, particularly to people living with lung disease.

Increasing heat waves put people with limited lung capacity at higher risk of hospitalization and death. Longer, hotter summers extend the ozone smog season, and increases the likelihood of unhealthy air days, cutting the gains we have made in reducing ozone precursors. More flooding means more displacement of medically vulnerable people and hinders access to medical care, and more allergenic pollen means greater risks for those with allergy-triggered asthma and misery for those who have allergies like hay fever.

Higher temps and greater droughts also increase the prevalence of wildfires, creating smoke plumes that travel hundreds of miles polluting the air where millions of people live.

The increasing effects of global warming are already having a direct impact on people's ability to breathe. It's putting vulnerable groups at risk, including babies, children, senior citizens, and those that live with chronic lung and heart conditions.

**Response:**

EPA has determined that elevated concentrations of greenhouse gases and climate change are reasonably anticipated to endanger public health and welfare, and that mitigation actions such as this rule are important steps towards reducing the rate of climate change and protecting public health.
10 Non-GHG Emissions Impacts and Their Associated Effects

10.1 Emissions Inventory Impacts

Organization: California Air Resources Board (CARB)

Neutral Comment to Provide Additional Information

Comment – NOx benefits from the extended use of APUs appear overestimated

According to page 40219 of the NPRM, to date, manufacturers are meeting the 2014 MY GHG standards without the use of automatic engine shutdown (AES) systems or APUs. U.S. EPA and NHTSA assume an APU/AES technology adoption rate of 90 percent for 2024+ MY class 7 and 8 tractors (page 40393 – 40394 of the NPRM). Given that manufacturers complied with Phase 1 without using APUs, CARB staff believes a 90 percent adoption rate may be too high. [EPA-HQ-OAR-2014-0827-1265-A1 P.172]

Additionally, CARB’s engine certification database shows that almost all of the 2014 MY engines which are sold in California (especially in class 8) are certified (as 50-State families) to the California clean idle engine requirements of 30 grams/hour NOx at idle. Following U.S. EPA and NHTSA’s projection of increased use of APUs during extended idling in combination tractors, the NPRM claims 34 percent NOx emissions reduction in year 2050 (page 40412 of the NPRM). Considering that APUs emit only a slightly lower NOx emissions than CA clean idle certified engines (because they are certified to CA clean idle requirements), such a high reduction in tailpipe NOx emissions (i.e., 34 percent) is not expected. [EPA-HQ-OAR-2014-0827-1265-A1 P.172]

Therefore, CARB staff encourages U.S. EPA and NHTSA to: [EPA-HQ-OAR-2014-0827-1265-A1 p.172]

1. Re-evaluate the projected level of AES/APU systems that will be used by manufacturers to comply with the requirements of the proposed regulation and;
2. Provide more information on the methodology and assumptions used to estimate the NOx emission benefits associated with this regulation.
3. Update the NOx emission benefit estimates to account for the current prevalence of clean idle certified engines.

Response:

In response to the comments from the proposal, the agencies have modified the projected adoption rates of idle reduction technologies. Additional details are provided in Chapter 2.4 and 2.8 of the RIA. Furthermore, the MOVES emission rates for extended idle and APUs were updated based on the analyses of the latest test programs that reflect the current prevalence of clean idle certified engines. This change resulted in smaller differences between emission rates for extended idle of the main engine and APUs for all criteria pollutants. Therefore, the emissions benefits of using APUs during extended idle, instead of the main engine, are much lower for non-GHGs in the final rulemaking than the proposal.
Additional details on the revised emission rates are provided in the memorandum to the docket.²⁰³

**Organization:** California Air Resources Board (CARB)

**Comment – Need to control PM emissions from APUs to prevent Phase 2 causing PM increases**

The NPRM requests comment on the need and appropriateness to further reduce PM emissions from APUs. The Phase 1 regulations included provisions to use extended idle reduction technologies as a compliance path to meet the GHG standards for sleeper cab tractors. In developing the Phase 1 GHG standards, U.S. EPA and NHTSA assumed that manufactures would install diesel-fueled APUs on all of the sleeper cab tractors to meet the Phase 1 GHG standards. Because the federal emission standards for APUs are less stringent than those for on-road heavy-duty engines, it was estimated that compliance with the Phase 1 standards using APUs as a compliance option would increase PM emissions by approximately 8 percent in 2030. Concerned about this potential increase in PM emissions, CARB and other stakeholders recommended that U.S. EPA and NHTSA regulate PM emissions from diesel-fueled APUs in the Phase 1 rulemaking.²⁰⁵ However, U.S. EPA and NHTSA chose not to take action on APUs because such action was outside the scope of the Phase 1 rulemaking. [EPA-HQ-OAR-2014-0827-1265-A1 p.178-179]

To date, CARB staff is not aware of any tractor manufacturers using APUs as a technology option to meet the Phase 1 GHG standards. Nonetheless, U.S. EPA and NHTSA are proposing the use of extended idle reduction technologies as a compliance option to meet the proposed Phase 2 standards. Moreover, like in Phase 1, the proposed rule does not require PM control from APUs. Thus, U.S. EPA and NHTSA’s inventory estimates project that compliance with the Phase 2 standards would increase federal PM emissions from heavy-duty trucks by approximately 10 percent in 2050 mainly due to PM increases from APUs. The NPRM requests comments on the need and appropriateness to further control PM emissions from APUs, taking into account cost, safety, noise, and energy factors. Although, as noted above, CARB staff believes the projection of APU use in the NPRM may be too high and hence the actual PM increases may be lower than projected, CARB staff is concerned about any such PM increases and believes they should be eliminated. [EPA-HQ-OAR-2014-0827-1265-A1 p.179]

75 See [http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0162-2354 for Phase 1 ](http://www.regulations.gov/#!documentDetail;D=EPA-HQ-OAR-2010-0162-2354 for Phase 1 ) Comment submitted CARB and for comments by others “EPA Response to Comments, EPA-420-R-11004, August 2011, Pages 136-140](http://www.epa.gov/otaq/climate/regs-heavy-duty.htm).

**Response:**

In addition to the CO₂ emission standards for tractors, EPA is adopting Phase 1 and Phase 2 requirements to control particulate matter (PM) emissions from diesel-fueled auxiliary power units (APU) installed in new tractors. Additional details are discussed in Section III.C.3 of the FRM Preamble.

10.2 Health Effects, Environmental Effects, and Air Quality Impacts of Non-GHG Pollutants

Organization: American Lung Association

This past April, the American Lung Association’s 16th annual State of the Air report once again found that cities in California ranked among the most polluted in the nation for both ozone and particle pollution. Transportation is leading source of pollution here, threatening the health of all residents of this region, but especially children, seniors, people living with asthma, COPD and other respiratory conditions. Pollution from the transportation sector is an added burden for those communities most disadvantaged by multiple pollution sources, including refineries, ports, rail yards and the freeways that carry the nation’s goods through these communities first and most. [NHTSA-2014-0132-0087-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.142-143.]]

The residents of Southern California and the San Joaquin Valley have perhaps the most to gain from a strong rule of any area in the nation. In the past months, Californians have experienced record temperatures, raging wildfires, torrential flooding and a persistent drought that has grown over the past four years into a major threat to air quality, water supplies, and the way of life that makes California unique. [NHTSA-2014-0132-0087-A1 p.2 [These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.143.]]

Organization: Bay Area Air Quality Management District (BAAQMD)

The San Francisco Bay Area (Bay Area) is home to more than 7 million people, and has one of the densest populations located adjacent to highways in the United States. The BAAQMD Community Air Risk Evaluation (CARE) program and California Air Resources Board (ARB) studies have shown that 85% of the risk from toxic air contaminants in the Bay Area comes from diesel Particulate Matter (PM). This is a significant air quality problem especially in the West Oakland area where an ARB health-risk assessment showed that up to 70% of the cancer risk is coming from on-road sources of air pollution. [EPA-HQ-OAR-2014-0827-1136-A1 p.1]

Organization: California Air Resources Board (CARB)

In 1998, CARB identified diesel PM as a toxic air contaminant. In 2012, the International Agency for Research on Cancer, which is part of the World Health Organization, also classified diesel engine exhaust as carcinogenic to humans. Numerous studies have shown diesel PM’s adverse effects on human respiratory and cardiovascular systems and its contribution to increased morbidity and mortality. Further details regarding diesel PM health effects is available on CARB’s website at http://www.arb.ca.gov/research/diesel/diesel-health.htm. [EPA-HQ-OAR-2014-0827-1265-A1 p.180]

The health risk posed by diesel PM is one of the largest public health problems tackled by CARB in recent decades, and even after an extensive control program including a series of air toxic control measures in California (see for example the mobile source measures listed at http://www.arb.ca.gov/toxics/atcm/atcm.htm), diesel PM remains responsible for 60 percent of the known risk for air contaminants. Hence, controlling diesel PM remains a huge priority for CARB. Diesel PM also contains black carbon, which is a powerful short-lived climate pollutant, so even beyond the toxicity reasons for controlling diesel PM, there are climate reasons as well. The PM 2.5 increases projected for the Phase 2 regulation are very significant – an increase of 1,631 tons and 2,257 tons of nationwide PM 2.5 in 2035 and 2050, respectively. To put those emission increases in perspective,
they are greater than the entire projected reductions of 1,058 tons statewide diesel PM in 2023 from CARB’s Truck and Bus Regulation. While this issue does not significantly affect California because CARB already requires DPFs on APUs, CARB staff supports adopting similar requirements at the federal level concurrent with the Phase 2 program. [EPA-HQ-OAR-2014-0827-1265-A1 p.180-181][This comment can also be found in section 4.6 of this comment summary]

Organization: California State Senator Ricardo Lara

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 57.]

In order to meet our reduction goals, we must invest in cleaner transportation technologies with a technology-neutral approach that incentivizes improvements in air quality along with reductions in greenhouse gases. We have made that commitment in California, investing millions of cap and trade dollars to the development of clean truck technology. However, we need an ambitious federal standard that complements and supports these efforts with stringent rules that will be implemented as soon as possible. [This comment can also be found in section 9.3 of this comment summary]

Organization: City of South Bend, Indiana

Locally, air quality affects our County, with ozone and particulates adversely impacting human health approximately eight days per year. With a diverse community and a poverty rate of 27.8 percent, we recognize that we must protect the health of vulnerable populations while being good stewards of limited taxpayer resources. Here in South Bend we are already replacing much of our fleet with cleaner-burning and lower-cost compressed natural gas vehicles. [EPA-HQ-OAR-2014-0827-1009-A1 p.1]

2 American Lung Association, 2015 State of the Air, St. Joseph County Indiana

3 U.S. Census Bureau, American Community Survey, 5-Year Estimates

Organization: Climate 911

35 million Americans live or work within 300 meters of a major roadway and are exposed to diesel pollution. Health consequences include adverse birth outcomes, childhood asthma, impaired lung
development, cancer, heart disease, and premature death. (EPA 2002, 2014). This hazardous exposure should be decreased to the greatest extent technically and economically feasible in the shortest possible amount of time. [EPA-HQ-OAR-2014-0827-1179-A1 p.1]

US EPA Update on Diesel Health Issues and EPA Actions 2014

Organization: Coalition on the Environment and Jewish Life

Finally, the proposed rule would reduce toxic air pollution from idling trucks and refineries that produce fuel, resulting in $37 billion in health and welfare benefits, including reductions in mortality and hospitalizations. Many refineries and areas where trucks idle for long periods of time are in low-income areas, so this rule will have a particularly important impact on these affected communities. [EPA-HQ-OAR-2014-0827-1249-A2 p.1]

Organization: Dignity Health

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 204.]

Dignity Health’s healing mission and values compel us to seek ways to further improve air quality and the health of communities throughout the Southwest.

Strict standards will provide incentives to increase investment in clean truck technology and to help the U.S. meet federal ozone standards, which Dignity Health activity supports.

Our nation’s current heavy-duty truck fleet poses significant health risks to Americans across the country.

Organization: East Yard Communities for Environmental Justice (EYCEJ)

These standards have the ability to help protect our most vulnerable populations from air pollution and the impacts of climate change. These impacts are disproportionately felt in low income and communities of color. From the idling of trucks to the refineries located next to homes and other sensitive receptors, it is the duty of the EPA to ensure that best practices are implemented to protect public health. Our members live on the fence line of oil and gas production, live with trucks idling nearby and rumbling through their neighborhoods, and shoulder the undue costs of these impacts through medications, hospitalizations, physical ailments, and premature deaths. [EPA-HQ-OAR-2014-0827-0843 p.1-2]

Organization: Environmental Law and Policy Center
They would save over a thousand lives each year.

The proposed regulation should do more to protect children's health. Asthma hospitalization rates in Chicago are nearly double those of the national average, and that's why we're so concerned that the proposed rule would actually increase particulate pollution by encouraging the use of auxiliary power units on trucks. We urge you to amend this rule by requiring that these units be equipped with particulate filters. This would eliminate the long-term increase in particulate pollution which may occur as a result of these regulations. [This comment can also be found in section 4.6 of this comment summary]

Organization: Gilroy, JD

Since I work as a health care utilization analyst for a large insurance company, I am very well aware that massive reductions in pollution can also yield great reductions in morbidity and mortality for residents susceptible to asthma, heart attacks, and other cardiovascular conditions. To speak anecdotally, while I take great joy in the beauty of the city of Chicago, the air quality here is notoriously bad, even years after the state of Illinois outlawed public indoor smoking and the city closed two old coal-fired power plants known as Crawford and Fisk. I have simply lost count of all the friends and family members who suffer from asthma or other more exotic medical conditions that are very probably linked in part to environmental toxins and irritants. [EPA-HQ-OAR-2014-0827-0751 p.2]

Organization: Houston-Galveston Area Council (H-GAC)

This rule, as proposed, will have substantial regional air quality and public health benefits. Projected emission reductions of 2.4 million tons of NOx emissions over the lifetime of the program should result in significant improvements of ground level ozone levels in our region. [EPA-HQ-OAR-2014-0827-1142-A2 p.1]

Organization: Illinois Public Interest Research Group (PIRG)

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 255.]

The standards are also important for public health. The reduction of toxic air pollution by the proposal rule will result in $37 billion in health and welfare benefits, including reductions in mortality and hospitalizations.

Organization: League of Women Voters of Los Angeles County

As we continue to learn that climate change is expected to increase to dangerous ozone levels in many areas and that the poorest people live within the areas closest to Los Angeles County's main port areas of Los Angeles and Long Beach and along the related freeway truck routes, it is abundantly clear that unless we adopt the proposed truck standards, air pollution will worsen asthma symptoms and trigger higher rates of asthma attacks among children and adults, along with other dire impacts on the health of citizens of Los Angeles County.
Emission reductions aimed at lowering emissions of the primary precursors of ozone such as volatile organic compounds (VOCs) and NOx, will have a positive impact on lower ambient ozone levels, climate change, as well as human health. [EPA-HQ-OAR-2014-0827-1210-A3 p.3]

The proposed standards will help protect our families from harmful climate change and from unhealthy air pollution. They will significantly reduce our national fuel consumption, and will save money for both truckers and consumers. [EPA-HQ-OAR-2014-0827-1341-A1 p.1][This comment can be found in 9.4 of this comment summary]

The health-based National Ambient Air Quality Standards require that states focus on reducing their ambient levels of criteria pollutants. California and the Northeast states are struggling to achieve existing federal ozone ambient standards, and are already preparing to meet tighter ozone NAAQS limits in the future. These states are concerned about GHG emissions as well as NOx from mobile sources such as heavy-duty engines since the mobile sector represent 50-80% of their NOx inventory.
Implicit in federal and state greenhouse gas emission analyses is the ability of these advanced powertrain options to meet the applicable criteria pollutant emission standards, such as CO, NOx, and non-methane organic gases (NMOG). All of these advanced, heavy-duty powertrain options combined with the appropriately designed and optimized emission control and efficiency technologies can meet all current and future federal and state criteria emission requirements. In this manner, advanced emission controls for criteria pollutants enable advanced powertrains to also be viable options for reducing greenhouse gas emissions. [EPA-HQ-OAR-2014-0827-1210-A3 p.4]

Organization: Moms Clean Air Force

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 64-65.]

While I, of course, am concerned about my child's health, I know that also frequently there are more freight depots and shipping companies in frontline neighborhoods where pollution is worse than in my neck of the woods. In Illinois, the rate of childhood asthma is at 13 percent, which is one percent higher than the national rate. The age adjusted asthma mortality rate here in Chicago is nearly five times higher in non-Hispanic blacks than in non-Hispanic whites. This rule will have a significantly positive impact on these affected communities.

Organization: Moving Forward Network

Eliminate loophole for Auxiliary Power Units (APUs), which will increase harmful Particulate Matter Emissions – As the California Air Resources Board has pointed out, a regulation that will increase the use of APUs more extensively throughout the nation will result in increased PM2.5 emissions unless these APUs are equipped with diesel particulate filters. We cannot sacrifice public health protections as we seek to battle climate pollution. We represent groups on the front lines battling deadly pollution from the freight industry. This approach that increase PM2.5 emissions is even more problematic given at least one state, California, has shown that diesel particulate filters can be required on APUs. The final rule should require the use of diesel particulate filters on APUs. [EPA-HQ-OAR-2014-0827-1130-A2 p.2][This comment can also be found in section 4.6 of this comment summary]

Organization: Northeast States for Coordinated Air Use Management (NESCAUM)

Ozone

Ozone remains a persistent pollution problem in parts of the NESCAUM region during warm weather months. The evolution of severe ozone episodes often begins with the passage of a large high pressure area from the Midwest to the middle or southern Atlantic states. Three primary pollution transport pathways affect air quality in the region: long-range, mid-level, and near-surface. During severe ozone episodes associated with high-pressure systems, these pathways converge on the Mid-Atlantic area, where sea and bay breezes act as a barrier and funnel ozone and other air pollutants up the Northeast Corridor. [EPA-HQ-OAR-2014-0827-1221-A1 p.4-5]

Collectively, NOx emissions and ambient ozone concentrations in the region have dropped significantly since 1997, along with the frequency and magnitude of exceedances of the health-based ozone national ambient air quality standard (NAAQS). Despite this demonstrated progress, some of the most populous areas of the region continue to violate the 2008 0.075 ppm ozone NAAQS. Attaining the standard in these areas will require significant additional NOx reductions within the Northeast and in upwind areas.
Looking toward the future, additional NOx reductions will be critical to ozone attainment in order to meet the recently revised 0.070 ppm ozone NAAQS, which EPA projects will continue to be exceeded in our region in 2025. [EPA-HQ-OAR-2014-0827-1221-A1 p.5][This comment can also be found in section 15.8.2 of this comment summary]

**Particulate Matter**

Scientific evidence has established a solid link between cardiac and respiratory health risks and transient exposure to ambient fine particle pollution that is capable of penetrating deep into the lungs. Exceedances of the fine particle NAAQS can occur at any time of the year, with some of the highest levels often reached in the winter. There are important differences in the chemical species responsible for high fine particle levels during summer and winter in the Northeast. Regional fine particle formation in the eastern United States is primarily due to SO2, but NOx is also important because of its influence on the chemical equilibrium between sulfate and nitrate particles during winter when nitrates can be a relatively greater contributor to urban PM2.5 levels. [EPA-HQ-OAR-2014-0827-1221-A1 p.5][This comment can also be found in section 15.8.2 of this comment summary]

**Acid Deposition**

Atmospheric sources of nitrogen are a primary contributor to acidification of forest soils and fresh water ecosystems in the Northeast. Nitrogen saturation results in a number of important changes in forest ecosystem functions, including: (1) increased acidification of soils and surface waters; (2) depletion of soil nutrients and the development of plant nutrient imbalances; and (3) forest decline and changes in species composition. More than 30 percent of the lakes in the Adirondacks and at least 10 percent of the lakes in New England are susceptible to the effects of acidic episodes that include long-term increases in mortality, emigration, and reproductive failure of fish, as well as short-term acute effects. Acidic episodes can occur at any time of the year but typically are most severe during spring snowmelt, when biological demand for nitrogen is low and saturated soils exhibit lower nitrogen retention. [EPA-HQ-OAR-2014-0827-1221-A1 p.5-6]

**Marine Eutrophication**

Airborne nitrogen is an important contributor to eutrophication, the process by which a body of water acquires a high concentration of nutrients that promote excessive growth of algae. As the algae die and decompose, high levels of organic matter and decomposing organisms deplete the water of available oxygen, causing the death of other organisms, such as fish. Atmospheric nitrogen is a major contributor to eutrophication of key coastal resources in the Northeast, including Barnegat Bay in New Jersey and Long Island Sound. The Chesapeake Bay is the largest estuary in the U.S. and its watershed stretches across more than 64,000 square miles, encompassing parts of six states, including New York. Since the 1950s, the bay has experienced a decline in water quality due to over-enrichment of unwanted nutrients such as phosphorus and nitrogen. The major contributors to nutrient discharge in the bay are wastewater effluent, urban and agricultural runoff, and air deposition. [EPA-HQ-OAR-2014-0827-1221-A1 p.6]

**Visibility Impairment**

Regional haze is a form of air pollution that obscures the views of city skylines as well as “pristine” scenic vistas. It is caused by fine particle air pollution and can cover hundreds of square miles in the East. Natural visibility conditions in the East are estimated at 60 to 80 miles in most locations. Under current polluted conditions, average visibility ranges from 20 to 40 miles. On the worst days, regional haze can reduce visibility to just a few miles. Outdoor recreation is a multi-billion dollar industry in the
U.S. and is of particular economic importance to communities near protected federal lands. Surveys indicate visitors have rated “clean, clear air” as among the most important features of national parks and have overwhelmingly ranked scenic views and clean air as “extremely” or “very” important. Studies have yielded estimates in the billions of dollars for the visibility benefits associated with substantial national pollution reductions. While sulfate, formed from SO2 emissions, is currently the most important particle constituent of regional haze in the East, reductions in other local and distant pollutant emissions, including NOx, will be necessary to achieve the nation’s long-term goal of restoring pristine visibility conditions year-round in national parks and wilderness areas. [EPA-HQ-OAR-2014-0827-1221-A1 p.6-7]

11 In 1999, EPA promulgated the Regional Haze Rule in pursuit of the national visibility goal created by Congress in the Clean Air Act to ultimately restore natural visibility conditions in 156 national parks and wilderness areas across the country (called “Class I” areas).

**Organization:** Respiratory Health Association

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p.129.]
Tailpipe derived particulate matter triggers asthma attacks and heart attacks, and drives increases in emergency room visits, and hospitalizations, and premature deaths. Eliminating those emissions as well as slashing ozone forming and toxic air pollution has reduced health risks and, in fact, has saved lives.

Response:

EPA agrees that emissions of non-GHG pollutants from heavy-duty vehicles contribute to ambient air pollution that poses significant health and environmental concerns. Along with reducing GHGs, the Phase 2 standards also have an impact on non-GHG, criteria and air toxic pollutant, emissions. As discussed in Section VIII.C of the Preamble, the standards will impact exhaust emissions of these pollutants from vehicles and will also impact emissions that occur during the refining and distribution of fuel (upstream sources). Reductions in emissions of NOX, VOC, PM$_{2.5}$ and air toxics expected as a result of the Phase 2 standards will lead to improvements in air quality, specifically decreases in ambient concentrations of PM$_{2.5}$, ozone, NO$_2$ and air toxics, as well as better visibility and reduced deposition. Section VIII of the Preamble for this final rule details the health and environmental impacts associated with non-GHG air pollutants. In addition, Section VIII.A.6 focuses on diesel exhaust and Section VIII.A.8 focuses on exposures and health effects associated with traffic. EPA also agrees that Environmental Justice (EJ) is an important principle and a more detailed discussion on EJ is included in Section VIII.A.9.

Several commenters noted concern about the fact that the proposal increased PM$_{2.5}$ emissions due to increased usage of auxiliary power units (APUs). EPA is adopting Phase 1 and Phase 2 requirements to control PM$_{2.5}$ emissions from APUs installed in new tractors, so we do not expect increases in downstream PM$_{2.5}$ emissions from the Phase 2 program. Additional discussion of the APU requirements can be found in Section 4.6 of this Response to Comments document.

11.1.1 Positive Comments on Economic Impact, Cost and Benefit Analysis

**Organization:** Burger, Mark

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 132.]

I want to emphasize the economic benefits that improved truck fuel efficiency standards will bring. Improved fuel efficiency standards resulting in demand destruction are one of the best tools to reduce pollution and keep fuel prices affordable. The fuel efficiency standards of cars and light trucks has resulted in the present savings of about three to four million barrels a day in the U.S.]
Organization: Business for Innovative Climate & Energy Policy
Stronger standards would be important drivers of economic growth, benefiting both businesses and consumers. A joint analysis by Ceres and the Environmental Defense Fund found that stronger standards would reduce freight costs by 6.8% in 2040, an annual savings potential of approximately $34 billion.2 [NHTSA-2014-0132-0095-A1 p.1]

Organization: Ceres

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 200-201.]

Strict standards will catalyze investment in high efficiency truck technologies, thereby serving to retain the U.S. leadership position in this sector, save businesses money, promote energy security, and reduce climate risk. Such standards would be important drivers of economic growth, benefitting businesses, the trucking industry, and American consumers.

Organization: City of South Bend, Indiana

With medium-and heavy-duty vehicles accounting for twenty percent of US oil consumption but only five percent of vehicles,1 the opportunity for improvement is significant. Requiring increased efficiency in a flexible, cost-effective way helps make U.S. businesses located in South Bend more competitive globally — especially beneficial to the rapidly-growing distribution and logistics companies that operate in our region. [EPA-HQ-OAR-2014-0827-1009-A1 p.1]

1 EPA and DOT propose greenhouse gas and fuel efficiency standards for heavy-duty trucks, NHTSA.

Organization: Clean Fuels Ohio (CFO)

Opportunities improving truck fuel efficiency are also great (and growing) based on already-existing technologies and others in the R&D pipeline that show future promise: [EPA-HQ-OAR-2014-0827-1192-A1 p.1]

The EPA has suggested that phase two would result in $230 billion total net benefits to society, including fuel savings, carbon reductions, health, energy security, and others. [EPA-HQ-OAR-2014-0827-1192-A1 p.2]

Clean Fuels Ohio encourages all parties to continue to work together as these rules are implemented to ensure maximum gains for efficiency that will produce longer-term cost savings, health and environmental benefits, overall economic benefits and gains in U.S. energy security while minimizing the disruptive impacts of higher up-front costs to commercial vehicle users. [EPA-HQ-OAR-2014-0827-1192-A1 p.2]

Organization: Coalition on the Environment and Jewish Life

In addition to the environmental benefits of reducing emissions, strong standards would create jobs, save households money, and protect public health. These standards will drive investments in fuel
efficient technology innovation and deployment, which will create new markets and tens of thousands of new jobs. [EPA-HQ-OAR-2014-0827-1249-A2 p.1]

**Organization:** Consumer Federation of America (CFA)

We next examine other, indirect benefits and costs. These are generally externalities that we would not expect producers and consumers to take into account in their decision making, but as important social costs and benefits, they should be taken into account in policymaking. Here we include macroeconomic considerations, including the rebound effect and public health effects. These benefits and costs increase the total value of the proposed rule significantly. [EPA-HQ-OAR-2014-0827-1336-A1 p.45]

The other two effectiveness tests involve environmental benefits. The economic benefits of fuel savings mean the environmental benefits are “free.”

With respect to the second measure, which is useful for comparisons to other GHG rules, the proposed standards would have overall $/ton costs similar to the HD Phase 1 rule.... less than $50 per metric ton of GHG (CO₂ eq) for the entire HD Phase 2 program. This compares well to... the agencies’ estimates of the social cost of carbon. Thus, even without accounting for fuel savings, the proposed standards would be cost effective. The third measure deducts fuel savings from technology costs, which also is useful for comparisons to other GHG rules. On this basis, net costs per ton of GHG emissions reduced would be negative under the proposed standards. [EPA-HQ-OAR-2014-0827-1336-A1 p.47-48]

This means that the value of the fuel savings would be greater than the technology costs, and there would be a net cost saving for vehicle owners. In other words, the technologies would pay for themselves (indeed, more than pay for themselves) in fuel savings. [EPA-HQ-OAR-2014-0827-1336-A1 p.48]

In addition, while the net economic benefits (*i.e.*, total benefits minus total costs) of the proposed standards is not a traditional measure of their cost effectiveness, the agencies have concluded that the total costs of the proposed standards are justified in part by their significant economic benefits. [EPA-HQ-OAR-2014-0827-1336-A1 p.48]

[T]his rule would provide benefits beyond the fuel conserved and GHG emissions avoided. The rule’s net benefits is a measure that quantifies each of its various benefits in economic terms, including the economic value of the fuel it saves and the climate-related damages it avoids, and compares their sum to the rule’s estimated costs. The agencies estimate that the proposed standards would result in net economic benefits exceeding $100 billion, making this a highly beneficial rule. [EPA-HQ-OAR-2014-0827-1336-A1 p.48]

The second largest source of benefit is the environmental and public health benefits, accounting for a little over a quarter of the total benefits. The value of the reduction in greenhouse gas emissions alone equals the total cost of the proposed rule. Other public health benefits are of similar magnitude to the value of greenhouse gas reductions. Environmental benefits are almost twice as large as the costs. [EPA-HQ-OAR-2014-0827-1336-A1 p.48]

---

34 EPA/NHTSA, PHASE II NOPR, p. 40169. As noted above, all costs and benefits are taken from the analysis which uses a 3% discount rate. Given the flat line of fuel economy over decades, we also report the results for the less dynamic base case. Other cases and discount rates support the same conclusions.
Combining all of the costs and benefits, the benefit to cost ratio is over 8-to-1. For tractor trailers, which account for two-thirds of the fuel consumption of medium and heavy duty trucks, the benefit cost ratio is 10-to-1. This is a very high benefit cost ratio that highlights the question of why EPA/NHTSA did not push the standard to a higher level. [EPA-HQ-OAR-2014-0827-1336-A1 p.49]

Organization: Consumer Federation of America (CFA)

New fuel economy standards proposed by EPA and the Department of Transportation represent an opportunity to deliver significant cost savings, reduce fuel consumption and reduce emissions. Some context: [EPA-HQ-OAR-2014-0827-1169-A1 p.1]

- Medium- and heavy-duty trucks only make up 7 percent of all vehicles on the road but consume 25 percent of the fuel used by all vehicles. [EPA-HQ-OAR-2014-0827-1169-A1 p.1]

- The heavy-duty vehicle sector is second largest and fastest growing segment of the U.S. transportation sector in terms of emissions and energy use. [EPA-HQ-OAR-2014-0827-1169-A1 p.1]

According to the American Trucking Association, fuel is the single largest expense for motor carriers — accounting for nearly 40 percent of operating costs. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

- Travel among heavy-duty vehicles is expected to increase by nearly 50 percent over the next 25 years according to the Energy Information Administration. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

- The Consumer Federation of America reports that fuel costs for goods and services delivered by medium-and heavy-duty trucks cost U.S. households an average of $1,100 in 2010. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

Because truck fuel consumption is so great (and growing), the benefits of improving truck fuel efficiency are also great (and growing): [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

- Finalizing a strong second phase rule is expected to save vehicle owners $170 billion in fuel costs while conserving 1.8 billion barrels of oil and cutting carbon pollution by nearly 1 billion metric tons over the lifetime of vehicles sold under the program. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

- In total, the program would result in $230 billion total net benefits to society, including fuel savings, carbon reductions, health, energy security, and others. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

- Fuel savings will help bring down the costs of transporting goods, with the average household saving $150 a year by 2030, assuming the savings and costs are passed through to consumers. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

As you can see, these new standards are a win for shippers, a win for businesses that rely on trucks to transport goods and materials, and a win for consumers who purchase products carried by trucks. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]
Finally, we know that improving truck fuel efficiency is achievable and can be done affordably: [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

- Through partnerships with the Department of Energy, major manufacturers have proven fuel economy ratings of over 12 mpg are achievable for combination tractors through advanced technologies. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

- In model year 2027, a new tractor-trailer owner would recoup the extra cost of technology used to achieve the standards within 2 years. [EPA-HQ-OAR-2014-0827-1169-A1 p.2]

According to the American Trucking Association, fuel is the single largest expense for motor carriers — accounting for nearly 40 percent of operating costs.

- Travel among heavy-duty vehicles is expected to increase by nearly 50 percent over the next 25 years according to the Energy Information Administration.

- The Consumer Federation of America reports that fuel costs for goods and services delivered by medium-and heavy-duty trucks cost U.S. households an average of $1,100 in 2010.

Because truck fuel consumption is so great (and growing), the benefits of improving truck fuel efficiency are also great (and growing):

- Finalizing a strong second phase rule is expected to save vehicle owners $170 billion in fuel costs while conserving 1.8 billion barrels of oil and cutting carbon pollution by nearly 1 billion metric tons over the lifetime of vehicles sold under the program.

- In total, the program would result in $230 billion total net benefits to society, including fuel savings, carbon reductions, health, energy security, and others.

- Fuel savings will help bring down the costs of transporting goods, with the average household saving $150 a year by 2030, assuming the savings and costs are passed through to consumers.

As you can see, these new standards are a win for shippers, a win for businesses that rely on trucks to transport goods and materials, and a win for consumers who purchase products carried by trucks.

Finally, we know that improving truck fuel efficiency is achievable and can be done affordably:

- Through partnerships with the Department of Energy, major manufacturers have proven fuel economy ratings of over 12 mpg are achievable for combination tractors through advanced technologies.

- In model year 2027, a new tractor-trailer owner would recoup the extra cost of technology used to achieve the standards within 2 years.

Organization: Edison Solar Inc.

Because truck fuel consumption is so great (and growing), the benefits of improving truck fuel efficiency are also great (and growing): [EPA-HQ-OAR-2014-0827-1176-A1 p.2]
• In total, the program would result in $230 billion total net benefits to society, including fuel savings, carbon reductions, health, energy security, and others. [EPA-HQ-OAR-2014-0827-1176-A1 p.2]

As you can see, these new standards are a win for shippers, a win for businesses that rely on trucks to transport goods and materials, and a win for consumers who purchase products carried by trucks. [EPA-HQ-OAR-2014-0827-1176-A1 p.2]

**Organization:** Energy Ohio Network

Strong fuel efficiency standards are good for American manufacturing because they stimulate innovation, making U.S. businesses more competitive globally. Through partnerships with the Department of Energy, major manufacturers have proven fuel economy ratings of over 12 mpg are achievable for combination tractors through advanced technologies. Further investment in the research, production, and deployment of vehicle innovation will give the United States an opportunity to lead international markets as countries like China and Japan consider additional efficiency requirements for trucks. [EPA-HQ-OAR-2014-0827-1331-A1 p.2]

---

7 http://energy.gov/eere/vehicles/articles/supertruck-team-achieves-115-freight-efficiency-improvement-class-8- long-haul

**Organization:** Environment America and other local citizens across America

Setting a strong second-phase standard will help fleets save more money on fuel. For example, manufacturers could improve the efficiency of transit buses, school buses, utility trucks and other “vocational” vehicles by almost a third by 2025, with technology that would pay for itself in fuel savings in less than 4 years (compared to an average life of 15 years for an average transit bus, for example). Payback times for heavy-duty pickups and vans would be less than three years. And for tractor-trailers, efficient technology could pay for itself completely in only 13 months.

---

**Organization:** Fuller, Tony

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 149.]

Increased standards would yield additional health, economic, and environmental benefits with minimal costs, especially when you factor in the long-term threats posed by climate change and the health and economic benefits.

**Organization:** Greenways to Go
The proposed standards would establish a level playing field to finding areas where American innovation can provide solutions that benefit society as a whole by continuing to lead the U.S. and the world on a path of responsibly managing man’s impacts on the earth’s ecosystems while reducing the need for the U.S. to import oil. This leads to economic stimuli, jobs, reduced risks, and reduced costs required to globally protect oil, and reduce trade deficits in a more competitive U.S. global economic profile. [EPA-HQ-OAR-2014-0827-1372 p.280-281]

These technical advances will soon come from somewhere in the world, and having the U.S. leading these improvements will result in exporting of U.S. technologies, meaning even more American jobs and cash flow. Initiatives like the fuel efficiency standards help educate all of us on why we should be mindful of proper stewardship of the finite air, water, and land resources we share. [EPA-HQ-OAR-2014-0827-1372 p.281]

Organization: Houston-Galveston Area Council (H-GAC)

The rule, as proposed, will result in economic benefits for the region, with national estimates showing that the average household will save $150 per year. Additionally, regional heavy-duty fleets serving our region are projected to see substantial savings over the lifetime of the proposed rule as well. [EPA-HQ-OAR-2014-0827-1142-A2 p.1]

Organization: Illinois Public Interest Research Group (PIRG)

Further, consumers support decreasing emissions. A Consumer Federation of America poll released in May 2015 found that a majority of Americans favor requiring manufacturers to increase the fuel efficiency of heavy duty trucks while less than one-quarter opposed this requirement. Consumers’ voices should be considered with these standards.

Organization: Investor Network on Climate Risk

Strong standards would be important drivers of economic growth, benefiting businesses, truck manufacturers and suppliers, and consumers. A joint analysis by Ceres and the Environmental Defense Fund found that strong standards would save $0.21 per mile by 2040. The same study indicated that strong standards would reduce freight costs by 3% in 2030 and 7% in 2040, an estimated $34 billion annual saving potential. [NHTSA-2014-0132-0113-A1 p.1-2]

Strict standards are also crucial for the United States to retain its leadership position in efficient truck manufacturing and expand job opportunities in that sector. We are currently the world leader in the development, production and use of energy-efficient and hybrid trucks. Without strong standards in place, companies and investors will lack the requisite certainty to invest in the development and production of new technologies that will allow us to retain our primary position and increase job growth. [NHTSA-2014-0132-0113-A1 p.2]
Organization: Los Angeles Cleantech Incubator (LACI)

It’s an exciting time to be at the center of the City’s primary economic growth strategy: driving innovation in clean technologies. The Los Angeles region is already the largest green economy in the nation, and there is an unprecedented economic opportunity as our city, state, and country rebuilds its energy and transportation infrastructure, shifting energy dependence away from fossil fuels and toward sustainable energy sources. [EPA-HQ-OAR-2014-0827-1291-A1 p.1]

It is because of that economic opportunity that we applaud your efforts to implement strong, achievable fuel efficiency and emission standards for medium- and heavy-duty vehicles. The new standards will help save consumers and businesses money at the pump, lessen the economic and national security threats presented by oil dependence and price volatility, and – importantly from our perspective - encourage the development of new technologies to drive the transportation sector forward. [EPA-HQ-OAR-2014-0827-1291-A1 p.1]

Strong fuel efficiency standards will stimulate domestic innovation and manufacturing. Further investment in the research, production, and deployment of vehicle innovation will give the United States an opportunity to lead international markets as countries like China and Japan consider additional efficiency requirements for trucks. It will also create opportunities for American companies and entrepreneurs to come up with breakthrough technologies to drive the transportation sector forward. [EPA-HQ-OAR-2014-0827-1291-A1 p.1-2]

Organization: Lubrizol Corporation

When finalized and implemented, the Phase 2 Rule will provide significant economic, health, environmental, and energy benefits from new trucks and buses built between 2018 and 2027. As EPA has estimated, the final Rule will cut CO₂ emissions by roughly 1 billion metric tons, save an estimated 1.8 billion barrels of oil, and deliver net benefits of $230 billion to society in fuel savings, environmental improvements, and reduced health costs. [EPA-HQ-OAR-2014-0827-1325-A1 p.2]

Organization: Mazza & Sons, Inc.

Strong fuel efficiency standards are good for American manufacturing because they stimulate innovation, making U.S. businesses more competitive globally. Through partnerships with the Department of Energy, major manufacturers have proven fuel economy ratings of over 12 mpg are achievable for combination tractors through advanced technologies. Further investment in the research, production, and deployment of vehicle innovation will give the United States an opportunity to lead international markets as countries like China and Japan consider additional efficiency requirements for trucks.²

² [http://energy.gov/eere/vehicles/articles/supertruck-team-achieves-115-freight-efficiency-improvement-class-8-long-haul]

Businesses and consumers across all sectors of the economy rely on trucks to move materials and products. Tractor-trailers and package delivery vans move $10 trillion worth of freight each year and commuter buses transport 3.5 million people to work every day. Furthermore, U.S. companies spent over $700 billion dollars on trucking services in 2014. As travel among heavy-duty vehicles grows by nearly 50 percent over the next 25 years, America will continue to rely on these trucks to support critical services needs as well as the growing economy.

Strong fuel efficiency standards are good for American manufacturing because they stimulate innovation, making U.S. businesses more competitive globally. Through partnerships with the Department of Energy, major manufacturers have proven fuel economy ratings of over 12 mpg are achievable for combination tractors through advanced technologies. Further investment in the research, production, and deployment of vehicle innovation will give the United States an opportunity to lead international markets as countries like China and Japan consider additional efficiency requirements for trucks.

The new standards will help businesses, like ours, that depend upon trucks to receive and then deliver our products and service to our customers. More fuel efficient trucks will not only save money at the pump, lower our costs, but will lessen the economic and national security threats presented by oil dependence.

Another great thing about finalizing even tougher fuel economy standards for newer tractor trailers, vocational vehicles, and heavy duty pickup trucks and cargo vans is that they comprise a no regrets transportation energy efficiency strategy. Besides promoting climate protection, they will also have other positive benefits, like cutting our oil consumption by an additional 200,000 barrels each day in...
2035; reducing hazardous air pollutants from idling trucks and operating oil refineries, saving the average tractor trailer driver roughly $30,000 annually in fuel costs in 2025; reducing the expenses for the owners of truck fleets; and driving -- pun intended -- the green energy innovation for inherently cleaner heavy duty vehicles.

Organization: Ohio Sustainable Business Council (SBC)

The new standards will help save consumers and businesses money at the pump, lessen the economic and national security threats presented by oil dependence and price volatility, and encourage American manufacturers to develop new technologies that spur investment in research, development, and production of advanced vehicles. [EPA-HQ-OAR-2014-0827-1177-A1 p.1]

OSBC represents a broad base of sustainable-minded business leaders, who favor sensible regulations that create opportunity, protect the public, save money, and serve the common good. [EPA-HQ-OAR-2014-0827-1177-A1 p.2]

Strong fuel efficiency standards are good for American manufacturing because they stimulate innovation, making U.S. businesses more competitive globally. Through partnerships with the Department of Energy, major manufacturers have proven fuel economy ratings of over 12 mpg are achievable for combination tractors through advanced technologies. Further investment in the research, production, and deployment of vehicle innovation will give the United States an opportunity to lead international markets as countries like China and Japan consider additional efficiency requirements for trucks. ---

7 http://energy.gov/eere/vehicles/articles/supertruck-team-achieves-115-freight-efficiency-improvement-class-8-long-haul

**Organization:** Solar Provider Group

Solar Provider Group committed to solar because it’s a technology that’s both good for the planet and delivers an increasingly beneficial return on investment, and we feel the same way about efficient trucking. We rely on medium- and heavy-duty trucks throughout our supply chain, and stand to benefit a great deal from more efficient vehicles that save us, our partners, and our clients money on transportation costs. The transportation sector also makes up 70 percent of all oil consumption in the United States and accounts for almost 30 percent of the nation’s greenhouse gas emissions, presenting a significant opportunity for improvement. [EPA-HQ-OAR-2014-0827-1235-A1 p.1]

**Organization:** Werner Enterprises

EPA and NHTSA have been presented a unique opportunity to play a major role in setting fuel efficiency standards that align with the goals of the heavy-duty vehicle, engine, and operating industry and could provide fleets like Werner with real world fuel savings that translate into reduced GHGs and savings across the market. Given fuel is one of the top operating expenses for Werner, we support the aims of improving fuel efficiency and reducing our carbon footprint. Improving fuel efficiency has long been a key component of optimizing our operations and is an effort that naturally aligns with the Agencies’ goal to reduce GHG emissions. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

**Response:**

We appreciate the commenters’ reviews of the agencies’ economic impact, cost and benefit analyses for this rulemaking and the citation of analyses from other organizations. These positive comments and citations of our economic impact analysis, cost and benefit estimates express support for the proposed HD Phase 2 program in general.

The Agencies agree with the commenters’ assertions that building on the success of the Phase 1 standards, this new phase of the national program would significantly reduce carbon emissions and fuel
consumption from a wide range of on-road vehicles – from semi-trucks and their trailers to the largest
pickup trucks and vans, and all types and sizes of work trucks and buses.

The Agencies estimate that Phase 2 program would cut GHG emissions by up to 1.1 billion metric tons,
conserve up to 2.0 billion barrels of oil, and lower fuel costs by about $170 billion over the lifetime of
the vehicles sold under the program for the HD vehicles.

In total, the program would result in up to 230 billion total net benefits to society, including fuel
savings, carbon reductions, health, energy security, and others, as shown in Table I-10, Preamble
Section I. D. (2).

The agencies agree with the commenters’ remarks that this national program would be an important
driver of economic growth, benefitting businesses, the trucking industry, and American consumers. The
agencies also agree with the commenters’ observation that the Phase 2 program will promote energy
security and give the United States an opportunity to lead international markets in this sector. The
Phase 2 program represents a more technology-forcing\textsuperscript{204} approach than the Phase 1 approach and will
benefit consumers and businesses by reducing the costs for transporting goods while spurring
investment and innovation in the clean energy technology sector.

11.1.2 Negative Comments on Economic Impact, Cost and Benefit Analysis

Organization: Competitive Enterprise Institute et al.(CEI)

It may be unrealistic to expect an agency to take responsibility for the very problem it seeks more power
over industry to solve. Nonetheless, given the administration’s high-profile commitment to
“transparency,” EPA and NHTSA should have at least addressed the issue. They have not done so.
[EPA-HQ-OAR-2014-0827-1251-A2 p.2]

Response:

In its comment, the Competitive Enterprise Institute (CEI) jointly with others makes several points in
questioning the agencies’ “transparency” in addressing issues such as the justification of the rules,
energy security benefits, and small trucking firm impacts. The agencies disagree with commenter’s
points and its claims, and our responses to these issues can be found in Sections 11.2, 11.10, and 15.2 of
this RTC, respectively. On the issue of “transparency,” we refer to our response in Section 15.5 of this
RTC, which illustrates how the agencies have gone beyond the procedural steps required by law to
promote transparency and public participation for this Phase 2 rulemaking.

Organization: Utility Trailer Manufacturing Company

THE AGENCIES’ COST-BENEFIT ANALYSIS IS FLAWED.

Executive Order 12866, which applies to significant rules issued under the Clean Air Act, requires the
Agency to assess systematically the regulation’s costs and benefits. The Agency properly acknowledges

\textsuperscript{204} In this context, the term “technology-forcing” is used to distinguish standards that will effectively require
manufacturers to develop new technologies (or to significantly improve technologies) from standards that can be
met using off-the-shelf technology alone. Technology-forcing standards do not require manufacturers to use any
specific technologies.
this obligation, and refers to its Regulatory Impact Analysis, in the Proposed Rulemaking. Although the
Agency has set forth its conclusions in this regard, the analysis is flawed as it significantly overstates the
benefits and understates the costs associated with the Proposed Rule. [EPA-HQ-OAR-2014-0827-1183-
A1 p.15]

Response:

The agencies disagree with the commenter’s assertion that the cost-benefit analysis is flawed. The
agencies use standard economic parameters (including discount rates) to measure the monetary value of
the rules’ impacts. These parameters, methods and assumptions are based on the best available data at
the time and are documented extensively in the Preamble and RIA that accompanies the rules.

The agencies acknowledge that a wide range of estimates is available for many of the primary inputs
that are used in the HD GHG emissions models. The agencies recognize that each of these values has
some degree of uncertainty. The agencies tested the sensitivity of their estimates of costs and benefits to
a range of assumptions about each of these inputs, and found that the magnitude of these variations
would not have changed the overall conclusions of the cost benefit-analysis; i.e., that the benefits of the
program far outweigh the costs. The Agencies considered uncertainty in its analysis by utilizing a range
of various estimates as well as other sensitivity analyses. These included:

- The benefits and costs of these rules, which are analyzed using 3 percent and 7 percent discount
  rates, consistent with current OMB guidance.
- The range of Social Cost of Carbon (SCC) values, by always considering all four SCC values
  developed by the interagency group (RIA Chapter 8.5.1)
- Fuel prices, by using the AEO reference fuel price case in all central analysis results but also
  calculating the net benefits using both the AEO High and Low fuel price cases (RIA Chapter
  8.12)
- Engineering costs, by calculating vehicle technology costs and maintenance costs relative to
two different baseline fleets.
- A range of PM2.5-related benefit per ton values, based on two different PM-related mortality
  studies and the two different discount rates
- A supplemental analysis of Calendar Year PM2.5- and ozone-related benefits derived from air
  quality modeling (see Appendix 8A in the RIA)

In total, the agencies’ analysis found that the benefits of the final rulemaking, including fuel savings and
many other benefit categories such as the Social Cost of Carbon, far outweigh the costs of the standards.
See Table I-10 at Preamble Section I. D. (2).

11.1.3 Conceptual Framework

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Energy efficiency gap
The NPRM requests comment on the slow adoption of cost-effective technologies for reducing fuel consumption. CARB staff supports the hypothesis that the end-users are not adopting readily available, cost-effective energy efficiency technologies because they do not have full information regarding their costs and benefits (this economic situation is known as the “energy efficiency gap” or “energy paradox”). CARB staff also recognizes that in the highly diverse and specialized heavy-duty vehicle sector, no manufacturer wants to be the first to absorb high upfront research and development costs for new technologies that other manufacturers will subsequently utilize at lower costs (the “first-mover disadvantage”). Overall, CARB staff agrees these issues necessitate further research in order to better understand the heavy-duty vehicle sector and to identify potential strategies and mechanisms to speed the adoption of fuel efficient technologies. [EPA-HQ-OAR-2014-0827-1265-A1 p.182]

Organization: CALSTART

An additional consideration involves market barriers to change. Even technologies showing strong results and solid payback face resistance in a marketplace where risk avoidance remains high. As an example, there is now strong data showing that technologies such as post-transmission hybrids can achieve 15-35 percent fuel economy gains in the right vocational applications, and their costs are dropping below $20,000 and approaching in some cases $10,000. Yet overcoming market inertia likely requires early and innovative measures to encourage OEMs and fleets to take this step. [EPA-HQ-OAR-2014-0827-1190-A1 p.6]

Organization: Caterpillar Inc, et al.

Regulation must take into account total cost of ownership

Given the many challenges faced by truck fleets over the last decade due to factors such as fuel cost volatility, slow economic growth, fleet consolidation, increasing regulation, and higher labor costs associated with driver shortages and increased turnover, any fleet successfully competing in today’s market considers a total cost of ownership view of vehicle life-cycles. Fleets capture this data down to tenths of a cent per mile and use this information to determine their purchase timing and truck selection. The Phase 2 stringencies are predicated on the penetration of specific technologies with consideration for the impacts of fuel, maintenance, and product costs on the vehicle owners; however, they should consider additional costs associated with this very basic economic principle. [EPA-HQ-OAR-2014-0827-1215-A1 p.7]

In their cost assessments, the Agencies should consider other key factors that impact total cost of ownership. [EPA-HQ-OAR-2014-0827-1215-A1 p.7]

Organization: Competitive Enterprise Institute et al.

Most of the projected benefits are fuel savings for heavy duty vehicle (HDV) owners and operators. However, EPA and NHTSA provide no solid evidence that the trucking industry’s alleged “under-investment” in fuel-saving technology is due to market failure. In fact, some of the agencies’ “hypotheses” suggest that truckers are simply behaving like prudent buyers. [EPA-HQ-OAR-2014-0827-1251-A2 p.2]

As in the Phase 1 rulemaking, EPA and NHTSA ignore a more credible and obvious explanation of the alleged “energy efficiency gap.” EPA’s diesel-engine emission standards, both by directly reducing the fuel efficiency of diesel engines, and by crowding out fuel economy-related R&D investment and
consumer spending, created the problem the agencies purport to solve via additional regulation. [EPA-HQ-OAR-2014-0827-1251-A2 p.2]

III. The rule implies that truckers, like children, are incapable of discerning and/or pursuing their own best interest.

If the proposed rule will have no detectable effect on climate change or energy security, what is the point? The new standards will save truckers a bundle of money, EPA and NHTSA contend. According to their calculations, the rule will increase the cost of new trucks and trailers by $20 billion to $30 billion over the lifetimes of the vehicles, but it will also cut fuel consumption by more than 70 billion gallons, saving truckers approximately $90 billion to $170 billion in reduced fuel expenditures. In other words, truckers will reap net benefits of approximately $70 billion to $140 billion. [EPA-HQ-OAR-2014-0827-1251-A2 p.10]

This should immediately raise a red flag. Trucking companies are in business to make money. As the agencies acknowledge, “Unlike light-duty vehicles – which are purchased and used mainly by individuals and households – the vast majority of HDVs are purchased and operated by profit-seeking businesses for which fuel costs represent a substantial operating expense.” Indeed, for many truckers, fuel is the single biggest operating expense, exceeding drivers’ wages and benefits combined. [EPA-HQ-OAR-2014-0827-1251-A2 p.11]

If every dollar invested to improve fuel economy yields savings of $4-$6, why hasn’t the market already made those investments? If the agencies’ recommended package of fuel-saving technologies is such a great bargain, why do truckers need a regulation compelling them to buy it? [EPA-HQ-OAR-2014-0827-1251-A2 p.11]

The proposed rule implies that truckers, like children, are incapable of discerning and/or pursuing their own best interest. Or it implies that manufacturers are too dim or lazy to expand market share by developing vehicles that give their customers a competitive edge. [EPA-HQ-OAR-2014-0827-1251-A2 p.11]

EPA and NHTSA don’t put things that way, of course. As in the Phase 1 rulemaking, the agencies offer “hypotheses” drawn from economics literature to explain the “paradox” of under-investment in fuel economy. None of the explanations provides solid evidence of market failure. In fact, some indicate truckers are just behaving like prudent buyers. Let’s look at each in turn. [EPA-HQ-OAR-2014-0827-1251-A2 p.12]

IV. The agencies’ “hypotheses” neither demonstrate market failure nor persuasively explain the “paradox” of “under-investment.”

The agencies summarize five hypotheses. [EPA-HQ-OAR-2014-0827-1251-A2 p.12]
(1) Imperfect Information in the New Vehicle Market. One possible reason for the supposed underinvestment is that information “about the effectiveness of some fuel-saving technologies” is “inadequate or unreliable.” But if the relevant information is inadequate or unreliable, how do EPA and NHTSA know the rule will deliver billions in net benefits to truckers? [EPA-HQ-OAR-2014-0827-1251-A2 p.12]

The hypothesis implies that the agencies possess technical information unavailable to industry. That is implausible, because EPA has made considerable efforts since the early 2000s to share fuel-economy information with the trucking industry, its leading firms, and trade associations. Surely the agencies’ general position that fuel-saving technology more than pays for itself is now well known throughout the industry, which has been subject to fuel-economy regulation since 2011. [EPA-HQ-OAR-2014-0827-1251-A2 p.12]

Through its voluntary SmartWay Transportation Partnership Program, EPA “has worked closely with truck and trailer manufacturers and truck fleets over the last ten years to develop test procedures to evaluate vehicle and component performance in reducing fuel consumption and has conducted testing and has established test programs to verify technologies that can achieve these reductions.” The program is a partnership between EPA and the freight goods industry, including the American Trucking Association and 2,380 truck carrier firms. All of the top 25 U.S. long-haul trucking companies are SmartWay Partners. [EPA-HQ-OAR-2014-0827-1251-A2 p.12]

With all the ‘verified’ fuel-saving information EPA has been providing, semi-truck owners should exhibit the smallest gap between actual investment in fuel economy and what the agencies consider optimal. Yet that’s where the alleged “energy efficiency gap” is largest. EPA and NHTSA estimate the rule will save semi-truck owners $144.9 billion in fuel expenditures – seven times more than the rule will save vocational truck owners ($20.4 billion) and eight times more than it will save HD van and pickup owners($17.5 billion). [EPA-HQ-OAR-2014-0827-1251-A2 p.12]

Note: The agencies also assume long-haul truckers will reap the biggest return on investment. Semitruck owners will have to spend more ($12.7 billion) than vocational truck owners ($7.8 billion) and HD pickup and van owners ($4.9 billion) to comply with the rule. However, the projected benefit-cost ratio for semi-truck owners (11.4:1) substantially exceeds those for vocational trucks (2.6:1) and HD vans and pickups (3.5:1). So the gap is largest for that segment of the HDV market that has the most agency provided information. In short, the hypothesis does not explain why truckers (supposedly) under-invest in fuel-saving technology. [EPA-HQ-OAR-2014-0827-1251-A2 p.13]

(2) Imperfect Information in the Resale Market. The agencies hypothesize that buyers in the new vehicle market may not be willing to pay more for fuel-efficient vehicles if buyers in the used market are unwilling “to pay adequate premiums” for improved fuel economy. But why would buyers in the used market shun vehicles that (allegedly) repay the price premium many times over? [EPA-HQ-OAR-2014-0827-1251-A2 p.13]

To our knowledge, nobody claims the resale market fails to consider the value of technologies that enhance vehicle reliability, performance, comfort, and amenities. After all, people generally are willing to pay more for a better vehicle, whether it’s new or used. [EPA-HQ-OAR-2014-0827-1251-A2 p.13]
Why should fuel economy be the exception to the rule? Maybe fuel-saving technology doesn’t add much to the price of used trucks because its money-saving potential is unproven or over-rated. [EPA-HQ-OAR-2014-0827-1251-A2 p.13]

(3) Principal-agent problems causing split Incentives. According to this hypothesis, those who own trucks are often different from those who operate the vehicles. The agencies’ discussion here is terse. According to the Phase 1 rulemaking, operators may have “strong incentives to economize” on fuel consumption whereas owners may place a higher priority on capital investment that “improves vehicles’ durability or reduces their maintenance costs.” Even if such split incentives exist, it would still not necessarily follow that owners under-invest in fuel economy. [EPA-HQ-OAR-2014-0827-1251-A2 p.14]

There are tradeoffs — opportunity costs — in every investment decision. Whether it is smart to invest more or less in fuel economy relative to vehicle durability or any other value depends on each firm’s unique circumstances. As the Phase 2 rulemaking acknowledges, “In general, businesses that operate HDVs face a range of competing uses for available capital other than investing in fuel-saving technologies, and may assign higher priority to these other uses, even when investing in higher fuel efficiency HDVs appears to promise adequate financial returns.” Spot on. The agencies, however, do not seem to grasp what that observation implies. EPA and NHTSA are in no position to divine an appropriate tradeoff for the industry as a whole, because the right tradeoff varies from firm to firm, and within each firm at different times. [EPA-HQ-OAR-2014-0827-1251-A2 p.14]

Besides, just because truck operators make the actual fuel purchases does not necessarily mean owners ignore fuel costs. An owner may delegate many purchasing decisions for many things to other people. He is nonetheless responsible for the firm’s bottom line. The tradeoffs the firm makes between fuel economy and other investments inevitably show up in the firm’s balance sheets. [EPA-HQ-OAR-2014-0827-1251-A2 p.14]

Strangely, the Phase 2 rulemaking postulates a split incentive that works the other way – supposedly, owners care about fuel costs but drivers don’t unless offered “financial incentives.” That the literature on split incentives is itself split on whether principal or agent undervalues fuel economy is reason enough to be skeptical of this alleged market failure. [EPA-HQ-OAR-2014-0827-1251-A2 p.14]

(4) Uncertainty about Future Cost Savings. Another possible reason companies don’t adopt fuel-saving technology as fast as EPA and NHTSA deem appropriate is that “HDV buyers may be uncertain about future fuel prices, or about maintenance costs and reliability of some fuel efficiency technologies.” Thus buyers may discount potential future savings at higher rates than those used in the agencies’ analysis. “In contrast, the costs of fuel-saving or maintenance-reducing technologies are immediate and thus not subject to discounting.” Exactly! Whereas the costs of investment in fuel-saving technology are certain and immediate, the payoff depends on unknown quantities — the future price of fuel and, perhaps more importantly, the “lifetime, expected use, and reliability of the vehicle.” [EPA-HQ-OAR-2014-0827-1251-A2 p.14]

According to the previously cited report prepared for American Truck Dealers, owners of trucks and engines designed to meet EPA’s model year (MY) 2004 and 2007 emission standards experienced “significant reliability, operating cost, and fuel economy concerns.” [EPA-HQ-OAR-2014-0827-1251-A2 p.15]

For example, it has been reported that for the eighth largest carrier in the U.S., “maintenance costs for Schneider’s 2007 model trucks were about 28.2% higher than vehicles manufactured before October
Reliability is critical for commercial fleets and owner-operators both because of the costs of keeping trucks in operation and the even greater potential costs associated with out-of-service equipment. In addition to higher truck prices and operating costs, anticipated reliability issues are often cited as contributing to the marketplace disruptions discussed herein. Companies are just being prudent when they invest less in fuel-saving technology than they would if Congress required EPA and NHTSA to compensate truckers for every dollar of projected fuel savings that fails to occur. As the agencies acknowledge in the Phase 1 rulemaking, mandatory investment in fuel saving technology “requires purchasers to assume a greater level of risk than they would in its absence, even if the future fuel savings predicted by a risk-neutral calculation actually materialize.”

Companies are just being prudent when they invest less in fuel-saving technology than they would if Congress required EPA and NHTSA to compensate truckers for every dollar of projected fuel savings that fails to occur. As the agencies acknowledge in the Phase 1 rulemaking, mandatory investment in fuel saving technology “requires purchasers to assume a greater level of risk than they would in its absence, even if the future fuel savings predicted by a risk-neutral calculation actually materialize.”

Adjustment and Transactions Costs. According to this hypothesis, drivers may be slow or reluctant to make the operational adjustments required for effective use of new fuel-saving technologies, and owners may be reluctant to incur costs associated with driver training or faster fleet turnover. This hypothesis is tantamount to saying there are costs of innovation. That is true in general, yet competition continually drives firms in most industries to innovate or get left behind. What makes fuel-saving technology the exception to the rule? The Phase 1 rulemaking offers this explanation: “Because of the diversity in the trucking industry, truck owners and fleets may like to see how a new technology works in the field, when applied to their specific operations, before they adopt it.”

Yes! Companies want real — road-tested — information about alternative investments. As Phase 2 similarly acknowledges, “businesses that operate HDVs may be concerned about how reliable new technologies will prove to be on the road, and whether significant additional maintenance costs or equipment malfunctions that result in costly downtime could occur.”

Truckers, apparently, take the agencies’ benefit-cost estimates with several grains of salt. That does not surprise us. After all, EPA and NHTSA are stakeholders – organizations with an interest in the rules they develop and administer. Regulators have an incentive to over-estimate the benefits and low-ball the costs of their rules, for at least three reasons. (1) New regulations typically increase agencies’ power, prestige, budgets, and/or staff. (2) When mandated technology malfunctions and vehicles are taken out of service, it’s the owners, not the agencies, who must pay for repairs and risk losing customers. (3) Ideological zeal for ‘greening’ the U.S. transport system is honored in both agencies.

All of which is to say, the market is not failing when businesses choose to be guided by real-world results rather than agency forecasts. To their credit, the agencies’ Phase 1 rulemaking acknowledges that “there may be no market failure” in the risk-aversion induced by adjustment and transaction costs, which, unlike the promised payoffs from fuel-economy investments, “are typically immediate and undiscounted.”

V. Alternative hypothesis: EPA’s diesel-engine emission standards have hindered HDV fuel economy.

Trucking industry profit-margins are thin and fuel is the single biggest operating expense. Consequently, truckers, especially those who haul freight long distances in “combination tractors” (semis), should have a strong incentive to purchase vehicles incorporating cost-effective improvements in fuel economy, and manufacturers, in turn, should have a strong incentive to compete for their
business. Yet the agencies claim to find a gap between current fuel efficiency and what is technically achievable at reasonable cost. How can that be? [EPA-HQ-OAR-2014-0827-1251-A2 p.16]

To some extent truckers may just be behaving like prudent buyers, as discussed above. Many reportedly feel they have been burned by previous technology mandates. Before incurring the certain and immediate costs of purchasing agency-approved fuel-efficiency technology, they want to see results – how much fuel is actually saved and what are the longer-term effects on truck reliability and maintenance costs. [EPA-HQ-OAR-2014-0827-1251-A2 p.16]

Considerable evidence suggests another, complementary explanation: EPA’s emission-control standards for diesel trucks caused or contributed to the very problem – stagnant fuel economy – the agencies now propose to solve with more rules. The Competitive Enterprise Institute (CEI) presented a case for a ‘government failure’ hypothesis in its comment on the Phase 1 rulemaking. Because EPA’s Response to Comments either inadequately addressed or simply ignored some of CEI’s arguments, we will restate and update the alternative hypothesis here. [EPA-HQ-OAR-2014-0827-1251-A2 p.16]

Opportunity Costs: Manufacturers

Every dollar engine manufacturers spend on R&D to make vehicles compliant with EPA diesel emission standards is a dollar they cannot spend on R&D to increase HDV fuel efficiency. Such expenditures are substantial. [EPA-HQ-OAR-2014-0827-1251-A2 p.17]

- Engine manufacturers would spend $385 million over five years on HDV diesel-engine design R&D and $220 million in catalyst systems R&D, yielding a “total R&D outlay for improved emission control of more than $600 million.” [EPA-HQ-OAR-2014-0827-1251-A2 p.17]

- Each of 11 major engine manufacturers would spend $7 million annually to deploy a “team of more than 21 engineers and 28 technicians to carry out advanced engine research.” [EPA-HQ-OAR-2014-0827-1251-A2 p.17]

In other words, over a five-year period, up to $600 million that might have been invested in fuel economy R&D was instead invested in emission-control R&D. In addition, up to 540 engineers and technicians who might otherwise have spent all or much of their time developing fuel-saving technology instead likely spent all or much of their time developing emission-control technology. [EPA-HQ-OAR-2014-0827-1251-A2 p.17]

EPA’s enforcement actions also diverted substantial resources that might otherwise have been available to enhance fuel-saving technology. During the 1990s, seven major truck manufacturers sold 1.3 million trucks equipped with “defeat devices” that bypass or disable on-board emission control systems. “These devices altered the engines’ fuel injection timing and, while this improved fuel economy, it also increased nitrogen oxide emissions by two to three times the existing regulatory limits,” GAO explained. EPA launched what it described as the “largest Clean Air Act enforcement action” in its history. The case was settled via consent decrees under which the manufacturers agreed to pay $83 million in civil penalties, invest almost $110 million in NOX control R&D, and spend more than $850 million to produce cleaner engines by October 1, 2002. [EPA-HQ-OAR-2014-0827-1251-A2 p.17]
The booming market in unlawful defeat devices was itself a reflection of the high value long-haul truckers place on cost-effective fuel-saving technology. How ironic that EPA punished manufacturers who promoted fuel savings by mandating $1 billion in expenditures for technologies that did not enhance fuel efficiency or even (as discussed below) reduced it! [EPA-HQ-OAR-2014-0827-1251-A2 p.17]

**Opportunity Costs: Buyers**

Every dollar owners spend to buy and maintain trucks compliant with diesel emission standards is a dollar they cannot spend on improved fuel-saving technology. The RIA for the 2007-2010 emission standards estimated that the rule would increase vehicle cost by $3,230 in the first year, declining to $1,870 in later years, and increase operating costs by $4,600. [EPA-HQ-OAR-2014-0827-1251-A2 p.18]

In November 2008, NERA Economic Consulting published a report on customer responses to the 2007 rule. NERA found that the rule increased the unit cost of a Class 8 truck by $7,000 between MYs 2006 and 2007 – more than twice what EPA estimated. In addition, NERA projected that EPA’s 2010 NOX standard would increase the cost of a Class 8 truck by another $7,000-$10,000. [EPA-HQ-OAR-2014-0827-1251-A2 p.18]

In March 2010, Kevin Jones, a reporter for The Trucker magazine, interviewed Daimler Trucks North America President and CEO Martin Daum at the Louisville, Ky. Mid-America Trucking Show. Daum told Jones that EPA’s emission standards added $20,000 to the cost of an 18-wheeler over the previous six years. As noted above, the 2012 report for American Truck Dealers estimates that during 2004-2010, EPA emission standards cumulatively increased the cost of Class 8 trucks by more than $21,000. [EPA-HQ-OAR-2014-0827-1251-A2 p.18]

Clearly, the standards took large bites out of customers’ budgets – dollars truckers could not spend on fuel-saving technology. The regulation-induced increase in the cost of new trucks since 2004 is roughly twice the estimated cost of the technology upgrades semis will have install to comply with the Phase 2 GHG/fuel economy rule. [EPA-HQ-OAR-2014-0827-1251-A2 p.18]

Truckers also incurred significant reliability and maintenance costs as a result of the penalties EPA imposed on the manufacturers who installed fuel-saving defeat devices. As part of the settlement agreement, manufacturers agreed to “accelerate by 15 months the schedule for meeting new, more stringent engine standards to October 2002 instead of the original mandatory date of 2004.” According to GAO, “Trucking companies maintain they need 18 to 24 months to road test an engine’s reliability in all weather and operating conditions and to develop their future purchasing plans.” The consent decree did not allow time for adequate road-testing, and many truckers experienced costly engine problems. [EPA-HQ-OAR-2014-0827-1251-A2 p.18]

For example, one company reported that roughly one-half of its 140 new heavy-duty engines experienced an engine valve failure prior to 50,000 miles. In addition, these officials noted that roughly 20 percent of their heavy-duty vehicles with the new engines are out of service at any given time due to maintenance concerns, compared to 5 percent for the remainder of their fleet. Several of these officials expressed a concern that some companies may have difficulty absorbing increased costs from such maintenance problems. [EPA-HQ-OAR-2014-0827-1251-A2 p.19]

**Tradeoff: Emission Standards and Fuel Economy**
In its Response to Comments (RTC) on the Phase 1 rulemaking, EPA acknowledged but summarily dismissed CEI’s hypothesis that mandatory investment in pollution control “crowds out” investment in fuel economy: [EPA-HQ-OAR-2014-0827-1251-A2 p.19]

Only if access to capital is significantly constrained would the industry consider these as alternative investments. The same principles apply for access to expertise: truck companies could hire additional engineers and technicians to work on either fuel efficiency or emissions reduction. In the absence of evidence of “crowding out” of investments in fuel economy, we are left with the puzzle of what appears to be a great deal of lack of adoption of cost-effective fuel saving technology.66 [EPA-HQ-OAR-2014-0827-1251-A2 p.19]

That response is unpersuasive. Regulatory mandates can have disruptive impacts on the market for new vehicles, leading to surges in buying pre-compliant vehicles (“pre-buying”) followed by revenue losses and layoffs (“sales cliffs”). As the agencies acknowledge: [EPA-HQ-OAR-2014-0827-1251-A2 p.19]

Several of the heavy-duty vehicle manufacturers, fleets, and commercial truck dealerships informed the agencies that for fleet purchases that are planned more than a year in advance, expectations of reduced reliability, increased operating costs, reduced residual value, or of large increases in purchase prices [as a result of technology mandates] can lead the fleets to pull ahead by several months planned future vehicle purchases by pre-buying vehicles without the newer technology. In the context of the Class 8 tractor market, where a relatively small number of large fleets typically purchase very large volumes of tractors, such actions by a small number of firms can result in large swings in sales volumes. Such market impacts would be followed by some period of reduced purchases that can lead to temporary layoffs at the factories producing the engines and vehicles, as well as at supplier factories, and disruptions at dealerships.69 [EPA-HQ-OAR-2014-0827-1251-A2 p.19]

The report prepared for American Truck Dealers contains a chart showing the regulation-induced surge in pre-buy orders before consent decree standards took effect in 2002, followed by a slump, and another surge in pre-buy orders in 2006 before the MY 2007 standards took effect, again followed by a slump.70 [EPA-HQ-OAR-2014-0827-1251-A2 p.19-20]

[Figure 1, 'Annual US Retail Sales for Class 4-8 Heavy-Duty Trucks', can be found on p.20 of docket number EPA-HQ-OAR-2014-0827-1251-A2]

Manufacturers experienced non-trivial employment impacts as a consequence of the pre-buy/sales cliff swings: [EPA-HQ-OAR-2014-0827-1251-A2 p.20]

For example, when faced with declining sales following the pre-buy, Volvo laid off 300 workers in March of 2001 and another 300 workers in April of that year. In 2006, Volvo’s Deputy Chief Executive Officer warned that the new environmental regulations would cause such a precipitous decline in sales that Volvo would have no choice but to lay off more people. Volvo ended up laying off nearly 600 workers in 2006; the direct result of the new emissions mandates. Also in 2006, Peterbilt cut their workforce by almost half. Freightliner laid off nearly 1,800 workers in 2007, followed by another layoff of 2,100 workers, and the complete shut down a manufacturing plant in 2009.71 [EPA-HQ-OAR-2014-0827-1251-A2 p.20]

Clearly, EPA emission standards have the power to “significantly constrain” manufacturers’ sales and work forces in particular years. Why should access to capital and expertise be immune to such effects? As a general matter, moreover, we find it hard to believe manufacturers would incur no opportunity
costs from continual increases in regulatory stringency and a $1 billion enforcement action. [EPA-HQ-OAR-2014-0827-1251-A2 p.20]

The RTC simply ignores the other side of the equation – the opportunity cost imposed on truck buyers by emission standards that increase the cost of new vehicles. [EPA-HQ-OAR-2014-0827-1251-A2 p.20]

More importantly, the RTC also ignores the point, widely acknowledged in the literature, that it is difficult and/or costly to boost (or maintain) diesel fuel economy while reducing diesel emissions. Consider this excerpt from a paper by diesel emission-control expert W. Addy Majewski: [EPA-HQ-OAR-2014-0827-1251-A2 p.21]

We should also mention that there is a certain cost for meeting these ambitious emission standards with future diesel engines. This cost consists of two components: (1) the cost of the emission control equipment and (2) a fuel economy penalty. The first component can vary greatly depending on the technology (some of which relies on expensive precious metal catalysts). The fuel economy penalty may be derived from a number of sources. First, traditionally there has been a correlation between engine-out NOX emissions and fuel consumption in the diesel engine, where higher engine efficiency and better fuel economy are associated with higher NOX. Second, exhaust after-treatment devices are associated with a varying additional fuel economy penalty caused by such factors as increased pressure drop and energy consumption for the regeneration of filters and/or NOX adsorbers. In the case of SCR catalysts, while there may be no direct fuel economy penalty, operating costs are increased by the cost of urea. [EPA-HQ-OAR-2014-0827-1251-A2 p.21]

Despite decades of technological advances, the Volkswagen scandal indicates that emission standards continue to impose a fuel-economy tradeoff on diesel-powered passenger vehicles. Why did VW take the insane risk of installing unlawful defeat devices in 11 million vehicles? Apparently, VW believed cheating on emissions tests was the only way to give consumers all the fuel-economy and performance they wanted at prices they could afford. As a recent article in Wired explains: [EPA-HQ-OAR-2014-0827-1251-A2 p.21]

Once the sting of the lie fades, the US customers who bought 482,000 of those cars will feel the real pain. Because Volkswagen will be forced to recall those vehicles and somehow make them meet federal standards. There are two apparent ways to do that, and owners who value performance, fuel economy, and trunk space won’t like either. [EPA-HQ-OAR-2014-0827-1251-A2 p.21]

One is to “reflash” the engine control module, recalibrating the software so the car always runs the way it does during EPA testing, and always meets emission standards. [EPA-HQ-OAR-2014-0827-1251-A2 p.21]

The downside here is that to achieve the drastic drop in NOX emissions, the cars in test mode sacrificed some fuel economy, or performance. Just how much is hard to say, but any drop in torque – one great thing about diesels is how they accelerate off the line – will not make drivers happy. And a drop in mileage would likely cost VW, since hundreds of thousands of drivers would have to spend more on fuel than VW promised at the time of sale. . . . [EPA-HQ-OAR-2014-0827-1251-A2 p.21]

The standard way of making a diesel run cleanly is to use selective catalytic reduction, a chemical process that breaks NOX down into nitrogen and water. Part of that process includes adding urea to the mix. The super effective system can eliminate 70 to 90 percent of NOX emissions, and is used by other diesel manufacturers like Mercedes and BMW. The downside is that it adds complication to the system,
and cost – $5,000 to $8,000 per car. And you need to periodically add the urea-based solution to your
car to keep it working.\footnote{EPA-HQ-OAR-2014-0827-1251-A2 p.21-22}

GAO’s report on EPA’s 1998 enforcement action against truck manufacturers who sold 1.3 million
illegal defeat devices has already been noted. That this unlawful practice was the industry norm for
years also attests to a non-trivial tradeoff between lower emissions and higher mileage.\footnote{EPA-HQ-OAR-
2014-0827-1251-A2 p.22}

As mentioned, because the settlement agreement accelerated from January 2004 to October 2002 the
schedule for producing less polluting vehicles, which did not allow truck owners adequate time to
roadtest those vehicles, owners engaged pre-buying. In the months preceding the October 2002
deadline, demand for new vehicles with older technology surged. According to GAO, roughly 19,000 to
24,000 (20%-26%) of the 93,000 large semis (Class 8 trucks) produced during April to September 2002
were prebuys. Conversely, sales of compliant vehicles after the deadline were much lower than EPA
had projected. Data for the first 13 of the 15 months “show that about 148,000 fully or partially
compliant heavy-duty diesel engines are on the road, compared to EPA’s estimate of 233,000 such
compliant engines for the entire 15-month time frame.”\footnote{EPA-HQ-OAR-2014-0827-1251-A2 p.22}

GAO found three main reasons for the pre-buy surge: (1) Trucks equipped with older emission-control
technology costs several thousand dollars less than trucks with the new emission-control technologies;
(2) the settlement agreement did not give the market time to sort out the effects of the new technologies
on truck durability and maintenance; and (3) the technologies were expected to reduce fuel economy.

\textbf{The four companies that pre-bought large numbers of trucks before the October 2002 deadline did so
primarily because they were concerned about the higher price and unproven reliability of the new
engines, according to company officials. They said that the new engines would have added from $1,500
to $6,000 to the purchase price of a new heavy-duty truck—whose base cost is about $96,000—and
would have reduced fuel economy by 2 to 10 percent. For 2002, these additional costs could have
ranged from about $4 million to $27 million per company in purchase price and about $3 million to $90
million per company in fuel costs. These trucking officials said that these additional costs would have
been problematic for some companies because, according to one representative, the industry only
returns 3 or 4 cents per dollar invested.}\footnote{EPA-HQ-OAR-2014-0827-1251-A2 p.22}

Industry expected further adverse impacts on fuel economy from EPA’s 2007 diesel emission standards
rule:\footnote{EPA-HQ-OAR-2014-0827-1251-A2 p.23}

Because the technologies needed to meet the 2007 standards are much more advanced than those
associated with prior upgrades, the trucking companies are concerned that the new engines will cost
much more and decrease fuel efficiency much more than EPA predicted in 2000 when it was developing
the standards. Consequently, according to representatives of 9 of the 10 trucking companies we
contacted, companies most likely will once again decide to buy trucks before the deadline, but in larger
numbers than they did in response to the consent decrees. This could again disrupt markets and
postpone needed emissions reductions.\footnote{EPA-HQ-OAR-2014-0827-1251-A2 p.23}

Specifically, trucking industry representatives opined that the 2007 standards would reduce fuel
efficiency by 3-5%. That’s a big deal for an industry where fuel is the single biggest operating expense
and profit margins can be as low as 2 cents per dollar earned: \footnote{EPA-HQ-OAR-2014-0827-1251-A2
p.23}
In addition, these officials are concerned that the 2007 trucks will experience another 3 to 5 percent loss in fuel economy — added to the 3 to 5 percent loss resulting from the consent decrees — that could increase their companies’ fuel costs by millions of dollars per year. Even minor increases in business costs can have adverse effects in the trucking industry, according to trucking industry officials we contacted, because these companies’ profit margins are very narrow — sometimes only 2 cents per dollar earned. The officials claim that the highly competitive nature of the trucking business precludes companies from passing such significant cost increases to their customers. [EPA-HQ-OAR-2014-0827-1251-A2 p.23]

In short, the industry representatives interviewed by GAO estimated the 2007 Rule combined with the consent decree could lower heavy-truck fuel economy by as much as 10%. [EPA-HQ-OAR-2014-0827-1251-A2 p.23]

In April 2007, Robert Guy Matthews reported in the Wall Street Journal that new trucks compliant with EPA diesel emission standards “got worse mileage” than older trucks. The fuel-economy penalty was big enough to affect company bottom lines: [EPA-HQ-OAR-2014-0827-1251-A2 p.23]

Previous-generation trucks average about nine or 10 miles to each gallon of diesel fuel. New engines designed to meet the more-stringent federal mandate on truck exhaust get about one mile less to the gallon. That may not seem like much, but it all adds up for large fleet owners that operate trucks crisscrossing the country. [EPA-HQ-OAR-2014-0827-1251-A2 p.23]

“For every additional mile-per-gallon lost, it costs us about $10 million in [total annual] fuel costs,” said YRC Worldwide Chief Executive Bill Zollars. YRC is one of the largest transportation providers in the country, operating a fleet of 20,000 trucks. . . . [EPA-HQ-OAR-2014-0827-1251-A2 p.23]

Freightliner LLC, the largest heavy-duty truck maker in North America, confirmed that some loss of fuel economy was inevitable for engines to comply with the new standards. Certain parts of the engine must run at a higher temperature to burn off pollutants, and that requires more fuel. [EPA-HQ-OAR-2014-0827-1251-A2 p.23]

EGR systems may be effective at reducing NOX emissions, but they undeniably reduce the fuel economy performance that would otherwise have been achieved. For example, Judy McTigue, director of marketing and planning research for Kenworth Trucks, stated that “2007-compliant engines equipped with exhaust gas recirculation systems suffered a fuel economy penalty of 5% to 9%.” EGR systems also contributed to a loss of 50 to 100 horsepower from heavy-duty engines. [EPA-HQ-OAR-2014-0827-1251-A2 p.24]

If we also factor in the opportunity costs of EPA’s emission standards program — foregone investment in fuel-saving technology R&D, foregone purchases of more fuel-efficient trucks – it is possible that EPA’s regulatory and enforcement actions account for all of perceived problem of lagging fuel economy in the heavy truck sector. Were it not for truckers’ use of regulatory avoidance strategies – buying trucks equipped with defeat devices in the 1990s, pre-buying older engines, and low-buying compliant engines
in the 2000s — heavy-truck fuel economy might be even lower. [EPA-HQ-OAR-2014-0827-1251-A2 p.24]}

EPA and NHTSA acknowledge the reality of a “NOX- CO₂ tradeoff,” but only as a rationale for using the “same test procedures” for both NOX and CO₂ to discourage engine manufacturers from gaming emission tests. [EPA-HQ-OAR-2014-0827-1251-A2 p.24] They discuss several “hypotheses” to explain industry’s alleged “under-investment” in fuel-saving technology without ever wondering whether the regulatory environment in which truckers operate might have something to do with it. [EPA-HQ-OAR-2014-0827-1251-A2 p.24]

Substantial evidence indicates that, during the 2000s, EPA’s diesel-truck emission standards held back HDV fuel efficiency and imposed significant opportunity costs on both manufacturers and truckers. Insofar as there is an “energy-efficiency gap,” it appears to be an example of regulation-induced government failure rather than of market failure. [EPA-HQ-OAR-2014-0827-1251-A2 p.25]

64 Draft RIA, p. 7-4
In these comments, the Consumer Federation of America (CFA) demonstrates the increasing fuel economy of medium and heavy duty trucks (work trucks) is an important consumer issue and that the proposal by EPA/NHTSA will yield substantial benefits to consumers. CFA takes a uniquely consumer approach to the analysis of performance standards, that asks a basic set of questions, always starting with the consumer pocketbook question: 

- Will increasing fuel economy save consumers money? Yes, and a well-designed performance standard will address the clear “efficiency gap in the work truck market. [EPA-HQ-OAR-2014-0827-1336-A1 p.3]
Our analysis of these questions in the work truck market shows that EPA/NHTSA has taken the correct approach and set a standard that is highly beneficial to consumers. While we fully support the standard, the fact that the cost per gallon of saved fuel is only $0.47 and the benefits are six time larger than the costs, leads us to call on EPA/NHTSA to provide better documentation and support for the decision not to set the standards at a higher level. [EPA-HQ-OAR-2014-0827-1336-A1 p.3]

In Section II, we estimate the potential benefits of increasing fuel economy in work trucks based on several sources including the EIA Residential Consumption Survey, the Department of Transportation’s, National Household Transportation Survey; the Energy Information Administration’s Annual Energy Outlook; the Bureau of Labor Statistics’ Consumer Expenditure Survey; and the U.S. Department of Transportation’s, Bureau of Transportation statistics each of which estimates fuel usage by types of vehicles. [EPA-HQ-OAR-2014-0827-1336-A1 p.3]

On a per household basis, we estimate that the cost of fuel consumed by work trucks is equal to almost half as much as households spend on gasoline and almost as much as they spend on electricity. [EPA-HQ-OAR-2014-0827-1336-A1 p.3]

Moreover, our analysis in Section III leads us to believe that these fuel costs are recovered from consumers in the cost of goods and service that rely on work trucks. The pass-through of costs is suggested and supported by analysis of macro-economic models and widely documented elasticities of demand. [EPA-HQ-OAR-2014-0827-1336-A1 p.3]

Respondents to national random sample surveys commissioned by CFA understand that they pay for big truck fuel in the cost of goods and services, and they support standards to improve truck fuel economy. The vast majority of the public (over 90%) understand that “some, most, or all” of the fuel costs of heavy-duty trucks, which transport virtually every consumer good, are passed on to consumers. In both of the CFA surveys, consumers clearly understood the possibility of these savings as nearly three quarters of the respondents favored requiring truck manufacturers to increase the fuel economy of large trucks. [EPA-HQ-OAR-2014-0827-1336-A1 p.3]

As discussed in Section IV, studies by half a dozen research organizations, including industry groups, the National Research Council, EPA/NHTSA, indicate that a substantial reduction in work truck energy consumption could be achieved at relatively low cost by adopting technologies that are currently available. So we look to answer the next logical questions about closing the efficiency gap: [EPA-HQ-OAR-2014-0827-1336-A1 p.3]

. Why is there an efficiency gap that appears to impose unnecessary costs on consumers? Because the work truck market exhibits numerous important market imperfections. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

Studies of the trucking sector that are summarized in Section IV indicate that there are market barriers, imperfections and obstacles that prevent these beneficial technologies from penetrating the work truck market. Table ES-1, shows the barriers are numerous and substantial. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

[Table ES-1 can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

. Is a standard an appropriate policy and, if so, is the proposed standard well-designed to achieve the goal of lowering consumer cost? Yes, EPA/NHTSA have taken an approach that will deliver significant
consumer savings. The only question is whether they should have chosen higher levels of fuel efficiency to deliver larger economic and environmental benefits. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

Our research, summarized in Section V, shows that performance standards are an ideal approach to overcoming the barriers to efficiency investments when the exhibit six characteristics. They need to be: long-term, technology neutral, product neutral, responsive to industry needs, responsive to consumer needs, pro-competitive. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

Based on our evaluation of the Phase II standard, in Section VI and summarized in Table ES-2, we conclude that EPA/NHTSA have done an excellent job designing the standards. While large additional potential savings lead us to call on the agencies in Section VII to give a hard second look at the factors that led them to not push the industry harder, the huge efficiency gap underscores the importance of the major advances the agencies have made in the economic analysis, including: [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

[Table ES-2 can be found on p.6 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

- Discount rate: Recognizing real world consumer discount rate of 3% and market imperfections driving observed discount rate. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

- Macroeconomic analysis: Reconciling important benefit of expansion of macroeconomic activity resulting from greater fuel economy with realistic assessment of the rebound effect. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

- National security: Looking carefully at the impact of imports on national security and consumption externalities created by large U.S. role in petroleum markets. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

- Effective design of standards: Designing standards that “command but do not control,” thereby unleashing forces of competition to ensure least cost implementation. [EPA-HQ-OAR-2014-0827-1336-A1 p.4]

**ACHIEVING FUEL COST SAVINGS WITH EFFICIENCY STANDARDS**

With such large potential economic gains available, this section offers answers to two important questions based on the reviews of freight truck sector by several major research institutions: [EPA-HQ-OAR-2014-0827-1336-A1 p.33]

- Why don’t market forces drive these technologies into the vehicles? [EPA-HQ-OAR-2014-0827-1336-A1 p.33]

- What policies can be implemented to achieve the economic gains? [EPA-HQ-OAR-2014-0827-1336-A1 p.33]
The evidence they provide is clear: [EPA-HQ-OAR-2014-0827-1336-A1 p.33]

. The medium/heavy duty truck market exhibits significant market obstacles, barriers and imperfections that inhibit investment in energy saving technologies, and [EPA-HQ-OAR-2014-0827-1336-A1 p.33]

. Performance standards are a very effective tool for overcoming these obstacles. [EPA-HQ-OAR-2014-0827-1336-A1 p.33]

We examined these questions at length in our comments supporting the recently adopted light duty vehicles efficiency standard.\(^23\) A recent paper on performance standards\(^24\) identified over three dozen market barriers, imperfections and other causes of market failure in the residential appliances and buildings, light duty vehicles and industrial sectors. Here we add the important findings from the medium/heavy duty truck sector to our earlier analysis. [EPA-HQ-OAR-2014-0827-1336-A1 p.33]

EXTERNALITIES LEAD TO UNDERINVESTMENT IN FUEL SAVING TECHNOLOGIES

Externalities as the source of market failure are well grounded in traditional economic analysis. These analyses of benefits and costs reviewed in the previous section recognize that externalities play a key part in driving policies to spur investment in energy saving technologies, but they focus on other obstacles to investment. Externalities are factors that are not directly included in typical cost-benefit analysis of business investment decisions. In the case of investing in fuel efficient technologies, the failure to consider externalities leads to the undervaluation of improving energy efficiency from the societal point of view and a resulting underinvestment in efficiency because these benefits do not factor into typical and immediate business decisions. Because these considerations never enter into business calculations, they are considered market failures. They are distinct from cases where businesses do make the calculations, but arrive at the results that fail to invest in cost beneficial technologies for any of a variety of reasons. Different authors apply different labels to the various types of obstacles that inhibit investment but the underlying obstacles are similar.\(^25\) [EPA-HQ-OAR-2014-0827-1336-A1 p.33-34]

There are negative externalities that result from fuel consumption which do not enter into the typical business cost/benefit calculations, for example: tail pipe emissions create environmental and health problems. An externality that is unique to transportation fuel is the national security implications of dependence on oil imports. While externalities are generally not factored into business decision making, from a societal perspective they can, and should, be an important factor in standard development. [EPA-HQ-OAR-2014-0827-1336-A1 p.34]

While these negative externalities that are reduced by high fuel economy receive the most attention, our focus in the prior section was on positive economic externalities. Investment in energy efficiency creates benefits for the broad public for which the firm making the investment cannot charge. As a result, the indirect macroeconomic effects of energy efficiency do not enter into typical cost/benefit decisions about investing in energy efficient technologies. While transportation companies capture some of the benefits in increased demand for their services, each company captures, at best, only a small part of the broader economic stimulus that reducing fuel consumption would cause. Therefore, such a benefit would be absent in each company’s typical internal cost benefit analysis of fuel saving technology. This category of externalities has expanded recently well beyond the public goods aspect that was identified in traditional economic analysis to include information and learning, network effects and innovation process. [EPA-HQ-OAR-2014-0827-1336-A1 p.34-35]
Similarly, U.S. consumption of transportation fuels is sufficiently large that a reduction in the quantity consumed has the effect of lowering the global (and therefore the national) price of crude oil. The public enjoys a large benefit, but the firms investing in efficiency receive only a small part of that total benefit because each individual firm receives a very small share of the total. This is called a consumption externality.\textsuperscript{26} [EPA-HQ-OAR-2014-0827-1336-A1 p.36]

In the freight truck sector, the link between efficiency induced fuel cost savings and positive economic impacts is particularly strong. Transportation is an important intermediate service. When truckers drive more, they are very likely to be carrying more goods or delivering more services, which means that the economy is expanding. Where the increase in truck freight results from a shift between transportation modes, it likely reflects the selection of a more efficient mode, which again indicates an improvement in the economy. [EPA-HQ-OAR-2014-0827-1336-A1 p.36]

**MARKET OBSTACLES, BARRIERS AND IMPERFECTIONS INHIBITING INVESTMENT**

In all of the economic analyses of efficiency discussed earlier, only direct economic costs and benefits were included. No value was placed on environmental or national security benefits; however these are significant additional benefits. Even though we did not include externalities in the cost benefit calculation, we found that the benefits far exceeded the costs. EPA reached exactly the same conclusion in the Phase I analysis. Since externalities cannot explain the failure of firms to invest in these attractive technologies, EPA shifts it attention to the other factors that inhibit investment. [EPA-HQ-OAR-2014-0827-1336-A1 p.36]

Not surprisingly, given the strong evidence of many factors that inhibit efficiency in the other sectors demonstrated in our earlier analysis,\textsuperscript{29} we find strong support for similar factors in the medium and heavy duty truck sector. Table V-1 shows the results of the analysis of the obstacles to investment in efficiency in the medium/heavy duty truck sector prepared by three major independent institutions. It also identifies the major documents upon which they rely. We also include the EPA/NHTSA Phase I analysis of the truck market, which has been vetted through litigation. In constructing this table, we use the same criteria as we applied in the analysis of Performance Standards – including empirical studies or summaries of the empirical literature from the past ten years. These studies support our findings in several important ways. [EPA-HQ-OAR-2014-0827-1336-A1 p.36]

[Table V-1 can be found on p.37-38 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

While some argue that there are no market barriers and imperfections to inhibit investment in energy saving technologies in the medium and heavy duty truck sector,\textsuperscript{30} the failure to make the previously cited investment in technologies, in spite of their clear benefits, indicates that there are significant inhibitors at work that have created an “efficiency gap.” [EPA-HQ-OAR-2014-0827-1336-A1 p.38]

In the Phase I analysis, EPA identified six broad categories of factors that have been offered as explanations for the failure of the truck market to pursue investment opportunities in fuel saving technologies that appear to be cost effective. The other major analyses identify these obstacles and several more, adding a great deal of detail. The findings from the medium and heavy duty truck sector reinforce several of the key aspects of our earlier analysis. [EPA-HQ-OAR-2014-0827-1336-A1 p.38-39]

The analysis involves commercial enterprises, which affirms the fact that economic motivation alone does not ensure optimum investment in efficiency. [EPA-HQ-OAR-2014-0827-1336-A1 p.39]
o Many of the same factors are confirmed as important obstacles to energy saving investment on both the supply and the demand sides of the market. [EPA-HQ-OAR-2014-0827-1336-A1 p.39]

o The supply and the demand sides interact and reinforce each other in a vicious circle. Policies that can break the circle are extremely attractive. [EPA-HQ-OAR-2014-0827-1336-A1 p.39]

o The diffusion of innovation unfolds as a process in which the early challenge is to provide reliable, verifiable information to trigger the diffusion process. Experience allows the sharing of information later in the process, which creates different challenges. [EPA-HQ-OAR-2014-0827-1336-A1 p.39]

The Environmental Protection Agency and the National Highway Traffic Safety Administration (EPA/NHTSA) examined the evidence that these barriers affect the truck market and summarized their conclusion as follows: [EPA-HQ-OAR-2014-0827-1336-A1 p.39]

On the other hand, the short payback period required by buyers of new trucks is a symptom that suggests some combination of uncertainty about future cost savings, transaction costs, and imperfectly functioning market. In addition, widespread uses of tractor-trailer combinations introduces the possibility that owners of trailers have weaker incentives than truck owners to adopt fuel-saving technology for their trailers...[EPA-HQ-OAR-2014-0827-1336-A1 p.39]

Because individual results of new technologies vary, new truck purchasers may find it difficult to identify or verify the effects of fuel saving technologies. Those who are risk averse are likely to avoid new technologies out of a concern over the possibility of inadequate returns on the investment, or with other impacts....[EPA-HQ-OAR-2014-0827-1336-A1 p.39]

Both baselines used project substantially less adoption than the agencies consider to be cost-effective. The agencies will continue to explore reasons for this slow adoption of cost-effective technologies.31 [EPA-HQ-OAR-2014-0827-1336-A1 p.39]

The report from the International Council on Clean Transportation summarized the supply-and demand side factors that inhibit innovation with a simple graph that depicts a recursive loop of factors that reinforce one another, as shown in Figure V-1. [EPA-HQ-OAR-2014-0827-1336-A1 p.39]

[Figure V-1 can be found on p.41 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

Given the thorough review by EPA/NHTSA, the NRC, and the International Council for Clean Transportation, as well as our own, suffice it to say that there is a significant energy efficiency gap in the medium and heavy duty truck market and there is no reason to doubt the economic analysis of the potential benefits of closing that gap. In fact, the benefits have likely been underestimated, not only because the full value of externalities has not been included in the economic analyses, but also because the costs of implementing the standards have likely been overestimated, as discussed below. [EPA-HQ-OAR-2014-0827-1336-A1 p.41]

PERFORMANCE STANDARDS AS A POLICY TOOL TO OVERCOME OBSTACLES TO INVESTMENT

These reviews of the literature on obstacles to investment in efficiency in the medium and heavy duty truck sector also identify and discuss the ways that performance standards can improve the market performance. The regulatory analyses are required to consider alternatives. They do not conclude that the alternatives (like simple information programs) will have no impact, but that the alternatives do not
address key obstacles effectively. As we showed in our Performance Standards paper, standards are attractive because they effectively address a wide range of obstacles. As shown in Table V-1, above, in the medium/heavy duty truck sector these beneficial effects include the following: [EPA-HQ-OAR-2014-0827-1336-A1 p.41-42]

- Partially internalize the externalities
- Provides experience with the new technologies, lowering hidden costs.
- Creates the market by embedding the technology in products, thereby lowering marketplace risk and risk of being the first mover.
- Triggers learning and economies of scale that lower cost
- Generates and makes available reliable information in a standardized manner
- Fosters cooperation, as the efficiency attribute is given higher visibility [EPA-HQ-OAR-2014-0827-1336-A1 p.42] [EPA-HQ-OAR-2014-0827-1336-A1 p.42]

We believe that one of the other major findings of our earlier analysis of fuel economy and performance standards applies in the medium/heavy duty truck sector as well. In order to effectively achieve the large net benefits, performance standards must be well-designed and carefully implemented. The following characteristics, which were critical for the success in the adoption of fuel economy standards for automobiles and light duty trucks, can successfully guide the development of performance for medium and heavy duty trucks: [EPA-HQ-OAR-2014-0827-1336-A1 p.42] [EPA-HQ-OAR-2014-0827-1336-A1 p.42]

**Long-Term:** Setting a progressively rising standard that targets a high long term goal over the course of a decade or more will foster and support a long-term perspective for the truck manufacturers, transportation companies and public, by reducing the marketplace risk of investing in new technologies. The long-term view gives the truck makers time to re-orient their thinking, retool their plants and help re-educate the transportation industry. It also gives the industry buying and using these trucks time to adjust. [EPA-HQ-OAR-2014-0827-1336-A1 p.42]

**Technology Neutral:** Taking a technology neutral approach to a long term standard unleashes competition around the standard that ensures that the industry will get a wide range of choices at that lowest cost possible. [EPA-HQ-OAR-2014-0827-1336-A1 p.42]

**Product Neutral:** The new attribute-based approach to standards accommodates buyer preferences; it does not try to supplant them. This levels the playing field between truck makers and removes any pressure to push inappropriate vehicles into the market. [EPA-HQ-OAR-2014-0827-1336-A1 p.43]

**Responsive to industry needs:** As was done in the light vehicle standards, establishing a long term performance standard recognizes the need to keep the standards in touch with reality. The standards can be set at a moderately aggressive level that is clearly beneficial and achievable. With thoughtful cost estimates, consistent with the results of independent analyses of technology costs, a long term performance standard will contribute to the significant reduction of the most significant cost in the transportation industry. [EPA-HQ-OAR-2014-0827-1336-A1 p.43]

**Responsive to consumer needs:** The approach to standards should be consumer-friendly and facilitate compliance. The attribute-based approach ensures that the standards do not require radical changes in the available products or the product features that will be available to consumers. The setting of a coordinated national standard that lays out a steady rate of increase over a long time period giving the market and the industry certainty and time to adapt to change. [EPA-HQ-OAR-2014-0827-1336-A1 p.43]
Procompetitive: All of the above characteristics make the standards pro-competitive. Producers have strong incentives to compete around the standard to achieve them in the least cost manner, while targeting the market segments they prefer to serve. [EPA-HQ-OAR-2014-0827-1336-A1 p.43]

THE COSTS OF IMPLEMENTING STANDARDS

A final, important observation on the literature of performance standards before we turn to the Phase II proposed rule deals with the tendency for costs to be overestimated because well-designed standards trigger the competitive and innovative processes noted above. The analysis often presented in regulatory proceedings is typically static and based on current costs. On the other hand, a thoughtful, well-designed performance standard will be dynamic and facilitate multiple responses to standard compliance rather than mandate specific technologies. If companies are given broad flexibility to meet standards, they will determine the most cost beneficial approach and they will learn how to lower the cost of adopting new technologies. History has shown in virtually every other standard compliance effort, the initial cost estimates always prove to have been too high, as shown in Figure V-2. There is clear and consistent evidence across a wide range of standards that the actual costs of implementing standards were consistently well below their original projections. [EPA-HQ-OAR-2014-0827-1336-A1 p.43-44] [This comment can also be found in section 11.3 of this comment summary.]

[Figure V-2 can be found on p.44 of docket number EPA-HQ-OAR-2014-0827-1336-A1] [This comment can also be found in section 11.3 of this comment summary.]

We then examine the explanation (theory) offered for why these costs and benefits have not been reflected in market transactions. Here we address both the issue of market imperfections and the pass-through of fuel costs. [EPA-HQ-OAR-2014-0827-1336-A1 p.45] [This comment can also be found in section 11.3 of this comment summary.]

Finally, we evaluate the overall design of the rule, according to the six criteria identified in the previous section. Because there are potentially large additional savings, we conclude with a section devoted to the question of whether the agencies have set the standards at a sufficiently high level. [EPA-HQ-OAR-2014-0827-1336-A1 p.45] [This comment can also be found in section 11.3 of this comment summary.]

The Efficiency Gap and Discount Rates

In justifying the rule, the agencies begin by reprising the explanation offered in defense of the Phase I rule, pointing to five specific market failures and imperfections. They then review recent research and not only conclude that those five factors are still relevant, but they add several others that might come into play. [EPA-HQ-OAR-2014-0827-1336-A1 p.49]

In the HD Phase 1 rulemaking (which, in contrast to these proposed standards, did not apply to trailers), the agencies raised five hypotheses that might explain this energy efficiency gap or paradox: Imperfect information in the new vehicle market... Imperfect information in the resale market:.. Principal-agent problems causing split incentives... Uncertainty about future fuel cost savings... Adjustment and transactions costs....[EPA-HQ-OAR-2014-0827-1336-A1 p.49]

All of the recent research identifies split incentives, or principal-agent problems, as a potential barrier to technology adoption... Uncertainty about future costs for fuel and maintenance, or about the reliability of new technology, also appears to be a significant obstacle that can slow the adoption of fuel-saving technologies... access to capital can be a significant challenge to smaller or independent businesses, and that price is always a concern to buyers... Other potentially important barriers to the adoption of
measures that improve fuel efficiency may arise from “network externalities,” where the benefits to new users of a technology depend on how many others have already adopted it.... Some businesses that operate HDVs may also be concerned about the difficulty in locating repair facilities or replacement parts, such as single-wide tires... Manufacturers may be hesitant to offer technologies for which there is not strong demand, especially if the technologies require significant research and development expenses and other costs of bringing the technology to a market of uncertain demand... it can take years, and sometimes as much as a decade, for a specific technology to become available from all manufacturers... [EPA-HQ-OAR-2014-0827-1336-A1 p.49]

Clearly, the efficiency gap that the market has failed to close can be readily explained by market barriers, obstacles, imperfections and failure. EPA/NHTSA go a step farther in this analysis and draw out an important implication of the pervasive set of market imperfections, something we have been pointing out in these proceedings for several years. When market actors are laboring under the weight of significant market imperfections, calculating discounts rates on the basis of observed market behaviors reflects the totality of market factors, not simply consumer and producer preferences. [EPA-HQ-OAR-2014-0827-1336-A1 p.50]

EPA/NHTSA stated this observation with respect to payback periods, but it applies equally to discount rates. [EPA-HQ-OAR-2014-0827-1336-A1 p.50]

In summary, the agencies recognize that businesses that operate HDVs are under competitive pressure to reduce operating costs, which should compel HDV buyers to identify and rapidly adopt cost-effective fuel-saving technologies...[EPA-HQ-OAR-2014-0827-1336-A1 p.50]

However, the short payback periods that buyers of new HDVs appear to require suggest that some combination of uncertainty about future cost savings, transactions costs, and imperfectly functioning markets impedes this process. Markets for both new and used HDVs may face these problems, although it is difficult to assess empirically the degree to which they actually do. Even if the benefits from widespread adoption of fuel-saving technologies exceed their costs, their use may remain limited or spread slowly because their early adopters bear a disproportionate share of those costs. In this case, the proposed standards may help to overcome such barriers by ensuring that these measures would be widely adopted.37 [EPA-HQ-OAR-2014-0827-1336-A1 p.50]

In 2008, we summarized the important role of supply side and market structural factors in affecting observed discount rates as follows; here we expand on that discussion.38 [EPA-HQ-OAR-2014-0827-1336-A1 p.50]

We view the apparent high discount rate attributed to consumers as the result of other factors not the root cause of the demand-side problem. We do not accept the claim that consumers are expressing irrational preferences for high returns on efficiency investments; irrational because they appear to be a return that is so much higher than they can get on other investments they routinely have available. Rather, we view the implicit discount rate as a reflection of the fact that the marketplace has offered an inadequate range of options to consumers who are ill-informed and unprepared to conduct the appropriate analysis and who lack the resources necessary to make the correct actions.39 [EPA-HQ-OAR-2014-0827-1336-A1 p.50-51]

The apparently grossly irrational discount rate reflects market imperfections and failures, not irrational consumers, a conclusion that has been clear in throughout the long history of the efficiency gap debate. [EPA-HQ-OAR-2014-0827-1336-A1 p.51]
The implicit discount rates calculated from consumer choices reflect not only individual time preferences but a whole collection of variables that may depress the ultimate level of investment. The calculated discount rate is affected by consumers’ price expectations and their levels of certainty about these; the extent to which available information is imperfect, mistrusted, or ignored; the purchase of some equipment to quickly replace nonfunctioning equipment rather than to minimize life-cycle cost; the presence in the market of builders, landlords, and other purchasers who will not pay for the energy the equipment uses; the fact that consumers with limited capital do not always purchase what they would if they had more capital; differential marketing efforts for different products, and so forth. Recognizing such possibilities, some analysts say that the data reflect “market discount rates.”

This observation on the market discount rate, combined with the recognition that a 3% discount rate is a good estimate for the consumer discount rate, provides a realistic framework for understanding consumer discount rates and applying them in economic analyses. We applaud the agencies for arriving at this view and encourage them to affirm both in the final rule so that future rulemakings can be grounded on this solid basis.

While the very large potential benefits lead us to call on the agencies to give a hard second look at the other factors that have led it to not push the industry harder, we believe that the huge efficiency gap also sends another strong message that should not be lost in the dickering over standard levels. The massive efficiency gap is testimony to a market that has performed abysmally for an extended period of time. We urge the agencies to seize the clear evidence on the failure of the medium/heavy duty truck market with respect to efficiency to transform the terrain of decision making in setting standards. As discussed above, they have moved in the right direction in at least half a dozen ways with the analysis of the proposed rule:

**Discount rate:** Recognizing real world consumer discount rate of 3% and market imperfections driving observed discount rate. [EPA-HQ-OAR-2014-0827-1336-A1 p.61-62]

**Efficiency Gap/Market Imperfection Analysis:** Recognizing 30 years of empirical evidence demonstrating validity of efficiency gap explanation and identifying specific barriers, imperfections and obstacles that afflict specific markets. [EPA-HQ-OAR-2014-0827-1336-A1 p.62]

**Merging energy and environmental analysis:** Recognizing major impact of fuel savings on assessment of rules. [EPA-HQ-OAR-2014-0827-1336-A1 p.62]

**Macroeconomic analysis:** Reconciling important benefit of expansion of macroeconomic activity resulting from greater fuel economy with realistic assessment of the rebound effect. [EPA-HQ-OAR-2014-0827-1336-A1 p.62]

**National security:** Looking carefully at the impact of imports on national security and consumption externalities created by large U.S. role in petroleum markets. [EPA-HQ-OAR-2014-0827-1336-A1 p.62]

**Effective design of standards:** Designing standards that “command but do not control,” thereby unleashing forces of competition to ensure least cost implementation. [EPA-HQ-OAR-2014-0827-1336-A1 p.62]
We applaud the agencies for crafting the proposed rule with the above factors in mind but urge that a careful examination be given as to whether greater savings that would benefit our economy and consumers can clearly be justified. [EPA-HQ-OAR-2014-0827-1336-A1 p.62]

24 Cooper, Performance Standards.

25 Cooper, Performance Standards, reviews the different approaches in the appliance, building, light duty and climate change literatures. Sanne Aarnink, Jasper Faber, Eelco den Boer, Market Barriers to Increased Efficiency in the European On-road Freight Sector, Delft, October 2012, introduce these distinctions for the medium/heavy duty truck sector.

29 Cooper, Performance Standards.

30 Mark Cooper, Performance Standards, examines the arguments in detail.

36 EPA/NHTSA, NPRM, p. 4043.

37 EPA/NHTSA, NPRM, pp. 40437-40438.

38 To underscore the fact that we have been pushing for the agencies to recognize this important reality of the efficiency gap, this discussion is taken directly from our 2009 light duty comments (Mark Cooper, Comments of the Consumer Federation of America, Environmental Protection Agency, Department of Transportation, Proposed Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas, Emission Standards and Corporate Average Fuel Economy Standards, 40 CFR Parts 86 and 600, 49 CFR Parts 531,633, 537, et al., November 27, 2009, which pointed back to our 2008 comments.

Several federal benefit-cost analyses report an energy paradox among firms in competitive markets and conclude that firms would benefit from mandates to increase the use of energy-saving technologies. Such findings appear incompatible with neoclassical views that private firms in competitive markets minimize costs. The Environmental Protection Agency, for example, presumes that owners of trailers pulled by tractors belonging to others underinvest in energy-saving technologies because trailer owners incur the costs while tractor owners get the benefits. We test this hypothesis by collecting data and modeling the use of energy-saving technologies as a function of fleet size, the intensity of truck usage, and proxies for management quality. We find effects consistent with conventional models but no evidence that different ownership of tractors and trailers is associated with reduced use of energy-saving technologies on trailers. Regulators should refrain from making claims that firms undervalue energy-saving technologies without first rigorously evaluating evidence for such claims. [EPA-HQ-OAR-2014-0827-1879-A2 p. 2]

The agencies have made several changes to the Phase 2 rule that are consistent with our previous comments. The explanation of the “energy efficiency paradox” also is consistent with many of our points on the first-mover disadvantage and the general lack of reliable information available to consumers. For more on Policy Integrity’s views on heavy-duty vehicle regulation, see our comments on the Phase 1 rulemaking. [EPA-HQ-OAR-2014-0827-1195-A1 p.3]

Available data and historical trends indicate the agencies include a flat reference truck efficiency baseline, with the sole exception of improvements in trailers that are linked to California’s regulations that affect trailers. The agencies’ continued consideration of fleet-wide vehicle efficiency improvements in the absence of new regulatory standards is unwarranted. The ICCT has supported many governments around the world in collecting and analyzing data. Based on our work to date, although technology improves and fleet-level efficiency improvements occur, there is not evidence to support the assumption of a new sales-fleet-averaged heavy-duty vehicle fleet CO₂ or fuel consumption reduction in the absence of regulations. In the case of analyzing the impact of the Phase 2 standards, including reference trailer improvements that are linked to the California regulations on trailer efficiency devices is warranted.
however, otherwise retaining flat efficiency characteristics for all engines, trucks, and tractors for scenarios would best reflect the evidence on historical trends in the U.S. [EPA-HQ-OAR-2014-0827-1180-A4 p.17] [This comment can also be found in section 8.2 of this comment summary.]

There are pervasive market barriers in the market, that have long prevented the uptake of even technologies with very attractive payback periods—for example, 6 months up to 2 years (see, e.g., Vernon and Meier, 2012; Roeth et al, 2013). Routinely, just small fractions of the fleet – a handful of technology-leading companies, representing a small fraction of the fleet, adopt technologies. The agencies consideration of technology adoption based on precise payback periods in the absence of regulation does not appear to be based on any empirical analysis of fleet-wide shifts. [EPA-HQ-OAR-2014-0827-1180-A4 p.17-18]

Organization:  Mannix, Brian, George Washington University Regulatory Studies Center

In response to a directive from President Obama, and using their respective statutory authorities, the Environmental Protection Agency (EPA) and the Department of Transportation’s National Highway Traffic Safety Administration (NHTSA) have jointly proposed a set of standards to regulate greenhouse gas emissions and (almost equivalently) fuel efficiency for medium and heavy-duty engines and vehicles. In contrast to the Corporate Average Fuel Economy (CAFE) Standards that NHTSA has long administered, the vehicles covered by the current proposal are almost entirely commercial vehicles used by businesses – not by households. [EPA-HQ-OAR-2014-0827-1222-A1 p.2]

The President said: “[I]mproving gas mileage for these trucks are [sic] going to drive down our oil imports even further. That reduces carbon pollution even more, cuts down on businesses’ fuel costs, which should pay off in lower prices for consumers. So it’s not just a win-win, it’s a win-win-win. You’ve got three wins… And businesses that buy these types of trucks have sent a clear message to the nearly 30,000 workers who build them: We want trucks that use less oil, save more money, cut pollution.” [EPA-HQ-OAR-2014-0827-1222-A1 p.2]

Do the proposed standards create a win-win-win? And if they do, why must they be mandated? Isn’t the “clear message” sent by the businesses that buy these trucks sufficient? These are the kinds of questions that should be answered in the Draft Regulatory Impact Analysis (RIA) that accompanies the proposed standards. Unfortunately, while the RIA contains some good economic analysis, it ultimately makes claims about the standards’ fuel-saving benefits that are not plausible. The majority of the forecast benefits take the form of cost savings by the businesses that buy and use the regulated vehicles – businesses that are already well-informed about their own cost structure, and are well-positioned to make the optimum choices. Forcing businesses to make investments that they have thoroughly studied, and rejected, cannot create economic surplus. [EPA-HQ-OAR-2014-0827-1222-A1 p.2]

There are, of course, other categories of benefits detailed in the RIA that are distinct from the private fuel savings. But the credibility of the overall analysis is undermined by the fact that it appears to be hard-wired to produce a “win-win-win” result. It is as if the analysis contains a “defeat device” designed to pass the benefit-cost test; the RIA demonstrates that the standards will produce very large net benefits on paper – benefits that the standards cannot possibly achieve on the road. [EPA-HQ-OAR-2014-0827-1222-A1 p.2]

It is important to remember why we do regulatory analysis. It is not to serve as a marketing tool, or to generate political talking points. Regulations have the force of law and, by their nature, are coercive. Before regulatory agencies use force against U.S. citizens, we ask them to justify it by demonstrating that the action will do more good than harm. That requires an honest appraisal of who is made better or
worse off, and by how much. This RIA is designed to tell a happy story where everybody wins, but it is a false one. The claim that the private benefits due to the Phase 2 standards will many times larger than the private costs cannot be reconciled with the basic principles of benefit-cost analysis. [EPA-HQ-OAR-2014-0827-1222-A1 p.4]

Private Benefits

Increasingly, agencies that issue regulations mandating increased energy efficiency have made the claim that they are producing “private benefits” – somehow making consumers better off by depriving them of the choices that they would make on their own. These claims are always suspect, and are sometimes justified by a claim that consumers suffer from “internalities” – behavioral anomalies that prevent consumers (but not regulators) from acting in their own best interest. Such claims become especially implausible in the case of the proposed Phase 2 standards. Under every scenario and set of assumptions, fuel savings are the largest component of benefits, accounting for more than 50 percent of all benefits. Yet this rule, because it applies to intermediate goods (vehicles) that are bought by sophisticated users, is ideal for illustrating what is wrong with the analytical techniques that are used to produce inflated estimates of private benefits. The RIA states the problem: [EPA-HQ-OAR-2014-0827-1222-A1 p.8]

Economic theory suggests that interactions between vehicle buyers and sellers in a normally-functioning competitive market would lead HDV manufacturers to incorporate all technologies that contribute to lower net costs into the vehicles they offer, and buyers to purchase them willingly. Nevertheless, many readily available technologies that appear to offer cost-effective increases in HDV fuel efficiency (when evaluated over their expected lifetimes using conventional discount rates) have not been widely adopted, despite their potential to repay buyers’ initial investments rapidly. This economic situation is commonly known as the “energy efficiency gap” or “energy paradox.” This situation is perhaps more challenging to understand with respect to the heavy-duty sector versus the light-duty vehicle sector. Unlike light-duty vehicles – which are purchased and used mainly by individuals and households – the vast majority of HDVs are purchased and operated by profit-seeking businesses for which fuel costs represent a substantial operating expense. Nevertheless, on the basis of evidence reviewed below, the agencies believe that a significant number of fuel efficiency improving technologies would remain far less widely adopted in the absence of these proposed standards. [EPA-HQ-OAR-2014-0827-1222-A1 p.8-9]

The RIA notes that one explanation for apparently irrational behavior on the part of regulated businesses is “requirements of other regulations on HDVs.” The RIA does not identify what these requirements are, nor does it explain how issuing conflicting regulations is supposed to make things better. It offers other candidate theories to explain the anomaly: [EPA-HQ-OAR-2014-0827-1222-A1 p.9]

Imperfect information in the new and used vehicle markets. Imperfect or asymmetrical information is often invoked as a reason to regulate, but it is difficult to make that case here. Vehicle buyers know how they plan to drive the vehicles, with what loads, under what conditions (altitude and temperature), and at what speeds. The RIA describes the industry as highly sophisticated and notes that some HDV buyers actually test the vehicles (including tractor-trailer combinations) for their performance under field conditions, with actual loads and drivers. This is far better information about fuel economy than EPA and NHTSA can ever hope to have. [EPA-HQ-OAR-2014-0827-1222-A1 p.9]

Principal-agent problems. The RIA speculates that the HDV buyer may not be directly responsible for its future fuel costs, or the individual who will be responsible for fuel costs may not participate in the HDV purchase decision. These are routine matters of internal corporate management or marketplace bargaining. Companies are very good at figuring out their cost structure, and all the evidence in the RIA...
indicates that they put a great deal of effort into getting the fuel economy right. The only parties to all these transactions who may have a principal-agent problem are the regulatory agencies, and that is a reason to refrain from regulating, rather than a reason to intervene. [EPA-HQ-OAR-2014-0827-1222-A1 p.9]

Uncertainty about future fuel cost savings. “HDV buyers may be uncertain about future fuel prices, or about maintenance costs and reliability of some fuel efficiency technologies.” And rightly so. Any casual observation of fuel prices in recent years leads to the conclusion that investments in fuel economy, even if they work exactly as intended, are among the riskiest investments that a business might make.25 [EPA-HQ-OAR-2014-0827-1222-A1 p.9-10]

Adjustment and transaction costs. These include the “costs associated with training drivers to realize potential fuel savings enabled by new technologies, or with accelerating fleet operators’ scheduled fleet turnover and replacement to hasten their acquisition of vehicles equipped with these technologies.” But these are real costs, and need to be accounted for in the benefit-cost analysis. Regulations cannot create economic benefits by instructing businesses to ignore these costs. EPA states: [EPA-HQ-OAR-2014-0827-1222-A1 p.10]

Other explanations for the limited use of apparently cost-effective technologies that do not involve market failures include HDV operators’ concerns about the performance, reliability, or maintenance requirements of new technology under the demands of everyday use, uncertainty about the fuel savings they will actually realize, and questions about possible effects on carrying capacity or other aspects of HDVs’ utility.26 [EPA-HQ-OAR-2014-0827-1222-A1 p.10]

These are not “failures of the HDV market,” however; they are rational business decisions. Regulators’ attempts to override them can only produce net private costs, not private benefits. Take, for example, uncertainty about fuel savings, which causes HDV buyers to discount such projected savings. One factor in this uncertainty is the price of fuel; the graph below is the retail price reported by Washington State’s Department of Transportation: [EPA-HQ-OAR-2014-0827-1222-A1 p.10]

[Graph can be found on p.11 of docket number EPA-HQ-OAR-2014-0827-1222-A1]

Investments in fuel-saving technology are among the riskiest investments that businesses make. And there are more risks beyond the price risk. Right now, millions of buyers of light Volkswagen diesel vehicles are very disappointed to learn that they are not getting the performance that they thought they would get. Buyers of HDVs must recognize that fuel-saving technology do not always deliver what they promise. [EPA-HQ-OAR-2014-0827-1222-A1 p.11]

Uncertainties like this are one reason why the apparent discount rate that businesses apply to fuel-saving technologies is so high. Yet the RIA applies discount rates of 3 and 7 percent. It is standard practice for the government to use risk-free discount rates to its own investments, because the government is large enough to self-insure, and no one project is more than a small component of a very large portfolio of government projects. But buyers of HDVs generally are not using government funds. It is inappropriate to apply the parameters of public finance to private businesses that face real opportunity costs, capital constraints, and financial risks. It does not create economic value when regulation forces private businesses to forego higher or more certain investments in order to make mandated investments. Before applying a risk-free social discount rate to the stream of private costs and benefits associated with a regulation, the capital costs imposed on businesses and individuals should be converted to a consumption-equivalent stream, using the actual discount rate of the businesses and individuals who experience them. [EPA-HQ-OAR-2014-0827-1222-A1 p.11-12]

26 RIA, p. 8-4.

The most troubling aspect of the private benefit numbers is the extent to which the agencies believe that coercive regulation, even in the absence of any externalities, will make businesses more economically efficient. [EPA-HQ-OAR-2014-0827-1222-A1 p.12]

Some of these explanations imply failures in the private market for fuel-saving technology beyond the externalities caused by producing and consuming fuel, while others suggest that complications in valuing or adapting to technologies that reduce fuel consumption may partly explain buyers’ hesitance to purchase more fuel-efficient vehicles. In either case, adopting this proposed rule would provide regulatory certainty and thus generate important economic benefits in addition to reducing externalities.27 [EPA-HQ-OAR-2014-0827-1222-A1 p.12]

The RIA has it backwards. These are not failures of the private market; these are failures of the economic analysis. Forcing businesses to make bad investments may provide regulatory certainty, but it emphatically does not “generate important economic benefits.” Some businesses may see this type of regulatory certainty as privately advantageous because it protects them from competitors, drives out small businesses, and creates barriers to entry and innovation. But this business support is not evidence of economic benefit; rather, it suggests that there are additional economic harms that will flow from the regulation. [EPA-HQ-OAR-2014-0827-1222-A1 p.12]

Conclusion

In conducting this Phase 2 rulemaking, EPA and NHTSA have completed extensive engineering and economic research, which is integrated into a Regulatory Impact Analysis that forecasts large benefits, mostly in the form of private fuel savings. Unfortunately the analysis fails to recognize that competitive markets are far better informed, and far better motivated, to pursue these fuel savings efficiently. The RIA’s attempts to explain that limiting businesses’ options will make them more efficient are not persuasive. The proposed Phase 2 standards seem likely to reduce both competition and innovation in MDV and HDV markets, resulting in additional costs not documented in the RIA. The net effect on U.S. households will be higher costs, not savings. There are other external benefits that might be used to justify the standards, but an honest RIA would acknowledge that these come at a price. This is not a win-win-win proposal. [EPA-HQ-OAR-2014-0827-1222-A1 p.12]

Organization: NAFA Fleet Management Association

Additionally, the proposed standards place greater strain on driver and technician resources (capability), which are two vocational areas where fleets are becoming more challenged to hire enough (and qualified) employees. [NHTSA-2014-0132-0111-A1 p.2-3] [This comment can also be found in section 11.12 of this comment summary.]

Many fleets have seen an increase in downtime, which has manifested itself in driver productivity issues, shop capacity concerns and an overall increase in the number of spare vehicles required to have on hand to ensure that enough units are available to serve customers. [EPA-HQ-OAR-2014-0827-1011 p.3] [This comment can also be found in section 11.12 of this comment summary.]

Lastly, fleets have had to increase training significantly to stay on top of the changes that have increased our technician counts across the country. [NHTSA-2014-0132-0111-A1 p.3] [This comment can also be found in section 11.12 of this comment summary.]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

According to the NPRM, the agencies “recognize that there is some uncertainty in projecting costs and effectiveness, especially for those technologies not yet widely available, but believe that the thresholds proposed for consideration account for realistic projections.” (Emphasis added). Whereas the agencies are content with the uncertainty of costs and effectiveness of the technologies, owner-operators do not unfortunately have that luxury. The livelihood of an owner-operator, who frequently operates his or her business on small profit margins, depends on affordable and reliable equipment in order to compete and survive in a highly competitive industry. OOIDA strongly believes that the market should drive fuel efficient technologies instead of expensive mandates. The agencies stated in their proposed rule that “both public and confidential historical information shows that tractor trailer fuel efficiency improved steadily through improvements in engine efficiency and vehicle aerodynamics over the past 40 years.” In particular, these improvements have been driven by fleet owners and owner-operators seeking fuel efficient trucks, as fuel is the number one expense of every trucking operation. The average one truck owner-operator spends approximately $70,000 in fuel every year. If there was affordable and reliable technology which improved fuel efficiency by 24% over the 2017 baseline, there would be no need of a mandate, as truck drivers would be more than willing to purchase such equipment. [EPA-HQ-OAR-2014-0827-1244-A1 p.5-6]
As part of the proposed rule the agencies stated, “We request comment on the sufficiency of the proposed Phase 2 structure, lead time, and stringency to avoid market disruptions. We note an important difference, however, between standards for criteria pollutants, with generally no attendant fuel savings, and the fuel consumption/GHG emission standards proposed today, which provide immediate and direct financial benefits to vehicle purchasers, who will begin saving money on fuel costs as soon as they begin operating the vehicles. It would seem logical, therefore, that vehicle purchasers (and manufacturers) would weigh those significant fuel savings against the potential for increased costs that could result from applying fuel-saving technologies sooner than they might otherwise choose in the absence of the standards.” (Emphasis added). While it would seem logical on paper, the real-world effect of costly and unreliable technology will prevent any owner-operator or fleet owner from purchasing such a vehicle. Again, fuel is the largest cost for the owner of a truck, and therefore reducing fuel consumption is crucial in operating a successful and viable business. Wherefore, it is of the utmost importance for regulators to allow innovation on part of the OEMs to continue by not overly constraining engine design. If OEMs were able to produce an affordable fuel efficient vehicle, then both owner-operators and fleet owners would readily purchase them in the market. Forcing unproven technologies will only impede the agencies objectives. [EPA-HQ-OAR-2014-0827-1244-A1 p.14-15]

18 Complete Vehicle Standards for Heavy-Duty Trucking.

Organization: Truck Renting and Leasing Association

However, TRALA has several concerns about the Proposed Standards, which we have set forth below: (1) the industry is self-motivated to conserve fuel, thus reducing GHG emissions through market forces instead of regulatory mandates [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

The Truck Renting & Leasing Industry is Self-Motivated to Conserve Fuel, Thus Reducing Tailpipe GHG Emissions through Market Forces, Not Regulation

The truck renting & leasing industry is self-motivated to seek fuel saving technologies without regulation to mandate that outcome. Through market forces, companies compete every day on aspects of unit performance, including improved fuel performance. Fuel consumption, of course, is a significant cost of doing business for fleet owners and operations. Because of this, we question the entire premise of the regulatory action – i.e., that governmental mandates are necessary to achieve desired societal objectives. Further, it must be recognized that as a consequence of this, trucks are already highly efficient leaving few remaining gains to be had. [EPA-HQ-OAR-2014-0827-1140-A1 p.2]

Organization: Utility Trailer Manufacturing Company

The cost-benefit calculation is flawed because it fails to give safety adequate consideration and weight.

The aerodynamic devices specified by the EPA are relative newcomers to the market. Manufactured of plastic, fiberglass, and light metal, they are easily damaged as the trailers travel over the road and railroad crossings, or – in the case of trailer tails – as drivers routinely back into docks, fences, and other trailers. Some number of these devices will become detached in over-the-road operations, resulting in
some number of increased accidents. [EPA-HQ-OAR-2014-0827-1183-A1 p.17][This comment can also be found in section 5.1 of this comment summary]

The additional technologies are also likely to increase accidents and the injuries and fatalities associated with them. As noted previously, adding the aerodynamic technologies to trailers that otherwise would run at full permitted weight will mean that cargo equal to the weight of the devices will have to be transported on additional trips. There is a correlation – some would say direct – between miles driven and accidents/injuries/fatalities. The Agencies have not accounted for this important societal cost in performing their cost-benefit analysis. [EPA-HQ-OAR-2014-0827-1183-A1 p.17][This comment can also be found in section 5.1 of this comment summary]

Finally, the effect of implementing a combination of technologies on a large scale is not yet sufficiently evaluated to be certain that there will not be unintended consequences. Other than its own side skirt, Utility Trailer does not know of any other aerodynamic device that has been certified to meet or exceed relevant DOT regulations. For example, some vendors market devices to cover the ends of axles, claiming they will reduce drag. But covering the wheel end may reduce airflow, causing the components to run hotter. Before installing such devices, a prudent manufacturer would require approval from the axle supplier, the bearing supplier, the hub supplier, the oil-seal and hubcap supplier, the lubricant supplier, the brake supplier, the wheel supplier, and the tire supplier. [EPA-HQ-OAR-2014-0827-1183-A1 p.17-18][This comment can also be found in section 5.1 of this comment summary]

Response:

The agencies discuss the existence of the energy efficiency gap and its role in the market for fuel-saving technologies for HD vehicles in Preamble Section IX.A. and RIA Chapter 8.2. The commenters display a split of opinions on the existence of the efficiency gap and possible explanations of it. CARB, CALSTART, CFA, Institute for Policy Integrity at NYU School of Law (IPI), and ICCT support, either in whole or in part, the agencies’ arguments for potential barriers to market adoption. Caterpillar Inc. et al., CEI, Mr. Mannix (George Washington University Regulatory Studies Center), George Mason University Mercatus Center (Mr. Lutter), NAFA Fleet Management Association, OOIDA, Truck Renting and Leasing Association (TRALA), and Utility Trailer Manufacturing Company (UTMC) express skepticism or raise concerns about the agencies’ discussion. Here we first provide responses related to the supportive comments, and then to the skeptics. In both cases we begin with the general issues, and then provide more detailed responses to detailed critiques.

11.1.4 Response: Comments supportive of the agencies’ energy paradox discussion

The commenters who are generally supportive of the agencies’ discussion for the most part agree that the energy efficiency gap exists and that the hypotheses raised in Preamble Section IX.A and RIA Chapter 8.2 provide potential explanations for the efficiency gap. They often provide some additional support for these hypotheses.

CFA notes that the benefits of the standards are six times larger than the costs and asks the agencies for “better documentation and support for the decision not to set the standard at a higher level” and “urge that a careful examination be given as to whether greater savings that would benefit our economy and consumers can clearly be justified.” In fact, the agencies did very carefully consider an array of alternatives with varying standards and GHG/fuel consumption reductions; our decisions in setting each standard are well documented throughout our Preamble, especially in our discussions of individual sectors in Sections II-IV and summarized in Preamble Section X. In the final program, the agencies’
careful assessment of new data and comments has resulted in increases in our estimates of market penetration and effectiveness of key technologies, leading to increases in stringency such as with the diesel engine standards. The agencies are adopting these standards because, based on the information available at this time and careful consideration of all comments, we believe they best fulfill our respective statutory authorities when considered in the context of available technology, feasible reductions of emissions and fuel consumption, costs, lead time, safety, and other relevant factors. The agencies consider the standards to represent a reasonable choice under Section 202(a) of the CAA and the maximum feasible under NHTSA’s EISA authority at 49 U.S.C. 32902(k)(2).

CFA expects that the cost savings will be passed along to consumers. EPA has not made a determination of the final disposition of cost savings; see the discussion of employment impacts associated with the fuel savings in Preamble Section IX.L.3.c and RIA Chapter 8.11.3.3. CFA argues as well that the net benefits may be underestimated, due to exclusion of the full value of externalities. The agencies have monetized external benefits and costs when the underlying research is sufficient to support that monetization; see Preamble Section IX and RIA Chapter 8 for the benefit-cost analysis, and in particular Section IX.G and RIA Chapter 8.5 for monetized GHG impacts, Section IX.H and RIA Chapter 8.6 for monetized non-GHG health impacts, Section IX.I and RIA Chapter 8.9 for energy security impacts, and Section IX.J and RIA Chapter 8.7 for other impacts. Preamble Section IX.K. and RIA Chapter 8.10 summarize the benefits and costs. CFA lauds the standards for being long-term, technology neutral, product neutral, responsive to industry needs, and responsive to consumer needs. The agencies have considered these factors in its deliberations related to the standards. We agree as well that “the implicit discount rates calculated from consumer choices reflect not only individual time preferences but a whole collection of variables that may depress the ultimate level of investment,” and that these rates should not be used for calculating net social benefits.

11.1.5 Response: Comments skeptical of the agencies’ energy paradox discussion

11.1.5.1 General Concern

The concerns raised in skeptical comments generally center on the idea that private markets provide sufficient incentives to lead to adoption of all cost-effective fuel-saving technologies. CEI, Mr. Mannix, OOIDA, and TRALA argue that it is “implausible” (Mr. Mannix) that the standards produce “private benefits,” gains to vehicle buyers in fuel savings that exceed increased technology costs, because private markets should already provide all cost-effective technology. They consider the hypotheses presented by the agencies either to represent rational, business-based reasons that companies have not adopted the technologies, such as higher or additional costs, or to be not well supported. Mr. Lutter provides a working paper that states that the agencies should conduct empirical analysis of inefficiency in firms’ use of technologies before claiming that firms are operating inefficiently.

We note first that the purpose of the standards is not to provide private benefits, as TRALA in particular suggests; nor are the standards being promulgated out of “ideological zeal for ‘greening’ the U.S. transport system” (CEI). Rather, the standards are contributing to EPA’s Clean Air Act obligation to reduce GHG emissions -- that is, emissions which contribute to the greenhouse gas air pollution which endangers public health and welfare (CAA section 202 (a)(1)). Emissions of GHGs are “externalities,” impacts of private market behavior that do not accrue solely to the participants in the private markets. Those who generate externalities bear only a fraction of the consequences of their generation; as a result, those who generate them will not have appropriate incentives to avoid their production. Control of externalities is widely accepted as a rationale for government intervention in private markets. The fuel savings, in this context, are an ancillary benefit or a reduction in opportunity costs associated with the GHG reductions, though they are clearly a very large one.
The evidence of these net savings is the expected technology costs and effectiveness. If those estimates are reasonably correct, and take into account all relevant costs and benefits (including such factors as reliability), then an energy efficiency gap exists, and the net savings from these standards are real. Explaining why the gap exists is a separate and difficult challenge, because of the difficulties involved in developing tests of the different possible explanations. (As discussed further below, Mr. Lutter presents one such analysis. It examines one particular form of one hypothesis, and does not find evidence to support that hypothesis). The difficulties in developing tests to explain the gap, or assertions of the unlikelihood of the explanations offered, do not provide evidence that the gap doesn’t exist. Arguing against the hypotheses that the agencies have offered does not affect the question of existence, but rather the reasons for its existence.

11.1.5.2 Additional Costs

Demonstration of costs that are understated or not included in the analysis, or benefits that are overstated, would be evidence that the efficiency gap may not exist. Caterpillar, Mr. Mannix, NAFA Fleet Management, OOIDA, and UTMC express concerns in particular about maintenance and reliability problems. Reliability comments are addressed in RTC Sections 1.5 (Lead Time); 3.4 (Projected Engine Technologies, Effectiveness, & Cost); 4.3 (Projected Tractor Technologies, Effectiveness, and Cost); 4.5 (Compliance Provisions and Flexibilities for Tractor Standards); 5.1 (Trailers, General Comments); 5.3 (Proposed Trailer Standards for CO₂ and Fuel Consumption); 6.2 (Proposed Vocational Vehicle Standards for CO₂ and Fuel Consumption); 6.3 (Projected Vocational Vehicle Technologies, Effectiveness, & Cost); 7.3 (Projected Vocational Vehicle Technologies, Effectiveness, & Cost); and 8 (Stringency). Except for UTMC’s comments about aerodynamic devices, the issues raised by these commenters are not specific to these standards nor to these technologies. NAFA Fleet Management, for instance, cites increases in maintenance and repair costs from 2008 to 2013 in its comments; the HD GHG Phase 1 program did not begin until MY 2014. The effects of the standards on maintenance expenditures are discussed in Preamble IX.D. and RIA Chapter 7.2.3. As discussed there, in our continuing effort to provide sound estimates of the benefits and costs of the standards, the FRM accounts for maintenance costs for more technologies than in the NPRM. The effects of the aerodynamic standards on trailer safety is discussed in Preamble IV.A(2)(d)).

11.1.5.3 Comments on the Agencies’ Hypotheses

As discussed previously, the agencies’ determination of an efficiency gap is based on the analysis of costs and benefits. We agree that the large ancillary benefits from the fuel savings suggest questions about the efficiency of the market for fuel efficiency in HD vehicles. The agencies have not determined which, if any, of these hypotheses are true and thus explain the efficiency gap. All of these hypotheses have been raised in publications or in comments. We review the evidence on each in Preamble Section IX.A. and RIA Chapter 8.2. As noted above, the positive commenters generally support the plausibility of some or all of these explanations. The skeptical commenters generally dismiss them either as implausible, or as arguments supporting the efficiency of the market for fuel efficiency.

Some commenters provide thoughts specific to five hypotheses discussed in Phase I:

**Imperfect Information:** The agencies hypothesize that buyers are skeptical of the claims of manufacturers related to fuel-saving technologies (Preamble Section IX.A, RIA Section 8.2). CEI and Mr. Mannix find this hypothesis troubling because it implies that the agencies have information on the effectiveness of these technologies that the private sector does not. In particular, it argues that the gap should be smallest for semi-truck owners, because the SmartWay Program has been providing that
sector with information for a number of years; yet the savings to semi-truck owners are substantially larger than the savings to vocational or HD van and pickup owners.

This comparison of gains to tractor/trailers with gains to vocational or HD van and pickup owners does not provide evidence against the asymmetric information hypothesis, because the differences between these vehicle types are not limited to access to the SmartWay Program. Class 7 and 8 vehicles travel many more miles per year: the useful life of a Class 8 tractor, for instance, is 10 years or 435,000 miles (see Preamble Table III-6), while for vocational vehicles, pickups, and vans, the useful life is 150,000 miles or 15 years (see Preamble Section V.D.1). This difference in use has a great effect on the potential net benefits. Second, the diversity of purposes and designs in the vocational vehicle fleet is much greater than in the tractor fleet; thus, the effectiveness of technologies to address the vocational vehicle is likely to be much more variable than in the tractor fleet. If there are economies of scale in developing efficiency technologies, the greater variability in the vocational vehicle fleet may reduce innovative options in that sector. Because the differences between Class 7 and 8 vehicles on the one hand, and vocational, vehicles, pickups, and vans on the other, go beyond access to the SmartWay Program, this difference in net benefits does not provide insight into the asymmetric information hypothesis.

Imperfect information in the resale market. CEI says that, “To our knowledge, nobody claims the resale market fails to consider the value of technologies that enhance vehicle reliability, performance, comfort, and amenities.” Mr. Mannix similarly argues that “it is difficult to make that case here.” As discussed in Preamble Section IX.A and RIA Section 8.2, Klemick et al. 2015, Roeth et al. 2013, and Aarnink et al. 2012 found evidence both in favor of and against the hypothesis of imperfect information in the market for used HDVs.

Principal-agent problems causing split incentives. CEI states that, even if split incentives exist, they do not necessarily imply under-investment in fuel economy. We agree that the presence of split incentives does not guarantee under-investment, but we believe that it creates that possibility. Mr. Mannix considers companies to be capable of solving these problems internally, and regulatory agencies instead to be the ones with this problem. We agree that its incentives and those of the HD industry are not aligned; we do not expect the private sector to put the same weight on GHG emissions as the agency does. We continue to consider private-sector split incentives to be a potential problem in the private sector.

CEI also comments that the proposed rule “postulates a split incentive that works the other way” – in particular, that drivers don’t care about fuel costs unless they have financial incentives, while owners do care. This example comes from Vernon and Meier, whose study finds that split incentives “have the potential to significantly increase fuel consumption through avoided investments, insufficient maintenance, and fuel-wasting practices.” In this case, the owner may not face disincentives to install fuel-saving technologies; in fact, the owner may consider investing in technologies (for instance, a

---

variable speed limiter, or an efficient automatic transmission) that limit a driver’s ability to use excess fuel. We raised this possibility, among others where there may be disincentives to technology investment, as examples of the complexity of motivations involved in fuel savings and the choice of technologies. As discussed above, our finding of an efficiency gap does not hinge on this one hypothesis.

Mr. Lutter submits a working paper207 that examines data collected from observing tractors with box trailers on a convenience sample of 3 stretches of highway and along one road trip. The authors find that, for the two outer tires observed on one side of trailers, less than half were both low-rolling-resistance (LRR) trailer tires; some had LRR tractor tires, some mixed tractor and trailer tires, and some mixed conventional and LRR tires. They offer as potential explanations for this odd mixing that companies are extending the use of tractor tires on trailers, potential cost advantages in bulk purchase of tires, management costs, or belief that the correct tires are not as efficient as claimed. They then regress the existence of side skirts (an aerodynamic device) on controls that include fleet miles per year divided by fleet size (average miles per truck), log of fleet size, compliance variables, and whether the tractor and trailer differ in ownership (based on U.S. Department of Transportation registration numbers). They do not find a statistically significant or negative relationship when the trailer has different ownership than the tractor. This finding does not provide evidence in support of the split-incentives problem between tractors and trailers. They conclude that the agencies should review empirical evidence more carefully “before using estimates of large net economic gains in rulemakings” (p. 30), and allocating resources to collect data for such an analysis.

As the discussion above indicates, the evidence for the efficiency gap is the analysis showing that cost-effective fuel-saving technologies are not adopted. Split incentives provide one hypothesis to explain the existence of the gap. As discussed above, split incentives can take many forms; split incentives specifically related to the difference in ownership between tractors and trailers are one part of that hypothesis. Thus, the Fraas et al. (2016) paper is one piece of evidence on one hypothesis. While its results on side skirts may be consistent with neoclassical economics, it does not actually provide evidence on the existence of the efficiency gap for side skirts – that is, whether the side skirts save more money than they cost. We also note that the evidence presented on LRR tires does not suggest best or consistent practices for use of those tires on trailers. Finally, the paper’s conclusion that the agencies conduct a broader data collection effort suggests that the authors themselves consider this work exploratory rather than conclusive; we agree with its assessment of the study as exploratory.

Preamble IX.A. and RIA Chapter 8.2 include our review of all evidence that we have found on the efficiency gap in HD vehicles. While the authors of the paper may consider their data collection efforts to have been “relatively inexpensive and quick” and therefore easily implemented by the agencies, data collection by federal agencies is governed in part by the Paperwork Reduction Act, which typically requires internal and public review of data collection methods and survey design before a data collection protocol may be implemented. Even if observation of vehicles at specific places were not subject to those requirements, the agencies would take into consideration potential public response to federal observation of vehicles before it instituted such an effort.

Uncertainty about future cost savings. CEI and Mr. Mannix agree that this hypothesis may explain lack of adoption of fuel-saving technologies and characterize it as prudent buyer behavior. As discussed in Preamble Section IX.A. and RIA Chapter 8.2, if all buyers prudently wait for reduced uncertainty before

adopting new technologies, then effective technologies may not be adopted. In addition, uncertainty about future fuel cost savings should provide incentives for a risk-averse company to invest in fuel-saving technology: if fuel prices unexpectedly increase, fuel-saving technology reduces the impacts.

Adjustment and transactions costs. CEI agrees that this hypothesis may explain lack of adoption of fuel-saving technologies, as a cost of innovation and the need to have personalized information. As discussed regarding imperfect information, not having personalized information can be a barrier to adoption. Mr. Mannix mentions various costs, including concerns about vehicle quality and utility. As discussed regarding additional costs, commenters have not documented increased reliability or maintenance costs associated with technologies to reduce GHG emissions; rather, the references are to concerns over controls of non-GHG emissions, including nitrogen oxides (NO\textsubscript{x}). Because the technologies for controls of those pollutants are not the same as those for GHG reductions, any problems associated with those controls do not provide evidence on problems associated with GHG-reducing technologies.

CEI raises an alternative hypothesis: that EPA’s diesel-engine emission standards have hindered HD fuel economy. While some of what CEI states is correct, it overstates that role in the context of the energy paradox. It is true that some first generation NO\textsubscript{x} controls included fuel consumption penalties as manufacturers retarded fuel injection timing to lower peak combustion temperatures and pressures. However, the opposite is true for SCR technology, which actually allowed manufacturers to improve fuel consumption. Another flaw in the CEI hypothesis is that it applies only for engines and engine manufacturers. It does not explain choices made with respect to vehicle technologies, such as improved transmissions. For many of these technologies, it is actually the component suppliers that make the investments to develop technology. CEI provides no basis to believe that emission control costs borne by engine manufacturers would have any impact on investments by suppliers of other key components such as transmissions, axles, and aerodynamic devices. Finally, in the context of the likelihood of new NO\textsubscript{x} controls sometime during the Phase 2 time frame, the CEI hypothesis would seem to be more supportive of a flatter reference case than a more dynamic scenario.

CEI suggests that HD vehicle buyers may “pre-buy,” that is, increase purchases of vehicles just before the standards go into effect, and reduce their purchases afterwards, resulting in temporary layoffs. As discussed in Preamble IX.F.2 and RIA Chapter 8.4.2, the 2010 NAS HD report noted that there was some evidence of pre-buy in response to the 2004 and 2007 heavy-duty engine emissions standards, but it also recognized that fuel economy improvements that can offset purchase costs will lessen those potential impacts. See also Chapter 11.7.2 of this Response to Comments. A working paper by Rittenhouse and Zaragoza-Watkins (2016)\textsuperscript{208} investigates pre-buy and identifies it at the time of the 2007 standards, but not around the time of 1998, 2002, or 2010 criteria pollutant standards. They find that sales and production increased in the 7 months before the 2007 standards, and dropped afterward by about the same amount. The evidence on employment is less clear; their findings suggest a possible increase in hours before the standards, but they do not find a decrease afterward. Its data go through January 2015. It does not examine pre-buy when the Phase 1 standards went into effect; scatter plots of sales residuals do not show major outliers (that would suggest pre-buy or post-rule reductions) except for the 2007 standards. EPA disagrees that any lessons from the 2007 NO\textsubscript{x} standards regarding pre-buy are likely to apply to the HD GHG standards.

In sum, the agencies find that the commenters have not provided specific evidence to change the results of the benefit-cost analysis. As a result, we still find an energy efficiency gap. As discussed in Preamble

\textsuperscript{208} Rittenhouse, Katherine, and Matthew Zaragoza-Watkins (2016). “Strategic Response to Environmental Regulation: Theory, and Evidence from the U.S. Freight Truck Industry.”
IX.A. and RIA Chapter 8.2, we have identified a number of potential explanations for the existence of the gap, but we make no definitive finding on the cause.

11.2 Vehicle-Related Costs

Organization: ABC Bus Companies, Inc.

On the face value of these extremely large documents, it seems that a huge compliance burden to the coach manufacture's as well as a huge maintenance burden to motorcoach operators will be a realistic outcome. This seems to be proven true as we have experienced in the Phase 1 implementation. ABC is concerned about the long term reliability of increased emission technologies and unreliable cost estimates that are projected so far into the future. [EPA-HQ-OAR-2014-0827-1430-A2 p.1]

The numbers of 'Skilled Technicians' available to the motorcoach industry are becoming more limited every time more and new vehicle technology is introduced. With the average motorcoach fleet being only 10 buses, it is nearly impossible for an operator to have the expensive tools, software, hardware, and technical training needed to maintain the technologies proposed in Phase 2. Motorcoach operators are still trying to cope with the Phase 1 elevated operating costs. Small fleets could be put into a position to forgo the bus business altogether because of mounting infrastructure costs and federal red tape. The unintended consequence of these actions would be that more cars and light trucks would be on the US highways as motorcoach operators could go away. Much of the Phase 2 cost estimates focus on reduced fuel consumption as reasons for implementing and justifying these proposed standards. However, estimated fuel savings can be quickly eaten up by administrative paper work, increased equipment costs, untested technology, stranded passengers, etc. [EPA-HQ-OAR-2014-0827-1430-A2 p.1-2]

The current position that CARB has taken forcing Phase 1 technologies on vehicles not engineered to accept these components has substantially increased the financial burden upon small operators to provide economic transportation in the State of CA. If this were to occur on a national basis, the same outcome could be seen. [EPA-HQ-OAR-2014-0827-1430-A2 p.2]

Given the low numbers of intercity coach bus sales, these motorcoach manufacturers are limited to components from the Class 7 and 8 truck suppliers. This can mean extra engineering costs and delayed implementation of proposed standards. [EPA-HQ-OAR-2014-0827-1430-A2 p.3]

Response:

The Phase 1 requirements applicable to motor coaches were predicated solely on an improvement to the rolling resistance of tires. The agencies fail to understand how that requirement has led to motorcoach operators having difficulty coping with the Phase 1 operating costs. EPA does not believe that the Phase 2 requirements could lead to more cars and light trucks on US highways due to motorcoach operators going out of business. EPA and NHTSA have in place a set of GHG and fuel economy standards applicable to cars and light trucks that will be implemented through 2025. So requirements are being placed on both industries and both sets of requirements provide very large benefits relative to their costs. The final standards also provide optional custom chassis standards. One of the subcategories which could utilize these standards are motorcoaches. The agencies believe that these optional standards ease the potential compliance burden and address many of the concerns expressed in this comment.

Organization: Allison Transmission, Inc.
The RIA Section 2.12.3.1 summarizes the cost estimates related to adding two additional gears for vocational vehicles. Allison believes that the DMC of $413 in 2018 is understated. A more complex architecture will add weight, and most likely length which will result in a higher material cost than the transmission with fewer gears. A “clean sheet of paper” design and validation process would be required and one design would not be adequate to cover the breadth of LHD, MHD, and HHD vehicles. Additionally, the manufacturing capital costs are higher for HDV transmissions over LDV transmissions because the HDV manufacturers do not have a common cadence for introduction of changes. This requires the transmission manufacturer to build both the old and new versions of a transmission until the market can be shifted to a common configuration. Allison’s experience is that this transition time is years, not months. The capital costs include, but are not limited to facility, machinery and equipment, and tooling. Since the cost recovery for the transmission manufacturer is included in the DMC, Allison’s assessment it that the DMC is understated to reflect both increased material costs and investment cost recovery for new transmissions. [EPA-HQ-OAR-2014-0827-1284-A1 p.15]

EPA and NHTSA Underestimate Costs, Precluding Alternative 4

EPA has estimated that manufacturers would need an additional $6.5 Million/year investment for the years 2021-2024 ($26 Million in total) to achieve Alternative 4. It is unclear in the RIA how much of this investment is for hybrids instead of other technologies. Allison, with the support from an ARRA grant from the U.S. Department of Energy, invested over $130 Million for a hybrid system for heavy-duty trucks, which far exceeds hybrid cost estimates in this rulemaking. We recognize that there is investment as part of the proposal’s baseline that is additive to the $26 Million referenced above. In our view, the amount of investment in this area that would be required to make a significant impact on the adoption of hybrids in the market is much greater than that assumed by EPA and NHTSA. [EPA-HQ-OAR-2014-0827-1284-A1 p.53]

Investments for heavy-duty hybrids will be made by component suppliers, not the vehicle manufacturers. The battery, inverter, and motor suppliers must make investments in addition to the system supplier. In this regard – for a small market like the heavy-duty hybrids – a significant investment, under current conditions, must be seen as risky and unlikely to occur. In general, private sector investments will only be made if there are reasonable prospects of earning a return on the investment through volume sales. Since EPA’s assumption is that the technology will be purchased by the vehicle manufacturer at the DMCs as shown in the RIA Tables 2-180, 2-181, and Table 2-182, investments will be recovered by the suppliers through the DMC. Allison believes the DMC estimates are significantly too low to account for the total cost of the components and the investment cost recovery. [EPA-HQ-OAR-2014-0827-1284-A1 p.53]

As a general matter, Allison believes that many of the costs projected for the regulatory options that were considered by EPA and NHTSA and that are presented as alternatives in this rulemaking are understated.\(^\text{18}\) This underestimation of costs is fundamental to EPA and NHTSA’s ability to determine whether an alternative is consistent with statutory authority that requires EPA to give “appropriate consideration to the cost of compliance”\(^\text{19}\) and which requires NHTSA to adopt “cost-effective” standards.\(^\text{20}\) In this rulemaking, the projection of costs is tied directly to the stringency of standards. Cost projections affect the estimated penetration rates for different technologies and thereby EPA and NHTSA’s calculation of what level of stringency is appropriate and feasible. [EPA-HQ-OAR-2014-0827-1284-A1 p.13]
18 For example, the EPA Light-Duty Technology Cost Analysis, Report on Additional Case Studies (RIA Chapter 2 Reference 123) served as a basis for the statement “the direct incremental cost to build a six-speed wet dual clutch transmission was determined to be roughly $100 less than the cost of a six-speed automatic transmission. We estimate the components and engineering to design a heavy-duty torque converter automatic transmission are at least as costly and complex as those to design a dual clutch transmission. Therefore, the agencies estimate switching from AT to DCT would have zero incremental cost for vocational vehicles.” (RIA page 2-121) Allison does not believe that this report is a valid basis on which to make relative cost assumptions for HDVs. The referenced report was based on front wheel drive transmissions with different gear schemes and much higher volumes that offer lower cost opportunities based on manufacturing processes.

19 CAA section 202(a)(2).

Response:

Allison takes exception to our estimate for adding two gears to an automatic transmission. We have based our estimate on an actual tear down of a light-duty automatic transmission and have then scaled that estimate upward by a factor of 6 (based on torque differences between light-duty and heavy-duty vocational). We believed at proposal and continue to believe that this is a reasonable estimate of the cost associated with adding two gears to an existing automatic transmission. Allison has qualified why they think our estimate is too low but, unfortunately, has not provided any quantitative information that would help develop an estimate that Allison would find more agreeable. Therefore, we continue to use the same estimate as used in the proposal except for updates from 2012$ to 2013$.

This remainder of Allison’s comment is really directed at the proposed Alternative 4 which the agencies have rejected in the final rules due to concerns over lead time, pace of standard phase-in and overall risk associated with technology implementation. Further, the proposal did use a cost estimate for the dual clutch transmission on urban and multipurpose vocational vehicles that was cost neutral to an automatic transmission, and a cost estimate for heavy HD regional vocational vehicles that was cost neutral to an AMT, or $3864 (direct manufacturing cost, 2012$, in 2018, see draft RIA Table 2-152). For the final rules, we are not projecting any use of this type of transmission for compliance. Because we have rejected Alternative 4 and are not projecting any use of dual clutch transmissions in vocational vehicles, we believe that the commenter’s concerns about the cost effectiveness of the standards and concerns over how that cost effectiveness is impacted by our dual clutch transmission costs, should be obviated.

The commenter also mentions concerns over the R&D estimates, especially with respect to Alternative 4 and hybrid technologies. Importantly, we are not finalizing Alternative 4, but we are projecting hybrid technologies to meet the final standards. We provide further detail about our R&D estimates below (in this Section 11.3) in our response to Daimler Trucks North America.

Organization: American Trucking Associations (ATA)

Market Penetration Rates for Certain Tractor Technologies are Overly Aggressive

The agencies’ estimated market penetration rates (“MPRs”) form the cornerstone of the rule. If these MPRs are set too high, original equipment manufacturers (“OEMs”) will be facing an uphill battle from the start in meeting their targets. The MPRs appear to be optimistically aggressive, resulting in overly stringent emission standards. The stringency of the standards should be set based on the needs of the market, realistic goals, and on products customer can afford to purchase. Targets under the rule should not rely on the optimism of technology providers who stand to financially benefit from the setting of high, and possibly unrealistic, standards. Customers should not be forced to buy technologies in order
for an OEM to meet a regulatory target. If Phase 2 results in customers being led down a path to purchase technologies that are not proven, cost-effective, or reasonable for a fleet’s applications, fleets will keep their vehicles and trailers longer and will pre-buy in advance of the changes, followed by a subsequent no-buy after the new standards take effect. We have witnessed these buying patterns frequently, the most recent being in 2002 and 2006. A repeat of this pattern will delay both environmental and fuel consumption aims and impede the success of the rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.5]

ATA formed a Fuel Efficiency Advisory Committee (“FEAC”) comprised of fleet and trailer representatives to offer perspectives and provide guidance to ATA on the rule. Over the last two years the FEAC has met with EPA, NHTSA, OEMs, and suppliers on a regular basis to share data, information, industry survey results, and provide overall input. The FEAC developed 15 Guiding Principles on the Phase 2 Rule which have served as the framework for ATA’s positions. Two specific principles relating to the introduction of new technologies are of critical importance to the trucking industry, namely: (1) the advancement of GHG and fuel consumption reductions must be based upon sound science and must be economically achievable, and (2) such standards must not be technology-forcing. [EPA-HQ-OAR-2014-0827-1243-A1 p.5]

Another example is the 2004-2010 rulemakings to reduce particulate matter and nitrogen oxide emissions from on-road heavy-duty engines. EPA estimated the proposed standards would add a cumulative cost of more than $5,000 to a new vehicle. In reality, the trucking industry saw record-setting cost increases of more than $20,000 per new vehicle, a four-fold increase. Ancillary costs incurred by fleets as a result of these rulemakings include missed and late loads and, in some cases, lost hauling contracts. Fleet owners also run the risk of losing drivers if they are forced to operate trucks having new, unproven technologies while other fleets continue to operate vehicles with proven technologies. The trucking industry can ill-afford to lose any drivers as we currently face a severe shortage of 35,000 drivers. In fact, this figure could balloon to nearly 200,000 drivers by 2025 given current employment trends. While it remains uncertain as to how costs over a decade away were derived, it is a fact that several of these costs will be off by several orders of magnitude. [EPA-HQ-OAR-2014-0827-1243-A1 p.10-11]

7 American Trucking Associations, Economics Department.

Response:

The agencies respond to market penetration rate comments related to tractors in Chapter 4 of this RTC, trailers in Chapter 5 of this RTC, vocational vehicles in Chapter 6 of this RTC and pickups and vans in Chapter 7 of this RTC. Regarding comments pertaining to pre-buys associated with earlier criteria pollutant regulations, these comments are not germane to this GHG and fuel consumption regulation; we address such comments in Chapter 15.10.4 of this response to comments.

Organization: BYD Motors

BYD Trucks
BYD’s current battery electric trucks are approximately 3 times as expensive as diesel trucks. In order to reduce the price gap original equipment manufacturers must make sizable investments in research and development and manufacturing scale. Similar investments have already been made by BYD in the bus market and as a result current electric buses are priced at only a 60% premium over diesel buses, a premium at which the fuel and maintenance savings result in approximately a 3 year payback and a favorable total cost of ownership. We believe a similar achievement is possible in the truck markets, driven by the following cost drivers: [EPA-HQ-OAR-2014-0827-1182-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.229.]]

- The largest cost for electric vehicles is the batteries and BYD has achieved a 7% year over year improvement during each of the last 4 years. We are forecasting a 10% annual improvement each year through 2020. [EPA-HQ-OAR-2014-0827-1182-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.229.]]
- Price will also be reduced from scale economies from investing in large scale manufacturing for components and assembly, and from purchasing power from ordering large quantities from vendors. Based on similar price reductions from buses and taxis, BYD estimates a 15% price reduction once our truck models are broadly commercialized. [EPA-HQ-OAR-2014-0827-1182-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.229.]]
- Lastly, BYD will include amortized engineering costs in the price for initial truck orders. After recouping those investments from the initial 1,000 orders for each truck model, BYD will be able to drop price by an additional 10%. [EPA-HQ-OAR-2014-0827-1182-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.229.]]

These price reductions alone will make electric trucks compelling by 2020. However, customers will also experience significant maintenance and fuel savings with electric trucks, which will drive adoption. Fleets generally consider a 3 year payback when assessing these savings. Combining the price reduction outlined above with 3 years of operational savings results in electric trucks that are more affordable than diesel trucks, a scenario that is realistic by 2020. An analysis for four different BYD model trucks is shown below. [EPA-HQ-OAR-2014-0827-1182-A1 p.1-2]

[Table of BYD model trucks analysis can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-1182-A1]

Response:

The agencies appreciate this comment. We note that our attempt is to estimate costs since pricing involves many factors outside the purview of our regulatory analyses.

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Indirect cost estimates

The NPRM requests comment on the estimation of indirect costs. CARB staff supports the use of indirect cost multipliers over retail price equivalent multipliers to capture the difference in research costs associated with varying technology complexities. [EPA-HQ-OAR-2014-0827-1265-A1 p.183]
Response:

Thank you for your comment. EPA agrees that the ICM approach provides a better cost estimate associated with regulatory programs.

Organization: Consumer Federation of America (CFA)

THE COSTS OF IMPLEMENTING STANDARDS

A final, important observation on the literature of performance standards before we turn to the Phase II proposed rule deals with the tendency for costs to be overestimated because well-designed standards trigger the competitive and innovative processes noted above. The analysis often presented in regulatory proceedings is typically static and based on current costs. On the other hand, a thoughtful, well-designed performance standard will be dynamic and facilitate multiple responses to standard compliance rather than mandate specific technologies. If companies are given broad flexibility to meet standards, they will determine the most cost beneficial approach and they will learn how to lower the cost of adopting new technologies. History has shown in virtually every other standard compliance effort, the initial cost estimates always prove to have been too high, as shown in Figure V-2. There is clear and consistent evidence across a wide range of standards that the actual costs of implementing standards were consistently well below their original projections. [EPA-HQ-OAR-2014-0827-1336-A1 p.43-44].

[Figure V-2 can be found on p.44 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

We then examine the explanation (theory) offered for why these costs and benefits have not been reflected in market transactions. Here we address both the issue of market imperfections and the pass-through of fuel costs. [EPA-HQ-OAR-2014-0827-1336-A1 p.45]

Finally, we evaluate the overall design of the rule, according to the six criteria identified in the previous section. Because there are potentially large additional savings, we conclude with a section devoted to the question of whether the agencies have set the standards at a sufficiently high level. [EPA-HQ-OAR-2014-0827-1336-A1 p.45]

Other benefits include reduced fueling time and increased freight hauling. These benefit the trucking industry directly and might well be reflected in the reduction of the cost of transportation service. [EPA-HQ-OAR-2014-0827-1336-A1 p.48]

The largest source of costs is the technology and maintenance costs of adding fuel saving technologies. Other costs, involving factors like increased congestion and accidents resulting from carrying more freight are small. [EPA-HQ-OAR-2014-0827-1336-A1 p.49]

Response:

Thank you for your comments and we agree that “a thoughtful, well-designed performance standard will be dynamic and facilitate multiple responses to standard compliance rather than mandate specific technologies. If companies are given broad flexibility to meet standards, they will determine the most cost beneficial approach and they will learn how to lower the cost of adopting new technologies.”

Organization: Daimler Trucks North America LLC
Alternative 4 – In section 2.7.11 of the RIA, the agencies recognize that the Alternative 4 raises costs to manufacturers and vehicle buyers due to the pull-ahead of technology, which reduces the possibility of learning effects and increased mark-ups. We agree with the agencies that Alternative 4 increases costs, although we question whether the agencies’ analysis covers all of the increased costs. 2.7.11 of the RIA [EPA-HQ-OAR-2014-0827-1164-A1 p.74]

DTNA has reservations about the agencies’ cost-benefit analysis. First and foremost, the agencies underestimate the costs (both up-front costs and indirect costs) of several of the technologies on which the agencies premise the proposed rules. For example, the agencies assume that the cost of an APU is approximately $3,000 (based on RIA Tables 2-26 to 2-28 for penetration rates and Tables 2-36 to 2-38 for penetration rate-adjusted costs), when in fact the cost is closer to [redacted]. The agencies could have found correct information just from DTNA’s sales information. But instead, by using a cost a fraction of the real one, the agencies incorrectly found that APUs are significantly more cost-effective than they really are. Another similar example is the assumption that manufacturers can change the aftertreatment system for $7. (See RIA Table 2-11, and note that the application rate is or should have been 100%, as changes to aftertreatment will likely have to be made across the product line due to certification requirements and the realities of engine manufacturing). Changing an aftertreatment is not so simple. It involves a major tear up the filter, catalyst, coatings, as well as redesigning the combustion system in the engine and control logic to align with the new aftertreatment design. Any one of these changes dwarfs the $7 per vehicle number. In fact, the costs of changes cannot be taken in a vacuum; each part affects the others (which is why we recommended a full-vehicle approach to regulation). [EPA-HQ-OAR-2014-0827-1164-A1 p.127]

Second, in some cases, the agencies used questionable prices for technologies, such as the price of tires, estimated relying on prices from studies (in some cases studies over 10 years old) as opposed to real-world data. How have the agencies improved their cost estimates by responding to the comments made by peer reviewers of the Tetra Tech/Southwest Research cost report? Again, the agencies could have used DTNA’s sales information for realistic prices, which would have resulted in a decreased cost-effectiveness compared to the agencies’ estimates. Third, we believe that the agencies failed to properly account for the increased maintenance and replacement costs for FE technologies. In the Preamble (80 FR 40325) the agencies state “In this proposal, the only maintenance costs we have quantified are those for tire replacement, as described in Section IX.C.3.” Given that the agencies have stated this rule will be technology-forcing and the level of sophistication of the technologies the agencies assume will be used to meet the new standards, it does not seem reasonable to only credit increased maintenance costs to that of low rolling resistance tires. For example, based on the agencies’ assumed market of APUs – it should be the case that these stand-alone diesel engines will require maintenance at regular intervals which will increase overall maintenance costs of a vehicle. [EPA-HQ-OAR-2014-0827-1164-A1 p.127]

Again, the agencies could have used DTNA’s sales information for realistic prices, which would have resulted in a decreased cost-effectiveness compared to the agencies’ estimates. [EPA-HQ-OAR-2014-0827-1164-A1 p.128]

Third, the agencies underestimate the costs of research and development required to bring to market the technologies on which the regulations were premised. The agencies assume $240M per year for four years to develop all of the technologies required for the Phase 2 program, for a total of $960M. By comparison, the Super Truck program cost approximately $80M and took five years, yet it involved just one type of vehicle and did not require R&D into manufacturing processes. The agencies expect that manufacturers could do the necessary R&D on hundreds of types of disparate vehicles and their production processes, in a shorter time frame, and with only twelve times the cost. That is simply unrealistic. [EPA-HQ-OAR-2014-0827-1164-A1 p.128]
Fourth, the agencies overestimate the value of the learning effect. For example, the agencies assume that manufacturers will begin learning from WHR in 2015-2017 and accelerating in 2018, 2019, and 2020. (See RIA Section 2.12.2.15 and Table 2-136). But that technology is not slated for production in any of those years. It is currently only in early development in laboratories like our Super Truck ones. So the agencies are incorrect in calculating learning effect benefits so early. Conversely, the agencies seem to assume there remains room for some learning effects with APUs, a technology that has been around for so long that the agency acknowledges “this technology is on the flat portion of the learning curve.” (See RIA Section 2.12.6.1.). This assumption is questionable. In short, there are a number of potentially faulty assumptions regarding learning effects with the various technologies. [EPA-HQ-OAR-2014-0827-1164-A1 p.128]

Fifth, the agencies underestimate compliance costs. Most glaring of the errors is the assumption of an industry-wide annual cost for powertrain testing of $335,000 or less than $100,000 per major manufacturer. With the agencies premising so much of vehicle-side improvements on “deep integration,” which we understand to be demonstrable only through powertrain testing, and with powertrain testing costing on the order of $100,000 per powertrain, the agencies are orders of magnitude\(^3\) wrong on this cost. Similarly, the agencies failed to account for rear axle test facilities, testing, and reporting costs. The agencies failed to account for additional costs of general reporting, as increasing the number of GEM inputs require manufacturers to better track and control each input in order to ensure compliance. The agencies failed to account for the vastly increased cost of aerodynamic testing that would be required under the agencies’ proposed program, given that (among other things) the program requires \(F_{\text{alt}_\text{aero}}\) testing for all major models. In short, the agencies dramatically underestimated compliance costs. [EPA-HQ-OAR-2014-0827-1164-A1 p.128]

There are several other concerns that have been raised about the agencies’ cost-benefit analyses, including the concerns raised in ERG’s report Peer Review Of “Costs Of Medium- And Heavy-Duty Vehicle Fuel Efficiency And Emissions Reduction Technologies For My 2019 – 2022,” April 21, 2015. For example, the reviewers were concerned that numbers were not based on sufficient literature search, that the tire cost numbers were inappropriate, that NHTSA’s study appears not to have taken account for the costs associated with FE technologies’ adding weight that push vehicles over legal weight thresholds, etc. [EPA-HQ-OAR-2014-0827-1164-A1 p.129]

The agencies should have considered the cost to a heavy-duty vehicle operator of being stranded by the side of the road with a breakdown, a risk that the agencies recognized (80 FR 40236) but failed to quantify. The operator generally has a load to deliver by a certain time and thus must get someone to pick up that load for him. He may lose business from shippers who see him as unreliable if he fails to deliver a load. He may have to get his vehicle towed for repairs, to pay for roadside assistance, or to spend his (valuable) time doing his own repairs. New and added technologies on a vehicle increase the risk of vehicle operators incurring such costs, notwithstanding our warranties and our best efforts to avoid any failures. The agencies should have increased technology costs for all technologies by a risk-adjusted amount reflecting these costs. [EPA-HQ-OAR-2014-0827-1164-A1 p.129]

The agencies should have included in costs to carriers in regards to weight of new technologies on their vehicles in decreased carrying capacity. Heavy-duty vehicles are subject to Bridge Law limitations on their loads. Any increased technology on a vehicle, be it a WHR system or a small additional computer, decreases the load that the vehicle can haul. For certain of our customers, who haul indivisible loads that take their vehicle to its maximum capacity under the law, any increased tare weight means that the vehicle cannot haul the load, such that mere pounds added mean a complete loss of work. The agencies should have factored in the potential for lost carrying capacity and for entirely lost loads as a result of
the technologies that the agencies use to premise the Phase 2 standards. [EPA-HQ-OAR-2014-0827-1164-A1 p.130]

Response:

Regarding the first point made by the commenter, that the agencies underestimate the costs (both up-front costs and indirect costs) of several of the technologies on which the agencies premise the proposed rules. The commenter first points to our estimated APU cost stating that the agencies assume that the cost of an APU is approximately $3,000 (based on RIA Tables 2-26 to 2-28 for penetration rates and Tables 2-36 to 2-38 for penetration rate-adjusted costs). In fact, the agencies estimated the cost of an APU at $4853 (Direct manufacturing cost (DMC) in 2012$ applicable in 2014, see proposed RIA Chapter 2.12.6.1), considerably higher than the $3000 cost erroneously suggested by the commenter. In the final rules, the agencies have increased that cost estimate to $5882 (DMC in 2013$ applicable in 2014, see final RIA Chapter 2.11.6.1). Regarding the cost of aftertreatment improvements, the commenter suggests that we estimated the cost at $7 when, in fact, we estimated the cost at more than double that amount at $16 (DMC in 2012$ applicable in 2014, see proposed RIA Chapter 2.12.2.1). In the final rules, we carry the same cost as the proposal with updates to 2013$; the final rule cost is estimated at $16 per vehicle (DMC in 2013$ applicable in 2014, see final RIA Chapter 2.11.2.1).

Regarding the second point that “the agencies used questionable prices for technologies, such as the price of tires, estimated relying on prices from studies (in some cases studies over 10 years old)”, we have chosen to base our tire costs on the National Research Council’s 2010 report which showed a $30 price estimate. Using that value, we removed the indirect costs (by dividing by 1.36) to arrive at our final cost estimate of $22 per tire (direct manufacturing cost, 2013$). That cost is an incremental cost for the lower rolling resistance tire relative to a standard tire and is not meant to reflect to full cost of the tire.

Regarding the third point, that the agencies failed to properly account for the increased maintenance and replacement costs for FE technologies since the agencies had considered such costs only for lower rolling resistance tires, the agencies agree and have significantly increased those costs for the final rules. We now have estimated maintenance costs for many technologies, as described in detail in the final RIA Chapter 7.2.3.

Another comment states that the agencies underestimate the costs of research and development required to bring to market the technologies on which the regulations were premised. The comment states that the agencies assume $240M per year for four years to develop all of the technologies required for the Phase 2 program, for a total of $960M. The commenter misunderstands an important element of our cost estimates. Normal R&D spending is included in the markups used to estimate indirect costs. That normal R&D spending is on the order of 3-4% of revenues. The final RIA Chapter 7.2.1.1 shows that EPA has estimated the technology costs at just under $26 billion (2013$, discounted to 2015 at a 3 percent discount rate, MYs 2018-2029). If 3.5 percent of that is R&D, then the R&D spending would be roughly $898 million. To that, we have added an additional R&D spending of $818 million (2013$,
discounted to 2015 at a 3 percent discount rate, MYs 2018-2029). The total R&D spending estimated is roughly $1.7 billion (2013$, discounted to 2015 at a 3 percent discount rate, MYs 2018-2029).

Another comment states that the agencies have overestimated the effect of learning, especially with respect to waste heat recovery and APUs. However, the updated WHR costs for the final rules are “based” in 2021 with learning cost reductions being applied in 2022 and forward. As a result, no learning-based cost reductions are being applied in years prior to our projected implementation. As for APUs and the application of learning impacts, EPA generally believes that industry never stops learning and applying cost reductions to technology.

The agencies do not believe that the added technology, some of which reduces weight, will result in increased vehicle weight such that weight limits will be exceeded. As for drivers being stranded due to breakdowns, we believe that this comment stems from earlier criteria pollutant standards and technologies employed to comply with those requirements. We do not believe that the technologies expected in response to the new standards will result in any increase in breakdowns or driver strandings.

**Organization:** Diaz, Miguel

The inclusion of aerodynamic trailers and the engines is one advance technology that should be included in the society since we have the technology to implement stronger standards. However, many of these points raise multiple concerns that should be revised and not taken lightly. [EPA-HQ-OAR-2014-0827-1848-A1 p.2]

First, many of these technologies are to be applied to most of the trailers and trucks to reduce the fuel used in these vehicles by 2025, but not every driver has a strong economic situation to acquire many of these technologies. Some of them don’t possess the most recent models that could facilitate the users to get repairs, advance technology or upgrades to their vehicles. EPA should concern about implementing solutions and strategies before actually imposing new restrictions to those users that can’t afford upgrading their vehicles every 5 years. For example, some trucks cannot be equipped with fuel efficient tires or change their fuel usage to another more efficient because their model is outdated. They continue to use the same old elements that cause the same level of emissions and constantly deteriorate through time. A more reasonable concern should be impose restrictions to the manufacturers to avoid the further production of pollutant-elements. They should also give a certain amount of time to those persons who are struggling to acquire a more recent model, but make them understand that they should stop buying old repairs and the most harmful fuel to stop the amount of emissions that are actually being produce. [EPA-HQ-OAR-2014-0827-1848-A1 p.2]

**Response:**

The agencies believe that the commenter is suggesting that manufacturers be required to apply new, GHG reducing technology (“impose restrictions to the manufacturers to avoid the further production of pollutant-elements”) and is concerned that owners of today’s trucks should not be required to equip existing trucks with new technology (“some trucks cannot be equipped with fuel efficient tires or change their fuel usage to another more efficient because their model is outdated”). The final standards require the former and do not require the latter. Therefore, the commenter should not be concerned, if we interpret correctly those concerns.

**Organization:** Environmental Law and Policy Center
Second, because trucks consume so much fuel, this regulation is cost-effective. Paying a little more now for a more fuel efficient truck will result in huge savings at the pump. In fact, tractor trailer owners can repay their costs and start earning money on this investment in just two years. Overall, the new regulations are expected to save society $230 billion over the life of this program. And when truckers are buying 75 billion less gallons of diesel fuel, that money is available to spend on other things that strengthen our domestic and local economies.

Response:

The agencies agree that the new standards are cost-effective.

Organization: FedEx Corporation

3. Return on Investment: Phase 2 must not force technology that does not reduce the total cost of ownership for equipment. It is our objective and desire that technology investment produce a payback within the first 18 months of operation. [EPA-HQ-OAR-2014-0827-1302-A1 p.4]

Response:

The agencies estimate that the Phase 2 rule will significantly reduce the total cost of ownership for nearly all of the equipment subject to the final standards (the one possible exception being motor homes). We do not agree that the 18 month payback “bogey” is the correct bogey for any GHG or fuel consumption related rulemaking. EPA is setting these, and all of our transportation-related GHG standards, due to the need to control climate changing emissions. EPA does not set these standards to provide fuel savings or cost paybacks to buyers or drivers of vehicles. We estimate a payback metric because we know that the buyers and users of impacted vehicles find that metric to be of interest. However, the payback metric is not used in our determination of the appropriateness of proposed or final standards.

Organization: First Industries Corporation

The extremely wide variety of applications our trucks are placed in (over the highway, heavy load and in-field services) creates an extremely important requirement to incorporate a wide variety of variables into any decisions concerning costs and serviceability of new and unproven technologies. [EPA-HQ-OAR-2014-0827-1145-A2 p.1]

The heavy-duty industry—both truck manufacturers and truck purchasers—has faced regulations requiring historic emissions reductions in the past several decades. Our customers and our OEM have met these challenges, but not without enormous development costs, resource demands, and increased product cost, as well as significant costs associated with warranties and customer downtime. [EPA-HQ-OAR-2014-0827-1145-A2 p.1]

As dealers, we are on the frontline of customer relations. We experience the same frustration they do when additional controls force truck prices upward. Over the past 7 years our customers have stretched budgets to purchase new or newer used Medium Duty (MD) and Heavy Duty (HD) vehicles equipped with the latest technology, from the 2007 standards through 2010 and into Phase 1. With Phase 2, there is a serious concern among our customer base that the new technology will only end up costing more
and doing less. In fact, there is anticipation of a major pre-buy should the standards fail to address the real world cost concerns and potential penetration rates of barely emerging technology. [EPA-HQ-OAR-2014-0827-1145-A2 p.1-2]

EPA and NHTSA must ensure that their assumptions about various technologies match with market reality and that their cost estimates are comprehensive and accurate so that environmental benefits and efficiency gains are realized in a logical and cost-effective way. Our customers need it. [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

In our direct review of the proposed standards, there are three key areas in the Phase 2 Proposed Rule that require further agency consideration and revision. In order to better understand the marketplace, the agency needs to reevaluate technology penetration rates and the actual cost and payback periods of these proposed technologies. Specifically: [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

(1) EPA’s penetration rates for vicarious technologies are too aggressive, resulting in overly stringent emission standards [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

EPA’s Market Penetration Rates for Various Technologies Are Overly Aggressive

We understand our customers and their unique equipment needs. For dealership operations to be successful we rely on our OEM to provide us with quality products that will work for the customers that have come to know and trust us. When we are responding to proposed regulation it is out of concern for our customers. We feel that the stringency of the standards should be based on products customer can actually afford to purchase. Customers should not be forced to buy technologies in order for an OEM to meet a regulatory target. [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

If a regulation requires customers to buy technology that is not proven, cost-effective, or reasonable for the customer's application, customers will keep their vehicles longer and will pre-buy vehicles in advance of the emission standard changes, leading then to a subsequent no-buy after the new standards take effect. This happened in 2005 & 2006 when a record number of HD Vehicles were sold. Our customers purchased equipment ahead of the 2007 engine standard. Thousands if not hundreds of thousands of those trucks are still on the road today across the United States, besides California. [EPA-HQ-OAR-2014-0827-1145-A2 p.2]

Response:

Much of this comment seems to focus on the 2007/2010 criteria pollutant rulemaking rather than the Phase 2 GHG/fuel consumption rule. Please see our other responses in Section 11.7.1 below, such as those to comment EPA-HQ-OAR-2014-0827-1922-A1, pertaining to specific concerns about pre-buy. With regard to the issue of technology penetration rates, we discuss these in more detail in their respective chapters above (Chapter 3 – Engines, Chapter 4 – tractors, Chapter 5 – trailers, Chapter 6 – vocational vehicles, as well as in chapter 2 of the RIA in the respective sections dealing with each of these standards.

Organization: Idle Smart

2. Extended Idle technology costs – direct, indirect and incremental – are driven by outdated inputs that are drawn from source material and calculations that are incomplete and, more importantly, do not reflect current market dynamics. As with any model, the validity of the outputs and conclusions are directly correlated to the rigor and precision of the inputs. EPA and NHTSA
estimated the cost APUs based on the costs discussed in the Phase 1 rule. That technology was estimated at $4,586 (DMC, 2008$, in 2014). With updates, that cost becomes $4,853 (DMC, 2012$, in 2014) for Phase 2. [EPA-HQ-OAR-2014-0827-1128-A1 p.2]

These estimates substantially understate the true costs of an APU and rely upon information that is, at best, dated. For example, many of the inputs to the Phase 1 rule were driven by a study completed on behalf of the EPA over 5 years ago (Investigation of Costs for Strategies to Reduce Greenhouse Gas Emissions for Heavy-Duty On-Road Vehicles). While it’s interesting that the aforementioned report, completed in 2010, highlighted that midrange APUs cost in the range of $8,000-$9,000 (installed) and that some are as much as 50% more expensive8 (but yet still came up with the $4,586 value in Phase 1), it is nonetheless unclear why the Phase 2 process did not utilize the substantial market data at its disposal to update its estimates to reflect today’s market reality and changes that have taken place over the past five years. [EPA-HQ-OAR-2014-0827-1128-A1 p.3]

For example, in the report that accompanied the work performed by Southwest Research Institute (SwRI) in collaboration with the NHTSA on fuel efficiency and emissions reduction technologies, total incremental price for a diesel APU is stated to be $10,000 and $9,187.77 at production volumes of 50,000 and 300,000 units, respectively. Using either of those values in the Total Cost as Applied to a Technology Package (TCp) from the Phase 2 draft increases the TCp for Idle Reduction technology by over 110% in 2027 ($5,508 vs. $2,596) and Tractor Technology Incremental Costs in the 2027 Model Year by over 22% ($12,842 vs. $15,754) [EPA-HQ-OAR-2014-0827-1128-A1 p.3]

Qualitatively, and outside of our own distribution channel checks which would substantiate these findings, the peer review completed in April, 2015 of Costs of Medium- and Heavy-Duty Vehicle Fuel Efficiency and Emissions Reduction Technologies for MY 2019 – 2022 (referenced above)9 highlights similar deficiencies in quality, scope, and rigor of the methodology used to calculate the incremental retail prices. Comments range from “the literature review was not thorough” through “I think it is a matter of clearly showing what they are doing. This is missing from this report overall” and perhaps even more telling is that half of the peer reviewers, using a scale of 1 (Acceptable as is) to 4 (Not acceptable), rated the Costs report a 3, or “Acceptable with major revisions.”10 Without accurate inputs and with a cost model that underestimates the true incremental cost, the Phase 2 implementation runs the risk of not meeting its well-intentioned and important GHG emissions and fuel goals. [EPA-HQ-OAR-2014-0827-1128-A1 p.3]

8 Investigation of Costs for Strategies to Reduce Greenhouse Gas Emissions for Heavy-Duty On-Road Vehicles, July, 2010

Response:

In the final rules, the agencies started with an estimated APU price of $8,000 (retail price, 2013$). From there, we have adjusted the cost to arrive at a direct manufacturing cost of $5882 (DMC, 2013$, applicable in MY2014)). So the $4800 value mentioned by the commenter has been adjusted upward to $5882, and should be understood to be a direct manufacturing cost. This is explained in Section III.D of
the Preamble and in the final RIA Chapter 2.11.6.1. The commenter has done much to attempt to discredit the estimate used in the proposal but has done little to improve upon our estimate by providing a citable value that could be used. EPA notes that using “market data,” as suggested, is not really a viable strategy for EPA. Market data is generally in the form of prices for a given device or piece of technology which has little to no real relevance to the actual cost of that device (cost being the metric sought by EPA, not price). This is particularly true when “prices” can vary according to quantities ordered, so 1 device might be priced at $10,000/unit while 500 might be priced at $8000/unit. The “cost” behind each of those “prices” would be lower, to some extent anyway, and roughly similar regardless of the quantity ordered. This is part of what makes cost estimation so difficult.

Organization: International Foodservice Distributors Association

While IFDA supports efforts to reduce greenhouse gas emissions and increase fuel efficiency, it is critical that the Phase 2 final rule focus on achieving the greatest efficiency improvements at the least overall cost. EPA and NHTSA must not use outsized assumptions requiring the adoption of unproven technologies to justify stricter emissions targets that will prove impossible to meet. Customers depend on efficient cost effective service from foodservice distributors to provide Americans with the food away from home experience they have come to expect. It is important that any final rule be achievable without forcing equipment end users to pay for additional technology that is unproven, unnecessary or does not meet the requirements of each unique transportation operation. [EPA-HQ-OAR-2014-0827-1258-A1 p.2]

Thank you for the opportunity to comment on this rulemaking. IFDA urges both EPA and NHTSA to work closely with industry to ensure any final rule is cost effective, based on realistic assumptions of technological innovation and adoption and does not result in unnecessary cost increases for transportation companies and the consumers who rely on them. [EPA-HQ-OAR-2014-0827-1258-A1 p.2]

Engine manufacturers were able to use off the shelf technologies to meet the Phase 1 emissions requirements. Even with this readily available technology, the average cost per vehicle increased far more than EPA estimates. While EPA estimated an average increase of between $1,200 and $1,900 per new vehicle depending on size, the industry saw increases of up to $20,000, making the return on investment on this new equipment extremely questionable. A second round of cost increases, which are likely to be even more significant given the advanced nature of the technology required would result in exploding transportation costs that would ripple throughout the American economy. [EPA-HQ-OAR-2014-0827-1258-A1 p.2]

Response:

The agencies have worked closely with industry and have developed a final set of standards that we consider to be cost effective, technologically feasible and necessary for the purpose of environmental protection. We do not agree with the assertion that the return on investment is not reasonable. However, we note that return on investment is not the purpose of the new standards – protection of the environment and reduced fuel consumption is the purpose while a favorable return on investment is a favorable side effect.

Regarding the comment about Phase 1 costs between $1,200 and $1,900 and actual increases being $20,000, we believe this comment is really directed at the 2007/2010 criteria pollutant rule rather than the Phase 1 HD rule (which had higher tractor cost estimates than the $1,200 to $1,900 noted). We respond to such comments in Section 15 of this document.
**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

The draft stringency requirements assume market penetration rates for technologies. If those assumptions are inaccurate, the regulation will be undermined as customers are forced to adopt technologies that are not cost effective or do not provide real world benefits. We have heard credible concerns from several stakeholders regarding penetration rates and costs of several technologies discussed in the draft proposal. For example, assuming a 15% penetration rate for waste heat recovery by 2027 seems overly optimistic considering it is not currently in the market. The proposal also assumes this technology will cost up to $11,000. Of course, the actual costs are unknown and new technology often cost more than anticipated. Moreover, the additional costs for maintenance and downtime need to be fully accounted for. Also, the potential benefits of waste heat recovery vary substantially depending on the duty cycle and powertrain. The same can be said for other new technologies. [EPA-HQ-OAR-2014-0827-1248-A2 p.8]

The 60% penetration rate for 6x2’s is potentially problematic considering that six states have laws limiting tire and axle loading in such a way that 6x2’s cannot be used as intended. Fleet owners are not likely to purchase trucks that cannot operate in all 50 states. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]

Underestimating the costs of technologies could further complicate compliance and lead to unintended consequences. Higher technology costs lengthens payback period. New technologies generally require increased warranty costs, increased maintenance costs, and costs associated with increased downtime. We urge EPA and NHTSA to reexamine their cost assumptions to ensure they are based on the most accurate data. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]

UAW members and their families remember the disruption of forcing unproven technology to market and urge the EPA and NHTSA to strive for a regulation that promotes fuel-efficiency and emission reducing technology that is cost-effective and reliable for a market that is sensitive to cost of ownership and real world operational benefits. If customers have to buy technologies just so an OEM can reach a target, they are more likely to pre-buy. We strongly support ongoing dialogue between the EPA, NHTSA and other stakeholders that aim for continuous improvement in testing protocols and cost estimates. [EPA-HQ-OAR-2014-0827-1248-A2 p.9]

**Response:**

We respond to comments regarding technology penetration rates in Sections 3 through 6 of this document. We have developed an updated costs for waste heat recovery and describe that in Chapter 2.11.2.15 of the final RIA. We have reduced our technology penetration rates of 6x2 axles relative to the proposal, now showing a 30 percent penetration and only on Class 8 tractors. We include increased warranty costs as part of the indirect cost markups, and we have significantly increased our estimated maintenance costs relative to the proposal by including many more technologies expected to require maintenance.

**Organization:** Midwest Truckers Association

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 265-266.]
The cost associated with achieving this goal and the payoff time may be a little bit debatable, but even conservative figures that have been suggested point to a tangible return of extra dollars invested to improve fuel economy. Of course it depends on the number of miles traveled that will determine the payback level also, be it a local truck or be it an over the road truck.

For our average member, we expect a four-year payback based on the reality that regional and local drivers are not going to meet the same expectations as a fleet of over the road vehicles. And based on a typical depreciation schedule, the local and short haul trucks are going to be around longer, possibly meaning that an even bigger return on investment may be possible because they do keep that truck maybe up to 10 years.

**Response:**

Thank you for your comments. The agencies agree that the longer a vehicle meeting the new standards is kept, the greater the return via fuel savings on the upfront investment. Further, that vehicle will continue to provide savings to subsequent owners/drivers for its full life.

**Organization:** National Automobile Dealers Association (NADA)

**NEW TRUCK AND ENGINE STANDARDS MUST BE AFFORDABLE AND MUST NOT COMPROMISE PERFORMANCE**

Even in years when freight demand is high and the industry is profitable, only a few hundred thousand potentially regulated trucks and engines are built for sale nationwide. This number pales in comparison to the 10-17 million new light-duty vehicles sold nationwide each year. Moreover, while light-duty customers often may not place a high value on fuel efficiency, fuel cost is the number one variable cost for the trucking industry. Consequently, the final rule should leverage, not resist, the fact that an acceptable return on investment is critical to commercial motor vehicle purchasers. [EPA-HQ-OAR-2014-0827-1309-A1 p.3-4]

Top of mind for commercial truck customers are their practical work needs. Vehicle and drivetrain features must meet expected use conditions. Every commercial vehicle potentially covered by the Phase 2 proposal has a work purpose that must be met through the design, specification, ordering, and manufacture process. And customer needs can vary widely. To its credit, the Phase 2 proposal builds on the Phase 1 rule’s attribute-based categories for combination tractors and avoids cross-cutting mandates for vocational trucks. On the other hand, the proposal’s technology forcing nature and potential for overly stringent mandates could force manufacturers to offer products that unduly limit customer choice through reduced vehicle performance or increased vehicle cost. [EPA-HQ-OAR-2014-0827-1309-A1 p.4]

Cost is always a concern. The fact that some of the nation’s largest fleets can afford to be “early adopters” and to experiment with new fuels and high-cost technologies, while commendable, is by no means representative. The vast majority of prospective new truck buyers are businesspersons who must carefully consider the up-front cost of vehicle features, especially during times when credit is tight and/or freight rates and profit margins are low. [EPA-HQ-OAR-2014-0827-1309-A1 p.4] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, p.71.]]

To be effective, commercial fuel economy mandates must pass economic muster. Prospective customers almost always have the option to keep existing vehicles on the road longer, opting for enhanced maintenance and repair strategies that may even include engine and/or vehicle re-building.
Alternatively, customers may meet their needs with a used truck or tractor, often at a cost significantly lower than that of a new federally-compliant vehicle. Again, fuel efficiency/GHG mandates must be affordable and cost justifiable up front to be successful in the marketplace. [EPA-HQ-OAR-2014-0827-1309-A1 p.4] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1372, pp.71-72.]]

New mandates must not compromise or even appear to compromise vehicle performance, a lesson taught by the disruptive introduction of new commercial vehicle emissions mandates in 2004, 2007 and 2010. Commercial customers will avoid expending the substantial investments necessary to purchase new vehicles when they fear they’ll face significant performance compromises, such as reduced freight hauling capability or increased downtime. Especially with respect to engine and other drivetrain components, improving one performance feature (such as fuel efficiency) must not diminish others. [EPA-HQ-OAR-2014-0827-1309-A1 p.4]

Response:

The agencies do not believe that there will be a loss of performance due to the new standards. Instead, we believe that the new fuel consumption characteristics of these engines and vehicles will be attractive and preferred by future buyers. We discuss more about pre-buys in Section 11.7.2 of this document.

Organization: Navistar, Inc.

Each of the discussions in this Comment should be read with the cost analysis in mind, as all of the concerns expressed in this Comment also have a direct bearing on costs. For instance, when the rule effectively advances a deadline as a result of the structure of the rule, and that impact is not recognized by the cost analysis in the NPRM, that calls into question EPA’s assumptions as to the cost of developing the technology. The provision of less lead time compresses the time the manufacturer has available to develop the technology and necessarily increases development costs. In addition, the penetration rates of new technologies are similarly very questionable and these assumptions are reflected throughout the rule; if they are incorrect, then the agencies’ assumptions as to costs and payback periods are wrong as well. [EPA-HQ-OAR-2014-0827-1199-A1 p.6]

It is difficult for Navistar to adequately comment on the cost analysis, since the underlying assumptions are so far off. However, one important area where we suspect the analysis is off is engine costs, driven by engine model year. As discussed further below, Navistar calculates that a compliant engine will have to be created more than a year before the nominal date when the standards take effect, in order to have an engine fuel map to use with GEM. If one looks at the estimates of costs in the RIA, costs for tractor/trailers are shown as $0 prior to 2021, except as they relate to trailers. This is not accurate, as costs will begin earlier than that, in order to generate compliant engines and engine maps prior to 2021. None of the cost estimates show those accelerated costs. That is just one example that demonstrates how the underlying assumptions can throw off cost estimates. [EPA-HQ-OAR-2014-0827-1199-A1 p.6]

In addition, there were significant costs that were not predicted for Phase 1, that we think will be even higher in Phase 2. One of these is the cost of technology to track the data for reporting and managing the data necessary to comply with a rule this complex. This cost ran into several million dollars for Navistar. However, this cost is not even part of the estimate for the Proposed Rule. On that point alone, the agencies have underestimated the cost of this rule. In this regard, we also completely agree with the EMA comments. [EPA-HQ-OAR-2014-0827-1199-A1 p.7]

For these reasons and others we believe the cost analysis is flawed and understates the costs of the Proposed Rule. The ramifications of this are considerable. If pay back periods are incorrect, customers
will simply overhaul and keep their current vehicles longer instead of purchasing new, more efficient vehicles. The industry will also be damaged, since it will not be able to sell as many vehicles as it would have in the absence of the regulations and the vehicles it does sell will be more costly. [EPA-HQ-OAR-2014-0827-1199-A1 p.7]

The vehicle certification procedure will use the greatly expanded and updated Phase 2 GEM model. The Phase 2 GEM requires many more inputs than the Phase 1 GEM including engine fuel maps, torque curves, transmission type, gear ratios, number of gears, etc. The more complex GEM is required to properly estimate the vehicle fuel use and CO\textsubscript{2} emissions from Phase 2 vehicles. However, providing the input data for GEM and run the GEM model will require large investments in upgrading vehicle manufacturer IT systems. This investment is on the order of several million dollars per manufacturer. In addition to the IT cost the labor cost to track and report all of the inputs to GEM and generate the annual reports will increase dramatically. [EPA-HQ-OAR-2014-0827-1199-A1 p.41]

It is not clear that EPA has accounted for this compliance cost in the Phase 2 cost estimates. Page 7-6 of the RIA has an annual cost estimate of $95,000 and $240,000 industry-wide for vocational and tractor, respectively, powertrain test reporting. This estimate is well below the actual IT and reporting costs that are being realized for Phase 1 and that will be realized for Phase 2. EPA must adequately estimate all new compliance costs for the Phase 2 implementation. [EPA-HQ-OAR-2014-0827-1199-A1 p.41]

6 RIA at 7-3.

Response:

In the proposal, the agencies estimated additional compliance costs at roughly $6 million every year. For the final rules, we have increased that estimate by nearly double to $11 million every year. Importantly, those costs are in addition to the costs already included in the indirect cost markups used in estimating technology costs. In the final rules, we estimate that our indirect costs account for over $300 million per year in the early years and up to $700 million per year in the later years of the program (2027-2029). Some portion of that $300 to $700 million annual indirect costs would include the compliance costs that are included in the markups we use to estimate indirect costs.

The commenter is correct that our analysis does not show these costs occurring the year prior to implementation and, instead, shows them occurring in conjunction with implementation. The costs are in fact accounted for; it is simply an issue of presentation. We have gone back and forth on this presentation issue in the past – showing costs in advance at times and showing costs aligned with implementation at times. Showing costs in advance often times has confused readers expecting to see costs aligned with implementation. Showing costs aligned with implementation has confused readers who understand that some costs occur in year(s) prior to implementation. The important thing is that we have included all of the costs that we believe will be incurred, and that our cost estimates reflect costs incurred in years preceding actual compliance with the standards.

Organization: North American Die Casting Association (NADCA)

NADCA is also concerned about the cost-benefit analysis conducted and encourages the Administration to adopt more realistic expectations of the expenses involved in the research, development, and commercialization of these new technologies. The Association and its members invest millions each year to develop new technologies and the latest production methods to improve their global
competitiveness. A concern raised by others is not only the costs involved with investing in the research, but also whether customers will pay a higher price for the finished product as manufacturers must ultimately pass along some of the additional costs to the purchaser. [EPA-HQ-OAR-2014-0827-1283-A1 p.3]

Response:

The agencies believe we have provided realistic expectations of the expenses involved in R&D associated with the final standards. The commenter has not provided any data or suggested revisions to the analysis estimates. We expect that customers will pay a higher price for finished products given that the costs for those products will be likely be higher. However, we expect significant fuel savings as a result of those increased upfront costs. Further, we expect significant environmental and social benefits associated with the final standards.

Organization: Odyne Systems LLC

Odyne believes fleet adoption rates of plug-in hybrid technology – a technology Odyne Systems has developed and deployed in partnership with the DOE and private fleets – will exceed the 10% market penetration rate assumed by the EPA in the proposed rule by 2027 and at fuel consumption and emission reduction levels (16% specifically for vocational) far beyond the current projections for various applications of vocational vehicles. [EPA-HQ-OAR-2014-0827-1239-A1 p.3] [[This comment can also be found in EPA-HQ-OAR-2014-0827-1239-A1 p.3]]

ROI Projections

The sales price of a PHEV system in 2021 is estimated to be approximately $15,400 based upon a total cost of components of $10,000, and including installation cost of $800 and gross margin of 30%. [EPA-HQ-OAR-2014-0827-1239-A1 p.14]

2021 ROI of 3 years: Annual fuel savings are estimated to be over 1000 gallons per year based upon telematics data from the current vehicles in operation, at 250 workdays per year and 4 gallons per day of fuel savings as shown in Table 2. At an estimated cost per gallon of fuel in 2021 (includes price of fuel per gallon, labor cost during estimated refueling time and non-productive miles driven to reach refueling station) of $4 per gallon in 2021, total savings per year including engine maintenance and fuel savings is estimated to be $5000 per year, resulting in a payback in years of approximately 3 years, significantly shorter than goals discussed by the EPA of 6 years for vocational trucks. [EPA-HQ-OAR-2014-0827-1239-A1 p.14]

The sales price of a PHEV system in 2027 is estimated to be approximately $10,000 based upon the total cost of components of $6,500, and including installation cost of $500 and gross margin of 30%. [EPA-HQ-OAR-2014-0827-1239-A1 p.14]

[Table 2, Odyne Fuel Consumption, can be found on p.15 of docket number EPA-HQ-OAR-2014-0827-1239-A1]

2027 ROI of 2 years: Annual fuel savings are estimated to be over 1000 gallons per year based upon telematics data from the current vehicles in operation, at 250 workdays per year and 4 gallons per day of fuel savings as shown in Table 2. At an estimated cost per gallon of fuel in 2027 (includes price of fuel per gallon, labor cost during estimated refueling time and non-productive miles driven to reach refueling station) of $4 per gallon in 2027, total savings per year including engine maintenance and fuel savings is
estimated to be $5000 per year, resulting in a payback in years of approximately 2 years, significantly shorter than goals discussed by the EPA of 6 years for vocational trucks. [EPA-HQ-OAR-2014-0827-1239-A1 p.15]

Response:

The projections of technology adoption should be viewed as a potential path toward compliance and not the path. If the commenter is correct about the benefits of hybridized systems, then we would expect that the market will move toward that approach to compliance. Certainly nothing in the Phase 2 rules impedes such market acceptance. We discuss comments regarding the rationale behind our vocational vehicle hybrid technology penetration rates in Section 6.3 of this Response to Comments.

Organization:  Owner-Operator Independent Drivers Association (OOIDA)

[Table 1 can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1244-A1]

Though the agencies have estimated rather high penetration rates, EPA has historically overestimated penetration rates while also underestimating the cost to OEMs to implement the required changes to the engine and drive-train. [EPA-HQ-OAR-2014-0827-1244-A1 p.12]

The Cost/Benefit Equation

The agencies estimated a $10,000 to $13,000 increase in the cost of a new truck and a $1,400 increase for a new trailer by MY 2027 as part of Alternative 3. OOIDA believes that these estimates are far below the actual costs of proposed technologies, and thereby suggests that the agencies reevaluate their cost and benefit analysis in order to more appropriately reflect reality. For example, the agencies have estimated that the cost of an APU will be $4,327 by MY 2027. Nonetheless, the OOIDA Foundation, which has received two grants through EPA and the SmartWay Program in order to assist OOIDA members in purchasing APUs, has helped over 500 members purchase and install APUs in their truck. The average cost however was $8,000 with an additional installation cost of between $100 and $500. According to the market today, an APU produced by Thermo King costs $11,000. Moreover, the agencies failed to include maintenance costs within their analysis as APU’s require standard service maintenance after a minimum of 2,000 hours of operation, the cost of which is approximately $250. The agencies have grossly underestimated the cost of APU’s, and thus have created false benefits and costs in their analysis, especially considering the agencies excessively high adoption rates. [EPA-HQ-OAR-2014-0827-1244-A1 p.40]

In addition to the underestimation of APUs, the agencies have not properly addressed the costs associated with LRR tires. Because of their lessened tread depth, LRR tires do not have the same lifespan as other tires, meaning that they will need to be replaced more often. The agencies have failed to recognize that the purchasing of tires is not the only cost an owner-operator must account for, instead labor costs, which include the removal of the wheel, removal of the tire, mounting of the new tire, balancing of the wheel, remounting of the wheel, and finally the FET, must be considered over the useful value life of 10 years. The table below is an example of such a cost. [EPA-HQ-OAR-2014-0827-1244-A1 p.40]

[Table 2 can be found on p.41 of docket number EPA-HQ-OAR-2014-0827-1244-A1]

A total cost of $336.71 for fees which do not include the actual tire is substantial. This fee would be repeated for each axle, which for a standard 18-wheeler would amount to $1,434.32. While the agencies
“expect minimal increases in maintenance costs under the proposed standards, having estimated increased maintenance costs associated only with installation of lower rolling resistance tires,” OOIDA believes that the agencies did not adequately analyze the costs of maintenance associated with the proposed technologies. [EPA-HQ-OAR-2014-0827-1244-A1 p.41]

Cost of Trailers

In addition to the increase in price for a tractor, the agencies projected a $1,400 increase for a new trailer by MY 2027 as part of Alternative 3. According to the California Air Resource Board, the retail price for a set of side skirts, which weigh between 150 and 350 pounds on average depending on the material, length, and configuration of the skirt, ranges between $1,000 and $2,600, not including the cost of installation, front trailer fairings cost between $800 and $1,000, and rear trailer fairings cost approximately $2,000.47

[Table 4 can be found on p.43 of docket number EPA-HQ-OAR-2014-0827-1244-A1]

The costs detailed above do not take into account annual maintenance costs, which are projected to be almost $300 annually, or replacement costs, for example a trailer side skirt can cost between $80 and $500. Additionally, it is imperative to note that some owner-operators, and most fleet owners, own more than just one trailer, while also hauling different types of cargo. Overall, the current trailer to truck ratio is approximately 2.8. Therefore, you can expect these costs to double for many owner-operators. [EPA-HQ-OAR-2014-0827-1244-A1 p.43-44]

Ultimately, the potential economic savings must be more concrete or proven in order for these proposed technologies to present a good enough incentive for owner-operators to purchase new, more expensive trucks and trailers. [EPA-HQ-OAR-2014-0827-1244-A1 p.44]

Is it more than probable that the increased price of both a truck and trailer will mean that some truck owners will not be able to afford to purchase new equipment (or even afford a used truck with an increased price). A dramatic increase in the price of a truck and trailer might act as an incentive for many truck owners to hold on to their older equipment for a longer period of time, therefore not gaining the benefit of the promised improved fuel economy and denying the agencies their projected gains in air quality improvement. [EPA-HQ-OAR-2014-0827-1244-A1 p.44]

Response:

The commenter notes the “cost” of an APU at $8000. The agencies interpret that “cost” to be the “price” paid for the APU. In the final rules, we have started with an estimated APU price of $8,000 (retail price, 2013$). From there, we have adjusted the cost to arrive at a direct manufacturing cost of $5882 (DMC, 2013$, applicable in MY2014)). So the $4800 value mentioned by the commenter has been adjusted upward to $5882, and should be understood to be a direct manufacturing cost (see final RIA 2.11.6.1). Importantly, we seek the cost of the device, not the price paid at point of sale which includes many factors beyond the scope of our analysis. The commenter also notes that we failed to consider maintenance on the APU. While true of the proposal, we have changed that in the final rules by estimating maintenance costs at $300 (APU), $310 (battery APU) and $400 (APU with DPF) at 100,000
mile intervals (see final RIA 7.2.3). These estimates appear to be in-line with the commenter’s suggested maintenance costs.

As for the comment regarding lower rolling resistance tires and tread wear, we respond fully to that issue in Section 4.3 of this RTC document.

We have not included maintenance costs associated with aero treatments on trailers due to lack of data that could be used to support the estimates. The commenter suggests an annual maintenance cost of $300 but provided no data or study upon which that estimate was based. It is possible that the estimate is based on anecdotal evidence of a small number of problem installations rather than an average of all trailers equipped with aero treatments. Without the study it is not possible for us to know. Since we are not aware of widespread maintenance issues surrounding aero treatments on trailers, we have not included any increased maintenance costs.

Organization:  Recreational Vehicle Industry Association (RVIA)

RVIA contracted with John Dunham and Associates\(^{31}\) (Dunham) to assess the economic impact that compliance with the proposed Phase 2 standards could have on the motorhome industry. The methodology for this model is available in Appendix C. In simplistic terms, Dunham’s model assumes that some change in price will have an impact on motorhome sales (shipments)\(^{32}\) and that this impact on sales will in turn impact industry jobs, wages, economic output, government tax revenue, etc. RVIA asked Dunham to estimate the economic impacts for the following four scenarios: [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.7 and 11.12 of this comment summary]

**Scenario 1:** Motorhomes buyers factor 100% of fuel savings into their purchase decision (8.5 years of discounted fuel savings were subtracted from estimated incremental cost increases; costs based on EPA ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.7 and 11.12 of this comment summary]

**Scenario 2:** Motorhomes buyers factor 100% of fuel savings into their purchase decision (8.5 years of discounted fuel savings were subtracted from estimated incremental cost increases; costs based on motorhome industry ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.7 and 11.12 of this comment summary]

**Scenario 3:** Motorhome buyers do not factor fuel savings into their purchase decision (costs based on EPA ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.7 and 11.12 of this comment summary]

**Scenario 4:** Motorhome buyers do not factor fuel savings into their purchase decision (costs based on motorhome industry ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.7 and 11.12 of this comment summary]

The results of Dunham’s assessment for 2021MY, 2024MY and 2027MY are found in the following three tables below. Additional details are located in Appendix D. [EPA-HQ-OAR-2014-0827-1261-A1 p.21][This comment can also be found in section 11.7 and 11.12 of this comment summary]

[Charts, economic impacts, can be found on p.21-22 of docket number EPA-HQ-OAR-2014-0827-1261-A1]
In RVIA’s view, Scenario 4 represents the most likely outcome. Scenario 4 reflects costs based on an ICM that is more representative of actual practice in the motorhome industry which, as we have already discussed, is distinctly different from other vocational vehicle segments (largely because motorhomes are not purchased for commercial purposes). [EPA-HQ-OAR-2014-0827-1261-A1 p. 22][This comment can also be found in section 11.7 and 11.12 of this comment summary]

31 John Dunham & Associates (JDA) is an economic specialist in regulatory analysis. JDA generates economic and fiscal impact studies from a national level down to geographic regions, municipalities, marketing areas or Federal and state legislative districts. See http://guerrillaeconomics.com/.

32 According to John Dunham and Associates, the base elasticity for motorhomes is -0.905, suggesting that a 10 percent change in prices will reduce demand by 9 percent (see Appendix C).

Response:

We respond in Section 11.12 to these comments raised by RVIA. Note, however, that the final standards include an optional custom chassis standard for motorhomes which are based on different technologies than those addressed in the comment, and should result in a standard which is less costly (should a motorcoach OEM choose to certify to that standard).

Organization: Triple Decker Transport Ltd.

As the trucks become more expensive fewer Owner Operators will be able to afford the “newest” technology thereby decreasing the desired effect on the GHG Emissions. While the desired increased fuel economy will potentially mitigate the “overall” cost of the new trucks, THE UPFRONT COST will be higher and this money will have to be financed [EPA-HQ-OAR-2014-0827-0908-A1 p.2]

I still remember the original EPA quote of the 2004 -2010 standards costing approximately $6500-$7500 USD per truck. The actual capital costs were $30,000 plus the extra’s we suffered (listed above)! Since the EPA missed so badly on these cost estimates I am terrified that the “Real World Cost” will be over $25,000 for the latest GHG Proposals. [EPA-HQ-OAR-2014-0827-0908-A1 p.3]

The moniker that this regulation only affects the OEM is incorrect. The OEM will pass on the cost to the purchaser. We will suffer again if the newest technology is not proven BEFORE we buy it. [EPA-HQ-OAR-2014-0827-0908-A1 p.3]

Response:

The agencies have made every effort to provide the best estimate possible of the costs of the standards. We respond to comments regarding our earlier criteria pollutant rules in Section 15.10.4 of this Response to Comments. We fully understand that the standards do not impact only the OEM but also the end purchaser and all of society. For that reason, we have estimated the net social benefits of the rule which are substantially positive.

Organization: Truck Renting and Leasing Association

The Agencies Underestimate Compliance Costs & Fail to Appreciate the Unique Economic Position of the Truck Renting & Leasing Industry
The Proposed Standards are historic in scope and complexity, regulating a wide array of customized vehicles including a broad range of tractor applications, utility trucks, street sweepers, concrete mixers, local delivery trucks, dump trucks, buses, motor coaches, and more. They come on top of similar regulations implemented under Phase 1 of the program. Over the last eight years, the agencies have compelled the trucking industry to absorb approximately $20,000 - $30,000 in additional costs to the price of a truck for technology, some of which has not always worked properly or as quickly as was promised because the manufacturers were not given sufficient time to perfect those technologies. Proposed Standards, at 40153. Under the Proposed Standards, at minimum an additional $11,680 per truck would be incurred. Id. at 40165. It is important to note that these figures do not even include the costs of the 12% Federal Excise Tax that is imposed on the purchase price of any truck with a Gross Vehicle Weight Rating of 33,000 pounds or more. [EPA-HQ-OAR-2014-0827-1140-A1 p.2-3]

The costs shown by the agencies are for the average of all vehicles in that regulatory subcategory based on technology penetration rates. To develop “average costs,” the agencies effectively divided the cost of technologies by the number of engines/trucks estimated to be sold in the future. This methodology is invalid as customers will actually pay the increase in the cost of the individual technologies they are forced to buy; stated another way, purchasers pay the actual cost of a vehicle, not the average cost. The agencies’ costing methodology does not reflect the cost of a vehicle with the technologies installed, since that vehicle must absorb 100% of the technology cost. All vehicles will not need or have all technologies, but some, like waste heat recovery, are expensive items as the agencies note. This means the cost will not be a few hundred dollars in 2021, but rather thousands of dollars of added cost for the vehicle that has it installed. In fact, the agencies estimate waste heat recovery alone will cost as much as the average cost per vehicle of the entire rule. [EPA-HQ-OAR-2014-0827-1140-A1 p.3]

Moreover, these elevated costs will be borne over a shorter vehicle life that results from inclusion of advanced technology with scant operational experience in the real world. The leasing industry’s experience to date with the types of technologies discussed in the Proposed Standards is a shortening in vehicle life. Several years ago, it was not unusual for a leasing company to operate a unit up to approximately 1 million miles. In recent years, however – to include under Phase I of the program – it is not unusual for units to be removed from service after only 750,000 miles. This means higher costs of vehicles are spread out over less time and with less available use. [EPA-HQ-OAR-2014-0827-1140-A1 p.3]

And while the truck leasing industry is happy for its customers to save money, the Proposed Standards end up imposing disparate, and potentially punitive, costs on leasing companies. This is because most of the Proposed Standards’ savings are anticipated to arise during vehicle operations when less fuel would be consumed. Accordingly, TRALA members will be forced to raise lease and rental rates. Like any other business, they will pass on much of these cost increases, rather than simply absorbing all of the costs themselves. [EPA-HQ-OAR-2014-0827-1140-A1 p.4]

Thus, the supposed savings to customers because of improved fuel efficiency could prove illusory, because they will be nullified by the increased lease and rental rates. The Proposed Standards’ mandated inclusion of advanced technologies could add an additional layer of increased lease costs that would primarily be borne by the vehicle’s lessee. The additional layer of increased lease costs could arise, for example, from the greater level of maintenance that the agencies are requiring. [EPA-HQ-OAR-2014-0827-1140-A1 p.4]

Response:
Regarding inclusion of the federal excise tax, this tax is not included in our cost estimates since the tax is not paid by the original equipment seller but rather by the end purchaser. While we recognize that the tax is a cost to the end purchaser, it is actually a transfer payment within the context of the benefit-cost analysis since that tax is passed back to society via tax supported services. Similarly, our benefit-cost analysis does not include fuel taxes when calculating fuel savings. In our payback analysis, we do include the excise tax since the payback analysis is meant to be a consideration from the perspective of the end purchaser. Similarly, in the payback analysis, we include retail fuel prices (i.e., inclusive of taxes) since those are the prices paid for the fuel by the user.

The comment regarding the “average” vehicle versus the vehicle equipped with a specific device or devices is an interesting take on our analysis. However, in aggregate, the average cost estimated in our analysis is the best and most meaningful measure of the projected cost of the new standards. We do not expect that a “maximum” or a “minimum” technology tractor will be built. Instead, we estimate that, on average, tractors will gradually improve fuel consumption and decrease GHG emissions such that a variety of prices and performance characteristics will continue to be available. Just because every vehicle is not “average” does not mean that we are underestimating costs, nor are we overestimating costs.

The commenter also is concerned about vehicle lifetimes being cut short due to the new standards. We do not believe that the technologies expected in response to the new standards will result in any decreased lifetimes. Further, we are not aware of any data that suggests that vehicle lifetimes have been cut short due to the Phase 1 rule which is only in its third year of implementation or, what was probably meant by the comment, the 2007/2010 criteria rule.

As for the agencies failing to recognize the unique position of the truck renting and leasing industry, we are not quite sure what the commenter would suggest we do. We are requiring new trucks to meet more stringent GHG and fuel consumption standards. We expect that new trucks, purchased by leasing companies will cost more in the future. We expect those trucks to consume less fuel thereby saving money for those buying their fuel. Those savings should not be nullified by increased lease and rental rates any more than they would be nullified by increased purchase costs for buyers of new tractors. How the truck costs and savings are shared between truck lenders and truck lessees, is beyond the scope of our analysis.

**Organization:** United Parcel Service (UPS)

**Market Penetration Rates for Tractor Technologies are Overly-Aggressive**

UPS fully supports the ATA’s position on this issue. In particular we agree that assuming overly aggressive market penetration (MPR) rates will likely result in reliance on unproven technologies. [EPA-HQ-OAR-2014-0827-1262-A1 p.2]

This will lead to fleets holding on to their fleets longer and pre-buying in advance of the introduction of unproven technologies. ATA cites the years of 2002, 2006, and 2009, in which the industry reduced truck buys because of, or in anticipation of, rulemaking where the industry was uncomfortable about the technology being pressed upon them. In our own case, UPS normally purchases 600 — 800 trucks a year, but in 2003, we bought only 1 class 8 diesel truck, in 2005 we bought only 8 of them, and in 2010, we bought only 3. [EPA-HQ-OAR-2014-0827-1262-A1 p.4]

UPS also agrees with the 15 Guiding Principles adopted by the Fuel Efficiency Advisory Committee (FEAC) as UPS participated in the FEAC. [EPA-HQ-OAR-2014-0827-1262-A1 p.4]
Technology Costs Remain Suspect

UPS fully supports the following from ATA's comments. In the beginning of our comments we have already discussed the trucking industry's unfortunate experience with the diesel emissions control systems available to meet the 2007/10 Diesel Emission Rule. In our fleet, the actual cost of these systems, including maintenance, was about 4 times what EPA predicted. [EPA-HQ-OAR-2014-0827-1262-A1 p.6]

'ATA believes the agencies underestimated the costs of various technologies making the payback period on these technologies much longer than is stated in the proposed rule. A fleet owner typically demands an 18-month payback on technology purchases. If the actual cost payback extends beyond 24 months, it will likely lead to the risk of increased fleet pre-buys/low-buys/no-buy scenarios. The Phase 2 Rule currently envisions a 24-month payback period. If variables such as technology costs, MPRs, and fuel costs are not accurate, fleet payback periods for equipment will not be recognized during the period of equipment ownership. Moreover, likely additional costs for maintenance and downtime for new technologies need to be wholly accounted for under the rule. If payback on equipment purchases is pushed beyond ownership periods, there is little or no incentive for fleets to make the initial investments in technologies under Phase 2. [EPA-HQ-OAR-2014-0827-1262-A1 p.7]

'The trucking industry remains wary of future cost projections of the agencies. A good example of why ATA remains skeptical of such projections is the recent rulemaking to reduce particulate matter and nitrogen oxide emissions from on-road diesel engines commonly referred to as the EPA's 2007/2010 Diesel Engine Emissions Rule. The EPA estimated that the proposed standards would add about $1,200 to $1,900 per new vehicle depending on the vehicle size. However, the trucking industry saw record-setting cost increases up to $20,000 per new vehicle which equates to an increase between 1,567% and 1,667%. Additional costs incurred by fleets under the phase-in of the 2007 standards included missed loads, late loads, and lost hauling contracts.' [EPA-HQ-OAR-2014-0827-1262-A1 p.7]

Increased Warranty, Maintenance and Downtime Costs Should be Included

UPS fully supports the following comments from the ATA as it is consistent with our fleet's experience: [EPA-HQ-OAR-2014-0827-1262-A1 p.8]

'The proposed Phase 2 standards represent a more technology-forcing approach than Phase 1, predicated on use of both off-the-shelf technologies and emerging technologies that are not yet in widespread use. Past experience with emerging technologies in heavy-duty engines has shown that warranty claims, where an operator takes a vehicle out of service to a maintenance facility to have a part under warranty replaced, tend to be higher during the initial years of introduction. [EPA-HQ-OAR-2014-0827-1262-A1 p.8]

'As shown in Appendix 3, based on warranty claims data required to be submitted to CARB, particulate filter-related warranty claims were at 35% during their initial year of introduction (2007), decreased to 18% during the second year and fell to 4% during the fifth year (2011, the last year of data provided). Similarly, SCR-related warranty claims were at 20% during their initial year of introduction (2010) and decreased to 10% during the second year (2011). Also of note is how other technologies were affected during the introduction of a new technology. For example, warranty claims for engine/ECM/other components increased from 22% prior to the introduction of particulate filters to 90% during the first year this technology was introduced.' [EPA-HQ-OAR-2014-0827-1262-A1 p.8]
UPS agrees with ATA that additional warranty, maintenance and downtime costs result when new or significantly altered technologies are introduced. It appears the proposed rule only includes increased maintenance costs associated with tires. UPS also agrees with ATA’s requests of the agencies to further examine the warrantee claims and operational cost data to develop an algorithm that accounts for additional warranty, maintenance and downtime costs as part of the final rule. [EPA-HQ-OAR-2014-0827-1262-A1 p.8]

Response:

We respond to comments regarding pre-buys in Section 11.7.2 of this Response to Comments. Further, we do not believe that extending paybacks beyond 24-months will result in pre-buys/low-buys/no-buys.

We have included far more maintenance costs in the final rules than in the proposal (see final RIA 7.2.3). In addition, while important in considering levels of standards and presenting impacts of standards, we do not determine nor set new standards based on payback metrics. Lastly, many of the UPS comments pertain to prior rulemaking efforts about technologies that are not expected for use to comply with the new standards being set via this GHG/fuel consumption rule.

Organization: Volvo Group

Testing Burden

Additional testing for GHG/Efficiency certification adds to the engineering development workload and reduces our capacity to implement changes. Engineering budgets and resources are limited to the amount that can be supported from product sales margins, so all added burdens detract from actual product development. Beyond the testing requirements carried over from Phase 1 to support the redundancy of a separate engine standard, new testing required or expected in this proposed rule includes engine mapping, aerodynamic testing, vehicle chassis dyno testing, powertrain testing, axle testing, and possibly alternative engine testing. These all have the effect of elevating cost for each related development program or siphoning off budget for development. [EPA-HQ-OAR-2014-0827-1290-A1 p.33]

COST ANALYSIS PROCESS

The Agencies’ cost analysis of compliance for engine and vehicle manufacturers, as well as impacts to end-users, is woefully underestimated. [EPA-HQ-OAR-2014-0827-1290-A1 p.33]

Indirect Cost Determination as Inputs to MHD and HHD Manufacturers

As noted in Preamble section 2.12.1.2, the Agencies used Indirect Cost Multipliers (ICMs) to determine markup factors that have the benefit over the previous method of including technology complexity to determine expected retail pricing. The ICM is calculated as: [EPA-HQ-OAR-2014-0827-1290-A1 p.33]

ICM = (direct cost + adjusted indirect cost)/ (direct cost)

Direct costs cover those costs directly associated with producing one unit (e.g. materials, labor, and warranty). Indirect costs are all costs associated with producing one unit that are not direct costs (e.g. R&D and Sales and Administration costs). The adjusted indirect cost takes into consideration the fact that indirect costs may not be the same for different technologies. [EPA-HQ-OAR-2014-0827-1290-A1 p.33]
This method was used for cost estimation of the light duty MYs 2012-2016 and MYs 2017-2025 rulemakings, as well as for the HD Phase 1 rulemaking. [EPA-HQ-OAR-2014-0827-1290-A1 p.33]

One shortcoming, however, is the lack of consideration for return on investment in the determination of the ICMs. After the development of the LD ICMs for the aforementioned rulemakings and the publication of a peer-reviewed report the Agencies revised the methodology to account for an internal rate of return on investments. In the Phase 2 rulemaking the Agencies are applying this new methodology to the heavy-duty pickup and van cost projections since “the manufacturers involved in this segment of the heavy-duty market are the same manufacturers that build light-duty trucks.” However, for MHD and HHD combination tractors, vocational vehicles, and heavy-duty engine cost projections the Agencies are using the Phase 1 ICMs which do not account for a return on the cost of capital. It is unclear why the Agencies have determined that accounting for a return on investment only applies to LD engine and vehicle manufacturers, but they state that “There was no serious disagreement with this approach in the public comments” to any of the above mentioned rulemakings. This commenter believes that this was likely due to an oversight given the sheer volume of documentation or potentially limited understanding on behalf of the commenters. [EPA-HQ-OAR-2014-0827-1290-A1 p.33]

Regardless, it is Volvo Group’s position that any industry should be considered as requiring a return on its investment related to all indirect costs associated with the development and marketing of new technology, with the MHD and HHD engine and vehicle industries being no exception. As such, Volvo Group requests the Agencies revise the MHD and HHD cost calculations for the Phase 2 rule to account for a reasonable return on investment. The Preamble does account for net present value in Table IX-3, but uses a 3% and 7% discount rate which is insufficient to cover the cost of capital to heavy vehicle manufacturers, let alone account for a positive net profit. [EPA-HQ-OAR-2014-0827-1290-A1 p.34]

**Learning Effect Methodology**

Volvo Group disagrees with the Agencies analysis of cost reduction based on learning curve effects (reference RIA section 2.12.1.3) in that the base assumption assumes a doubling of volume in a fixed two year period. For a steep curve, used for new and highly complex technologies, this corresponds to a 20% cost reduction. [EPA-HQ-OAR-2014-0827-1290-A1 p.34]

It is understood that for more mature technologies the steep portion of the curve is not used in favor of a flatter curve with varying degrees of learning-based cost savings, but Volvo Group does not support the reductions in the first few years on many of the “flat curves” shown in Table 2-101 and Figure 2-33, as we have not experienced these levels of cost reduction without focused initiatives and associated investment. As well, since the learning effect curves are based on volume growth and many of the technologies accounted for in the referenced section are put into production in “cliff events” (Friday to Monday production change), it is unclear whether even the shallowest curve could be realized. [EPA-HQ-OAR-2014-0827-1290-A1 p.34]

[Table, Year-by-year Learning Curve Factors for the Learning Curves Used in this Analysis, can be found on p.34 of docket number EPA-HQ-OAR-2014-0827-1290-A1]

[Graph, Year-by-year Learning Curve Factors for the Learning Curves Used in this Analysis, can be found on p.35 of docket number EPA-HQ-OAR-2014-0827-1290-A1]

**Technology Costs**
In performing cost analysis of technologies the Agencies have severely underestimated those costs, even when accounting for conversion from 2012$ to expected MY 2021$. In addition, the technology costs are subject to misunderstanding due to the 2012$ conversion and the penetration rate inclusion in the package costs. One example of this is Waste Heat Recovery, which is assumed at a total cost of $10,780 in 2012$ in calendar year 2021, but with the penetration rate of 1% applied the cost is given as $105 in 2012$. It is also unclear why the costs for WHR go down annually from 2018 given no penetration until 2021 (this may be a conversion effect, but the only table found in the RIA and Preamble for conversion to 2012$ was for 2005-2013). [EPA-HQ-OAR-2014-0827-1290-A1 p.35]

As noted above, Volvo Group has significant concerns regarding technology costs as determined by the Agencies. To be brief Volvo Group is only providing examples for one current and one future technology, but the concerns can be addressed to nearly all technology cost determinations. [EPA-HQ-OAR-2014-0827-1290-A1 p.35]

**The Cost of Downtime**

Though EPA and NHTSA mention the high cost of downtime in both the RIA and the Preamble, they have ignored these costs in their analysis for the rule. They have also not considered the additional fuel spent in the case of a break down and the resultant pollutants generated. [EPA-HQ-OAR-2014-0827-1290-A1 p.36]

Most large fleets today must purchase 3%-5% more trucks than necessary for their freight demand, to be available to replace down trucks. Even then, once a truck does go down, the fleet must dispatch a tow truck to recover it. If the repair cannot be made immediately, they must send another truck sometimes many hundreds of miles to recover the load and carry it to its final destination. If the load is time sensitive they could be liable for penalties for missed delivery timing. The driver must be transported home, or to the location of another truck and load. Any repair parts not available locally must be sent by expedited freight to minimize the amount of time the truck is in the shop. If the truck was not towed to a fleet’s own maintenance facility they must then send a driver to recover the unit once it has been repaired. Added up, these costs can total thousands of dollars and account for significant additional burned fuel. Smaller fleets that do not have the capital to purchase additional trucks to sit idle waiting for break downs must absorb all of these costs while losing revenue. [EPA-HQ-OAR-2014-0827-1290-A1 p.36-37]

**Additional Concerns**

There are a few additional concerns Volvo Group would like to note in brief, where the Agencies have not considered the following at realistic levels or have not included them in their cost analysis: [EPA-HQ-OAR-2014-0827-1290-A1 p.37]

- Reliability and durability issues potentially resulting in tens to hundreds of millions of dollars in warranty costs to the vehicle manufacturer and increased cost of ownership to the ultimate purchaser in the form of more down-time and increased repair costs beyond the warranty period.
- Resale values that do not reflect added purchase cost of technologies (and may even be reduced for complex technologies that drive up maintenance cost) driving down the ultimate purchaser’s vehicle lifetime earnings.
- Customer expectations of a 12-18 month payback period on vehicle purchases.
Despite this backdrop of growing pressure to further regulate NO\textsubscript{x} emissions from medium and heavy-duty vehicles, there has been little consideration given to this anticipated demand in the Phase 2 notice. This is a considerable oversight, given not only the well-documented inverse relationship between NO\textsubscript{x} and CO\textsubscript{2} emission for internal combustion engines\textsuperscript{10}, but also considering the impact to manufacturers’ resource demands if they must develop an even broader array of technologies to simultaneously reduce NO\textsubscript{x}. [EPA-HQ-OAR-2014-0827-1290-A1 p.59][This comment can also be found in section 15.8 of this comment summary]

The development necessary to meet the proposed GHG standards should not be taken lightly. In many ways, we’re embarking into a new era. The development work to meet the NO\textsubscript{x} and PM reduction challenges required by EPA’s 2004/2007/2010 standards was based on widespread deployment of mostly singular technologies – first Exhaust Gas Recirculation, then Diesel Particulate Filters, and finally Selective Catalytic Reduction. In this Phase 2 GHG regulation, however, EPA and NHTSA are counting on manufacturers to develop a series of technologies, each targeting a subset of applications. Manufacturers lack the development capacity to meet the multiple, parallel development demands for Phase 2. Waste-heat recovery, stop-start, hybrids in widely different vocational applications, engine/transmission control integration, etc. – all of these are major engineering challenges. On top of this is the strong possibility that this will be complicated by, and supplemented with, additional development to address NO\textsubscript{x} reductions is not even considered in the NPRM. There are limitations to the capabilities of manufacturers to deliver on all fronts. Overstressed delivery demands lead to product launches with poor reliability and delayed purchases, which undermine all stakeholders’ goals. [EPA-HQ-OAR-2014-0827-1290-A1 p.59-60][This comment can also be found in section 158 of this comment summary]

\textsuperscript{10} EPA even established a formula for the NO\textsubscript{x}/GHG tradeoff in the Alternative CO\textsubscript{2} Standards – 40 CFR Part 1036.620.

**Response:**

The commenter states, with regard to EPA’s indirect cost multipliers used for HD tractors, “One shortcoming, however, is the lack of consideration for return on investment in the determination of the ICMs. After the development of the LD ICMs for the aforementioned rulemakings and the publication of a peer-reviewed report the agencies revised the methodology to account for an internal rate of return on investments. In the Phase 2 rulemaking the agencies are applying this new methodology to the heavy-duty pickup and van cost projections since “the manufacturers involved in this segment of the heavy-duty market are the same manufacturers that build light-duty trucks.” The commenter also states that “for MHD and HHD combination tractors, vocational vehicles, and heavy-duty engine cost projections the agencies are using the Phase 1 ICMs which do not account for a return on the cost of capital.” This statement reflects a lack of understanding with EPA’s development and use of ICMs. In the draft RIA supporting the Phase 1 proposal, we stated, with regards to our HD ICMs, “The ICMs used in this analysis include a factor for profit that is a 0.05 share of direct costs, as calculated in the RTI report, for the Class 7/8 tractor, vocational vehicles, and heavy-duty engine cost projections.” (see EPA-420-D-10-901, page 2-4) So, in fact, the HD ICMs have always included a factor for the return on capital and, therefore, there is no omission to correct.

The commenter also states that learning effects and their impacts on technology costs have been overestimated. However, the commenter provides no better or suggested learning effects. Importantly,
the commenter does not appear to suggest that learning effects are not real. In the absence of better estimates, have, in general, used the same learning effects in the final rules as in the proposal.

As for technology costs and conversions to 2012$ while showing costs in MY2021, and the application of learning effects in years prior to any adoption, we are confused by the first and understanding of the second. As regards the first, the proposed analysis calculated all monetized values in terms of 2012$. That use of 2012$ has no relation to the year in which the estimates are valid. It simply means that all values are expressed in 2012$ and, should a future study make use of the values in the analysis, the values should be adjusted from 2012$ terms to the dollars used in that future study. In other words, a widget costing $100 in 2012$ will cost $100 in 2012$ regardless of the year, absent any cost reductions that may occur in the production of that widget. If, in some future analysis, all monetized values are expressed in terms of 2018$, then the $100 (in 2012$) widget will, presumably, cost something slightly more given the effects of inflation and, again, absent any learning effects that may occur. Again, this discussion ignores the possible impacts of learning effects. As for the application of learning effects to technologies despite lack of adoption, this is a valid point for some of our technologies, notably waste heat recovery in the context of the proposal (note that, for waste heat recovery, our final cost estimate does not show learning occurring in years prior to implementation in 2021). Cost estimation is admittedly an inexact science. Some cost estimates assume early days of a technology’s existence, while others assume full production and adoption. This is how we form the “base” or “basis” of our cost estimates. For something like waste heat recovery, the systems have changed considerably since their first days on development vehicles. Costs for those systems have come down despite lack of adoption of the systems in the market. In short, we attempt to develop the best cost estimates available and to estimate how those costs might change over time. Admittedly, overestimating learning effects could lead to overly aggressive standards. However, underestimating them could lead to inappropriately lax standards. We strive to determine that middle, most likely outcome, and have documented the reasonable basis for each of our assumptions and conclusions.

As regards the costs of downtime, we understand that such costs can be significant. However, the commenter makes no specific comment nor provides specific data upon which to estimate such costs in association with the technologies expected to be used in response to the new GHG/fuel consumption standards. As noted in other responses, one reason the agencies are not adopting pulled ahead standards (alternative 4) is due to the possibility of inadequately tested technology leading to downtime and incurred costs.

As regards the other concerns stated by the commenter, we note that ICMs do include factors to cover warranty costs. The commenter provides no data pertinent to concerns over reliability. Issues surrounding potential future NOx regulations are not germane to these GHG and fuel consumption standards.

Organization: Walmart Transportation

We support a strong Phase 2 rule that will drive innovation in truck technologies to viable solutions at a pace that ensures the technologies will have the intended triple bottom line outcomes without unintended consequences. Estimates of penetration rates, commercialized cost, and ROI of new technologies are most robust when gained through independent lab and real world testing, as well as from a survey of diverse stakeholders including the component manufacturers, OEMs, and users. Even within one subset like the long-haul combination tractor-trailer market, results will be heavily dependent on duty cycle and application. Within this complex environment, the trucking industry has proven its ability to innovate and drive efficiency when given the right flexibility, incentives and resources. [NHTSA-2014-0132-0117-A1 p.1]
Response:

Thank you for your comments.

Organization: Werner Enterprises

In many aspects, the proposed rule could be detrimental to our business through the projected increase in costs of trucks, engines, and trailers. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

There are several key areas the Agencies need to address: [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

- Penetration rates for various technologies are too aggressive, resulting in overly stringent emission standards. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

Response:

We respond to issues surrounding technology adoption rates in the individual and respective sections of this Response to Comments document, as well as the respective sections of RIA Chapter 2.

Organization: XL Hybrids

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 241-242.]

One, we recommend improvements to the hybridization cost models. The learning curve cost models in the regulatory impact analysis table 2-100 for mild and strong hybrids does not appear to account adequately for the highly specialized manufacturing cost and scaling that is unique to the lithium battery market.

Response:

We would be interested in understanding what sorts of improvements should be made. However, no details were provided by the commenter.

11.3 Changes in Fuel Consumption and Expenditures

Organization: ABC Bus Companies, Inc.

1) ABC supports improved fuel economy as a means to provide economic transportation to rural areas of the country and efficient movement of passengers as a way to reduce highway congestion and CO₂ emissions. [EPA-HQ-OAR-2014-0827-1430-A2 p.2]

Organization: Amy's Kitchen et al.

The availability of fuel-efficient trucks is critical to reducing our carbon footprints as well as our fuel costs. Shippers already spend $650 billion a year on trucking services, and fuel costs account for 39% of the per mile cost of owning and operating a truck. As compared to the proposed standards, a 40% reduction in fuel use would cut an additional 200,000 barrels of oil daily in 2035 and provide 33% more in fuel cost savings. Strong efficiency standards for heavy trucks will help our companies avoid billions of dollars in fuel costs and at the same time support the U.S. economy by keeping product...
transportation affordable and insulating freight costs from volatile global and regional crude oil prices. [NHTSA-2014-0132-0232-A1 p.3]

Organization: Burger, Mark

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 133-134.]

There are five risk factors to fuel prices in the near and long term. First is possible global pricing of carbon emissions. At $25 to $50 per metric ton, that can means adding $10 to $20 to the price of a barrel of oil, or up to 25 to 50 cents per gallon of fuel. The second global risk factor is a geopolitical event up to and including warfare that could disrupt or interrupt oil and gas shipments. The last one is declining rates of extraction by cost or available resources.

For U.S. supply and pricing, there are two major risks to oil and gas prices and supply. First if the lifting of the ban on petroleum exports and development of robust infrastructure to facilitate shipment, especially for liquefied natural gas. The result will likely be U.S. prices of oil and gas moving upward toward global market prices.

At present there is only about a 10 percent spread between Brent and West Texas intermediate petroleum prices. The greater risk, however, U.S. natural gas prices rising to European or Asian levels of two to four times greater. The other risk factor is shale extraction of petroleum and natural gas may be far more short-lived than traditional extraction. Combined with exports to higher priced markets puts the U.S. gasoline and diesel consumer at greater risk. It also neutralizes the premise that shifting heavy truck fuel from diesel to natural gas will be a cost saver without higher efficiency standards.

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p.105.]

And, as we heard, these will have benefits for companies in fuel savings and energy efficiency.

Organization: City of West Hollywood

Fuel is the largest expense for many vehicle fleets. Improvements in fuel economy represent a crucial way for government fleets to control costs while continuing to deliver exemplary service. [NHTSA-2014-0132-0056-A1 p.1]

The 2011 standards will deliver on the order of $50 billion in cumulative fuel savings to vehicle owners and operators over time. The standards will reduce fuel consumption in the overall heavy-duty vehicle fleet by 390,000 barrels per day in 2030 - roughly equivalent to the amount of oil we import each year

Page 1550 of 2127
from Iraq. However, we can accomplish more. According to analysis by experts, by 2025 we have the potential to cut fuel consumption of new trucks by at least 40 percent compared to 2010 levels. Standards that extend beyond 2025 could achieve even larger savings. [NHTSA-2014-0132-0056-A1 p.2]

**Organization:** Clean Fuels Ohio (CFO)

Opportunities improving truck fuel efficiency are also great (and growing) based on already-existing technologies and others in the R&D pipeline that show future promise: [EPA-HQ-OAR-2014-0827-1192-A1 p.1]

According to EPA data, the second phase rule is expected to save vehicle owners $170 billion in fuel costs while conserving 1.8 billion barrels of oil and cutting carbon pollution by nearly 1 billion metric tons over the lifetime of vehicles sold under the program. [EPA-HQ-OAR-2014-0827-1192-A1 p.1]

**Organization:** Consumer Federation of America (CFA)

Section IV examines analyses of the technological potential for and cost of reducing freight truck fuel consumption. We show that there is a great deal of technically feasible and cost beneficial fuel savings available. [EPA-HQ-OAR-2014-0827-1336-A1 p.9]

**POTENTIAL FUEL AND COST SAVINGS FOR MEDIUM AND HEAVY DUTY TRUCKS**

**LIGHT DUTY TECHNOLOGY EXPERIENCE AS CONTEXT FOR HEAVY DUTY STANDARDS**

In 2002, after the first gasoline price spike of the 21st century, the National Academy of Science undertook an analysis of the technological potential to increase the fuel economy of light duty vehicles. It concluded that there was substantial opportunity to reduce fuel economy at relatively low costs. They determined that the value of the fuel savings was larger than the cost of the technology needed to reduce fuel use. As shown in Figure IV-1, other well-respected research reached similar conclusions over the course of the decade. [EPA-HQ-OAR-2014-0827-1336-A1 p.25]

[Figure IV-1 can be found on p.25 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

Although there were differences in the estimates, a clear consensus emerged showing a significant amount of economic benefit in developing new fuel saving technologies. This universal conclusion was a key reason why the doubling of the fuel economy standards for light duty vehicles (CAFE) was adopted in 2012. It was particularly significant that this standard was fully supported by diverse segments of the market including: car companies, unions, consumer groups, and environmentalists. [EPA-HQ-OAR-2014-0827-1336-A1 p.25-26]

Figure IV-2 shows the development of new light duty vehicle mileage since the adoption of fuel economy standards. The CAFE program was instituted by legislation in 1975. Mandated increases ceased in 1986. The Energy Independence and Security Act of 2007, reformed and restarted the program. The first proposed rule was issue in 2008 and went into effect in 2011. In 2009, standards through 2016 were proposed. The long term rule to double fuel economy was finalized in 2012. [EPA-HQ-OAR-2014-0827-1336-A1 p.26]
MEDIUM AND HEAVY DUTY TRUCK TECHNOLOGY EFFICIENCY TECHNOLOGY CURVES

The consensus around the potential for increased fuel economy and the results of recent increases in the standard in the light duty vehicle arena provide an important context for the heavy duty truck rule. The medium and heavy duty truck sector is a much more complex product space than light duty vehicles. Nevertheless, while there are different types of vehicles, equipment configurations, and use patterns, a similar consensus has emerged with respect to medium and heavy duty trucks—expenditures on fuel efficient technology will be more than offset by savings in fuel costs. [EPA-HQ-OAR-2014-0827-1336-A1 p.26-27]

Figure IV-3 presents fuel savings in terms of percentage reduction (rather than gallons) for tractor trailers. Tractor trailers, defined as Class 8 trucks, are the most significant category of medium and heavy duty trucks, accounting for 60-75 percent of the fuel consumption for medium and heavy duty trucks. Therefore, throughout this analysis we focus attention on these vehicles. [EPA-HQ-OAR-2014-0827-1336-A1 p.27]

As Figure IV-3 shows, various studies predict that significant percentages of fuel reduction (10-20%) can be made with technology investments of $10,000-$20,000. In addition, substantial percentages of reduction (40-50%) can be made with investments of $40,000-$50,000. This high reduction in fuel consumption is for Class 8 trucks, and other categories may not present equally rich fuel saving potential, but the potential is substantial in all classes of trucks. [EPA-HQ-OAR-2014-0827-1336-A1 p.27]

Compared to the figures for light duty vehicles, the cost of adding efficiency technologies to heavy duty trucks may appear large. However, heavy duty trucks are driven many more miles and fuel costs between $100,000-$150,000 annually. Given the much larger number of miles driven per year of heavy duty trucks and the much lower mileage per gallon, as well as the higher cost of diesel, the average annual expenditure on fuel for heavy duty trucks is almost ten times the expenditure for light duty vehicles. A ten percent reduction in fuel consumption will support a much larger investment in fuel saving technology. [EPA-HQ-OAR-2014-0827-1336-A1 p.28]

With estimates of the technology costs and fuel savings, the National Research Council report on medium and heavy duty trucks simplifies the cost benefit analysis by focusing on the cost side and not making assumptions about fuel prices (See Figure IV-4). Instead of engaging in the uncertain and sometimes contentious exercise of projecting fuel costs over long periods, the National Research Council estimates the price per gallon that would be necessary to break even on an investment that incorporates technologies to reduce fuel consumption in medium and heavy duty trucks. [EPA-HQ-OAR-2014-0827-1336-A1 p.29]

NRC includes a discount rate, representing the time value of money, set at 7% to compare the estimated costs of saved fuel to projections for the future cost of fuel. As shown in Figure IV-4, the NRC estimated that fuel prices would have to be just $1.09 per gallon for a very large investment in new technology to earn a 7% real rate of return. As actual fuel prices are currently over three times this
amount and expected to rise over time, the payout from these technologies would far exceed their cost. [EPA-HQ-OAR-2014-0827-1336-A1 p.29-30]

In Figure IV-4, we have also converted the results of several other recent studies to this break-even approach. While there are some differences among these studies, there is a clear consensus that large investments in increasing the fuel economy of medium and heavy duty trucks are very attractive. All but one of the analyses show that investments in technology to improve fuel economy would earn more than the 7% discount rate at diesel prices of $2 and substantially more at higher gas prices. [EPA-HQ-OAR-2014-0827-1336-A1 p.30]

EIA’s projected fuel prices over the next quarter century will average close to $4.00 per gallon, as shown in Figure IV-5. With average prices that high, over the next 25 years, the investment in energy saving technology would yield a very attractive return. [EPA-HQ-OAR-2014-0827-1336-A1 p.30]

Figure IV-6 shows the size of potential fuel savings compared to technology costs. It suggests that a goal of cutting tractor trailer fuel consumption by 40 to 50 percent is economical in the long run. In order to cut fuel consumption in half, one must double the fuel economy of the vehicle. [EPA-HQ-OAR-2014-0827-1336-A1 p.30]

This is exactly the target that was adopted for light duty vehicles in the 2012 CAFE rule. For example, if you reduce consumption by 50%, the breakeven cost of fuel is $1.50, which means that as long as fuel is more than $1.50, the cost of technology will be a money saver. [EPA-HQ-OAR-2014-0827-1336-A1 p.30]

These analyses leave little doubt that there is a significant amount of technology available that would lower the consumption of fuel in the medium and heavy duty truck sectors at a very attractive cost. Consumer savings would be substantial. The next question is, why hasn’t the marketplace witnessed these investments. [EPA-HQ-OAR-2014-0827-1336-A1 p.30]

We begin with a discussion of the fuel savings benefits and the technology costs that must be incurred to achieve the reduction in fuel consumption. Although we recognize there are other economic costs and benefits, these make up the vast majority of the total costs and benefits. They are the most obvious consumer pocketbook benefits and costs. Because they are direct and not externalities, in a properly functioning market they would be reflected in the investment decisions that affect energy consumption. The analysis shows they are not, indicating significant market imperfections, obstacles and failures. [EPA-HQ-OAR-2014-0827-1336-A1 p.45]

**DIRECT ECONOMIC IMPACTS**

Our discussion of economics developed a simple economic criteria as a way to easily summarize the very complex economic analysis – the cost of saved energy. EPA/NHTSA start with this approach, which is derived by dividing the real, discounted economic costs (including capital and maintenance costs), by the total number of gallons saved.\(^{32}\) The results are eye-popping. For the proposed rule, the improvement in fuel economy works out to a cost of only $0.40 per gallon. [EPA-HQ-OAR-2014-0827-1336-A1 p.45-46]

As discussed below, the agencies estimate that over the lifetime of heavy duty vehicles produced for sale in the U.S. during model years 2018–2029, the proposed standards [Alternative 3] would cost about
$30 billion and conserve about 75 billion gallons of fuel, such that the first measure of cost effectiveness would be about 40 cents per gallon. Relative to fuel prices underlying the agencies’ analysis, the agencies have concluded that today’s proposed standards would be cost effective...

Our current analysis of Alternative 4 also shows that, if technologically feasible, it would have similar cost effectiveness but with greater net benefits (see Chapter 11 of the draft RIA). For example, the agencies estimate costs under Alternative 4 could be about $40 billion and about 85 billion gallons of fuel could be conserved, such that the first measure of cost effectiveness would be about 47 cents per gallon. However, the agencies considered all of the relevant factors, not just relative cost effectiveness, when selecting the proposed standards from among the alternatives considered. Relative cost effectiveness was not a limiting factor for the agencies in selecting the proposed standards. It is also worth noting that the proposed standards and the Alternative 4 standards appear very cost effective, regardless of which reference case is used for the baseline, such that all of the analyses reinforced the agencies’ findings.33

With fuel prices projected to be about $4.00 per gallon, there is no doubt that the investment induced by the proposed rule would be very beneficial. The other measures of economic impact tell the same story. The value of fuel savings are over six times as large as the technology costs associated with the rule and over five times as large as the total cost. The payback period is less than two years for tractor trailers, which account for 65 percent of the total costs and savings of the rule, less than 4 years for medium and heavy duty pickups and vans, and less than 7 years for vocational vehicles. [EPA-HQ-OAR-2014-0827-1336-A1 p.46]

The economics of the standard are so highly favorable that they raise a concern that is in the opposite direction of the usual concern about standards--Why didn’t the agencies include additional technologies that would yield very positive economic returns? As suggested by the quote above, there are other considerations, in addition to simple economics, that come into play, which led the agencies to reject including technologies that would increase costs and benefits moderately and yield a cost per gallon of only $0.47. We will address this question at the end of this section. [EPA-HQ-OAR-2014-0827-1336-A1 p.46-47]

19 It is important to note that a 50% fuel consumption decrease is equal to a 100% increase in fuel economy. In other words, when the fuel economy doubles, the fuel consumption is cut in half.

20 For example, the American Council for an Energy Efficient Economy estimates potential fuel savings from two phases of technology improvement at between 30% and 46% for heavy duty pickups and vans and Class 8 trucks respectively, http://aceee.org/files/pdf/fact-sheet/hd-oil-reduction.pdf. There are many opportunities to reduce fuel consumption that have been studied recently. See for example, Ben Sharpe and Nigel Clark, Trailer technologies for increased heavy-duty vehicle efficiency, Technical, market, and policy considerations, International Council on Clean Transportation, June 2013; Donald W. Stanton, Systematic Development of Highly Efficient and Clean Engines to Meet Future Commercial Vehicle Greenhouse Gas Regulations, Safe International, 2013-01-2421, September 2013; TA Engineering, DOE SuperTruck Program Benefits Analysis, December 20, 2012. It should also be noted that the cost analyses are being updated and, reflecting the findings in Cooper, 2013, the actual costs are likely to be lower than early estimates.
Energy Information Administration, Monthly Energy Review for fuel consumption, of 4.26 gallons per heavy duty truck of 4126 gallon and 460 gallons per light duty vehicle in 2011. Diesel was over 7% more expensive than gasoline.

The discount rate also refers to the interest rate used in discounted cash flow (DCF) analysis to determine the present value of future cash flows... takes into account not just the time value of money, but also the risk or uncertainty of future cash flows; investopedia.com/terms/d/discountrate.asp

EPA/NHTSA, PHASE II NOPR, p. 40169, lists the cost per gallon saved as the first of three ratios of cost Effectiveness.” It is the only one of the three that is based on economics. The other two ratio involve the value of greenhouse gas reductions.

EPA/NHTSA, NPRM, p. 40169.

Organization: Diaz, Miguel

While the transportation system is only responsible for just 27%, is a really big number when you consider that is the second group that most emissions produce after electricity. The measures taken by EPA are indeed the right call and a smart decision for it will help to reduce millions of dollars in oil use, reduce billions of greenhouse gas emissions, and start reducing the extraction of the world’s natural resources that are limited like petroleum. Even though, only 7 percent of the vehicles are considered to be freight trucks now days, they use about 1/4 of the fuel currently used in the country. They (the vehicles) produce a huge quantity of emissions and demand for oil, equipment and resources.

Organization: Energy Ohio Network

Businesses and consumers across all sectors of the economy rely on trucks to move materials and products. Tractor-trailers and package delivery vans move $10 trillion worth of freight each year and commuter buses transport 3.5 million people to work every day. Furthermore, U.S. companies spent over $700 billion dollars on trucking services in 2014. As travel among heavy-duty vehicles grows by nearly 50 percent over the next 25 years, America will continue to rely on these trucks to support critical services needs as well as the growing economy.

Fuel is the single largest expense to motor carriers – accounting for nearly 40 percent of operating costs, or about $73,000 annually for a combination trailer that gets about 6.5 miles to the gallon (mpg). These charges are passed on to consumers through higher priced products. The Consumer Federation of America reports that fuel costs for goods and services delivered by medium-and heavy-duty trucks cost U.S. households an average of $1,100 in 2010.

Organization:  Environmental Defense Fund (EDF)

B. Increased efficiency provides savings across the supply chain

A more robust final rule will also deliver greater economic benefits. More efficient heavy-duty trucks secure cost savings across the entire supply chain – from the fuel cost savings by independent drivers and fleets who purchase the vehicles, to shippers who deliver goods, to the American consumers who buy those goods. [EPA-HQ-OAR-2014-0827-1312-A1 p.17]

The average semi-truck today burns 20,000 gallons of diesel fuel a year – the same volume of fuel used by 50 new passenger cars.77 Accordingly, fuel has been the largest single cost for trucking fleets, accounting for 39% of the cost of ownership in 2013.78 More efficient trucks drive down the fuel costs for drivers and fleets. An analysis by EDF and others found that a robust rule that reduces fuel consumption by 40 percent over 2010 levels could save average tractor-trailer owners and drivers about $30,000 per year in fuel.79 [EPA-HQ-OAR-2014-0827-1312-A1 p.18]

EDF and CERES examined how strong standards would affect the cost of moving freight by trucks, finding that strong standards will save companies nearly $10 billion dollars in 2030, as the cost-per-mile to move freight would decrease by $0.06 per mile. [EPA-HQ-OAR-2014-0827-1312-A1 p.18]

By 2040, these savings could grow to $34 billion annually, as the net effect of the second phase of the standard alone could reduce the per-mile cost of moving freight by 21 cents.80 [EPA-HQ-OAR-2014-0827-1312-A1 p.18]

77 Assumes Class 8 truck VMT of 120,000 miles and average fuel economy of 6.1 MPG, and sedan VMT of 11,318 and average fuel economy of 31 MPG. Energy Information Agency (EIA), Annual Energy Outlook 2014, Table 68; Freight Transportation Energy Use. Heavy Duty Fuel Efficiency, Existing Trucks by Size Class. University of Michigan Eco-Driving Index available at www.umich.edu/~umtriswt/data/UMTRI_sales-weighted-CAFE_April-2015.xls; and Federal Highway Administration, Table VM-1 American Public Transit Association’s Public Transportation Fact Book Tables 8, 16, and 21.

Today, freight trucks account for only seven percent of the vehicles on the road, but guzzle roughly one-quarter of all fuel. Indeed, freight trucks are the fastest growing source of oil use and climate pollution in the transportation sector. The proposed standards would significantly reduce oil use, saving 1.8 billion barrels of oil and 1 billion metric tons of carbon pollution over the lives of the trucks sold. These cost-effective improvements would not only save truck drivers more than $170 billion in fuel costs, those fuel savings will be passed on to consumers as goods are shipped to market. [EPA-HQ-OAR-2014-0827-1477-A1 p.1]

Analysis shows that we can reduce new truck fuel consumption 40 percent by 2025, compared to 2010 trucks. [EPA-HQ-OAR-2014-0827-0814-A1 p.1]

Heavy-duty trucks account for only seven percent of the vehicles on the road, but consume roughly one-quarter of all fuel. Furthermore, heavy-duty trucks are the fastest growing source of oil use in the transportation sector. The proposed standards would cut oil use by over a million barrels every two days. The standards would also save truck drivers more than $170 billion in fuel costs, and those savings would be passed on to consumers through lower goods prices. [EPA-HQ-OAR-2014-0827-0913-A1 p.1]
Analysis by the Union of Concerned Scientists (UCS) shows that we can cost-effectively reduce new truck fuel consumption 40 percent by 2025. If the proposal is strengthened in line with UCS analysis, it would save an additional 200,000 barrels of oil per day in 2035 and avoid an additional 40 million metric tons of global warming emissions annually—equivalent to shutting down 12 coal-fired power plants. [EPA-HQ-OAR-2014-0827-0913-A1 p.1]

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 65.]

If finalized as proposed, the standards would cut oil use by over a million barrels every two days. By not burning that oil, the United States would over the lifetime of trucks affected by the rule avoid one billion metric tons of global warming emissions. That's roughly equivalent to the emissions created by powering all U.S. households for a year. That creates not only cleaner air, but a future that our children can count on.

I think we need to do more than the proposed standard. To protect our children, we need standards to be strengthened to achieve 40 percent fuel savings by 2025. If the final proposal is strengthened in this way, it would save an additional 200,000 barrels of oil per day and avoid an additional 40 million metric tons of global warming emissions annually, which is the equivalent to shutting down 12 coal-fired power plants. Imagine the incredible impact that would have on children's health and all of our futures.

Organization: Natural Resources Defense Council (NRDC)

Fuel efficiency and carbon pollution standards can also help truck manufacturers be more resilient in the face of market changes outside of their control. For example, fuel-efficient vehicles will be less vulnerable to sales declines when diesel and gasoline fuel price spikes. On the other hand, fleets dependent on fuel-guzzling vehicles will have to spend more to fuel their fleet and their budgets for new vehicle purchases will shrink. [EPA-HQ-OAR-2014-0827-1220-A1 p.11]

Organization: Navistar, Inc.

Another item of concern relates to the basis for adoption rates as influenced by oil and diesel prices. The RIA uses the early 2014 Annual Energy Outlook (AEO) forecast for expected diesel prices. Since then, the projections have dramatically decreased. A May 2015 forecast shows a reference crude oil price in 2020 that is approximately $20 per barrel lower in the 2015 estimate than in the AEO2104 estimate used in the RIA. Within the period covered by the rule the projection is lower at all points by approximately $20 a barrel. The primary/reference fuel price in 2020 and 2027 (interpolated) are 14% and 10%, respectively, lower in the 2015 forecast than the 2014 forecast (while the average for 2020 and 2027 is 6% lower). [EPA-HQ-OAR-2014-0827-1199-A1 p.6]

Looking specifically at diesel price forecasts, one sees the same revision downward. For example, the AEO2015 shows diesel prices at $3.17 per gallon in 2020, as opposed to the $3.67 forecast from 2014
used in the RIA. The table below shows the differences in the estimates between the 2014 and 2015 AEO forecasts for the relevant time periods. [EPA-HQ-OAR-2014-0827-1199-A1 p.6-7]

Clearly, the estimated price of diesel over the years encompassed by this rule declined significantly. Reducing fuel costs by 10% would add 6-12 months to vocational and bus payback periods, which are already calculated in the RIA at 5-6 years. This payback period will meet or exceed the expected life of many of these vehicles. Larger fleets are also able to reduce fuel costs by 30% by purchasing in bulk with long-term contracts and other mechanisms, which can add approximately 6 months to tractor payback periods. [EPA-HQ-OAR-2014-0827-1199-A1 p.7]

Tractor-trailers and package delivery vans move $10 trillion worth of freight each year and commuter buses transport 3.5 million people to work every day. Furthermore, U.S. companies spent over $700 billion dollars on trucking services in 2014. As travel among heavy duty vehicles grows by nearly 50 percent over the next 25 years, America will continue to rely on these trucks to support critical services needs as well as the growing economy.

Fuel efficiency is good for business. Fuel is the single largest expense to motor carriers –accounting for nearly 40 percent of operating costs, or about $73,000 annually for a combination trailer that gets about 6.5 miles to the gallon (mpg). These charges are passed on to consumers through higher priced products. [EPA-HQ-OAR-2014-0827-1177-A1 p.1]

The Consumer Federation of America reports that fuel costs for goods and services delivered by medium-and heavy-duty trucks cost U.S. households an average of $1,100 in 2010. [EPA-HQ-OAR-2014-0827-1177-A1 p.2]

The first round of truck standards, affecting model year 2014 through 2018 vehicles, is estimated to save a total of $50 billion in fuel costs and reduce carbon pollution by 270 million metric tons. Finalizing a strong second phase rule will generate $230 billion dollars in net benefits to the U.S. over the lifetime of vehicles sold between 2021 and 2027. Vehicle owners will save $170 billion while conserving 1.8 billion barrels of oil and cutting carbon pollution by nearly 1 billion metric tons under the regulatory timeframe. Furthermore, a new long-haul truck owner in 2027 will recoup the upfront cost of more efficient technologies less than 2 years through fuel savings. [EPA-HQ-OAR-2014-0827-1177-A1 p.2]
There are economic problems with oil, too. Global supply cannot keep up with demand. The price will keep going up, hitting all of us at the pump. With this rule, vehicle owners will save an average of $170 billion in fuel costs over the lifetime of the vehicles sold. Increasing truck efficiency saves money, which will be reflected in the price of consumer goods. Furthermore, when the price of oil spikes, the military must repurpose funds away from training, maintenance, and readiness programs to offset the cost, putting missions at risk. [EPA-HQ-OAR-2014-0827-1175 p.2] [[These comments can also be found in EPA-HQ-OAR-2014-0827-1372, p.194.]]

**Organization:** Operation Free

Fuel economy is only one factor truckers must use in making equipment decisions.

There are many factors in a tractor, engine, or trailer that a truck owner must consider when making an equipment purchase. Fuel economy is certainly one of those factors, as it is the greatest expense of the owner-operator, but other needs and requirements of the job matter. Primary among these is reliability and the equipment specifications required by the function served by different types of truck operation in our economy. For example, while lower rolling resistant (LRR) tires can be beneficial for a trucking company operating around the flat plains of Kansas, they can become a safety hazard while operating in the mountainous regions, such as the Tejon Pass in California or the Loveland Pass in Colorado. Additionally, the National Academy of Sciences (NAS) has demonstrated that the fuel efficiency will decrease for a sleeper cab tractor pulling a flatbed trailer if it is equipped with a full-height air deflector because the high roof sleeper increases the frontal area of the truck beyond what the trailer requires. Thus, there are many equipment decisions which affect the purchase of a truck. [EPA-HQ-OAR-2014-0827-1244-A1 p.6]

**Organization:** Owner-Operator Independent Drivers Association (OOIDA)

Businesses and consumers across all sectors of the economy rely on trucks to move materials and products. Tractor-trailers and package delivery vans move $10 trillion worth of freight each year and commuter buses transport 3.5 million people to work every day. Furthermore, U.S. companies spent over $700 billion dollars on trucking services in 2014. As travel among heavy duty vehicles grows by nearly 50 percent over the next 25 years, America will continue to rely on these trucks to support critical services needs as well as the growing economy. [EPA-HQ-OAR-2014-0827-1334-A1 p.1]

Response:

Many of the comments here are supportive comments, some of which suggest that the standards should be more stringent to ensure more fuel savings and greater environmental protection. As a specific example, CFA points to the more stringent proposed Alternative 4 as appearing to be similar to proposed program (Alternative 3) in terms of cost effectiveness, but with greater net benefits. As discussed in Section XI of the Preamble, the agencies do not believe the Alternative 4 standards to be feasible overall, and we are consequently unable to accurately estimate costs for them. CFA is correct that the agencies had other factors to consider in setting the final standards, including available technology, feasible reductions of emissions and fuel consumption, costs, lead time, safety, and other relevant factors. For the final standards, we are adopting those elements of the proposed Alternative 4 where we have determined them to be feasible in the lead time provided, resulting in a final program that is more stringent that what was proposed (as discussed in Preamble Sections II-VI). For more responses to comments that generally call for more stringent standards, see Section 8.1.1 of this RTC. Per Navistar’s comment about AEO fuel prices, we note that agencies have updated to EIA’s 2015 AEO price forecasts, the most recent available at the time that we conducted the analysis presented in the rulemaking documents. The agencies have routinely used the Annual Energy Outlook as a source of estimating future fuel prices since making such estimates is outside our area of expertise. We also consider the projections made in the AEO to be better data than current or recent spot prices since the projections take into consideration estimates of future economic activity. We conclude that the standards continue to have benefits that greatly exceed costs, and, as noted, fairly short payback periods. We conducted sensitivity analyses using the AEO High and Low fuel price cases (RIA Chapter 8.12) and these conclusions still stand.
11.4 Maintenance Expenditures

Organization: ABC Bus Companies, Inc.

GHG, CO₂, emission technology's costs seem to be only calculated only on the new purchase cost of vehicles. Total maintenance and life cycle costs are not accounted for. [EPA-HQ-OAR-2014-0827-1430-A2 p.4]

Response:

We include maintenance costs for the full life of the vehicle. In the proposal, we included those lifetime costs for tires. In the final rules, we include those costs for many items. Please refer to RIA 7.2.3 for more details regarding the maintenance items included in the final rules and for the full lifetime of vehicles equipped with each technology.

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Maintenance costs

The NPRM requests comment on the estimation of maintenance costs for hybrid electric vehicles. CARB staff supports the inclusion of all maintenance costs across vehicle technologies. Maintenance costs of hybrid buses 80 and small fleets of hybrid delivery vans 81 have been estimated as part of several recent research projects. In addition, changes in electricity expenditures associated with BEVs should also be included in the estimation of fuel costs for advanced technology vehicles. In other words, the costs and savings resulting from changes in electricity consumption, not just savings based on the decreased use of liquid fuels, must be incorporated into the fuel cost savings calculation. [EPA-HQ-OAR-2014-0827-1265-A1 p.183]

Response:

We have included many more maintenance items in the final rules than were included in the proposal. For example, we include savings associated with fewer oil changes on hybrid equipped vocational vehicles. Please refer to RIA 7.2.3 for more details.

Organization: Daimler Trucks North America LLC

Seventh, the agencies failed to quantify maintenance costs. Indeed the agencies state on 80 FR 40325 and 40445 that they only quantified the cost of tire maintenance. The cost of maintaining hybrid batteries and other such items dwarfs the costs of tires and likely turns the agencies’ cost-benefit analysis on its ear. [EPA-HQ-OAR-2014-0827-1164-A1 p.129]
Response:

The final rule analysis includes maintenance costs on batteries included in hybridized vocational vehicles. Please refer to RIA 7.2.3 for more details.

Organization: NAFA Fleet Management Association

Fleet managers appreciate the importance of continual improvement in emissions, but many have seen maintenance cost increases triple the rate of inflation since 2007 as a result of government emissions regulations. Many fleets have also seen increases in engine, exhaust, cooling and fuel system repair costs from 2010-2014 related to engine emissions complexity. Complexity further compromises the industry’s ability to ensure technician capability is maintained, forcing fleets to maintain higher vehicle counts due to costs, complexity and capability. [NHTSA-2014-0132-0111-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.179-180.]]

NAFA urges the EPA and NHTSA to undertake a more robust sensitivity analysis with respect to maintenance and potential scenarios. The proposal and the Regulatory Impact Analysis do not go far enough in looking at potential maintenance costs. Projected fuel savings assumed by the proposed standards will not offset operational costs in every instance. Fuel costs are only one element of the cost architecture of a vehicle. Other costs include maintenance and repair, depreciation, and costs associated with doing business. [NHTSA-2014-0132-0111-A1 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.180.]]

Response:

We have included far more costs associated with maintenance in the final rules than in the proposal. Please refer to RIA 7.2.3 for more details.

Organization: Owner-Operator Independent Drivers Association (OOIDA)

Warranty, Maintenance, and Downtime Costs

The proposed rule will force new technologies into the market and with new technologies will come increased warranty costs, maintenance costs, and costs associated with increased downtime. The proposed rule only counts some of the increased maintenance costs associated with tires. In doing so, the agencies are greatly underestimating the overall impact of new technology. The agencies should calculate in the analysis additional warranty, maintenance and downtime costs. In an April 2014 Board Meeting, OOIDA Board Member Lewie Pugh presented to the EPA a 7-foot long printout of everything that had gone wrong with the MaxxForce engine truck that he had purchased in 2011. He said, “When the truck breaks down, the mechanics don’t even know what’s wrong. They don’t know how to work on them. The dealership I go to is packed with trucks with emission problems.” [EPA-HQ-OAR-2014-0827-1244-A1 p.45][This comment can also be found in section 11.12 of this comment summary]

If an Alternative that forces new technologies is chosen by the agencies, the impact of increased repairs beyond traditional warranty coverage needs to be taken into account. Small business owners and fleets cannot continue to bear the cost of forced technologies and the ensuing repairs. The irony with this situation is that any increased warranty coverage would increase the purchase price of a new truck. Additionally, this will negatively impact the resale value of the truck. For example, the trucks subject to the Phase I standards, such as the MaxxForce engine which caused large amounts of downtime, will be passed along to the new consumer, without an extended warranty, many owner-
operators could be placed out of business. According to the OOIDA Foundations Member Profile Survey, 74 percent of owner-operators purchase used trucks. Any unreliable or problematic truck produced as a consequence of the Phase II standards will eventually be placed on the used market, thus adversely impacting owner-operators who purchase them several years into the future. [EPA-HQ-OAR-2014-0827-1244-A1 p.45-46][This comment can also be found in section 11.12 of this comment summary]

48 “EPA takes notes on OOIDA concerns.”

**Response:**

In the final rules, relative to the proposal, we have included many more routine maintenance items and, as such, are estimating considerably higher maintenance costs as a result (see final RIA Chapter 7.2.3). We do not believe that the technologies expected for complying with the new standards will result in additional down time. Instead, we believe that maintenance costs at the sort of routine maintenance intervals in today’s fleets will be higher, but not necessarily more frequent (i.e., no additional down time). Further, we do not believe that breakdowns will occur at higher rates due to the new technologies being added. We understand that past criteria pollutant rules lead to technology introductions which had adverse impacts with respect to vehicle breakdowns. However, we believe that the primary culprit was lack of appropriate lead time to enable a smooth implementation of the technologies added at that time. For these new GHG and fuel consumption standards, we believe that the lead time being provided is much more favorable and, perhaps more importantly, the pace of implementation afforded by the phase-in of additional stringency levels should provide sufficient flexibility to enable a smooth implementation of new technologies. This is part of the reason we have not moved forward with Alternative 4 from the proposal which, based on our engineering judgement, carried with it higher risks of insufficient lead time and phase-in flexibility.

**Organization:** Truck Renting and Leasing Association

Indeed, to satisfy the Proposed Standards, new technologies will almost certainly have to be integrated into vehicles, especially heavy-duty equipment. The agencies have stated they expect minimal increases in maintenance costs, yet they have only estimated such costs associated with lower rolling resistance tires; this rule has the potential for higher repair and maintenance costs, vehicle downtime, high replacement vehicle costs, and dissatisfied customers. These impacts should be studied more thoroughly. Higher frequency of maintenance is a particular concern as it will tend to frustrate consumer acceptance of the new regulations while increasing costs across the board. As an example, the 2010 EPA product performance from all manufacturers has generally resulted in high, repetitive maintenance and repair expense, including significant vehicle replacement costs and likely negative impact on resale values. Anecdotally, TRALA members can document increased numbers of maintenance issues and costs on vehicles subject to Phase I of the program, with no one manufacturer being immune. [EPA-HQ-OAR-2014-0827-1140-A1 p.3]

**Response:**

We have included many more maintenance items in the final rules analysis than were included in the proposal. Please refer to RIA 7.2.3 for more details.

**11.5 Analysis of the Rebound Effect**

**11.5.1 General Rebound**
Organization: American Council for an Energy-Efficient Economy (ACEEE)

Rebound

Also pertinent to the estimate of benefits of the proposed standards are the assumptions made about the rebound effect associated with the standards, and in particular the extent to which better fuel efficiency results in more miles traveled by the regulated vehicles. The agencies maintain the assumptions of 10% rebound for heavy-duty pickups and vans, 15% for vocational vehicles, and 5% for combination trucks using in the Phase 1 rule. Absent further evidence, the agencies’ current estimates are reasonable. In particular, the 10% rebound assumption that has been used in the light-duty vehicle fuel economy rulemakings is the best starting point for heavy-duty pickups and vans. With regard to the other vehicle categories, however, it should be noted that the working paper by Energy and Environmental Research Associates that the agencies placed in the docket concludes: “The results suggest that in recent decades, fuel price elasticities for U.S. trucking VMT (combination and single-unit trucks) and fuel consumption (combination trucks) are near zero or not statistically different than zero.” [EPA-HQ-OAR-2014-0827-1280-A1 p.27]

This and other relevant work warrant further consideration for the final rule. [EPA-HQ-OAR-2014-0827-1280-A1 p.27]

Recommendation: Rebound

- Consider newly available research on the effects of improved fuel efficiency on heavy-duty vehicle driving behavior to determine whether the rebound values used in the proposal should be retained in the final rule. [EPA-HQ-OAR-2014-0827-1280-A1 p.27]

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Rebound effect

The NPRM requests comment on the assumptions related to the rebound effect for heavy-duty vehicles. CARB staff believes further research is needed in this area. Emerging research from Winebreak et al. (2015) on fuel price elasticity in the U.S. combination trucking sector suggests fuel price inelasticity of demand for vehicles miles traveled and fuel consumption. This result implies that existing estimates of the rebound effect in the combination trucking sector could be overstated and calls for additional analysis. CARB staff suggests that, when feasible, short-run and long-run rebound effects should be estimated separately as research suggests the response to changes in efficiency varies over time. [EPA-HQ-OAR-2014-0827-1265-A1 p.184]

In addition, CARB staff recommends additional research on the indirect and economy-wide portions of the rebound effect. Freight system interactions, fuel surcharges, and changes in capacity may impact the direct rebound effect in the heavy-duty sector, resulting in compensating changes outside of fuel consumption. The price elasticity of energy demand may be preferred over the use of the price elasticity of VMT in the heavy-duty sector. [EPA-HQ-OAR-2014-0827-1265-A1 p.184]

The RIA cites Guerrero (2014), which simulates the California freight network and concludes that the rebound effect could offset 40 to 50 percent of vehicle efficiency emission reductions. CARB staff does not support the findings of Guerrero (2014) in assessing the relationship between fuel saving
technology and the management of vehicle fleets. Guerrero (2014) estimates the rebound effect of long-haul trips only, which is not representative of the entire heavy-duty vehicle fleet. The analysis fails to account for existing market failures that currently are impediments to the adoption of cost-effective fuel saving technology, resulting in potential overestimation of the rebound effect with optimal adoption of fuel saving technology. Guerrero (2014) is based on a commodity flow data and not heavy-duty vehicle activity, which is more representative of the sector and utilized in Winebreak (2015). CARB staff appreciates the use of sensitivity analysis in regards to the rebound effect and suggests additional sensitivity cases to incorporate varying discount rates, and additional estimates of indirect and economy-wide rebound, when feasible. [EPA-HQ-OAR-2014-0827-1265-A1 p.184-185]

Organization: Consumer Federation of America (CFA)

Ironically, these positive economic externalities can create concerns from the energy and environmental points of view. When consumers use their savings from lower fuel costs to buy more goods and services, they are likely to indirectly increase their use of energy. However, the increase in consumption due to this dynamic, called the ‘rebound effect,’ is much smaller than the direct reduction in energy consumption, so the net effect is still to reduce overall energy consumption.\(^\text{27}\) From the point of view of consumer and macroeconomic analysis, “the rebound effect” represents a positive economic result for consumers. It means that consumer welfare is increasing. How consumers use their increased disposable income is of secondary importance to the fact that they have more income to spend on other goods and services. However, if the goal is to reduce energy consumption, one must subtract the rebound effect from the benefits column. But experience shows that the rebound effect erases only a fraction of the energy savings.\(^\text{28}\) [EPA-HQ-OAR-2014-0827-1336-A1 p.35]

2. Pass-through

A second theoretical explanation that played an important part in the earlier analysis and was addressed by EPA/NHTSA is the question of the pass-through of cost savings to consumers. [EPA-HQ-OAR-2014-0827-1336-A1 p.51]
As a result of this proposed rulemaking, it is anticipated that trucking firms will experience fuel savings. Fuel savings lower the costs of transportation goods and services. In a competitive market, some of the fuel savings that initially accrue to trucking firms are likely to be passed along as lower transportation costs that, in turn, could result in lower prices for final goods and services. Some of the savings might also be retained by firms for investments or for distributions to firm owners. Again, how much accrues to customers versus firm owners will depend on the relative elasticities of supply and demand. Regardless, the savings will accrue to some segment of consumers: Either owners of trucking firms or the general public, and the effect will be increased spending by consumers in other sectors of the economy, creating jobs in a diverse set of sectors, including retail and service industries.41 [EPA-HQ-OAR-2014-0827-1336-A1 p.51-52]

The pass-through issue also turns up in another key aspect of the overall analysis, the rebound effect. The increase in consumption associated with the rebound effect occurs because consumers have more money to spend. The first effect is through the reduction of the cost of travel, but there is a second effect through the increase in disposable income available for other consumption. [EPA-HQ-OAR-2014-0827-1336-A1 p.52]

Elasticities with respect to fuel price and fuel cost can provide some insight into the magnitude of the HDV VMT rebound effect. Freight price elasticities measure the percent change in demand for freight in response to a percent change in freight prices, controlling for other variables that may influence freight demand such as GDP, the extent that goods are traded internationally, and road supply and capacity. This type of elasticity is only applicable to the HDV subcategory of freight trucks (i.e., combination tractors and vocational vehicles that transport freight). One desirable attribute of such measures for purposes of this analysis is that they show the response of freight trucking activity to changes to trucking rates, including changes that result from fuel cost savings as well as increases in HDV technology costs. Freight price elasticities, however, are imperfect proxies for the rebound effect in freight trucks for a number of reasons. For example, in order to apply these elasticities we must assume that our proposed rule’s impact on fuel and vehicle costs is fully reflected in freight rates. This may not be the case if truck operators adjust their profit margins or other operational practices (e.g., loading practices, truck driver’s wages) instead of freight rates. It is not well understood how trucking firms respond to different types of cost changes (e.g., changes to fuel costs versus labor costs).42 [EPA-HQ-OAR-2014-0827-1336-A1 p.52]

These observations make it clear that there is a significant level of pass-through of cost savings. Given the competitiveness of the trucking industry and its importance, we believe it is substantial. EPA/NHTSA conclude that there will be pass-through, but they do not provide an estimate. Their estimate of the rebound effect is moderate – 10% – based on a variety of factors. We have discussed this earlier. Given the very large economic benefits, the magnitude of the rebound effect does not significantly affect the bottom line of the analysis. Without specifying the precise level, it is clear that pass-through is significant and has important macroeconomic benefits. [EPA-HQ-OAR-2014-0827-1336-A1 p.52-53]

Lastly, we think that the agencies’ estimates of the rebound effect appear reasonable. [EPA-HQ-OAR-2014-0827-1164-A1 p.130]

**Organization:** Environmental Defense Fund (EDF)

### b. Rebound

*New studies should be used to inform final rebound values*

The agencies have proposed to maintain the same rebound values finalized in the Phase 1 program – 5% for tractor trailers, 15% for vocational and 10% for pickups and vans – stating they had “insufficient evidence to justify revising the rebound effect values that were used in the Phase 1 analysis.” New analyses by Winebrake et. al., however, indicate that these Phase 1 values may be too high. [EPA-HQ-OAR-2014-0827-1312-A1 p.23]

A 2015 paper by Winebrake et. al. looks at fuel price elasticity estimates for single-unit truck activity (vocational trucks), as measured in VMT, and concludes they “cannot reject a null hypothesis that fuel price elasticities for single-unit truck VMT is zero.”¹¹³ The authors state that the elasticities in their paper may be used as a proxy for rebound in certain cases – and, at the very least, to inform the choice of a rebound estimate for the vocational sector. [EPA-HQ-OAR-2014-0827-1312-A1 p.23-24]

Similarly, another 2015 paper by Winebrake et al. looks at fuel price elasticities of combination trucking operations in the U.S. between 1970 and 2012 and concludes that “we are in a period of time where fuel price elasticities for US combination trucking VMT and fuel consumption are near zero.”¹¹⁴ Again, the authors argue that their results may be used as a proxy for rebound under certain circumstances but at the very least should be used to inform the rebound values chosen for tractor trailers. [EPA-HQ-OAR-2014-0827-1312-A1 p.24]

EDF asks the agencies to consider these two new studies by Winebrake et al. in finalizing rebound values for vocational vehicles and tractor-trailers and, at minimum, include sensitivities reflecting lower rebound values. [EPA-HQ-OAR-2014-0827-1312-A1 p.24]

**EDF supports inclusion of welfare benefits of rebound effect**

To the extent the Agencies retain some positive rebound value, it is important to estimate the beneficial impacts of that rebound effect. As discussed in a 2014 Resources for the Future discussion paper on “The Rebound Effect and Energy Efficiency Policy,” rebound often has a misconceived ‘evil’ connotation because policymakers tend to focus solely on energy minimization (in this case, fuel...
consumption reduction) and ignore welfare maximization. However, this does not capture the entire impact of rebound because any time a consumer changes his or her behavior (for example, by buying a more efficient truck), it means that there is some inherent welfare benefit to that consumer (relative to no change in behavior). It is therefore important that “[r]ather than consider[ing] the rebound effect as a deterrent from passing energy efficiency policies, policymakers should include these welfare gains in the tally of benefits of a policy.” For this reason, we support the Agencies’ decision to estimate the benefits of increased travel associated with rebound driving. [EPA-HQ-OAR-2014-0827-1312-A1 p.24]

116 Id.

117 Preamble at 40474.

**Organization:** International Council on Clean Transportation (ICCT)

The agencies continue to extensively apply controversially high rebound factors in their assessment based on theoretically sound, but non-empirically validated, evidence. The latest state-of-the-art peer-reviewed research indicates that the rebound effect for combination tractor-trailers and regional delivery and service trucks in the U.S. is not statistically significantly different from zero (Winebrake et al, 2015a, b). As a result we believe that the only scientifically defensible approach to this question is to assume the rebound effect for fuel savings associated with the regulation is zero, unless or until new peer-reviewed work that is empirically based on more comprehensive and more recent U.S. data is published. We recommend that the agencies incorporate the most applicable, state-of-the-art research and assume that the rebound effect from increased fuel efficiency is zero. [EPA-HQ-OAR-2014-0827-1180-A4 p.18]

**Organization:** Mannix, Brian

**Rebound Effect**

The RIA makes a considerable effort to characterize and quantify the “rebound effect” – the changes in fuel consumption and in other variables that result when more energy-efficient vehicles are used more intensively because the cost of using them has declined. The agencies should be applauded for recognizing the importance of rebound effects, which other agencies have been known to ignore. Markets are elastic, in countless dimensions, and it can be very difficult to anticipate the ways in which their dynamic response to regulatory interventions may differ from the static model that may represent the regulator’s intent. There is an unfortunate tendency in the literature to coin new terms (see “leakage,” and “backfire effect,” in addition to “rebound”) to describe these market responses, as if they
were something new and surprising. The reality is that economists have known for a long time about the complexity and responsiveness of dynamic markets. Generally, unless a regulatory intervention is very carefully designed, the various price elasticities and cross-elasticities will tend to frustrate the attempts of regulators to move markets in a direction they are not willing to go, so that the forecast benefits may not fully materialize. Agencies should be encouraged to use models that fully reflect the elasticity of markets in the real world, and should be prepared to abandon regulatory strategies that, however well intentioned, do not appear to be effective under real-world conditions. [EPA-HQ-OAR-2014-0827-1222-A1 p.4]

VMT Rebound

The agencies’ assumptions for a vehicle-miles-traveled (VMT) rebound factor appear to overestimate the potential for improved efficiency to increase heavy truck mileage. The agencies assume a 5 percent VMT rebound factor for combination tractor-trailers and 15 percent for vocational vehicles. Recent analysis by Winebrake et al suggest that VMT rebound for both combination trucks and single-unit vocational vehicles could be zero. NRDC urges the agencies to review this analysis to ensure the rule is not overestimating the VMT rebound effect. [EPA-HQ-OAR-2014-0827-1220-A1 p.10]

Organizations: Owner-Operator Independent Drivers Association (OOIDA)

Again, while reducing the weight of the truck and trailer appears to work on paper, the real-world effects are often different. As part of the agencies analysis, they described in detail what is known as a “rebound effect.” According to the NPRM, “The “rebound effect” has been defined a number of ways in the literature, and one common definition states that the rebound effect is the increase in demand for an energy service when the cost of the energy service is reduced due to efficiency improvements.” The agencies attributed this effect to vehicle miles traveled; however, they did not consider the rebound effect for weight reduction. In the reality of a highly competitive industry, if the weight of the tractor and trailer is reduced then the shipper will simply add weight to the load being hauled, essentially making any proposed or mandated weight reduction ineffective. [EPA-HQ-OAR-2014-0827-1244-A1 p.33-34]

Today, many tractors and trailers are already specified for maximum weight savings based upon the vehicle usage. For example, it is common for an aluminum end dump trailer with aluminum wheels and wide based tires to be loaded to the max in order to take full advantage of the weight savings. It is a common occurrence for such trucks to be loaded while on a scale so that they can be loaded until the total vehicle weight reaches 80,000 lbs. It is imperative that the agencies consider the rebound effect beyond just vehicle miles traveled. [EPA-HQ-OAR-2014-0827-1244-A1 p.34]
It also worth noting that the topic of a “rebound effect” validates that the trucking industry is well aware of methods to conserve fuel, and thereby decrease GHG emissions, and will actively pursue them when it they are appropriate for their operation. [EPA-HQ-OAR-2014-0827-1244-A1 p.34]

Organization: Resources for the Future

The comment is based on statistical analysis of truck-level data, in which we estimate the rebound effect for tractor-trailers and vocational trucks, and the effect of economic activity on miles traveled. The estimated rebound effect is substantially larger for tractor trailers than that used by the agencies in the regulatory impact analysis (RIA), but the rebound effect for vocational trucks is similar to that used in the RIA. We find that vehicle miles traveled respond less than proportionately to economic activity. Using these estimates in the RIA would provide a stronger foundation for the analysis. This would reduce the net benefits of the rule, although probably not by a substantial amount. [EPA-HQ-OAR-2014-0827-1200-A1 p.1]

Overview

To estimate the benefits of the Phase 1 and proposed Phase 2 greenhouse gas and fuel efficiency standards for medium and heavy-duty trucks, the agencies have included assumptions about the rebound effect on truck miles travelled as a result of the standards. The Agencies acknowledge that there is limited data for analysis of the rebound effect, and little research exists on this issue, especially in the U.S. We are submitting a comment that summarizes the conclusions of our new paper titled “Fuel Costs, Economic Activity, and the Rebound Effect for Heavy Duty Trucks” (Resources for the Future Discussion Paper 15-43, http://www.rff.org/files/document/file/RFF-DP-15-43.pdf) [EPA-HQ-OAR-2014-0827-1200-A1 p.1]

We use microdata from the U.S. Census’ Vehicle Inventory and Use Survey (VIUS) to assess the magnitude of the rebound effect on vehicle miles travelled (VMT) in the trucking sector. We use individual truck level data for six waves of the VIUS survey, in which trucks in all fifty states were surveyed every five years from 1977 to 2002. The period of the survey was a time with almost no regulation of fuel economy. [EPA-HQ-OAR-2014-0827-1200-A1 p.1]

The rebound effect is important because although the standards target the rate of emissions per mile travelled, the social benefits depend on how much trucks are driven. As fuel economy improves due to the tighter standards, the cost per mile of driving will decrease and the number of miles driven will tend to increase. The resulting increase in trucking miles traveled is the rebound effect, and it partially offsets the decrease in fuel use and emissions that would occur from the fuel consumption rate alone. The greater is the expected reduction in fuel intensity from the regulation, the larger the effect on cost per mile of driving and the rebound effect. [EPA-HQ-OAR-2014-0827-1200-A1 p.1]

In the trucking sector, the rebound effect in the short run is likely to be different from the long run rebound effect. Because only new trucks are regulated, the cost of driving new trucks is relatively less costly compared to other trucks in the fleet, and fleet managers may shift miles driven from old trucks to new trucks. This type of substitution can temper the rebound effect in the short-term. This effect disappears in the long run, however, as the cost per mile will fall by the same proportion for all trucks. Our analysis, which uses individual truck level data, is able to separate each truck from its competitors allowing us to estimate both short and long run rebound effects. [EPA-HQ-OAR-2014-0827-1200-A1 p.1]
The Agencies have reviewed the available literature and have done some of their own analysis to estimate the magnitude of the rebound effect. Both the relevant studies and the Agencies’ own analysis use data on truck VMT aggregated to the state or national level. The aggregate data include assumptions about how trucks in the fleet are driven. In contrast, the VIUS data provide individual truck information including VMT, state registration, miles travelled in and out of state, average miles per gallon and average cargo weight, along with detail about the type of truck, products shipped and its business affiliation. Our analysis is able to use this extensive set of controls for truck characteristics that are likely correlated with fuel economy to improve our estimates of the cost of driving on miles travelled, the key relationship being estimated. [EPA-HQ-OAR-2014-0827-1200-A1 p.2]

In our paper, to fully exploit the advantages of the microdata, we decompose total trucking miles traveled into the product of two components: miles traveled per truck, and the number of trucks operating in the market. We estimate separate equations for each of these two components. The first, miles traveled per truck is estimated as a function of the truck’s fuel costs per mile, economic activity, truck, business and geographic characteristics, and a time trend. We believe fuel costs are likely to be endogenous both for reasons of reverse causality and omitted variables. When trucks are driven more miles they are likely to be driven with heavier loads, reducing fuel economy. Additionally, truck owners likely to drive long miles are more likely to purchase more fuel-efficient trucks. Therefore, we instrument cost per mile with the contemporaneous crude oil price. We use gross state product (GSP) as a proxy for economic activity. [EPA-HQ-OAR-2014-0827-1200-A1 p.2]

In the second equation we estimate the number of trucks as a function of the fuel cost per mile economic activity, truck, business and geographic characteristics, and a time trend. As in the truck-level estimation, we instrument for fuel costs per mile and use GSP to proxy for economic activity. [EPA-HQ-OAR-2014-0827-1200-A1 p.2]

Implications for long-run rebound effects

The results for both VMT and truck count equations are shown in Tables 2-5 in the paper. We use the elasticities of VMT and truck counts with respect to the fuel cost variable to infer the rebound effect for changes in fuel economy standards for the two truck types, tractor-trailers and vocational vehicles. Because total truck VMT is the product of miles travelled per truck and the number of trucks operating and we have estimated the both equations in logs, the total rebound effect will be the sum of the two estimated coefficients on cost per mile. Table 6 in the paper provides a detailed summary of the inferred rebound effects with confidence intervals. We reproduce Table 6 here. We show the estimates for both the VMT elasticity and the truck count elasticity with respect to fuel cost per mile and the sum of the two. The truck count elasticities are not statistically different from zero, and therefore the cumulative estimates have relatively large standard errors. [EPA-HQ-OAR-2014-0827-1200-A1 p.2]

The total VMT elasticity estimate for tractor trailers has a mean that is much larger than the 5% used by the Agencies in the assessment of the Phase 1 standards and the large confidence interval does not include the Agency estimate. In contrast, our estimate of the VMT elasticity for vocational vehicles is only slightly less than the Agencies’ and the confidence interval includes their estimate of 15%. [EPA-HQ-OAR-2014-0827-1200-A1 p.2]

Evidence of short-run and long-run differences in rebound effects
The elasticities presented above and the inferred rebound effects are both long-run estimates. We also estimate a short-run elasticity by allowing the miles travelled by each truck to depend not only on its own cost per mile, but on the cost per mile of its competitors in the fleet. We define competitors as other trucks in the same survey year, truck category, body type and business. Body type is an obvious category for competition: tow trucks will not compete with concrete mixers, nor will delivery vans compete with logging trucks. Business is also necessary, as it separates trucks used, for example, for construction, for-hire transportation, manufacturing, and personal transportation. We have estimated models using other competition definitions and have found them to be generally comparable to our results. [EPA-HQ-OAR-2014-0827-1200-A1 p.3]

The results for tractor trailers suggest that the short-run impact of fuel economy standards may not lead to much of a net rebound effect, as VMT of relatively fuel efficient new trucks will substitute for VMT of relatively fuel inefficient used trucks as the standards become binding. In the long run, however, once existing used trucks are scrapped and new truck fuel economy is on average equal to used truck fuel economy, the impact of the standard on total gallons of gasoline consumed is measured by the sum of the log cost per mile and log average competition cost per mile, as the standards influence the cost per mile of all trucks by the same proportion, including truck and truck’s competitors. For tractor trailers, the sum of these two coefficients is -0.188, which is statistically indistinguishable from our rebound effect reported in column (3) of Table 2. We do not find evidence that there is a similar short-run effect for vocational trucks. [EPA-HQ-OAR-2014-0827-1200-A1 p.3-4]

The effect of economic activity on miles driven

The benefits of the fuel efficiency standards depend on the difference between outcomes for fuel consumption and emissions with the standards in place compared to business as usual (BAU) with no new standards. In forecasting the BAU and “with standards” cases for the future, an important relationship is one between economic activity and total truck miles driven. In most existing models miles traveled depend on economic activity and operating costs relative to other transportation modes. Either gross domestic product or gross output typically serves as a proxy for economic activity and demand for trucking services in these models. Lower operating costs for trucks relative to other transportation modes cause more shipping via trucks. Furthermore, an increase in economic activity typically increases demand for trucking services, such as transporting goods for retail sale. It may be reasonable to assume that shipments respond proportionately to economic activity—in fact, the analysis by EPA and NHTSA implicitly assumes a proportionate relationship—but we are not aware of direct empirical evidence supporting this assumption. In our study, we estimate the relationship between economic activity and total miles travelled. [EPA-HQ-OAR-2014-0827-1200-A1 p.4]

We use GSP to proxy for economic activity and estimate an elasticity of miles traveled per truck to GSP of 18 percent for both tractor trailers and vocational trucks. The elasticities of truck count with respect to GSP are larger than the VMT elasticities for both tractor trailers and vocational vehicles, and both are significant at 1% levels. [EPA-HQ-OAR-2014-0827-1200-A1 p.4]

The VMT and truck count elasticities with respect to GSP are summarized in the paper in Table 7, which we show below. We compute a cumulative effect by summing the VMT elasticity and the truck count elasticity. The cumulative effect for each group is economically and statistically significant, and the point estimates are both are less than one. This result has important implications for estimating expected gasoline consumption and emissions reductions from the fuel efficiency standards. The benefits of the standards depend on forecasted business-as-usual (BAU) total VMT. Cumulative elasticities less than one imply that BAU total VMT will grow less rapidly than economic activity, so that expected gasoline consumption and emissions reductions stemming from fuel economy standards
will be less dramatic than a setting where VMT and truck counts grow in proportion with economic activity. Another noticeable result is that the elasticity for tractor trailers is substantially less than the elasticity for vocational vehicles. Since tractor trailers represent a large fraction of emissions from heavy duty trucks, the fact that this elasticity is relatively small implies even lower expected fuel and emissions savings as a result of the standards. [EPA-HQ-OAR-2014-0827-1200-A1 p.4]

[Table 7, ‘Summary of GSP Elasticities’, can be found on p.5 of docket number EPA-HQ-OAR-2014-0827-1200-A1]

Robustness checks

We test the sensitivity of our results to using alternative measures of economic activity, alternative measures of cost per mile, and estimating models of ton miles traveled instead of miles traveled for tractor trailers and vocational vehicles. The results are summarized in Tables 8 – 12 of the paper. [EPA-HQ-OAR-2014-0827-1200-A1 p.5]

Summary

We appreciate the opportunity to submit our comment on the proposed phase 2 greenhouse gas and fuel economy rule for trucks, and hope our analysis is helpful to your review of this issue for the final rule. To summarize, we find that the estimated rebound effect is substantially larger for tractor trailers than that used by the agencies in the regulatory impact analysis (RIA), but the rebound effect for vocational trucks is similar to that used in the RIA. We find that vehicle miles traveled respond less than proportionately to economic activity. We believe that using these estimates in the RIA would provide a stronger foundation for the analysis. It appears that using these estimates would reduce the net benefits of the rule, although probably not by a substantial amount. [EPA-HQ-OAR-2014-0827-1200-A1 p.5]

1 The substitution results for tractor trailers and vocational vehicles can be found in column 4 of Tables 2 and 4, respectively.

Response:

The ‘rebound effect’ has been defined numerous ways in the energy policy and economics literature. One common definition states that the rebound effect is the increase in demand for an energy service when the cost of the energy service is reduced due to efficiency improvements. In the proposed Phase 2 rulemaking, the Agencies focused on one widely-used metric to estimate the rebound effect associated with all types of more intensive HDV use, the increase in vehicle miles traveled (VMT) that results from improved fuel efficiency. VMT can often provide a reasonable approximation for all types of more intensive HDV use. For simplicity, we refer to this as ‘the VMT rebound effect’ or ‘direct VMT rebound,’ although we acknowledge that it is an approximation to the rebound effect associated with all types of more intensive HDV use.

For the proposal, the agencies used VMT rebound effect values of five percent for combination tractors, 10 percent for heavy duty pickup trucks and vans and 15 percent for vocational vehicles. The agencies acknowledged that there was a limited amount of literature on this topic and that the literature that did exist showed a wide range of HDV rebound effect estimates. At the time of the proposal, the Agencies committed to review and consider revising their VMT rebound estimates by truck class in the Final
Rule, taking into consideration all available data and analysis, including submissions from public commenters and new research on the HDV rebound effect.

Also for the proposal, EPA communicated that it had contracted with Energy and Environmental Research Associates (EERA), to analyze the HDV VMT rebound effect for regulatory assessment purposes. Excerpts of EERA’s initial Report to EPA are included in the docket that contain detailed qualitative discussions of the rebound effect as well as data sources that could be used in quantitative analysis. EERA also conducted a follow-on quantitative analyses focused on estimating the impact of fuel prices on HDV VMT and fuel consumption. EPA included a Working Paper in the docket on this effort, and sought comment on this work. EPA also noted in the proposal that EERA’s Working Paper had not been available at the time the agencies conducted the analysis of the HDV rebound effect, but the Agencies would consider this work, as well as any other analytical work, to support the Final Rule.

A number of commenters are open to the idea that the Agencies consider newly available research on the effects of improved fuel efficiency on HDV driving behavior to determine whether the VMT rebound values used in the proposal should be retained in the Final Rule. Several environmental NGOs (NRDC, EDF, ACEEE) suggested that the Agencies factor the Winebrake et al. work into the HDV direct rebound estimates used in the final rule. The Winebrake study found no responsiveness of truck travel to diesel fuel prices, suggesting that VMT rebound for vocational trucks and combination trucks could be essentially zero. One industry commenter (Diamler Trucks North America) suggested that Agencies rebound numbers used in the proposal appear reasonable. One environmental NGO (ICCT) suggested the HDV rebound estimates used in the proposed HDV Rule are overestimates, and suggested using the Winebrake et al. estimates instead.

Resources for the Future (RFF) submitted a comment that summarizes the conclusions of a new RFF Working Paper entitled “Fuel Costs, Economic Activity, and the Rebound Effect for Heavy Duty Trucks” by Leard et al. Leard et al. use microdata from the U.S. Census’ Vehicle Inventory and Use Survey (VIUS) to assess the magnitude of the rebound effect on VMT in the trucking sector. The individual truck use data is for six waves of the VIUS survey, in which trucks in all fifty states were surveyed every five years from 1977 to 2002. Instead of using aggregate data, the VIUS data provides individual truck information including VMT, state registration, miles travelled in and out of state, average miles per gallon and average cargo weight, along with detail about the type of truck, products shipped and its business affiliation.

The Leard et al. paper concludes that the total VMT rebound estimate for combination trucks is larger than the five percent used by the Agencies in the proposed standards and also has a larger confidence interval that does not include the Agencies’ estimate. When considering the VMT response to lower fuel costs for combination trucks, Leard et al. estimates an 18.5 percent rebound effect. When considering the increase in the number of combination trucks in response to lower travel costs, the Leard et al. estimates a total rebound effect of 29.7 percent. The Leard et al. estimate of the VMT rebound for vocational vehicles is smaller than the Agencies’ value used in the Phase 2 proposal and the confidence interval includes their estimate of 15 percent. When considering the VMT response to lower fuel costs for vocational trucks, Leard et al. estimate a 12.2 percent rebound effect. When considering the increase in the number of vocational trucks in response to lower travel costs, the Leard et al. estimates a total rebound effect of 9.3 percent. While the study uses a rich data base and does not appear to have any obvious methodological flaws, the Agencies are concerned that the rebound effects reported by Leard et al. are based upon an older time period, 1977 to 2002, and that truck travel patterns and infrastructure conditions (e.g., congestion on highways) may be quite different that the time period for
which the Phase 2 program is being implemented. We also note that the Leard et al. paper is a Working Paper, and in revising the HD VMT rebound estimates for the final program, the agencies found it more appropriate to give greater consideration to the findings of Winebrake et al. because it is peer-reviewed and published; see discussions in Section IX.E. of the Preamble and in RIA Chapter 8.3.

In the Phase 2 proposal, the agencies cited a study by Guerrero (2014), which simulated the California freight network and concluded that the HDV rebound effect could offset 40 to 50 percent of vehicle efficiency emission reductions. CARB Staff reviewed the Guerrero study and does not support its findings. CARB Staff pointed out that the Guerrero estimates are for long-haul trips only, which is not representative of the entire heavy-duty vehicle fleet. In addition, the CARB Staff points out that the Guerrero study is based on a commodity flow data and not heavy-duty vehicle activity and travel. We are in general agreement with CARB Staff on their assessment of the Guerrero study.

One commenter (Owner-Operator Independent Drivers Association) suggested that the agencies should factor in changes in freight tonnage into the rebound effect as a result of this rulemaking. The commenter suggests that if the weight of combination trucks is reduced as a result of the Rule that the shipper could add weight to the load being hauled. We interpret this comment as suggesting that weight reduction could play a role as a mechanism that actually lowers VMT because more cargo is going on the vehicle, thus saving trips. We are in general agreement with this observation, but we did not include this information to lower our VMT rebound estimates since it is hard to quantify. We hope to consider this topic in future VMT rebound work.

Consumer Federation of America (CFA) pointed out that consumers may use their savings from lower fuel costs as a result of the direct rebound effect to buy more goods and services, which indirectly increases the use of energy. In the energy policy and economics literature, this effect has been labeled the so called “indirect rebound” effect. CFA states that the indirect rebound effect represents a positive economic result for consumers, since consumer welfare increases. However, if the goal of a Rulemaking is to reduce energy consumption, one must subtract the rebound effect from the benefits of the Rule. In a similar comment, EDF referred to an 2014 Resources for the Future discussion paper on “The Rebound Effect and Energy Efficiency Policy,” that states that “[r]ather than consider[ing] the rebound effect as a deterrent from passing energy efficiency policies, policymakers should include these welfare gains in the tally of benefits of a policy.” We agree with these commenters in their assessment of some of the trade-offs that need to be considered when assessing rebound effects.

Plant Oil Powered Diesel Fuel Systems (comment below) asserts that Agencies failed to take into account any indirect rebound effect of overall embedded energy expended to produce new goods entering the marketplace as a result of improved fuel efficiency and the resulting lowered cost of truck transport. The Commenter believes that the estimates of fuel savings and greenhouse gas emissions reductions are lower than what the Agencies estimated for this Final Rulemaking. An addition commenter (CARB Staff) recommended additional research on the indirect and economy-wide portions of the HDV rebound effect. One private citizen suggested that the Agencies should use models that fully reflect the responsiveness of markets in the real world. The Agencies believe that there are no available, credible studies of indirect and economy-wide rebound effects for HDVs that could be used in this Rulemaking. We agree that more work in the area of indirect and economy-wide HDV rebound effects, as well as direct VMT rebound effects, is needed.

11.5.2 Response to POP Diesel
2. The GHG Standards are inconsistent with law for the additional reason that two agencies fail to take into account any indirect rebound effect of overall embedded energy expended to produce new goods entering the marketplace as a result of improved fuel efficiency and the resulting lowered cost of truck transport. [EPA-HQ-OAR-2014-0827-1125-A1 p.4]

2. The Failure of the Two Agencies to Consider Indirect Rebound Effects Arising from the Fuel Efficiency Standards Renders the GHG Standards Inconsistent with Law Due to Their Failure to Reduce Overall Energy Consumed and Resulting GHG Emissions

Energy economist Harry D. Saunders, Ph.D., submits the new declaration that is Exhibit 10 (exhibit 10 can be found on p.58 of docket number EPA-HQ-OAR-2014-0827-1125-A1) explaining in logical detail that the proposed Truck Rule 2 acknowledges the rebound effect that improved fuel efficiency will directly cause increased vehicle miles traveled (VMT's) and, therefore, increased energy expended and greenhouse gases emitted in rebound, but that this Rule fails to consider and quantify the indirect implications of this direct rebound effect. Generally speaking, the indirect rebound effect is the additional energy expended, and greenhouse gases emitted, to produce additional goods that will be put onto the market as a result of the lower vehicle operating costs occasioned by improved fuel efficiency. Dr. Saunders calls this the 'embedded energy' rebound effect. [EPA-HQ-OAR-2014-0827-1125-A1 p.11]

In an addendum appearing after paragraph 58 of his original declaration from 2012, a corrected copy of which is attached to his new declaration at Exhibit 10, he conducted a careful analysis of the 'embedded energy' indirect rebound effect, based on the two agencies' own assumptions about the magnitude of the direct rebound effect and relying on U.S. government databases. In conclusion, he quantified it as being between 117% and 1,408%. In other words, due to the 'embedded energy' indirect rebound effect alone, the Truck Rule will cause between 17% and 13 times more overall energy to be consumed, and presumably resulting GHG's emitted, than if the fuel efficiency standards did not come into effect at all. [EPA-HQ-OAR-2014-0827-1125-A1 p.11-12]

As Dr. Saunders points out in paragraph 11 of his new declaration, the two agencies state at Federal Register Volume 80, page 40450 that improved fuel efficiency may increase truck capacity and loaded weight. Increased vehicle miles traveled are not the same as increased capacity and loaded weight; the latter are in addition to the former. Thereby, the two agencies acknowledge the existence of this indirect rebound, since it would be additional goods entering commerce that would create the demand for and supply this added capacity and weight. The two agencies, while acknowledging increased capacity and loaded weight which mean additional goods entering commerce, fail altogether to account for this indirect rebound effect in their own, quantified estimates. [EPA-HQ-OAR-2014-0827-1125-A1 p.11-12]

In paragraph 5 of his new declaration, Dr. Saunders responds to a footnote in the Preamble to the proposed Truck Rule 2 questioning the credibility of his analysis. Since he has published 12 peer-reviewed articles on the subject of the rebound effect, Dr. Saunders is in a position to state that his conclusions regarding the two agencies' ignoring of the indirect, 'embedded energy' rebound effect and therefore, their vast underestimating of the total rebound effect caused by the truck fuel efficiency standards do not require peer review. He is simply applying the same conceptual approach that he applied with approval in some of his peer-reviewed articles, but to a new context: truck engine efficiency and resulting energy consumed across the economy. The consideration of overall energy consumed, like lower greenhouse gases in the atmosphere (and not simply GHG's emitting from the tailpipe) is the ostensible target of the Truck Rule 2. The logic of his analysis is unimpeachable. The
data that Dr. Saunders runs through his accepted analytical method, as he also points out in paragraph 5, is U.S. government data that is beyond reproach. Dr. Saunders’s new declaration, as well as his original one and its precise quantifying of the ‘embedded energy’ rebound effect, merit the two agencies’ careful review for the inconsistency it demonstrates in their compliance with statutory purposes. [EPA-HQ-OAR-2014-0827-1125-A1 p.12]

Response

We received comments from POP Diesel which argued that EPA should account for the energy and GHG emissions impact associated with the so-called “indirect” rebound effect (distinct from the “direct” rebound effect). These effects could arise from the decline in fuel costs as a result of the rule, which could make goods and services transported by the U.S. trucking industry less expensive. In turn, less expensive goods and services could result in increased consumption of goods and service in the overall economy. Producing extra goods and services requires that more energy be used. This extra energy use can be thought of as “embedded” in the extra goods and services. Hence the term used in the POP Diesel comment for this type of indirect rebound effect is the “‘embedded energy’ rebound effect.

To support this claim, POP Diesel relies on two affidavits written by Dr. Harry Saunders, in which Dr. Saunders argues that the proposed rulemaking would result in significant indirect rebound and that EPA has not appropriately considered this impact. One of the affidavits is identical to an affidavit submitted to EPA by POP Diesel as part of a 2012 petition to reconsider the Phase I GHG emissions standards and fuel economy standards for medium- and heavy-duty engines and vehicles. EPA responded to this affidavit in our denial of POP Diesel’s petition.

The second affidavit, which is unique to POP Diesel’s comments on this rulemaking, does not present any new data or evidence, but rather presents new analysis of the same (purported) evidence presented in the 2012 affidavit, as well as additional reasons why EPA should accept the conclusions of the 2012 affidavit, the result being that estimates of the indirect rebound effect should be included in the rule’s effect in our economic analysis. The underlying evidentiary and analytical support for Dr. Saunders’ conclusions remain the same as those set forth in the 2012 affidavit. We note further that although EPA voiced many of these same concerns and critiques in denying the reconsideration petition, the new comment addresses none of EPA’s responses. For this reason, our unrebutted concerns with this analysis remain the same as those published in our denial of POP Diesel’s 2012 petition for reconsideration.

In his 2012 affidavit, Dr. Saunders cited only one published study quantifying indirect rebound effects (Druckman et al., 2011). Saunders affidavit para. 16. Although this UK-based study could offer insights into how to estimate indirect rebound effects in some contexts, the method appears inappropriate here for many reasons. First, the U.S. economy, transport system, and consumer behavior is likely to differ from other countries’ (e.g., Americans have different product and service preferences and our products and services have different levels of embedded energy). Similar data and models may not exist to replicate the UK study in a U.S.-context. Second, the study is generally designed to examine consumer behavioral strategies (e.g., lowering thermostats, reducing food waste, and biking instead of using a car) rather than firms’ behavior associated with improving technology. Among other things, the study does not consider business capital expenditures associated with energy savings that could dampen any increase in consumption of additional goods and services (e.g., our rule increases the cost of new vehicles, which offsets the fuel cost savings that trucking firms may pass along to shippers,

---

209 77 FR 51701-5.
which in turn, would dampen any decrease in product prices that shippers pass along to consumers). Third, the study does not consider the potential for economic restructuring in response to decreased energy consumption (i.e., it does not consider “general equilibrium” effects), which could lead to either lower or higher energy consumption as a result of our rule. Fourth, the authors recognize that there is a major limitation of the study: they have only a very small number of expenditure categories in their model and there is considerable disparity in GHG intensities of commodities within each category (p. 3578). Fifth, the study does not directly explore the market mechanism through which our rule could influence the amount of goods and services consumed since it focuses on energy efficiency improvements that more directly increase consumers’ disposable income rather than on the more complex and indirect pathway where greater heavy duty vehicle fuel efficiency may result in lower-priced goods and services. Finally, the authors do not attempt to quantify the additional benefits to consumers associated with increased consumption of goods and services, which would be important to consider if we were assessing the overall costs and benefits associated with potential indirect rebound effects from our rule.

At the time of our response to POP Diesel’s 2012 petition for consideration, EPA was not aware of any data to indicate that the magnitude of indirect rebound effects, if any, would be significant for this rule. Since the finalization of the Phase I rulemaking, EPA has considered this issue further, but we are aware of no new peer reviewed studies or other research that would alter our assessment of the current state of knowledge about indirect rebound as it relates to fuel economy. Research on indirect rebound effects remains nascent. The magnitude of effects from our rule postulated in the Saunders affidavit still has little support in the literature, still reflects no expert peer review, and in the end remains speculative. It appears highly improbable that all of the GHG emissions benefits of this rule would be negated by putative indirect rebound effects, and the state of the literature on indirect rebound does not provide EPA with a sufficient basis to decide (or think) otherwise.

There remain substantial unanswered questions that the literature on indirect rebound must study further before EPA can consider including such estimates in our economic analysis. As discussed in this proposed rule, all of the fuel costs savings will not necessarily be passed through to the consumer in terms of cheaper goods and services. First, there may be market barriers that impede trucking companies from passing along the fuel cost savings from the rule in the form of lower rates. Second, there are upfront vehicle costs (and potentially transaction or transition costs associated with the adoption of new technologies) that would partially offset some of the fuel cost savings from our rule, thereby limiting the magnitude of the impact on prices of final goods and services. In turn, it is not clear how the fuel savings would be spent and the consequences of the spending on greenhouse gas emissions.

EPA raised these same questions in response to POP Diesel’s 2012 petition for reconsideration. However, the new Saunders affidavit does not consider these questions, but rather argues that it must be the case that increased fuel economy will make the cost of freight transportation service cheaper, and will result in further demand for goods. But the affidavit provides no studies of historical data, of decision-making in the trucking sector, nor any other evidence to support this claim. In the case of the direct rebound effect, the Winebrake et al. papers discussed in detail in the Preamble of this final rulemaking suggest that the effect may not be significantly different from zero. It is therefore feasible that the indirect rebound effect might also not be significantly different from zero. Until the literature on indirect rebound studies these questions more thoroughly, any estimates of the existence and magnitude of an indirect rebound effect remain speculative. At this point in the development of that body of literature, it would be unreasonable for EPA to include any estimate of the indirect rebound effect in our economic analysis.
11.6 Impact on Class Shifting, Fleet Turnover, and Sales

11.6.1 Impact on Class Shifting & Other Concerns

**Organization:** American Trucking Associations (ATA)

**Manufacturers Should not Limit Vehicle Purchasing Options**

OEM’s will comply with the rule by selling more efficient engines, tractors, and trailers. Shortfalls in meeting their targets can be supplemented with either early introduction or over-compliance credits. The trucking industry is very diverse and vehicles and trailers are traditionally ordered with equipment tailored for specific applications. As under Phase 1, ATA and its member fleets remain concerned that certain equipment the industry has relied upon by the industry may no longer be manufactured and offered for sale due to their lower overall efficiency numbers. If such a scenario does in fact play out, fleets may be forced to purchase equipment that is, in fact, less efficient since the equipment is no longer properly paired with its specific work application. [EPA-HQ-OAR-2014-0827-1243-A1 p.21]

This scenario is a real concern for the trucking industry. Fleets want to be assured that the vehicles they purchase are best-suited for their needs. Trucking customers are so specific with their truck orders that they would rather wait to get the exact truck they need than take what is available. In a worst-case scenario, a fleet may explore the newer, used truck market or extend their normal trade-in cycles. This situation has occurred recently with the elimination of cab-over tractors. Companies that were employing these tractors, in many cases to comply with vehicle length limitations, have been forced to extend the life of their existing tractors and forego vehicles with advanced emissions controls, or reconfigure to shorter trailers, resulting in more truck trips. Technologies that add additional weight to a truck and/or increase a company’s capital costs without optimizing fuel consumption and GHG reductions will reduce the potential benefits of the rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.21]

**Organization:** Diesel Technology Forum

We believe these are also important considerations for EPA in developing a final Phase 2 rules, as follows: [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

- **That this rule is compatible with the needs and complexities of the diverse marketplace:** Commercial trucks encompass a wide range of types, shape and sizes with primary and secondary manufacturers of commercial vehicles, along with many vehicles customized to meet the needs of a broad range of specific work tasks. Efforts to impose fuel economy standards should not affect vehicle choice or such efforts could have unintended consequences of causing shifts in the marketplace to less productive and more vehicles on the road. [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

**Response**

The Phase 2 standards are performance-based, meaning that the industry will have a significant range of technology choices to be considered for compliance. It is important to emphasize here that the agencies are not mandating the use of a specific technology to meet the Phase 2 standards, rather manufacturers would be able to choose the technologies, or combinations of technologies, that are best for them in achieving the standards. The agencies do not believe the new regulation would limit or prohibit any specific product, such as cab over tractors. However, manufactures might choose not to produce less energy efficient tractors in order to meet the new standards (for example, the cab over tractor is
aerodynamically worse than the regular tractor). One the other hand, manufactures might choose to produce this kind of tractors by using the flexibility program (such as credit trading) built in the new standards because of special market demand (we note that cab over tractor has been phased out in recent years even before the HD Phase 1 rule because of market competition (worse in aerodynamics, less fuel efficiency, and higher operation cost)). Even vehicles with lower fuel consumption should be marketable to consumers, because they will have lower operating costs. For most trucking companies, fuel costs are the highest business cost, outside of driver labor. Indeed, if consumers consider even a few years’ worth of fuel savings in deciding what vehicles they will buy, the vehicles with increased fuel economy may be more attractive to them than vehicles with lower fuel economy. As a result, the agencies believe that few, if any, companies will extend the lives of older vehicles instead of buying new ones.

The rule has associated costs, as calculated in the RIA Chapter 8, and summarized in Section IX.D of the Preamble to the final rule, but the fuel savings greatly exceed those expenses. The net benefits calculation indicate that average buyer will experience net benefits, as shown in Section IX.D of the Preamble to the final rule. These benefits are in addition to the benefits that motivate the rule, reduced GHG emissions and improved energy security. To the extent that the comments imply that different assumptions about a specific technology would reduce the benefits of the program, we refer the reader to our extensive technology and cost discussions presented in Chapters 2 and 7 of the RIA and discussed throughout Sections II-VI and Section IX of the Preamble. Similar to our response to Section 11.1.2 above, changes in assumptions for any one technology would not change the overall conclusions of the cost benefit-analysis; i.e., that the benefits of the program far outweigh the costs. However, as shown in this RTC document, where commenters have provided data to support changes in technology assumptions, including cost, we have considered those data in setting our final standards and in our final cost-benefit analysis.

**Organization:** National Automobile Dealers Association (NADA)

The Phase 2 rule must not put dealerships in the position of having to take the delivery of vehicles they may be forced to sell at a loss. Prospective truck customers have very specific needs and will wait to get the exact truck to meet them rather than purchase a less suitable one from stock. Experience with the 2004, 2007, and 2010 truck emissions standards and with the “great recession” left dealerships with unpopular trucks and tractors sitting on lots for months and even years, all the while incurring expensive floorplan interest costs while becoming less desirable. If and when floorplan curtailments of ten percent or more are incurred on vehicles costing upwards of $150,000, it can put a small truck dealership out of business. [EPA-HQ-OAR-2014-0827-1309-A1 p.4]

At the beginning of a model year, truck OEMs tend to follow an annual plan, in part based on regulatory mandates. First they establish pricing and production schedules for “work ready” trucks. Dealers and some larger customers buy trucks; with customers putting them to work and dealers offering them for sale. As the year progresses, OEMs make changes to their production mix to adjust for compliance with their fuel efficiency and GHG targets. As a practical matter, the only way to “mix shift” is to sell more of something and less of something else. OEMs typically accomplish this by offering financial and other concessions on the vehicles they must sell, so that they become attractive enough to dealerships and prospective customers who otherwise would not order them. [EPA-HQ-OAR-2014-0827-1309-A1 p.4-5]

This complex scenario is made even more complex by the fact that newly ordered and delivered units may have a concession (or concessions) that similar trucks already in dealer stock don’t, as OEMs sometimes fail to re-invoice dealers for stock vehicles at the new concession level. Consequently,
inventory becomes older and more difficult to sell and the rule’s public policy goals also take a hit. [EPA-HQ-OAR-2014-0827-1309-A1 p.5]

**Organization:** United Parcel Service (UPS)

UPS believes that there is also a danger that premature deployment of technology will actually hurt the environment, especially the carbon footprint of trucking in America. It is important that we get this rule right from the start. The use of immature technologies will also eat up the limited engineering expertise of engine and truck manufacturers. [EPA-HQ-OAR-2014-0827-1262-A1 p.2]

The prime example from the past of such premature deployment is the emissions control after-treatment technology present on diesel trucks today, both medium and heavy. Its cost, difficulty in service and in maintenance, and lack of customization all have discouraged the use of diesel engines and shifted trucking toward the spark-ignited, Otto cycle engine. The latter, is substantially less thermodynamically efficient that the compression ignition engine. The dual-fuel diesel/LNG class 8 tractor that UPS has run in service since 2002, has disappeared from the market, replaced with a spark-ignited LNG engine that is significantly less efficient than its predecessor. This translates directly into enhanced carbon emissions, as compared to a compression engine. We believe a large part of this shift to the spark ignition engine was due to the unavailability of diesel emission after-treatment systems that are tailored to that dual-fuel application. We see the consequences in our fleet's fuel consumption and carbon emissions. [EPA-HQ-OAR-2014-0827-1262-A1 p.2-3]

The situation with medium delivery trucks is even worse. One need only look at the number of such trucks that have shifted away from diesel, to gasoline. Since 2009, UPS alone has shifted 25,000 of its class 6 trucks to gasoline instead of diesel. The maintenance requirements of these emission control systems forced truck owners to operate outside their normal duty cycle for no reason other than to meet the needs of the emissions control system. The added cost and maintenance nightmares have led truck owners to shift to gasoline engines and the low gasoline prices today only aggravate this shift. We believe that the attendant loss in engine efficiency and increase in carbon emissions is equal to or beyond anything the Phase II rule hopes to achieve in carbon reductions. [EPA-HQ-OAR-2014-0827-1262-A1 p.3]

This phenomenon is completely unaddressed by the proposed rule, and indeed what the rule might achieve would only add to the environmental benefits of a shift back to efficient diesel engines. UPS has raised this issue to DOE and our suppliers. In short, we need a better mousetrap to clean diesel emissions more cheaply and conveniently. Our fear is that the engineering talent needed for such an improvement in emissions after-treatment will instead chase the next premature technology, very likely the exhaust heat recovery system that is not commercially available today. Again, as best we can tell, the proposed rule does not attempt to address the problem we describe, and indeed it could not until improved emissions control technology is ready. [EPA-HQ-OAR-2014-0827-1262-A1 p.3]

**Response:**

The agencies disagree with commenters that the new standards will have the same effect as the commenter states for the 2004, 2007, and 2010 standards. Those standards imposed costs without providing financial returns in the form of fuel savings. For the new standards, the fuel savings reduce the net costs of the standards. Moreover, with respect to the delivery vehicles of concern to UPS, the vocational vehicle standards are subcategorized to reflect appropriate duty cycles (there are no comparable subcategories in the 2004, 2007, and 2010 criteria pollutant standard rules), these vehicles can be certified to any of the subcategories (urban/regional/multi-purpose) which the OEM believes best fits in-use driving patterns.
Organization: Transfer Flow, Inc.

Necessity is the mother of invention, and as such the idea that regulation drives technological innovation rather than industry meeting demands through application of technology is not only backward, but such an ideological approach lacks the foresight to understand that human nature will find ways to meet needs while remaining compliant when technology fails. Currently, vehicle and equipment manufacturers have been unable to meet all regulatory constraints through the application of technology. By attempting to drive technological innovation through regulatory decree instead of allowing industry to address customer needs through application of current technologies, we find ourselves in the current situation where people have found creative ways to operate within regulatory constraints without purchasing newer lower emission vehicles and equipment. [EPA-HQ-OAR-2014-0827-1922-A1 p.1]

One example of technological failures that have led to creative solutions are exhaust treatment technologies imposed on heavy duty diesel vehicles which have caused reliability to come into question. In addition to reliability issues, the time needed for regeneration cycles that often do not fit well into the operator’s schedule lead to frustration and often the regeneration is not allowed to occur when necessary to maintain vehicle performance. We then find ourselves in a situation where a new efficient vehicle is now consuming more fuel per mile than the older inefficient counterpart vehicle because new operational parameters are not followed. If vehicle demands are continued to be ignored and the vehicle is operated further, component failure can result that can result in dire unintended consequences. This was demonstrated as reported by Diesel Net by the September 7th 2011 fire in Washington State where a Cleaire Long Mile filter that was potentially overloaded with soot experienced an uncontrolled regeneration resulting in a fire that destroyed over 100 structures including 29 homes. [EPA-HQ-OAR-2014-0827-1922-A1 p.1]

As a result of incidents such as the Cleaire fire, older vehicles which allegedly pollute more due to lack of technologies imposed on newer vehicles have become more desirable in the marketplace. Vehicle and equipment owners now find themselves in the predicament of either having to service an aging fleet or purchase new vehicles that have technology implemented on them that is not reliable and causes complications in their business practices as well as potentially ruinous malfunctions. This has been demonstrated by the downturn in new heavy duty vehicle sales. The regulatory implementation of technology has had the unintended consequence of forcing owners to keep vehicles in service that would have been previously retired. [EPA-HQ-OAR-2014-0827-1922-A1 p.1]

Another way owners are able to meet customer demands while maintaining fleet compliance is through segmentation by purchasing multiple lighter class vehicles or equipment with smaller currently unregulated engines to perform the same function as one heavier class vehicle did previously. Multiple lighter class vehicles or smaller engines consume more fuel to accomplish the same function than one larger engine that previously performed the same task. When viewed from a cradle to grave model the use of multiple smaller pieces of equipment or vehicles to accomplish the same task that was previously accomplished with one vehicle or piece of equipment has exponential ramifications. In this case there are now multiple engines, tires, drivetrains or pieces of equipment to service and maintain in order to perform the same function as was previously performed by one engine, drivetrain and piece of equipment. Highway maintenance, traffic congestion, engine emissions, equipment maintenance and operational costs all increase when this type of problem solving is employed. However, given the current regulatory situation, business owners have no choice but to employ the most cost sensitive solution even though it is more complicated and less desirable. [EPA-HQ-OAR-2014-0827-1922-A1 p.2]
Vehicle manufacturers are able to meet fleet averages by producing light duty vehicles that are now rated to higher payloads using smaller more efficient engines than their predecessors. These vehicles are typically not employed in a vocational work capacity but account for a large percentage of vehicles sold. These lighter vehicles appear to have the same capabilities of older medium duty vehicles. New, heavier, medium duty vehicles that are used in a vocational work capacity largely have gone unchanged in engine options and fuel efficiency. The largest gasoline engines are still offered in these vehicles with the same efficiencies and emission systems that they have had for several years. There have been particulate filters implemented on medium duty diesel vehicles that have caused lower fuel efficiencies and share all the same frustrations and complications that are present on heavy duty diesel vehicles with the same types of devices. [EPA-HQ-OAR-2014-0827-1922-A1 p.2]

Since there are now more vehicles rated to a higher payload that account for a large percentage of vehicle sales, it would appear that there are more fuel efficient medium duty vehicles being purchased into the work force. However, if vehicle sales are broken down by application, we see that newer light duty vehicles, with a higher payload capacity than their predecessors, which appear as medium duty vehicles, are still not largely purchased for vocational work applications. Vehicle manufacturers can now state that they are selling more fuel efficient vehicles into a higher weight class; however those vehicles are largely still employed as they have always been in a non-vocational capacity. For all the attempt to reduce emissions from vehicles that travel the most miles and account for the largest percentage of emissions generated by requiring manufacturers to offer more fuel efficient vehicles, not much has been accomplished other than some creative labeling of vehicles. [EPA-HQ-OAR-2014-0827-1922-A1 p.2]

Once again we see that regulatory overreach has had the opposite effect of its initial intention. If the true intention of the regulation was to drive economic stimulation of the tax base through restructuring business practices, then this is a job well done. Companies have gone from purchasing one large piece of equipment to multiple purchases of smaller pieces of equipment that surpass the cost of the larger purchase and then require higher maintenance cost. Instead of a regulatory approach of a problem looking for a place to happen, perhaps a realistic approach of true problem solving could accomplish the emissions reduction goal. [EPA-HQ-OAR-2014-0827-1922-A1 p.2-3]

Response:

In its comment, Transfer Flow questions the agencies’ justification for the standards, and also raises concerns regarding the agencies’ proposed standards. Transfer Flow claims the proposed standards would have unintended consequence of forcing owners to keep vehicles in service that would have been previously retired because of concerns regarding the technological reliability of the exhaust treatment imposed on HD trucks. If those technologies are not reliable, older vehicles have become more desirable in the marketplace. In addition, Transfer Flow claims that new standards might change the truck owner’s choice in purchasing the vehicle. The fleet owner might choose multiple lighter class vehicles or equipment with smaller currently unregulated engines to perform the same function as one heavier class vehicle did previously in the vocational vehicle category.

We agree with Transfer Flow that market forces induce innovation, but we disagree with the claim that regulations do not. Preamble Section IX.A. and RIA Chapter 8.2 discuss some potential explanations for private markets not investing in new technologies that can provide private net benefits. For instance, as discussed there, regulations may help to overcome “network externality” problems associated with new technologies: e.g., in the absence of regulation, repair facilities may not stock low-rolling-resistance tires unless large numbers of vehicles use them, but people may not install them if replacements aren’t available in repair facilities. Also as discussed there, there may be first-mover disadvantages to investing in new technologies because of the up-front costs; standards can level the playing field by
spreading the risk across all market participants, rather than concentrating it on a small number of participants. Regulations can help to overcome these problems by providing incentives for market participants to overcome these barriers. We also disagree that “vehicle and equipment manufacturers have been unable to meet all regulatory constraints through the application of technology.” In fact, all HD vehicles being sold now are required to meet regulatory constraints.

We do not envision that new standards would have unintended consequences as described by Transfer Flow, where operators would keep HD trucks in the service longer because they perceive the new technology to be unreliable. The new standards will not impose a specific technology for manufacturers to meet the standards but will allow manufacturers to optimize technology packages to meet the new standards. Market and consumers will recognize or determine if one specific exhaust treatment is more reliable, cost effective, and fit their need. The agencies understand the potential impact that fleets delaying purchases could have on the program’s environmental and fuel savings goals, and have taken steps in the design of the program to avoid such disruption. These steps include the following:

- Providing considerable lead time
- Adopting standards that will result in significantly lower operating costs for vehicle owners (unlike the 2007 standard, which increased operating costs)
- Phasing in the standards
- Structuring the program so the industry will have a significant range of technology choices to be considered for compliance, rather than the one or two new technologies the OEMs pursued to comply with EPA’s 2007 criteria pollutant standard
- Allowing manufacturers to use emissions averaging, banking and trading to phase in the technology even further

We do not envision that the regulatory program would cause fleet owners to purchase multiple lighter class vehicles or equipment with smaller currently unregulated engines to perform the same function as one heavier class vehicle did previously. As described at Preamble Section IX. F, we do not envision the new standards would cause the class shifting within the vocational vehicle weight class or within the duty cycles (particularly given that manufacturers can choose essentially without constraint whether to certify as regional, urban, or multi-purpose). Specifically with respect to the commenters concerns about a shift to lower weight vehicles in an effort to circumvent more stringent standards, we note that the Phase 2 vocational vehicle standards are more stringent for lower weight classes than for the higher weight class standards. We have designed standards to avoid incentivizing the purchase of truck sizes that have not been optimized for their intended applications. As vocational vehicles include a wide variety of vehicle types, and serve a wide range of functions, the diversity in the vocational vehicle segment can be primarily attributed to the variety of customer needs for specialized vehicle bodies and added equipment, rather than to the chassis. The new standards would lead a small increase in the incremental cost per vehicle. However, these cost increases are consistent across the board for both vocational vehicles and the engines used in the vehicle as shown in Table V-30, Preamble Section V.C.3. The agencies believe that the utility gained from the additional technology packages would outweigh the additional cost for vocational vehicles.

11.6.2 Impact on Fleet Turnover and Sales

Organization: Allison Transmission, Inc.
The RIA recognizes the possibility of a pre-buy, but the analysis concentrates only on what is viewed as favorable fuel costs and savings that will be recognized by vehicle owners. Specifically, the agencies “are not projecting a change in fleet turnover characteristics due to this regulation.”\textsuperscript{10} Allison recommends a more thorough analysis of the market history to predict behaviors and economic impact due to the technology risks that are inherent in the proposed rule. Based on that analysis, changes in timing or stringency levels may have merit. For example, fuel costs per mile were calculated using EIA’s 2014 Annual Energy Outlook for diesel prices. Yet more recent EIA projections indicate a substantial decline.\textsuperscript{11} This is significant since the agencies’ assumptions concerning “pre-buy” are that the value of saving money in future fuel purchases will outweigh the upfront additional costs of new vehicles. [EPA-HQ-OAR-2014-0827-1284-A1 p.11]

More broadly, EPA and NHTSA must analyze other non-fuel costs factors – e.g., concern with regard to the performance of new technology – and their impact on vehicle purchases. The agencies do not appear to have considered this very real and significant factor in the MD/HD market when assessing the feasibility of Alternative 4. As noted above, the NAS has cited “unknown reliability” as a factor in the “profound fluctuations” buying behavior surrounding the transition to 2007 HD standards. [EPA-HQ-OAR-2014-0827-1284-A1 p.11]

\textsuperscript{10} RIA at 8-34.

\textsuperscript{11} Diesel fuel prices were 2.88 in the 3rd quarter of 2014 compared with $1.60 in the third quarter of 2015. See http://www.eia.gov/forecasts/steo/tables/pdf/2tab.pdf. Projections for 2016 are now $1.86. Id.

\textbf{Organization:} Daimler Trucks North America LLC

Sixth, the agencies failed to estimate a pre-buy or the costs associated with one. (See 80 F.R. 40456, stating that the agencies are not accounting for a pre-buy). Although it is true that the Phase 1 standards did not result in a pre-buy and that customers should have incentive to buy the new fuel saving technologies that Phase 2 will push, it remains likely that there will be a pre-buy. Unlike Phase 1, the agencies premise the Phase 2 standards on technologies that are not off-the-shelf and thus 1) are untested by fleets and 2) are in the stage of development during which manufacturers are still finding problems and developing solutions. (See the warranty information as a function of time, which DTNA shared with the agencies in 2014). Moreover, the agencies are pushing technologies that do not have the return on investment demanded by fleets; if the technologies did have such return on investment, then manufacturers would already be selling the technologies in high numbers. In turn, fleets have an incentive to spend their limited capital on the pre-Phase 2 vehicles. This creates a cost for manufacturers such as DTNA: we must increase staffing and production levels to meet pre-buy demand, and we have to decrease them the following year, possibly being forced to lay off staff (although we sincerely hope not). These swings in production cost money, both increasing capacity and scaling it back. The agencies failed to account for such costs. [EPA-HQ-OAR-2014-0827-1164-A1 p.128-129]

\textbf{Organization:} Environmental Defense Fund (EDF)

EDF preformed an extensive market analysis of heavy-duty vehicle purchases between 1992 and 2014 matched with the 2007 and 2010 engine standards.\textsuperscript{118} Appropriately controlling for macroeconomic trends, our analysis showed that there was smooth growth in vehicle demand prior to, and during, implementation of the 2014 Phase 1 fuel efficiency standards. As further evidence, model year 2014 heavy-duty trucks saw the highest sales since 2005.\textsuperscript{119} The results of our analysis support the premise
that fuel savings provide an advantage in the competitive market. Lower freight costs drive higher demand for freight transport and demand for freight transport drives demand for new vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.25][This comment can also be found in section 11.12 of this comment summary]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

As previously mentioned engine regulations in the past have had adverse economic consequences and contributed to a pre-buy/no-buy boom and bust cycle. This proposal must guard against creating these conditions. Severe market disruptions would not only be bad for workers, they would also be bad for the environment and would undermine the regulation’s foundational goal of reducing harmful greenhouse gas emissions and increasing fuel efficiency. If fleets and other customers pull ahead truck purchases due to concerns about increased cost or unproven technology, the end result is more higher-polluting and less fuel efficient trucks on the road for a longer period of time. [EPA-HQ-OAR-2014-0827-1248-A2 p.4] [This comment can also be found in section 11.12 of this comment summary.]

Organization: Odyne Systems LLC

Other factors could influence unit sales. Higher than expected component costs, lower than expected fuel costs or an easing in efficiency and emissions regulations could reduce demand. On the other hand, it may be possible to reach a higher percentage of the annual installed 145,000 unit PTO market if various scenarios including increased regulatory measures, higher fuel costs above $4 per gallon or component costs lower than projections were to occur. [EPA-HQ-OAR-2014-0827-1239-A1 p.17]

Organization: Owner-Operator Independent Drivers Association (OOIDA)

Prior to promulgating EPA’s 2000 emission standard, the EPA and the OEMs perhaps should have predicated the now famous pre-buys which occurred before the October 2002 deadline. According to five engine manufacturers that were contacted by the Government Accountability Office (GAO), the pre-buys caused a rippling effect on OEMs, which stated that in order to meet the increased demand for the pre-October 2002 MY engines, their companies hired new workers, increased operations, and experienced concurrently increasing sales. However, after the deadline, engine orders dropped and did not level off again until the end of the 2003 fiscal year. The rapid decline in orders forced the manufacturers to both lay off new-hires and to suspend operations at some plants. According to the engine manufacturers’ representatives, such instability resulted in increased costs and a net loss of revenue. In addition, according to the GAO, those manufacturers which produced cleaner engines lost out in the marketplace because their engines faced significant reliability and durability issues. Truckers using these engines paid the ultimate price in dollars and downtime and even reduced fuel mileage. [EPA-HQ-OAR-2014-0827-1244-A1 p.12-13]
As part of the 2000 emission standard, EPA estimated that within the first 15-months, 233,000 new clean engines would be on the road, when in market reality only 148,000 were actually on the road. EPA also estimated that the consent decrees would require 865,000 older trucks to adjust their computers in order to reduce NO\textsubscript{x} emissions. However, GAO found that only 12 percent of that number actually adjusted their computers. Further, a recent market analysis done by the American Truck Dealers in 2012, noted that the EPA grossly underestimated emission system costs to the industry. Looking at the cost estimates of EPA along with the actual increase in cost of the new cleaner engines, the report found that the actual cost was more than $21,000, while the EPA estimate was $5,000.\textsuperscript{15} All of the facts presented above demonstrate one of the most fundamental problems associated with EPA’s estimates and their myopic vision of emission standards, which is, though the agency can mandate cleaner engines, they cannot mandate that people buy them. This is known as “risk aversion,” and according to the National Economic Research Associates, is not accounted for in environmental policy evaluations.\textsuperscript{16} [EPA-HQ-OAR-2014-0827-1244-A1 p.13-14]

---

Organization: Recreational Vehicle Industry Association (RVIA)

The Proposed Rule will have negative impact on motorhome shipments and jobs. RVIA contracted with John Dunham and Associates\textsuperscript{31} (Dunham) to assess the economic impact that compliance with the proposed Phase 2 standards could have on the motorhome industry. The methodology for this model is available in Appendix C. In simplistic terms, Dunham’s model assumes that some change in price will have an impact on motorhome sales (shipments)\textsuperscript{32} and that this impact on sales will in turn impact industry jobs, wages, economic output, government tax revenue, etc. RVIA asked Dunham to estimate the economic impacts for the following four scenarios: [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.12 of this comment summary]

Scenario 1: Motorhomes buyers factor 100\% of fuel savings into their purchase decision (8.5 years of discounted fuel savings were subtracted from estimated incremental cost increases; costs based on EPA ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.12 of this comment summary]

Scenario 2: Motorhomes buyers factor 100\% of fuel savings into their purchase decision (8.5 years of discounted fuel savings were subtracted from estimated incremental cost increases; costs based on motorhome industry ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.12 of this comment summary]

Scenario 3: Motorhome buyers do not factor fuel savings into their purchase decision (costs based on EPA ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.12 of this comment summary]
Scenario 4: Motorhome buyers do not factor fuel savings into their purchase decision (costs based on motorhome industry ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.12 of this comment summary]

The results of Dunham’s assessment for 2021MY, 2024MY and 2027MY are found in the following three tables below. Additional details are located in Appendix D. [EPA-HQ-OAR-2014-0827-1261-A1 p.21][This comment can also be found in section 11.3 and 11.12 of this comment summary]

[Charts, economic impacts, can be found on p.21-22 of docket number EPA-HQ-OAR-2014-0827-1261-A1]

In RVIA’s view, Scenario 4 represents the most likely outcome. Scenario 4 reflects costs based on an ICM that is more representative of actual practice in the motorhome industry which, as we have already discussed, is distinctly different from other vocational vehicle segments (largely because motorhomes are not purchased for commercial purposes). [EPA-HQ-OAR-2014-0827-1261-A1 p. 22][This comment can also be found in section 11.3 and 11.12 of this comment summary]

Scenario 4 also reflects the fact that the average motorhome buyer, unlike the commercial vehicle fleet manager, likely places little value on future fuel savings when purchasing a motorhome. These are not vehicles purchased for daily driving or commercial purposes. Rather, the purchaser generally focuses on cost, features and other factors. [EPA-HQ-OAR-2014-0827-1261-A1 p. 22] [This comment can also be found in section 11.12 of this comment summary]

Looking at Scenario 4 and 2024MY standards, we estimate that a total of 1,553 jobs would be lost. Of these, 460 would be motorhome manufacturing jobs. This is over 5% of the existing 8,732 motorhome manufacturing jobs that exist today in the thirty-four motorhome manufacturing sites in the United States. With motorhome manufacturing jobs located in a handful of rural communities in a small number of states, applying the proposed standards will have serious negative impact on these communities. The rule would negatively impact not just motorhome manufacturing employees (460 lost jobs) but also motorhome dealers and component part suppliers (144 and 404 lost jobs, respectively). Also negatively impacted would be persons outside the industry who live in these manufacturing communities. Lost wages are estimated at nearly $118 million. Federal, state and local governments will also have about $34 million fewer tax dollars to invest in social programs, and infrastructure. [EPA-HQ-OAR-2014-0827-1261-A1 p.22][This comment can also be found in section 11.12 of this comment summary]

Regardless of the scenario and the extent to which our industry and the communities that manufacture motorhomes are affected, the negative impacts for our industry cannot be ignored. We have concrete evidence showing what happens when motorhome shipments decline. It has been only six years since 2009 when nearly two-thirds (64%) of all direct motorhome manufacturing employees lost their jobs. 33 As of 2013, the latest year for which data is available, there are 43% fewer motorhome manufacturer businesses and still 59% fewer motorhome manufacturer employees than pre-recession. [EPA-HQ-OAR-2014-0827-1261-A1 p.22-23][This comment can also be found in section 11.12 of this comment summary]

While the estimated job losses associated with this rule do not approach the numbers experienced just a few years ago during and after the recession, they will still result in much pain and suffering, particularly for a handful of low-income rural communities that are only now just starting to recover from the recession. At the very least, EPA must consider these economic costs and impacts under the
31 John Dunham & Associates (JDA) is an economic specialist in regulatory analysis. JDA generates economic and fiscal impact studies from a national level down to geographic regions, municipalities, marketing areas or Federal and state legislative districts. See http://guerrillaeconomics.com/

32 According to John Dunham and Associates, the base elasticity for motorhomes is -0.905, suggesting that a 10 percent change in prices will reduce demand by 9 percent (see Appendix C).

Organization: Truck & Engine Manufacturers Association (EMA)

Potential Pre-Buy/Low-Buy Concerns

Other issues exacerbate the problems associated with adopting Alternative 4 for medium-duty and heavy-duty vehicles. As the Agencies well know, there is significant elasticity in the demand for the commercial vehicles at issue in this rulemaking. The Agencies only regulate the manufacturing of new engines and vehicles. There is no obligation for customers to buy the new products – and certainly not at the time of implementation of a new regulation. Moreover, experience has shown that adverse economics, globally or affecting key market segments, have resulted in customers delaying vehicle purchases. Similarly, experience has shown that actual or perceived concerns about the cost, performance, durability, serviceability, or overall efficacy of new-tier vehicle technologies have also resulted in customer “pre-buys” of current-tier technologies and/or the delayed purchase of new-tier technologies. Neither manufacturers (who wish to start recovering their investment in new-tier engine and vehicle technologies as soon as possible) or regulators or the public (who wish to realize the benefits of new regulations as soon as possible) want to experience a pre-buy/low-buy response to the Phase 2 Standards. [EPA-HQ-OAR-2014-0827-1269-A1 p.56][This comment can also be found in section 1.5 of this comment summary]

Alternative 4 increases the risk for such a potential response since it likely would result in significantly higher per-vehicle cost increases (compared to Alternative 3), and could produce real or perceived concerns for product durability, reliability and maintenance issues. Those possible circumstances – necessarily more likely under Alternative 4 – could induce vehicle and fleet owners to revise their scheduled purchases of new Phase 2 vehicles. In that regard, and as the Agencies expressly acknowledge, Alternative 4 would deprive manufacturers of three-years of learning time and therefore would decrease the “learning-benefit” savings otherwise available under Alternative 3. [EPA-HQ-OAR-2014-0827-1269-A1 p.56][This comment can also be found in section 1.5 of this comment summary]

The net result could be that manufacturers will be unable to recoup their capital investments in the time period projected in the NPRM. Worse, the very marginal GHG emission benefits ascribed to Alternative 4 might not be realized, even if the three-year pull-ahead could be accomplished, if the Alternative 4 standards proved in the market to be perceived as problematic by customers. The higher costs and potential reliability issues associated with Alternative 4 could be enough to cause vehicle and fleet owners to keep their Phase 1 vehicles longer than otherwise. Consequently, Alternative 4 might actually result in higher aggregate GHG emissions than under Alternative 3, not marginally lower emissions.
This is another reason why the Agencies should not implement Alternative 4. [EPA-HQ-OAR-2014-0827-1269-A1 p.56][This comment can also be found in section 1.5 of this comment summary]

**Organization:** Truck Renting and Leasing Association

Because the technology-forcing nature of the Proposed Standards is anticipated to increase costs, pre-buys may also be expected as the natural result of market behavior. Pre-buys may counter some of the goals that the agencies are trying to obtain. Pre-buys, as were seen before the 2007 NOx regulation implementation, can result in unemployment in the truck manufacturing, component supplier, and service support industries.¹ This negatively impacts businesses, the economy, and solvency of the Highway Trust fund – the latter of which in particular remains in dire straits. Environmental benefits are also put in jeopardy as anticipated benefits are not obtained. [EPA-HQ-OAR-2014-0827-1140-A1 p.4]

**Organization:** Volvo Group

Heavy-duty trucks are commercial vehicles purchased to enhance the profitability of a business. Purchasers must consider the initial cost (including Federal Excise Tax and state tax), operating and maintenance costs, plus any cost of vehicle downtime. Class 8 tractors, in particular, are generally purchased for regional or long-haul operation accumulating 100,000 or more miles annually. Most fleets require payback for efficiency technology in 18-24 months to cover the risk factors (actual efficiency delivered, maintenance and downtime costs, etc.), recoup their investment, and to provide a profit margin within their 4-5 year trade cycle. Fleets are particularly leery of complex new systems with unproven reliability and unknown maintenance cost. Rather than purchase such technology, fleets have delayed new purchases by extending the life of older equipment and/or pre-buying vehicles before such systems were forced into the market. This was amply demonstrated in 2007 when diesel particulate traps were forced into the market by PM emissions targets. Factories ran at full capacity at the end of 2006 only to nearly shut down for long periods in 2007. Production was then further curtailed by the severe recession in 2008. Vehicle manufacturers’ and suppliers’ employees suffered from lay-offs, pay reductions, and lack of work. One major supplier, Caterpillar, dropped out of the on-road engine business. Since 2010, the increased cost and complexity of emissions technology has spawned a booming business in trucks built from glider kits, a completely new truck chassis and body that is up-fitted with a rebuilt engine, driveline and axle, skirting emissions and efficiency regulations. [EPA-HQ-OAR-2014-0827-1290-A1 p.18]

In the Phase 1 rule, EPA and NHTSA initiated a phased in approach using averaging, moderate changes in stringency, and a three year period to correct a failure to meet an annual target. This process, which would continue at an accelerated pace in Phase 2, helps to eliminate the need to force major new technology into the market at full volume. However, it introduces another problem - manufacturers must induce customers to purchase technologies in adequate volumes to achieve regulatory targets when the customers have the option not to purchase such technologies if they are not convinced of the merits. History shows a gradual market acceptance as technologies are tested by first users, then, if found to be cost effective, purchased by others in low volumes before becoming generally accepted. Accelerating this dynamic will certainly be challenging and could be very costly if manufacturers are forced to heavily discount new technology. Markets can also be greatly distorted if some manufacturers accrue large credit balances allowing them to delay technology introduction, thereby forcing competitors to compete against lower cost products. This issue will be particularly acute if truck owners do not
perceive adequate payback for technology. Conversely, technology that delivers good payback, reliability, and durability will be adopted without need for regulation. [EPA-HQ-OAR-2014-0827-1290-A1 p.18-19]

Response:

Several of the commenters (Daimler Trucks North American (DTNA), EDF, UAW, OOIDA, EMA, Truck Renting and Leasing Association (TRLA), and Volvo) discuss the concern that these standards may lead to “pre-buy,” that is, purchasers buying large numbers of new vehicles before the standards come into effect, in order to avoid the effects of the standards. As a result of pre-buy, sales would drop after the standards are effective. Employment would swing up before the effective date of the standards, and decrease afterward, in what the UAW calls a “boom and bust cycle.” In addition, because of delayed market penetration of the new vehicles, the environmental gains of the standards would be delayed as well. Commenters note standards put in place for criteria pollutants in the 2000s as leading to pre-buy.

The agencies agree with these commenters that pre-buy is an undesirable phenomenon, for environmental reasons as well as for impacts on the industry. The degree to which that concern applies to GHG/fuel economy standards, however, seems much lower than for the criteria pollutant standards of the 2000s. As discussed in Preamble IX.F.2 and RIA Chapter 8.4.2, those criteria pollutant standards differ from these GHG/fuel efficiency standards because the latter, unlike the former, provide fuel savings to users in addition to increased costs. The expectation of fuel savings should mitigate any attempt to avoid purchase of vehicles subject to the standards. Although DTNA and Volvo raise concerns that the return on investment is not as large as fleets demand, we nevertheless project fuel savings that exceed increased costs with payback periods between two and four years. Volvo argues that technologies with “good payback, reliability, and durability will be adopted without need for regulation.” Preamble Section IX.A. and RIA Chapter 8.2 discuss possible reasons that these technologies may not have been adopted in the absence of the standards, even with short payback periods. EDF points to research that it has done showing “smooth growth in vehicle demand prior to, and during implementation” of Phase 1 of the HD program – that is, it does not find evidence of pre-buy in response to the onset of Phase 1. It also notes that HD sales in 2014 were at their highest level since 2005. These observations suggest that pre-buy has not been a significant issue for Phase 1.

DTNA agrees that Phase 1 did not result in pre-buy, but it argues that the technologies expected under Phase 2 are untested, and manufacturers are still finding problems with them. Allison Transmissions and EMA raise concerns with pre-buy specifically in regard to proposed Alternative 4; Volvo expresses concerns related to the speed with which the standards become more stringent. We note that the decision not to finalize proposed Alternative 4 is largely to allow lead time for development and testing of new technologies. At the same time, the standards provide certainty to promote markets for efficiency technologies, as Odyne Systems points out. Odyne Systems and EMA also note that a wide range of factors affects sales; we agree with this observation as well. As one example, it is likely that the high sales EDF notes for 2014 are due heavily to recovery from the Great Recession; the effects of the standards on those sales levels could be positive or negative, and are likely to be small relative to the effects of the recovery.

Allison Transmission asks for an analysis “to predict behaviors and economic impact due to the technology risks,” and points out the use of EIA’s 2014 AEO price forecasts in the NPRM as potentially overstating fuel savings. We have not conducted a quantitative analysis of the effects of the standards on sales because we have not identified in the literature a suitable model or suitable data for making such estimates. We have updated to EIA’s 2015 AEO price forecasts, the most recent available at the time
that we conducted the analysis presented in the rulemaking documents. The standards continue to have benefits that greatly exceed costs, and, as noted, fairly short payback periods.

OOIDA cites risk aversion as a source of pre-buy, and suggests that risk aversion is not considered in environmental policy analysis. Risk aversion means that consumers prefer a certain value to an uncertain value whose expected value is the same as the certain value. It is unclear in OOIDA’s statement how risk aversion applies: up-front costs of meeting the standards, even those subject to the criteria pollutant standards of the 2000s, were built into purchase prices and thus not uncertain at the time of purchase. Perhaps they were uncertain before the vehicles went on sale, and may have thus contributed to pre-buy. This argument, however, leaves out an additional aspect of risk aversion especially important for GHG/fuel efficiency standards: future fuel costs are highly uncertain as well, due to fluctuations in world energy prices. Fuel-saving technologies reduce the impacts of those fluctuations and thus would benefit risk-averse buyers. Although OOIDA cites a claim that the agencies have not considered risk aversion in our analysis, Preamble IX.F.2. and RIA Chapter 8.4.2 discuss our recognition that the two factors affected by risk aversion, the up-front costs and future fuel savings, both affect buyer decisions. We have not identified reliable estimates to quantify these effects on vehicle sales, and thus have presented a qualitative argument.

RVIA expresses concern with the negative sales and employment impacts of the standards. To some extent, this comment is overtaken by events, since the final standards provide for (optional) custom chassis standards that differ from those proposed in ways that should address many of the commenter’s substantive concerns. In any case, the concern is that the RV industry is at risk to suffer significant negative effects due to the rule, based, in part, on the question of whether RV consumers will factor fuel savings into their purchase decisions. If consumers do not consider fuel savings, then increases in RV price due to complying with the rule could reduce sales, eventually leading to job losses. The RV industry was disproportionately hurt during the Great Recession and has only recently experienced a recovery.\textsuperscript{210,211} The maximum adverse effects on sales, in an analysis by John Dunham and Associates for RVIA, are based in part on the assumption that fuel savings do not affect vehicle sales. One of the drivers of the current recovery of sales appears to be low gas prices,\textsuperscript{212} which suggests that RV consumers do consider fuel costs in the purchase decision, and thus are likely to put some consideration on fuel savings from new technology. If so, the reduced fuel costs associated with these standards are likely to mitigate any adverse effects on vehicle sales. Section 11.12 of this Response to Comments discusses the employment impacts in detail.

\textbf{11.7 Monetized GHG Impacts}

\textbf{Organization:} ABC Bus Companies, Inc.

Phase 2 summaries of benefits, costs, emissions, reduced total fuel consumption, carbon footprints, etc., make no reference in the report that we can find that measures the motorcoach industry contribution to

reduced automobile traffic, emissions, congestion and highway damage, per numbers of passengers moved from point A to point B. In short, one 81 passenger motorcoach could potentially remove 81 cars, pickup trucks, or light duty vehicles from the American roadways. [EPA-HQ-OAR-2014-0827-1430-A2 p.2-3]

**Reductions in fuel consumption, emissions, carbon footprints, etc., on a per motorcoach basis, should be compared against the same consumption and discharge categories of smaller vehicles removed from the roadways.** [EPA-HQ-OAR-2014-0827-1430-A2 p.3]

Page 40294 refers to MOVES forecasts of 1,000 commercial intercity coach buses, 5,000 transit buses, 40,000 school buses, and 90,000 recreational vehicles in MY 2018. [EPA-HQ-OAR-2014-0827-1430-A2 p.3]

The average passenger capacity of an intercity coach bus is 56 passengers. Using the 1,000 yearly intercity coach bus figure provided in the report, the potential to remove 56,000 automobiles from the U.S highway system per year exists. The real impact of motorcoach GHG emissions should be offset by the numbers of automobile and light truck vehicles removed from the US highways. Reduced GHG, fuel consumption, and CO$_2$ figures could be based on ‘passenger’ MPG instead of ‘vehicle’ MPG. [EPA-HQ-OAR-2014-0827-1430-A2 p.3]

**Response:**

EPA does not consider impacts on a per-passenger basis as part of its standard-setting process. As a result, EPA does not relate fuel savings (or other impacts) to “cars-off-the-road” in our analysis.

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Social cost of non-CO$_2$ GHGs**

The NPRM requests comment on the inclusion of non-CO$_2$ GHGs in the estimated benefits of the proposed rulemaking. CARB staff supports the use of directly modeled peer-reviewed estimates of the social cost of all GHGs over the GWP approach but is concerned about consistency if not all GHGs are directly modelled. Currently, there is no proposed research to directly model the social cost of HFC-134a for example, which will result in biased estimation as the GWP-based approximation has been shown to underestimate climate benefits relative to direct modeling. CARB staff suggests that there is a need for additional research on the social cost of non-CO$_2$ GHGs such as black carbon including harmonization with the social cost of CO$_2$. [EPA-HQ-OAR-2014-0827-1265-A1 p.185]
Response:

EPA acknowledges this comment and notes that it has used the SC-CO\textsubscript{2} estimates as well as the Marten et al. (2014) social cost of methane (SC-CH\textsubscript{4}) and social cost of N\textsubscript{2}O (SC-N\textsubscript{2}O) estimates to monetize the climate-related impacts of this rulemaking. Regarding the comment that the social cost of carbon underestimates benefits, the EPA recognizes that none of the three integrated assessment models (IAMs) fully incorporates all climate change impacts, either positive or negative; see EPA response to comment EPA-HQ-OAR-2014-0827-1296-A1.

Regarding the comments about GHGs not monetized in the main benefit-cost analysis for the final rulemaking, e.g., HFC-134a, EPA notes that neither the interagency working group nor the EPA have established a methodology for valuing the social cost of HFC-134a or black carbon. EPA strives to identify, quantify, and monetize all relevant impacts from the rulemaking but may not be able to do so in practice due to methodological limitations. EPA recognizes the importance of quantifying and monetizing the benefits of regulations to the extent feasible, and discussing qualitatively any benefits that cannot be quantified. The RIA presents a thorough discussion of the GHG impacts expected from this final rulemaking.

Organization: Environmental Defense Fund (EDF)

Finally, in May 2013, the Interagency Working Group on the Social Cost of Carbon (IWG) published an updated assessment that increases the predicted threat that climate change poses and will continue to pose into the future. The IWG’s original estimate in 2010 provided four potential values to represent the cost that each metric ton of CO\textsubscript{2} emissions will impose on society for the year 2020: $7, $26, $42, and $81.\textsuperscript{66} The 2013 estimate increases those values to $12, $43, $65, and $129, respectively.\textsuperscript{67} While the Joint Environmental Commenters believe that these updated figures fundamentally underestimate the true cost of carbon emissions, they nonetheless reflect the same trend as seen in the scientific literature: not only does the potential harm from carbon emissions increase with each additional ton released into the atmosphere, but the severity of the predicted harm increases as our understanding of climate change grows. [EPA-HQ-OAR-2014-0827-1312-A1 p.14][This section can also be found in section 9.4 of this comment summary]

Social cost of carbon and social cost of methane

Please see separate comments submitted jointly to the docket by EDF, Institute for Policy Integrity, Union of Concerned Scientists and the Natural Resources Defense Council. [EPA-HQ-OAR-2014-0827-1312-A1 p.23][Comments can be found in docket number EPA-HQ-OAR-2014-0827-1296-A1]

\textsuperscript{67} Id.

Response:

EPA acknowledges this comment and notes that it has used the SC-CO\textsubscript{2} estimates as well as the Marten et al. (2014) social cost of methane (SC-CH\textsubscript{4}) and social cost of N\textsubscript{2}O (SC-N\textsubscript{2}O) estimates to monetize the climate-related impacts of this rulemaking. Regarding the comment that the social cost of carbon
underestimates benefits, the EPA recognizes that none of the three integrated assessment models (IAMs) fully incorporates all climate change impacts, either positive or negative; see EPA response to comment EPA-HQ-OAR-2014-0827-1296-A1.

**Organization:** Institute for Policy Integrity

**Institute for Policy Integrity, Excerpt 1:** Our organizations respectfully submit these comments regarding EPA and NHTSA’s valuation of the benefits of their greenhouse gas and fuel efficiency standards for medium and heavy-duty vehicles—specifically, the use of the Interagency Working Group’s valuation of the Social Cost of Carbon and the consideration of the Social Cost of Methane metric. Our organizations may separately and independently submit other comments regarding the proposed standards themselves. [EPA-HQ-OAR-2014-0827-1296-A1 p.1]

We strongly affirm that the current Social Cost of Carbon (SCC) values are sufficiently robust and accurate to continue to be the basis for regulatory analysis going forward. We further agree with EPA’s most recent assessment that the Social Cost of Methane approach is methodologically sound and should be applied to value methane emissions. As demonstrated below, if anything, current values are significant underestimates of the SCC and the Social Cost of Methane. As economic and scientific research continues to develop in the future, the values should be revised, and we also offer recommendations for that future revision. [EPA-HQ-OAR-2014-0827-1296-A1 p.1]

Our comments are summarized in six sections: [EPA-HQ-OAR-2014-0827-1296-A1 p.1]

1. Introduction: The SCC is an important policy tool.
2. The Interagency Working Group’s (IWG) analytic process was science-based, open, and transparent.
3. The SCC is an important and accepted tool for regulatory policy-making, based on well-established law and fundamental economics.
4. Recommendations on further refinements to the SCC.
5. Support for the Social Cost of Methane methodology, and recommendations on refinements.

**1. Introduction: The SCC is an important policy tool.**

The SCC estimates the economic cost of climate impacts—specifically the additional economic harm caused by one additional metric ton of carbon dioxide (CO₂) emissions. SCC calculations are important for evaluating the costs of activities that produce greenhouse gas emissions and contribute to climate change, such as burning fossil fuels to produce energy. The SCC is also important for evaluating the benefits of policies that would reduce the amount of those emissions going into the atmosphere. For example, in order to properly evaluate standards that reduce the use of carbon-intensive energy or that improve energy efficiency—like the proposed standards—it is important to understand the benefits they will provide, including the benefit of reducing carbon pollution and the harm it causes. [EPA-HQ-OAR-2014-0827-1296-A1 p.2]

As with all economic impact analyses, the exercise can only provide a partial accounting of the costs of climate change (those most easily monetized) and inevitably involves incorporating elements of uncertainty. However, accounting for the economic harms caused by climate change is a critical component of sound benefit-cost analyses of regulations that directly or indirectly limit greenhouse gases. This endeavor is important because benefit-cost analysis is a central tool of regulatory policy in
the United States, first institutionalized in a 1981 executive order by President Ronald Reagan. The executive order currently in effect provides that agencies:

- “[P]ropose or adopt a regulation only upon a reasoned determination that its benefits justify its costs (recognizing that some benefits and costs are difficult to quantify);...”
- “[S]elect, in choosing among alternative regulatory approaches, those approaches that maximize net benefits (including potential economic, environmental, public health and safety, and other advantages; distributive impacts; and equity);...”
- “In applying these principles, each agency is directed to use the best available techniques to quantify anticipated present and future benefits and costs as accurately as possible. Where appropriate and permitted by law, each agency may consider (and discuss qualitatively) values that are difficult or impossible to quantify, including equity, human dignity, fairness, and distributive impacts.” [EPA-HQ-OAR-2014-0827-1296-A1 p.2]

Benefit-cost analysis has long been a staple of agency rulemakings, usually conducted as part of the regulatory impact analysis associated with proposed rules. Even though the analysis is generally not able to encompass all of the effects of a policy, and it is challenging to translate impacts on health, mortality, and welfare into dollar values, benefit-cost analysis is an important economic tool to help inform decision-makers about the societal benefits of different policy choices. Of course, benefit-cost analysis cannot be the sole criterion for making regulatory decisions, especially in cases where there are overriding public health, equity, or safety imperatives. And in a few instances, legal protections prohibit the consideration of benefit-cost analysis. [EPA-HQ-OAR-2014-0827-1296-A1 p.2]

Without an SCC estimate, regulators would by default be using a value of zero for the benefits of reducing carbon pollution, implying that carbon pollution has no costs. That, sadly, is not the case, as evidenced by the large body of research outlining the sobering health, environmental, and economic impacts of rising temperatures, extreme weather, intensifying smog, and other climate impacts. If anything, most evidence points to the fact that current numbers significantly underestimate the SCC. It would be arbitrary for a federal agency to weigh the societal benefits and costs of a rule with significant carbon pollution effects but to assign no value at all to the considerable benefits of reducing carbon pollution. [EPA-HQ-OAR-2014-0827-1296-A1 p.2-3]

Response:

EPA acknowledges this comment and notes that it has used the SC-CO\textsubscript{2} estimates as well as the Marten et al. (2014) social cost of methane (SC-CH\textsubscript{4}) and social cost of N\textsubscript{2}O (SC-N\textsubscript{2}O) estimates to monetize the climate-related impacts of this rulemaking. Regarding the comment that the social cost of carbon underestimates benefits, the EPA recognizes that none of the three integrated assessment models (IAMs) fully incorporates all climate change impacts, either positive or negative; see EPA response to comment EPA-HQ-OAR-2014-0827-1296-A1.

Regarding EPA’s response to sections 2 through 6 of the letter submitted by Institute for Policy Integrity, see responses below to comment excerpts from EPA-HQ-OAR-2014-0827-1296-A1.

Organization:  Institute for Policy Integrity

Institute for Policy Integrity, Excerpt 2

2. The IWG’s analytic process was science--based, open, and transparent.
To facilitate accounting for the costs of climate impacts and the benefits of reducing carbon pollution in regulatory proceedings undertaken by different agencies, the United States government assembled an Interagency Working Group (IWG) to develop an estimate of a social cost of carbon that can be utilized in rulemakings and other pertinent settings across the federal government.4 The IWG’s estimates—first released in 2010 and updated in 2013 and 2015—have been used in numerous benefit-cost analyses related to federal rulemakings.5 The IWG recently released an updated set of SCC estimates, centered at approximately $40 per metric ton of CO\textsubscript{2} for emissions in the year 2015, in 2015 dollars at a 3% discount rate.6 The 2015 SCC estimates are higher than those from 2010, reflecting the growing understanding of the costs that climate impacts will impose on society. [EPA-HQ-OAR-2014-0827-1296-A1 p.3-4]

The increase in the SCC estimate is important because it reflects the growing scientific and economic research on the risks and costs of climate change, but is still very likely an underestimate of the economic cost of carbon emissions. The increase also reflects the costs of climate change that we are already experiencing, such as those associated with sea level rise and rising temperatures. Climate change is making coastal flooding, drought, and impacts from extreme weather worse. A rapidly increasing body of evidence has linked ever more recent events directly to climate change.7 [EPA-HQ-OAR-2014-0827-1296-A1 p.4]

The analytic work of the IWG has been transparent. The 2010 Technical Support Document (TSD) set out in detail the IWG’s decision-making process with respect to how it assessed and employed the models.8 Furthermore, the Government Accountability Office (GAO) found that “the working group’s processes and methods reflected the following three principles: Used consensus--based decision making, Relied on existing academic literature and models, and Took steps to disclose limitations and incorporate new information.”9 [EPA-HQ-OAR-2014-0827-1296-A1 p.4]

Because the 2013 IWG made no changes to the input assumptions and procedures for deriving its SCC estimates, the 2013 TSD discussed only how the three Integrated Assessment Models (IAMs) used in the analysis were updated in the academic literature over the three-year interim period by the independent researchers who have developed these models. The 2013 TSD also established that the increase in the SCC estimate from 2010 to 2013 resulted solely from updates to the three underlying IAMs.10 [EPA-HQ-OAR-2014-0827-1296-A1 p.4]

The 2015 TSD update provided detailed responses11 to public comments collected through an opportunity for public participation initiated by the Office of Management and Budget (OMB).12 Additionally, the comment period on these proposed standards are yet another opportunity for continued dialogue about areas requiring further study. Such repeated comment processes and updates demonstrate that the IWG’s SCC estimates were developed—and are being used—transparently. Given their strong grounding in the best science available, nothing should prevent the current, continued use of this well-established estimate. As economic and scientific research continues to develop, future revisions will be able to further refine existing estimates based on the latest peer-reviewed literature and the latest updates to the quality of the overall modeling exercise. [EPA-HQ-OAR-2014-0827-1296-A1 p.4-5]

Response:

The EPA acknowledges this comment and agrees that the process was science-based, open, and transparent.

3. The SCC is an important and accepted tool for regulatory policy-making based on well-established law and fundamental economics.

The legal and analytic basis for using the SCC is clear and well established. As a matter of law and economics, uncertainty in benefits estimates does not mean they should be excluded from regulatory impact analyses. No benefit or cost estimates are certain. Further, the courts have explicitly rejected the argument that uncertainty in assessing the costs of climate impacts provided a basis for ignoring them in assessing the benefits and costs of regulations, and executive orders dating back as far as the Reagan administration have all issued guidelines specifying explicit consideration of benefits even if the precise size of the benefit is uncertain. [EPA-HQ-OAR-2014-0827-1296-A1 p.5]

In 2008, the U.S. Court of Appeals for the Ninth Circuit determined that agencies could not assign a zero dollar value to the social costs of the impacts of climate change. It determined that failing to count SCC benefits would be illegal. In this case, the National Highway Traffic Safety Administration (NHTSA) had decided not to count any avoided climate damages in issuing fuel economy standards. The court concluded: “NHTSA’s reasoning is arbitrary and capricious for several reasons. First while the record shows that there is a range of values, the value of carbon emission reductions is certainly not zero (emphasis added).”[EPA-HQ-OAR-2014-0827-1296-A1 p.5]

Like the Court of Appeals, executive orders dating back to 1981 have also required agencies to assess benefits and costs even when significant uncertainty exists. Every president since (and including) Ronald Reagan has issued directives requiring that agencies conduct cost-benefit analyses of proposed regulations where permitted by statute.14 Specifically, agencies are directed to “take into account benefits and costs, both quantitative and qualitative... and use the best available techniques to quantify anticipated present and future benefits and costs as accurately as possible.”15 The IWG’s use of Integrated Assessment Models (IAMs) reflects the best available, peer-reviewed science to tally the benefits and costs of specific regulations with impacts on carbon dioxide emissions. While we address ways for improvement in the next section, current IAMs include benefits and costs that have been quantified to date. [EPA-HQ-OAR-2014-0827-1296-A1 p.5]

The bottom line is that the IWG has properly and lawfully used the best available techniques to quantify the benefits of carbon emission reductions, basing its analysis on the peer-reviewed literature. When agencies use the IWG’s estimates of the SCC to calculate the benefits of a rulemaking, they have taken, and will continue to take, comment on the SCC and the process used to derive that value. That is what the law—and good policy—requires. [EPA-HQ-OAR-2014-0827-1296-A1 p.5]

Response:

The EPA agrees with this comment.

Organization: Institute for Policy Integrity

Institute for Policy Integrity, Excerpt 4

The IWG Correctly Used a Global SCC Value.
To design the economically efficient policies necessary to forestall severe and potentially catastrophic climate change, all countries must use a global SCC value. Given that the United States and many other significant players in the international climate negotiations have already applied a global SCC framework in evaluating their own climate policies, the continued use of the global value in U.S. regulatory decisions may be strategically important as the United States seeks to set an example for other countries, harmonize regulatory systems, and take the lead in ongoing international negotiations. Binding legal obligations, basic ethical responsibilities, and practical considerations further counsel in favor of the United States using a global SCC value. [EPA-HQ-OAR-2014-0827-1296-A1 p.6]

To avoid a global “tragedy of the commons” and an economically inefficient degradation of the world’s climate resources, all countries should set policy according to a global SCC value. The climate and clean air are global common resources, meaning they are free and available to all countries, but any one country’s use—i.e., pollution—imposes harms on the polluting country as well as the rest of the world. Because greenhouse gases do not stay within geographic borders but rather mix in the atmosphere and affect climate worldwide, each ton of carbon pollution emitted by the United States not only creates domestic harms, but also imposes additional and large externalities on the rest of the world, including disproportionate harms to some of the least-developed nations. Conversely, each ton of carbon pollution abated in another country will benefit the United States along with the rest of the world. [EPA-HQ-OAR-2014-0827-1296-A1 p.6]

If all countries set their greenhouse gas emission levels based on only their domestic costs and benefits, ignoring the large global externalities, the collective result would be substantially suboptimal climate protections and significantly increased risks of severe harms to all nations, including to the United States. “[E]ach pursuing [only its] own best interest. . . in a commons brings ruin to all.” By contrast, a global SCC value would require each country to account for the full damages of its greenhouse gas pollution and so to collectively select the efficient level of worldwide emissions reductions needed to secure the planet’s common climate resources. [EPA-HQ-OAR-2014-0827-1296-A1 p.6]

Thus, well-established economic principles demonstrate that the United States stands to benefit greatly if all countries apply a global SCC value in their regulatory decisions. A rational tactical option in the effort to secure that economically efficient outcome is for the United States to continue using a global SCC value itself. The United States is engaged in a repeated strategic game of international negotiations and regulatory coordination, in which several significant players—including the United States—have already adopted a global SCC framework. For the United States to now depart from this implicit collaborative dynamic by reverting to a domestic-only SCC estimate could undermine the country’s long-term interests in future climate negotiations and could jeopardize emissions reductions underway in other countries, which are already benefiting the United States. A domestic-only SCC value could be construed as a signal that the United States does not recognize or care about the effects of its policy choices on other countries, and signal that it would be acceptable for other countries to ignore the harms they cause the United States. Further, a sudden about-face could undermine the United States’ credibility in negotiations. The United States has recently reasserted its desire to take a lead in both bilateral and international climate negotiations. To set an example for the rest of the world, to advance its own long-term climate interests, and to secure greater cooperation toward reducing global emissions, strategic factors support the continued use a global SCC value in U.S. regulatory decisions. [EPA-HQ-OAR-2014-0827-1296-A1 p.6-7]

Though the Constitution balances the delegation of foreign affairs power between the executive and legislative branches, “[t]he key to presidential leadership is the negotiation function. Everyone agrees that the President has the exclusive power of official communication with foreign governments.” The development and analysis of U.S. climate regulations are essential parts of the dialogue between the
United States and foreign countries about climate change. Using a global SCC value communicates a strong signal that the United States wishes to engage in reciprocal actions to mitigate the global threat of climate change. The President is responsible for developing and executing the negotiation strategy to achieve the United States’ long-term climate interests. Currently, the President has instructed federal agencies to use a global SCC value as one important step that encourages other countries to take reciprocal actions that also account for global externalities. The President’s constitutional powers to negotiate international agreements would be seriously impaired if federal agencies were forced to stop relying on a global SCC value. [EPA-HQ-OAR-2014-0827-1296-A1 p.7]

In fact, the United States has already begun to harmonize with other countries its policies on climate change and on the valuation of regulatory benefits. The recent U.S.-China agreement is but the latest example. For instance, the United States has entered into a joint Regulatory Cooperation Council with Canada, which has adopted a work plan that commits the two countries to synchronizing “aggressive” greenhouse gas reductions, especially in the transportation sector. A separate Regulatory Cooperation Council with Mexico calls generally for improving and harmonizing policy “by strengthening the analytic basis of regulations,” and its work plan acknowledges the transboundary nature of environmental risks. Mexico and Canada have both adopted greenhouse gas standards for vehicles that harmonize with the U.S. standards and that calculate benefits according to a global SCC value. Canada has also used the IWG’s global SCC value in developing carbon dioxide standards for its coal-fired power plants, estimating $5.6 billion (Canadian dollars) worth of global climate benefits. The direct U.S. share of the net benefits from that Canadian regulation will likely total in the hundreds of millions of dollars. [EPA-HQ-OAR-2014-0827-1296-A1 p.7-8]

Further efforts at regulatory harmonization are currently underway. For example, the United States is now negotiating a Transatlantic Trade and Investment Partnership with the European Union, and a key element is regulatory coordination. The European Union has already adopted an Emissions Trading Scheme (ETS) to cap its greenhouse gas emissions, and its Aviation Directive is just one of the climate policies that could be shaped by these negotiations. The European Commission has indicated its willingness to further reduce its ETS cap if other major emitters make proportional commitments—a result that will only occur if countries consider more than their own domestic costs and benefits from reducing greenhouse gas emissions. Moreover, several individual European nations—including the United Kingdom, France, Germany, and Norway—have adopted a global SCC value for use in their regulatory analyses. Some other European countries, such as Sweden, have adopted carbon taxes that implicitly operate as a high SCC that accounts for global externalities. [EPA-HQ-OAR-2014-0827-1296-A1 p.8-9]

As further evidence of how the United States’ use of a global SCC value is already influencing other international actors to follow suit, the International Monetary Fund (IMF) applies in its policy reviews an SCC estimate based on the IWG number. Given the potential influence of the IMF on the environmental policies of developing countries, the pull that the IWG’s global estimate has at the IMF could be very advantageous to the United States, by motivating industrializing countries to use similar numbers in the future. [EPA-HQ-OAR-2014-0827-1296-A1 p.9]

In addition to this compelling strategic argument—namely, that it is rational for the United States and other countries to continue their reciprocal use of a global SCC value to achieve the economically efficient outcome on climate change (and avoid catastrophic climate impacts)—legal obligations further prescribe using a global SCC value. A basic ethical responsibility to prevent transboundary environmental harms has been enshrined in customary international law. For the United States to knowingly set pollution levels in light of only domestic harms, willfully ignoring that its pollution directly imposes environmental risks—including catastrophic risks—on other countries, would violate
norms of comity among countries. The United States would be knowingly causing foreseeable harm to other countries, without compensation or just cause. Given that the nations most at risk from climate change are often the poorest countries in the world, such a policy would also violate basic and widely shared ethical beliefs about fairness and distributive justice. Indeed, taking a global approach to measuring climate benefits is consistent with the ideals of transboundary responsibility and justice that the United States commits to in other foreign affairs.⁴⁰ [EPA-HQ-OAR-2014-0827-1296-A1 p.9]

Binding international agreements also require consideration and mitigation of transboundary environmental harms. Notably, the United Nations Framework Convention on Climate Change—to which the United States is a party—declares that countries’ “policies and measures to deal with climate change should be cost-effective so as to ensure global benefits at the lowest possible cost.”⁴¹ The Convention further commits parties to evaluating global climate effects in their policy decisions, by “employ[ing] appropriate methods, for example impact assessments... with a view to minimizing adverse effects on the economy, on public health and on the quality of the environment, of projects or measures undertaken by them to mitigate or adapt to climate change.”⁴² The unmistakable implication of the Convention is that parties—including the United States—must account for global economic, public health, and environmental effects in their impact assessments. [EPA-HQ-OAR-2014-0827-1296-A1 p.9-10]

Similar obligations exist in domestic U.S. law as well. For example, the U.S. National Environmental Policy Act recognizes “the worldwide and long-range character of environmental problems”⁴³ and requires federal agencies to include reasonably foreseeable transboundary effects in their environmental impact statements.⁴⁴ While some individual statutes under which federal agencies will craft climate policies may be silent on the issue of considering extraterritorial benefits, arguably the most important statute for U.S. climate policy—the Clean Air Act—requires the control of air emissions that affect other countries and so encourages a global assessment of greenhouse gas effects. Specifically, Section 115 of the Clean Air Act directs EPA and the states to mitigate U.S. emissions that endanger foreign health and welfare.⁴⁵ The global perspective on climate costs and benefits required by that provision should inform all regulatory actions developed under the Clean Air Act, and may provide useful guidance under other statutes as well.⁴⁶ [EPA-HQ-OAR-2014-0827-1296-A1 p.10]

Presidential orders on regulatory analysis also support use of a global SCC value. In 2012, President Obama issued Executive Order 13,609 on promoting international regulatory cooperation.⁴⁷ The Order built on his previous Executive Order 13,563, which in turn had affirmed its 1993 predecessor, Executive Order 12,866, in requiring benefit-cost analysis of significant federal regulations.⁴⁸ Though White House guidance published in 2003 on regulatory impact analysis under E.O. 12,866 assumed that most analyses would focus on domestic costs and benefits, it ultimately deferred to the discretion of regulatory agencies on whether to evaluate “effects beyond the borders of the United States.”⁴⁹ More importantly, since the publication of that guidance, President Obama has issued his own supplemental orders on regulatory analysis, including E.O. 13,609, which clarified the importance of international cooperation to achieve U.S. regulatory goals. This 2012 order explicitly recognizes that significant regulations can have “significant international impacts,”⁵⁰ and it calls on federal agencies to work toward “best practices for international regulatory cooperation with respect to regulatory development.”⁵¹ By employing a global SCC value in U.S. regulatory development, and by encouraging other countries to follow that best practice and account for the significant international impacts of their own climate policies, federal agencies will advance the mission of this presidential order on regulatory harmonization. [EPA-HQ-OAR-2014-0827-1296-A1 p.10-11]

Finally, two practical considerations counsel in favor of a global SCC value. First, unlike some other significant international environmental impacts, no methodological limitations block the quantitative
estimation of a global SCC value. In recent regulatory impact analyses for major environmental rules, EPA has qualitatively considered important transnational impacts that could not be quantified. For example, in the Mercury and Air Toxics Standards, EPA concluded that a reduction of mercury emissions from U.S. power plants would generate health benefits for foreign consumers of fish, both from U.S. exports and from fish sourced in foreign countries. EPA did not quantify these foreign health benefits, however, due to complexities in the scientific modeling. Similarly, in the analysis of the Cross-State Air Pollution Rule, EPA noted—though could not quantify—the “substantial health and environmental benefits that are likely to occur for Canadians” as U.S. states reduce their emissions of particulate matter and ozone—pollutants that can drift long distances across geographic borders. Yet where foreign costs or benefits are important and quantifiable, other federal agencies frequently include those calculations. Given that sophisticated models already exist to quantify the global SCC, the global estimate is appropriate to use.

Second, a global SCC value is in the national interest because harms experienced by other countries could significantly impact the United States. Climate damages in one country could generate large spillover effects to which the United States is especially vulnerable. The mesh of the global economy is woven tightly, and disruptions in one place can have consequences around the world. As seen historically, economic disruptions in one country can cause financial crises that reverberate globally at a breakneck pace. In a similar vein, national security analysts in government and academia increasingly emphasize that the geopolitical instability associated with climatic disruptions abroad poses a serious threat to the United States. Due to its unique place among countries—both as the largest global economy with trade- and investment-dependent links throughout the world, and as a military superpower—the United States is particularly vulnerable to international spillover effects.

The 2010 TSD included a rigorous examination of global versus domestic SCC estimates. Consistent with the above discussion, the 2010 IWG reached the conclusion to estimate a global SCC value, citing both the global impacts of climate change and the global action needed to mitigate climate change. The IWG restated these arguments in the 2013 TSD, and refers back explicitly to its discussion in the 2010 TSD. EPA and NHTSA should continue using a global SCC estimate in their regulatory impact analyses.

Response:

EPA agrees that a focus on global SC-GHG estimates in RIAs is appropriate and has applied global SC-CO₂, SC-CH₄, and SC-N₂O estimates to the analysis of the benefits in the final rulemaking. In particular, EPA agrees with the commenter’s discussion of the global nature of GHG emissions—that each ton of GHGs emitted by the United States creates damages within the country and abroad—and with the commenter’s conclusion that “each ton of carbon pollution abated in another country will benefit the United States along with the rest of the world.” As noted by the commenter, the global economy is tightly interconnected and the United States is especially vulnerable to international spillover effects. The impacts of climate change that occur beyond the borders of the United States will affect the interests of U.S. citizens and U.S. national security interests. EPA agrees with the commenter’s interpretation, as described in this excerpt, of recent reports on geopolitical instability associated with climatic disruptions abroad and the threat such disruptions may pose to the United States. For example, the National Research Council Climate and Social Stress assessment concluded that it is prudent to expect that some climate events “will produce consequences that exceed the capacity of the affected societies or global systems to manage and that have global security implications serious
As discussed in Section I.A of the Preamble, the NRC National Security Implications assessment recommends that, due to climate change, the United States should be preparing for increased needs for humanitarian aid; responding to the effects of climate change in geopolitical hotspots, including possible mass migrations; and addressing changing security needs in the Arctic as sea ice retreats. Section I.A of the Preamble discusses other scientific assessments about the impacts of climate change and presents additional examples of climate change impacts within the United States.

Institute for Policy Integrity, Excerpt 5

4. Recommendations on further refinements to the SCC.59

The IWG process uses assumptions that accord with economic and scientific theory. Economic models, and the scientific analyses they draw from, are of course improving continuously. Future updates to the SCC should build on these and go further. As further refinements better account for climate change impacts not yet incorporated into the modeling, all indications are that the estimated benefits of curbing carbon pollution will rise substantially over current estimates. [EPA-HQ-OAR-2014-0827-1296-A1 p.12]

The IWG appropriately used consumption discount rates rather than returns on capital.

With respect to the discount rate, the IWG conducted sensitivity analysis of the results to three constant consumption discount rates: 2.5%, 3%, and 5%; for each of the discount rates, the TSDs reported the various moments and percentiles60 of the SCC estimates. [EPA-HQ-OAR-2014-0827-1296-A1 p.12]

The discount rate is one of the most important inputs in models of climate damages, with plausible assumptions easily leading to differences of an order of magnitude in the SCC. The climate impacts of present emissions will unfold over hundreds of years. When used over very long periods of time, discounting penalizes future generations heavily due to compounding effects. For example, at a rate of 1%, $1 million 300 years hence equals over $50,000 today; at 5% it equals less than 50 cents.61 [EPA-HQ-OAR-2014-0827-1296-A1 p.12]

The discount rate changed by a factor of five, whereas the discounted value changed by more than five orders of magnitude. Depending on the link between climate risk and economic growth risk, even a rate of 1% may be too high.62 Uncertainty around the correct discount rate pushes the rate lower still.63 [EPA-HQ-OAR-2014-0827-1296-A1 p.13]

The IWG correctly excluded a 7% discount rate, a typical private sector rate of return on capital, for several reasons. First, typical financial decisions, such as how much to save in a bank account or invest in stocks, focus on private decisions and utilize private rates of return. Private market participants typically have short time horizons. However, here we are concerned with social discount rates because

---

emissions mitigation is a public good, where individual emissions choices affect public well-being broadly. Rather than evaluating an optimal outcome from the narrow perspective of investors alone, economic theory would require that we make the optimal choices based on societal preferences (and social discount rates). Second, climate change is expected to affect primarily consumption, not traditional capital investments. OMB guidelines note that in this circumstance, consumption discount rates are appropriate. Third, 7% is considered much too high for reasons of discount rate uncertainty and intergenerational concerns (further discussed below). [EPA-HQ-OAR-2014-0827-1296-A1 p.13]

The IWG correctly adopted as one of its discount rates a value reflecting long-term interest rate uncertainty, and—as a primary extension to current results—should go further by directly implementing a declining discount rate. [EPA-HQ-OAR-2014-0827-1296-A1 p.13]

The IWG was correct in choosing as one of its discount rates an estimate based upon declining discount rates (2.5%). Since the IWG undertook its initial analysis, a consensus has emerged among leading climate economists that a declining discount rate should be used for climate damages to reflect long-term uncertainty in interest rates. Arrow et.al. (2013) presents several arguments that strongly support the use of declining discount rates for long-term benefit-cost analysis. [EPA-HQ-OAR-2014-0827-1296-A1 p.13]

Perhaps the best reason is the simple fact that there is considerable uncertainty around which interest rate to use: uncertainty in the rate points directly to the need to use a declining rate, as the impact of the uncertainty grows exponentially over time. The uncertainty about future discount rates could stem from a number of reasons particularly salient to climate damages, including uncertainties in future economic growth, consumption, and the interest rate reaped by investments. [EPA-HQ-OAR-2014-0827-1296-A1 p.14]

A possible declining interest rate schedule for consideration by the IWG is the one proposed by Weitzman (2001). It is derived from a broad survey of top economists and the profession at large in a climate change context and explicitly incorporates arguments around interest rate uncertainty. Arrow et.al. (2013, 2014), Cropper et.al. (2014), and Gollier and Weitzman (2010), among others, similarly argue for a declining interest rate schedule and lay out the fundamental logic. [EPA-HQ-OAR-2014-0827-1296-A1 p.14]

Moreover, the United States would not be alone in using a declining discount rate. It is standard practice for the United Kingdom and French governments, among others. The U.K. schedule explicitly subtracts out an estimated time preference. France’s schedule is roughly similar to the United Kingdom’s. Importantly, all of these discount rate schedules yield lower present values than the constant 2.5% Newell-Pizer rate, suggesting that even the lowest discount rate evaluated by the IWG is too high. The consensus of leading economists is that a declining discount rate schedule should be used, consistent with the approach of other countries like the United Kingdom. Adopting such a schedule would increase the SCC substantially from the administration’s central estimate, suggesting that even the high end of the range presented by the administration is likely too low. [EPA-HQ-OAR-2014-0827-1296-A1 p.14]

Response:

The EPA acknowledges this comment and notes that the discount rates have not changed in the final analysis.
Regarding the commenters’ recommendation that the interagency working group (IWG) use a declining discount rate for the social cost of carbon (SC-CO\textsubscript{2}): EPA agrees that this is an important area of emerging research and will share these recommendations with the IWG. However, no widely-accepted declining discount rate schedule has yet been developed. Some key technical issues warrant careful consideration before adopting a declining discount rate schedule, such as determining how to update the discount rate schedule as uncertainty is resolved over time and ensuring that the use of declining discount rates does not lead to the possibility of time-inconsistent choices. A workshop sponsored by the federal government resulted in a paper in Science authored by thirteen prominent economists who concluded that a declining discount rate would be appropriate to analyze impacts that occur far into the future (Arrow et al., 2014). However, additional research and analysis is still needed to develop a methodology for implementing a declining discount rate and to understand the implications of applying these theoretical lessons in practice. The EPA will continue to follow and evaluate the latest science on the use of declining discount rates in intergenerational discounting.

In addition, EPA and other members of the U.S. Interagency Working Group on the social cost of carbon are seeking independent expert advice on technical opportunities to update the SC-CO\textsubscript{2} estimates from the National Academies of Sciences, Engineering, and Medicine. A committee convened by the Academies is reviewing the state of the science on estimating the SC-CO\textsubscript{2}, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. The Academies’ review will focus on the SC-CO\textsubscript{2} methodology, but recommendations on how to update many of the underlying modeling assumptions will also likely pertain to the SC-CH\textsubscript{4} and SC-N\textsubscript{2}O estimates. Going forward, the EPA will evaluate its approach to estimating the SC-GHGs based upon any feedback received from the Academies’ panel.

**Organization:** Institute for Policy Integrity

**Institute for Policy Integrity, Excerpt 6**

*The IWG’s choice of three IAMs was fully justified but should still be revisited in its next iteration.*

In its calculations of the SCC, the IWG relied on the three Integrated Assessment Models (IAMs) available at the time, all with a long record of peer-reviewed publications that link physical and economic effects: the Dynamic Integrated Model of Climate and the Economy (DICE),\textsuperscript{72} the Climate Framework for Uncertainty, Negotiation, and Distribution (FUND),\textsuperscript{73} and Policy Analysis of the Greenhouse Effect (PAGE).\textsuperscript{74} The government’s first SCC estimates, published in 2010, used the then-current versions of the models; the recent update employed revised, peer-reviewed versions of the models but maintained the underlying assumptions of the 2010 IWG analysis. As stated by the 2010 IWG, “the main objective of [the 2010 IWG modeling] process was to develop a range of SCC values using a defensible set of input assumptions grounded in the existing scientific and economic literatures.”\textsuperscript{75} [EPA-HQ-OAR-2014-0827-1296-A1 p.14-15]

DICE, FUND, and PAGE are well-established, peer-reviewed models. They represent the state-of-the-art IAMs. Each of these models has been developed over decades of research, and has been subject to rigorous peer review, documented in the published literature. However, updates to the SCC should also consider other models that are similarly peer reviewed and based on the state of the art of climate-economic modeling. One such model is Climate and Regional Economics of Development (CRED); another is the World Bank’s Environmental Impact and Sustainability Applied General Equilibrium (ENVISAGE) model. [EPA-HQ-OAR-2014-0827-1296-A1 p.15]
CRED borrows its fundamental structure from William Nordhaus’s DICE and RICE models but also offers significant changes. For one, it uses updated damage functions and Marginal Abatement Cost Curves (MACC). Moreover, it uses different global equity weights, and uses additional state-of-the-art methodologies.\(^76\) [EPA-HQ-OAR-2014-0827-1296-A1 p.15]

ENVISAGE represents a broader modeling effort by the World Bank, where perhaps the largest contribution is a more detailed sectoral breakdown, using 57 different sectors.\(^77\) This level of analysis allows for a more detailed view of agriculture as well as food and energy sectors that are particularly important to any climate-economy modeling. [EPA-HQ-OAR-2014-0827-1296-A1 p.15]

Moreover, the broader policy and research community at large ought to consider creating the right incentive structure within the economic and scientific community to engage many more researchers on working with the core IAMs. Doing so could speed up the process of capturing the latest research on climate damages. [EPA-HQ-OAR-2014-0827-1296-A1 p.15]

No model fully captures the costs of climate impacts to society. In fact, virtually all uncertainties and current omissions point to a higher SCC value. That makes it essential to use the established IWG process, which provides for updating the SCC estimates every two to three years in order to capture the advances in physical and social sciences that have been incorporated into the models during the intervening period, in order to revisit both the choice of models and the key inputs used.\(^78\) [EPA-HQ-OAR-2014-0827-1296-A1 p.15]

Response:

The EPA acknowledges the commenters’ recommendations for potential opportunities to improve the social cost of carbon (SC-CO\(_2\)) estimates and has considered each one in the context of this rulemaking, which uses the Marten et al. SC-CH\(_4\) estimates. EPA recognizes the importance of the estimates to be as complete as possible and continues to engage in research on modeling and valuation of climate impacts. In addition, EPA and other members of the U.S. Interagency Working Group on the SC-CO\(_2\) are seeking independent expert advice on technical opportunities to update the SC-CO\(_2\) estimates from the National Academies of Sciences, Engineering, and Medicine. A committee convened by the Academies is reviewing the state of the science on estimating the SC-CO\(_2\), and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. The Academies’ review will focus on the SC-CO\(_2\) methodology, but recommendations on how to update many of the underlying modeling assumptions will also likely pertain to the SC-CH\(_4\) estimates. Going forward, the EPA will evaluate its approach to estimating the SC-CO\(_2\) and SC-CH\(_4\) based upon any feedback received from the Academies’ panel.

After careful evaluation of the full range of comments and associated technical issues described in this RTC, EPA has determined that it will continue to use the Marten et al. SC-CH\(_4\) estimates in the final rulemaking analysis. In particular, the Marten et al. SC-CH\(_4\) estimates represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental emissions changes into regulatory analysis. Therefore, EPA has presented the Marten et al. SC-CH\(_4\) estimates in this rulemaking. EPA will continue to consider these comments and will share the recommendations with the IWG as it moves forward with the Academies process.

In addition, regarding model selection: EPA agrees that the selection of the three IAMs—DICE, FUND, and PAGE—was the most appropriate for the purpose of estimating the SC-CO\(_2\). EPA and all of the other IWG members made this determination when they began developing the SC-CO\(_2\) estimates in 2009-2010. DICE, FUND, and PAGE are the most widely used and widely cited models in the...
economic literature that link physical impacts to economic damages for the purposes of estimating the SC-CO\textsubscript{2}. Moving forward, EPA will continue to follow and evaluate the latest peer reviewed literature applying IAMs. As previously noted, EPA and all of the other IWG members are seeking external expert advice on the technical merits and challenges of using additional models (e.g., CREDD, ENVISAGE) to estimate the SC-CO\textsubscript{2} and/or removing existing models from the ensemble (DICE, FUND, and PAGE) used to estimate the SC-CO\textsubscript{2}.

Finally, EPA agrees that it is important to update the SC-CO\textsubscript{2} periodically to incorporate improvements in the understanding of greenhouse gas emissions impacts. EPA will also share with the IWG the commenters’ recommendation that the “broader policy and research community at large…consider creating the right incentive structure within the economic and scientific community to engage many more researchers on working with the core IAMs.”

Organization: Institute for Policy Integrity

Institute for Policy Integrity, Excerpt 7

The IWG should update its socio-economic assumptions to reflect the latest Shared Socioeconomic Pathways (SSPs).

One key input is the use of socio-economic scenarios reflected in the choice of economic growth rates and emissions trajectories. Current IWG socio-economic and emissions scenarios were chosen from the Stanford Energy Modeling Forum exercise, EMF-22, and consist of projections for income/consumption, population, and emissions (CO\textsubscript{2} and non-CO\textsubscript{2}). The IWG selected five sets of trajectories, four of which represent business as usual (BAU) trajectories (MiniCAM, MESSAGE, IMAGE, and MERGE models) and a fifth that represents a CO\textsubscript{2} emissions pathway with CO\textsubscript{2} concentrations stabilizing at 550 ppm. Given the possibility of increases in emissions above those expressed by Business As Usual Scenarios, a high-CO\textsubscript{2} emissions pathway should also be considered. The assumptions used in calculating the SCC should be updated regularly to reflect the latest thinking around possible scenarios, reflecting the latest Shared Socio-economic Pathways (SSPs). These SSPs represent the latest, consistent pathways, feeding, for example, into the latest IPCC report. [EPA-HQ-OAR-2014-0827-1296-A1 p.16]

The current inclusion of CO\textsubscript{2} fertilization benefits likely overstates its effects.

The models do not reflect recent research on agricultural changes, which suggest the CO\textsubscript{2} fertilization is overestimated, particularly in the FUND model, and that much, if not all, of the fertilization benefits may be cancelled out by negative impacts on agriculture (e.g., extreme heat, pests, and weeds). If the agency is not able to adequately model all agricultural impacts it should, at a minimum, remove CO\textsubscript{2} fertilization benefits. [EPA-HQ-OAR-2014-0827-1296-A1 p.16]

The specific functional form assumptions in IAMs ought to be re-evaluated.

Climate damages in IAMs are assumed to affect levels of economic output rather than economic growth rates. Similarly, standard modeling assumptions assume multiplicative damage functions—i.e. substitutability across economic sectors—rather than additive functions—i.e. limited substitutability across sectors. IAMs ought to probe the impacts of both assumptions. Recent literature supports the conclusion that climate change will effect economic growth rates. [EPA-HQ-OAR-2014-0827-1296-A1 p.16]
Similarly, models ought to better capture the impacts of wildly heterogeneous climate damages. Each of the models used to calculate the SCC assume one representative household, going as far as to consider damages by relatively large regions. Such averaging ignores the enormously diverse effects of damages. It similarly contributes to not fully capturing the effects of extreme outcomes and tail risks. Instead, models ought to attempt to capture a much broader array of damages and climate impacts.\[EPA-HQ-OAR-2014-0827-1296-A1 p.16-17\]

The IWG used solid economic tools to address uncertainty and ought to go further in capturing the full extent of its implications. [EPA-HQ-OAR-2014-0827-1296-A1 p.17]

The IWG was rigorous in addressing uncertainty. First, it conducted Monte Carlo simulations over the IAMs specifying different possible outcomes for climate sensitivity (represented by a Roe and Baker Distribution).\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\] It also used five different emissions growth scenarios and three discount rates. Second, the IWG reported the various moments and percentiles\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\] of the resulting SCC estimates. Third, the IWG put in place an updating process, e.g., the 2013 revision, which updates the models as new information becomes available.\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\] As such, the IWG used the various tools that economists have developed over time to address the uncertainty inherent in estimating the economic cost of pollution: reporting various measures of uncertainty, using Monte Carlo simulations, and updating estimates as evolving research advances our knowledge of climate change. [EPA-HQ-OAR-2014-0827-1296-A1 p.17]

The Monte Carlo framework took a step toward addressing what is the most concerning aspect of climate change, the potential for catastrophic damages, i.e., low probability/high damage events. These damages come from: uncertainty in the underlying parameters in IAMs,\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\] including the climate sensitivity parameter; climate tipping points—thresholds that, when crossed, cause rapid, often irreversible changes in ecosystem characteristics; and “black swan” events—which refer to unknown unknowns.\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\]

The analysis used a right-skewed distribution of temperature (as captured in the Roe Baker climate sensitivity parameter) and an increasing, strictly convex damage function;\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\] this correctly results in right-skewed distributions of damage and SCC estimates. By using the mean values of these estimates instead of the median, IWG estimates partially captured the effects of small probability, higher damages from high-level warming events.\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\] To reflect uncertainty in estimates resulting from the right-skewed distribution of SCC estimates, the IWG reported the SCC value for the 95th percentile from the central 3% discount rate distribution.\[EPA-HQ-OAR-2014-0827-1296-A1 p.17\] This is done to reflect the estimation uncertainty in terms of the possibility of higher-than-expected economic impacts from climate change. [EPA-HQ-OAR-2014-0827-1296-A1 p.17-18]

While the IAMs take different approaches to explicitly modeling tipping points, which to a great extent is lacking in current versions of FUND and DICE, the IWG improved (but in no way fixed) the representation of uncertain catastrophic damages with the Monte Carlo analysis. Still, black swan events go completely unaddressed in the IWG modeling framework, and therefore the SCC estimates do not reflect the value of preventing the occurrence of catastrophic events.\[EPA-HQ-OAR-2014-0827-1296-A1 p.18\]

In addition to choosing an appropriate discount rate and sensitivity analyses around different SSPs, another important parameter to which the SCC estimates are sensitive is Equilibrium Climate Sensitivity (ECS)—how the climate system responds to a constant radiative forcing, which is typically expressed as the temperature response to a doubling of CO\(_2\) concentration in the atmosphere.\[EPA-HQ-OAR-2014-0827-1296-A1 p.18\] In its current iteration, the IWG conducted extensive sensitivity analyses over a range of equilibrium climate sensitivity estimates.\[EPA-HQ-OAR-2014-0827-1296-A1 p.18\] The assumptions are clearly stated in the TSD. In addition to its sensitivity analysis, the
IWG conducted a Monte Carlo simulation over the climate sensitivity parameter and the other random variables specified within the three IAMs.95 [EPA-HQ-OAR-2014-0827-1296-A1 p.18]

The range for the Equilibrium Climate Sensitivity (ECS) is derived from a combination of methods that constrain the values from measurements in addition to models. These include measured ranges from paleoclimate records, observed comparisons with current climate, as well as responses to recent climate forcings. The currently agreed “likely” range for the ECS (from both the IPCC TAR and AR5) is 1.5-4.5 degrees Celsius. Physical constraints make it “extremely unlikely” that the ECS is less than 1 degree Celsius and “very unlikely” greater than 6 degrees Celsius.96 [EPA-HQ-OAR-2014-0827-1296-A1 p.18]

A host of analyses points to the costs of such uncertainty—both for values that go outside the “likely” range and for uncertainty within it: in short, the optimal SCC tends to increase with increased uncertainty, sometimes dramatically so.97 While the current treatment of uncertainty around climate sensitivity by the IWG highlights a range of possible uncertainties, a reconsideration of the assumptions feeding into the SCC ought to take the latest advances highlighting the potentially higher costs of deep-seated uncertainty into account. Additionally, the IWG should consider whether it relies too heavily on its 95th percentile estimates as a catchall to cover for limitations in its treatment of uncertainty and catastrophic damages. [EPA-HQ-OAR-2014-0827-1296-A1 p.19]

Response:

The EPA acknowledges the commenters’ recommendations for potential opportunities for the IWG to update the scenarios for the SC- CO2 and has considered it in the context of this rulemaking, which uses the Marten et al. SC-CH4 estimates. EPA has acknowledged that the projection of the scenarios beyond 2100 has greater uncertainty than shorter-term projections and will continue to monitor the literature, including the development of extended RCP/SSP scenarios, for ways to improve the estimated trajectories and improve internal consistency. EPA and other members of the IWG on the SC-CO2 are seeking independent expert advice on technical opportunities to update the SC-CO2 estimates from the National Academies of Sciences, Engineering, and Medicine. A committee convened by the Academies is reviewing the state of the science on estimating the SC-CO2, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. The Academies’ review will focus on the SC-CO2 methodology, but recommendations on how to update many of the underlying modeling assumptions will also likely pertain to the SC-CH4 estimates. Going forward, the EPA will evaluate its approach to estimating the SC-CO2 and SC-CH4 based upon any feedback received from the Academies’ panel.

Regarding the remaining comments (i.e., treatment of CO2 fertilization benefits, the recommendation to re-evaluate the functional form assumptions in the IAMs, treatment of uncertainty): As noted in the OMB Response to Comments on SC-CO2, to date, the interagency working group (IWG) has accepted the models as currently constituted, and omitted any damages or beneficial effects that the model developers themselves do not include.214 The IWG recognizes that none of the three IAMs fully incorporates all climate change impacts, either positive or negative. Some of the effects referenced by commenters (e.g., "catastrophic" effects, disease, and CO2 fertilization) are explicitly modeled in the damage functions of one or more of the current models (although the treatment may not be complete), and the model developers continue to update their models as new research becomes available. In fact, the IWG undertook the 2013 SC-CO2 revision because of updates to the models, which include new or

enhanced representation of certain impacts, such as sea level rise damages. In addition, some of the categories mentioned by commenters are currently speculative or cannot be incorporated into the damage function for lack of appropriate data. Using an ensemble of three different models was intended to, at least partially, address the fact that no single model includes all of the impacts. EPA recognizes that there may be effects that none of the three selected models addresses (e.g., impacts from ocean acidification) or that are likely not fully captured (e.g. catastrophic effects).

EPA also recognizes that the impacts of climate change on agriculture is an area of active research and that methodological and data challenges persist. As a result there is uncertainty as to the magnitude of these impacts and the role of interactions between changes in the climate and other factors, such as CO$_2$ fertilization, temperature, precipitation, ozone, pests, etc. Additionally, these effects are likely to vary widely across regions and crops. However, with high confidence the IPCC (2013) stated in its Fifth Assessment Report (AR5) that "[b]ased on many studies covering a wide range of regions and crops, negative impacts of climate change on crop yields have been more common than positive impacts." As noted above, the IWG’s approach to date has been to rely on the damage functions included in the three IAMs by their developers.

EPA recognizes that it is important to update the SC-CO$_2$ periodically to incorporate improvements in the understanding of greenhouse gas emissions impacts and will continue to follow and evaluate the latest science on impact categories that are omitted or not fully addressed in the IAMs. EPA and other members of the U.S. Interagency Working Group on the social cost of carbon are seeking independent expert advice on technical opportunities to update the SC-CO$_2$ estimates from the National Academies of Sciences, Engineering, and Medicine. A committee convened by the Academies is reviewing the state of the science on estimating the SC-CO$_2$, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. The Academies’ review will focus on the SC-CO$_2$ methodology, but recommendations on how to update many of the underlying modeling assumptions will also likely pertain to the SC-CH$_4$ estimates. Going forward, the EPA will evaluate its approach to estimating the SC-CO$_2$ and SC-CH$_4$ based upon any feedback received from the Academies’ panel.

In addition, EPA notes that in two of the IAMs (DICE and FUND), climate damages do affect the realized rate of economic growth in the models. However, EPA recognizes that the magnitude and pathway by which climate change may affect economic growth rates is an active area research.

After careful evaluation of the full range of comments and associated technical issues described in this Response to Comments, EPA has determined that it will continue to use the Marten et al. SC-CH$_4$ estimates in the final rulemaking analysis. In particular, the Marten et al. SC-CH$_4$ estimates represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental emissions changes into regulatory analysis. Therefore, EPA has presented the Marten et al. SC-CH$_4$ estimates in this rulemaking. EPA will continue to consider these comments, including the commenters’ question about use of the 95th percentile estimate, and will share the recommendations with the IWG as it moves forward with the Academies process.

**Institute for Policy Integrity, Excerpt 8**

5. Support for the Social Cost of Methane methodology, and recommendations on continued improvements.
The agencies expect the heavy-duty truck standards to decrease methane emissions because of reduced refueling, the use of less methane-intensive auxiliary power units in lieu of diesel engines during idling, and upstream emission reductions as overall fuel demand falls. EPA also proposes a methane cap for engines and standards for natural gas vehicles. (EPA considers, if natural gas vehicles displace diesel vehicles, whether the resulting greenhouse gas impacts would be positive or negative, but make no conclusion other than the impact would be minor; however, clearly this could have a substantial impact on the net methane emissions of the rule.) The agencies estimate that the standards could reduce up to 232,000 metric tons of methane per year (which is up to 5.8 million metric tons of carbon dioxide-equivalent per year, according to the agencies’ low global warming potential estimate of 25, or approximately between 8.4 million and 20.4 million metric tons using the latest IPCC values for methane’s relative global warming potential).

EPA and NHTSA do not, however, include a monetary estimate of these methane reductions in their net benefits calculations. Instead, EPA conducts a sensitivity analysis that examines two different methodologies: (1) converting methane reductions to carbon dioxide-equivalent units using relative global warming potentials, or (2) directly estimating the Social Cost of Methane using a methodology based on the same techniques the Interagency Working Group developed to estimate the SCC. EPA indicates that it plans use the Social Cost of Methane approach in the rule’s final regulatory impact analysis, pending favorable review of a recent analysis conducted by Marten et al. That review has now, in fact, been completed, and EPA is already using the Social Cost of Methane approach in other proposed rulemakings. In the final heavy-duty truck rule, EPA and NHTSA should both use the Social Cost of Methane metric—to more accurately reflect the true benefits of the standards and to enhance the rigor and defensibility of the final rule.

The Interagency Working Group on the Social Cost of Carbon has, to date, focused exclusively on carbon dioxide. The SCC can be roughly adjusted to approximate the costs of other greenhouse gases by multiplying by the relative global warming potential of those gases. Scientists, however, have long argued that the full social costs of specific, non-carbon dioxide gases like methane should be assessed through separate models and methodologies, which would more accurately account for varying atmospheric life spans, among other differences. At least a dozen published studies, dating back to 1993, have estimated the social cost of non-carbon dioxide greenhouse gases, including methane.

EPA proposes to use Social Cost of Methane estimates based on one of the most recent peer-reviewed articles: Marten et al. Marten et al. takes a reasonable (although conservative) approach to estimating the Social Cost of Methane and currently constitutes “the best available science” to inform agency regulation. Specifically, Marten et al. builds on the methodology used by the Interagency Working Group to develop the SCC. The study maintains the same three integrated assessment models, five socioeconomic-emissions scenarios, equilibrium climate sensitivity distribution, three constant discount rates, and aggregation approach that were agreed upon by the Interagency Working Group. Consequently, many of the key assumptions underlying the Social Cost of Methane estimates have already gone through a transparent, consensus-driven, publically reviewed, regularly updated process, since they were borrowed from the Interagency Working Group’s thoroughly vetted methodology.

Yet while sharing that carefully built framework with the SCC estimates, Marten et al.’s Social Cost of Methane estimates directly account for the quicker time horizon of methane’s effects compared to carbon dioxide, include the indirect effects of methane on radiative forcing, and reflect the complex, nonlinear linkages along the pathway from methane emissions to monetized damages. Marten et al. was not only published in a peer reviewed economics journal, but EPA undertook additional internal and
peer review of the approach\textsuperscript{109} Marten et al.’s estimates thus are reasonable and appropriate measurements of the Social Cost of Methane. [EPA-HQ-OAR-2014-0827-1296-A1 p.20]

In fact, Marten et al.’s estimates are conservative and very likely underestimate the true Social Cost of Methane. To start, as the authors note, because their methodology followed the Interagency Working Group’s approach, all limitations that apply to inputs and modelling assumptions for the SCC also apply to the Social Cost of Methane. As discussed above, omitted damages, socio-economic assumptions, the treatment of uncertainty and catastrophic damages, and so forth all suggest the Social Cost of Methane is underestimated, just as the SCC is. [EPA-HQ-OAR-2014-0827-1296-A1 p.20]

Additionally, the integrated assessment models shared by both the Social Cost of Methane and the SCC include some features better suited to assessing carbon dioxide effects than methane effects, and so likely underestimate the costs of methane. For example, a countervailing benefit of carbon dioxide emissions—enhanced fertilization in the agricultural sector—is included in the underlying models used to develop both the SCC and Social Cost of Methane, yet does not apply to methane emissions\textsuperscript{110} Similarly, the damage functions used by the integrated assessment models assume some level of adaptation to climate change over time, but because methane is a much faster-acting climate pollutant than carbon dioxide, there is less opportunity for technological advancement or political progress to adapt to the climate damages imposed by methane emissions. Methane also has indirect but significant effects, via its contribution to surface ozone levels, on global health and agriculture, and such effects need to be included either in the Social Cost of Methane or elsewhere in the cost-benefit analysis, but currently are not.\textsuperscript{111} [EPA-HQ-OAR-2014-0827-1296-A1 p.20-21]

Overall, the Marten et al. methodology provides reasonable, direct estimates that reflect updated evidence and provide consistency with the Government’s accepted methodology for estimating the SCC. The agencies should use these Social Cost of Methane estimates in the final heavy-duty truck rule. Doing so would increase the total net present value of the rule’s greenhouse gas benefits by about $1.5 billion to $12 billion (2012$), or approximately 4 to 7 percent, depending on discount rate.\textsuperscript{112} [EPA-HQ-OAR-2014-0827-1296-A1 p.21]

At the same time, the agencies should work toward the future refinement of these Social Cost of Methane estimates. Because the Social Cost of Methane and the SCC share many assumptions and methods, it may make sense for the Interagency Working Group to review and update both metrics. In any case, any future improvements made to the SCC methodology should also be incorporated into and adjusted for the Social Cost of Methane estimates. [EPA-HQ-OAR-2014-0827-1296-A1 p.21]

If the agencies for some reason decline to follow the Marten et al. approach, they could still use the global warming potential adjustment as a less accurate, lower-bound estimate. However, instead of the outdated multiplier of 25 for methane, the agencies should utilize the latest global warming potential estimates for methane issued by the IPCC: 85 to 87 times greater than carbon dioxide after 20 years and 30 to 36 times greater than carbon dioxide after 100 years (after making the recommended adjustment for fossil methane).\textsuperscript{113} Given the short life of methane, the agencies should at least conduct sensitivity analysis over the entire global warming potential range, instead of merely utilizing the lower 100-year timescale range. Again, though, the Social Cost of Methane approach is the more reasonable and preferred way to value this rule’s important methane reductions. [EPA-HQ-OAR-2014-0827-1296-A1 p.21-22]
EPA acknowledges this comment and notes that the recommendation about using a global warming potential adjustment is no longer relevant because EPA has used the Marten et al. (2014) social cost of methane (SC-CH₄) and social cost of N₂O (SC-N₂O) estimates to monetize the climate-related impacts of this rulemaking. EPA has included those estimates in the main benefits analysis. EPA agrees that the Marten et al. methodology provides reasonable, direct estimates that reflect updated evidence and provide consistency with the interagency working group’s (IWG) SC-CO₂ estimates.

EPA recognizes the importance of the SC-GHG estimates to be as complete as possible and continues to engage in research on modeling and valuation of climate impacts, which would support improvements to SC-CH₄, SC-N₂O, and SC-CO₂ estimates. EPA will share with the interagency working group (IWG) the commenters’ recommendation to consider reviewing and updating both SC-CO₂ and the SC-CH₄. EPA will continue to follow and evaluate the latest science on impact categories that are omitted or not fully addressed in the IAMs. As previously noted, EPA and the other IWG members are seeking external expert advice on the technical merits and challenges of potential approaches to update the damage functions in future revisions to the SC-CO₂ estimates, which would likely inform updates to the SC-CH₄ estimates. See response to Institute for Policy Integrity, Excerpt 7, in RTC Section 11.8, for complete discussion.

**Organization:** Institute for Policy Integrity

**Institute for Policy Integrity, Excerpt 9**

6. **Conclusion: Recommendations on the use of the SCC and Social Cost of Methane in regulatory impact analyses.**

EPA and NHTSA should continue to use the latest IWG estimates of the SCC, and should start using the Social Cost of Methane estimates. The current estimates are biased downwards: more can and should be done to improve the estimates and to ensure, through regular updates, that they reflect the latest science and economics. However, the necessary process of improving the ability of the SCC and Social Cost of Methane to fully reflect the costs of climate impacts to society cannot hold up agency rulemaking efforts. The values provide an important, if conservative, estimate of the costs of climate change and the benefits of reducing carbon pollution. To ignore these costs would be detrimental to human health and well-being and contrary to law and Presidential directives to agencies to evaluate the cost of pollution to society when considering standards to abate that pollution. In the context of agency rulemakings, the SCC and Social Cost of Methane provide the best available means to factor those costs into benefit-cost analyses. [EPA-HQ-OAR-2014-0827-1296-A1 p.22]

In using the estimates in their regulatory impact analyses, however, EPA and NHTSA should also include a qualitative assessment of all significant climate effects that are not currently quantified in the monetized estimate. The IWG acknowledged its incomplete treatment of both catastrophic and non-catastrophic damages, and instructed agencies that “These caveats...are necessary to consider when interpreting and applying the SCC estimates.” Those instructions are consistent with Executive Orders on regulatory analysis, which tell agencies to “assess...qualitative measures of costs and benefits that are difficult to quantify, but nevertheless essential to consider.” Before the IWG published its first estimates in 2010, some agencies included a detailed chart of unquantified climate effects in their regulatory impact analyses. However, most recent rulemakings only reference unquantified benefits from non-CO₂ gases and from co-pollutants, and list none of the significant, unquantified climate effects from carbon dioxide. In the final greenhouse gas and fuel efficiency standards and the final regulatory impact analyses, EPA and NHTSA should detail all significant,
unquantified climate effects, as consistent with administration-wide policy, the IWG’s instructions, past agency practices, and best economic practices. [EPA-HQ-OAR-2014-0827-1296-A1 p.22-23]

We also suggest that EPA and NHTSA encourage the IWG to regularly update the SCC and Social Cost of Methane, as new economic and scientific consensus emerges. Such updates are in line with the stated intentions of the IWG, which committed to “updating these estimates as the science and economic understanding of climate change... improves.” [EPA-HQ-OAR-2014-0827-1296-A1 p.23]

1 Exec. Order No. 13,563 §§ 1(b)-(c), 76 Fed. Reg. 3,821 (Jan. 18, 2011); see also infra on how this and subsequent orders, including Exec. Order No. 13,609, inform the use of a global SCC value.

2 President Clinton issued Executive Order 12,866 in 1993, establishing new guidance for benefit-cost analysis and explicitly directing agencies to consider, in addition to costs and benefits for which quantitative estimates are possible, “qualitative measures of costs and benefits that are difficult to quantify, but nevertheless essential to consider.” Exec. Order No. 12,866 § 1(a), 58 Fed. Reg. 51,735 (Sept. 30, 1993).

3 Ctr. for Biological Diversity v. Nat’l Highway Traffic Safety Admin., 538 F.3d 1172, 1199 (9th Cir. 2008) (holding unlawful NHTSA’s fuel economy standards for passenger vehicles when NHTSA ascribed a value of “zero” to the benefits of mitigating carbon dioxide, reasoning that “NHTSA assigned no value to the most significant benefit of more stringent CAFE standards: reduction in carbon emissions” (emphasis added)).

8 See generally 2010 TSD, supra note 4.

10 The 2010 and 2013 IWGs did very little to adjust the three IAMs. The main adjustment by IWG was to DICE to ensure that the IAM had an exogenous growth path that matched FUND and PAGE for the purposes of modeling various socio-economic and emission scenarios. Id. at 24.

Order No. 12,114, Environmental Effects Abroad of Major Federal Actions, 44 Fed. Reg. 1957 §§ 1-1, 2-1 (Jan. 4, 1979) (applying to “major Federal actions... having significant effects on the environment outside the geographical borders of the United States,” and enabling agency officials “to be informed of pertinent environmental considerations and to take such considerations into account ... in making decisions regarding such actions”).

46 For details on the applicability of Section 115, see Petition from the Institute for Policy Integrity, to EPA, for Rulemakings and Call for Information under Section 115, Title VI, Section 111, and Title II of the Clean Air Act to Regulate Greenhouse Gas Emissions (Feb. 19, 2013); see also Nathan Richardson, EPA and Global Carbon: Unnecessary Risk, COMMON RESOURCES, Feb. 28, 2013 (explaining how Section 115 authorizes use of a global SCC value when regulating under other Clean Air Act provisions).

49 OMB, CIRCULAR A-4, at 15 (2003). In sharp contrast to the Circular’s ultimate deferral to agencies on the issue of considering transboundary efficiency effects, the Circular makes very clear that international transfers and distributional effects should be assessed as costs and benefits to the United States: “Benefit and cost estimates should reflect real resource use. Transfer payments are monetary payments from one group to another that do not affect total resources available to society. . . . However, transfers from the United States to other nations should be included as costs, and transfers from other nations to the United States as benefits, as long as the analysis is conducted from the United States perspective.” Id. at 38 (emphasis original). In other words, even if federal agencies use a global SCC value to assess efficiency effects relating to their climate policies, that global valuation will not prevent the agencies from also counting international transfers or distributional effects that benefit the United States as benefits. See Comments from the Institute for Policy Integrity, to EPA, on Proposed Rulemaking to Establish Light-Duty Vehicle Greenhouse Gas Emission Standards, at 12-13 (Nov. 27, 2009) (explaining that, depending on the relevant statutory mandate, agencies may calculate a monopsony benefit to the United States even while using a global SCC value).

50 77 Fed. Reg. at 26,414, § 3(b).

51 77 Fed. Reg. at 26,413, § 2(a)(ii)(B) (defining the goals of the regulatory working group).

52 EPA, REGULATORY IMPACT ANALYSIS FOR THE FINAL MERCURY AND AIR TOXICS STANDARDS at 65 (2011) (“Reductions in domestic fish tissue concentrations can also impact the health of foreign consumers... [and] reductions in U.S. power plant emissions will result in a lowering of the global burden of elemental mercury .....”).

55 Steven L. Schwarz, Systemic Risk, 97 GEO. L.J. 193, 249 (2008) (observing that financial collapse in one country is inevitably felt beyond that country’s borders).

57 2010 TSD, supra note 4, at 10-11.

58 2013 TSD, supra note 6, at 14-15.

60 The moments of a distribution (of SCC estimates in this case) are, loosely speaking, the various values that describe the distribution’s shape: what value is the distribution centered around (mean); how wide is the distribution (the variance); whether the distribution is lopsided (skewness); and whether it is tall and skinny or short and fat (kurtosis). A percentile is a statistical measure of the value (the SCC value in this case) below which a specified percentage of (SCC) observations falls. The 1st percentile indicates the SCC value above which (the other) 99% of observed SCC values fall. The 99th percentile indicates the SCC value below which 99% of all observed SCC values fall.

62 “If climate risk dominates economic growth risk because there are enough potential scenarios with catastrophic damages, then the appropriate discount rate for emissions investments is lower than the risk-free rate and the current price of carbon dioxide emissions should be higher. In those scenarios, the “beta” of climate risk is a large negative value and emissions mitigation investments provide insurance benefits. If, on the other hand, growth risk is always dominant because catastrophic damages are essentially impossible and minor climate damages are more likely to occur when growth is strong, times are good, and marginal utility is low, then the “beta” of climate risk is positive, the discount rate should be higher than the risk-free rate, and the price of carbon dioxide emissions should be lower.” Robert B. Litterman, What Is the Right Price for Carbon Emissions?, REGULATION, Summer 2013, at 38, 41, available at http://www.cato.org/sites/cato.org/files/serials/files/regulation/2013/6/regulation-v36n2-1-1.pdf
63 See following subsection.

64 “There are two rationales for discounting future benefits—one based on consumption and the other on investment. The consumption rate of discount reflects the rate at which society is willing to trade consumption in the future for consumption today. Basically, we discount the consumption of future generations because we assume future generations will be wealthier than we are and that the utility people receive from consumption declines as their level of consumption increases. . . . The investment approach says that, as long as the rate of return to investment is positive, we need to invest less than a dollar today to obtain a dollar of benefits in the future. Under the investment approach, the discount rate is the rate of return on investment. If there were no distortions or inefficiencies in markets, the consumption rate of discount would equal the rate of return on investment. There are, however, many reasons why the two may differ. As a result, using a consumption rather than investment approach will often lead to very different discount rates.” Maureen Cropper, How Should Benefits and Costs Be Discounted in an Intergenerational Context?, 183 RESOURCES 30, 33.

71 Using the IWG’s 2010 SCC model, Johnson and Hope find that the U.K. and Weitzman schedules yield SCCs of $55 and $175 per ton of CO₂, respectively, compared to $35 at a 2.5% discount rate. Laurie T. Johnson & Chris Hope, The Social Cost of Carbon in U.S. Regulatory Impact Analyses: An Introduction and Critique, 2 J. ENVTL. STUD. & SCI. 205, 214 (2012).

75 2010 TSD, supra note 4, at 1.

78 2010 TSD, supra note 4, at 1-3 (“The estimates are presented with an acknowledgement of the many uncertainties involved and with a clear understanding that they should be updated over time to reflect increasing knowledge of the science and economics of climate impacts . . . . Specifically, we have set a preliminary goal of revisiting the SCC values within two years or at such time as substantially updated models become available, and to continue to support research in this area.”).

82 See, for example, National Science Foundation-funded work by Per Krusell and Anthony A. Smith on “A Global Economy-Climate Model with High Regional Resolution” using 19,000 agents (each covering a 1 x 1° area of land).

83 See infra note 95.
84 See supra note 60.

85 The federal government has committed to continuing to update SCC estimates to account for new information. The IWG stated in its 2010 TSD that “[i]t is important to emphasize that the interagency process is committed to updating these estimates as the science and economic understanding of climate change and its impacts on society improves over time. Specifically, we have set a preliminary goal of revisiting the SCC values within two years or at such time as substantially updated models become available, and to continue to support research in this area. In the meantime, we will continue to explore the issues raised in this document and consider public comments as part of the ongoing interagency process.” 2010 TSD, supra note 4, at 3.

86 In this case, parameters are the various characteristic that describe the underlying climate and economic systems.

87 See generally Timothy M. Lenton et al., Tipping Elements in the Earth’s Climate System, 105 PNAS 1786 (2008).

88 Standard decision theory under uncertainty addresses “known unknowns,” which are unknowns for which we can specify a probability distribution function. In the cases of “unknown unknowns,” i.e., ‘black swan’ events, we cannot specify a probability distribution function, raising a host of additional questions. See, e.g., Richard J. Zeckhauser, Investing in the Unknown and Unknowable, CAPITALISM & SOCIETY vol. 1, iss. 2, art. 5 (2006).

89 An increasing, strictly convex climate damage function implies a damage function that is strictly increasing in temperature at an increasing rate.

90 The point here is that we miss the big picture if we ignore the “tails” (the upper-most values in the case of the right-skewed SCC), and as a result come to the wrong conclusions. An everyday analogy is airplane safety regulation: safety is protected by guarding against the low-probability but highly dangerous events. With climate change we do not have the luxury of knowing with certainty how damaging the extremes could be or whether they will be triggered by greenhouse gases accumulating in the atmosphere; all we know is that there is a very real possibility they could occur and could be devastating.

91 This approach partially captures catastrophic damages via tipping points through the PAGE model.

94 Specifying the climate sensitivity parameter as a random variable has a basis in PAGE02, which species a probability distribution function for the parameter. The IWG calibrated the Roe and Baker distribution, a right-skewed distribution, to characterize the probability distribution function of this parameter. The 2010 TSD explains the IWG’s choice of the Roe and Baker distribution. The right-skewed nature of the climate sensitivity parameter’s probability distribution function is independent of the IWG’s choice of the Roe and Baker distribution. Rather, this skewness results from the IPCC’s finding that values of the climate sensitivity parameter above 4.5 degree Celsius cannot be excluded. As
a result, all of the probability distribution functions fit by the IWG for the climate sensitivity parameter were skewed to the right (see Figure 2 in the 2010 TSD), including Roe and Baker. See 2010 TSD, supra note 4, at 14, fig. 2.

95 A Monte Carlo simulation will run an integrated assessment model thousands of times, each time randomly picking the value of uncertain parameters from a probability distribution function, i.e., a function that assigns a probability to each possible parameter value. In the case of the SCC, the IWG ran 10,000 Monte Carlo simulations for each of the three IAMs and five socio-economic scenarios, randomizing the value of climate sensitivity, i.e., the change in average global temperature associated with a doubling of CO$_2$, and all other uncertain parameters in the IAMs by the original authors. For each randomly drawn set of values, the IAM estimated the associated damages, with the final SCC estimate equaling the average value across all 10,000 runs, five socio-economic scenarios, and then across all three models. Therefore, each SCC estimate is calculated using 150,000 runs.

96 IPCC, supra note 93, at 14.

99 Id. at 40,175, 40,208, 40,510.

100 Id. at 40,510.

101 Id. at 40,404-05. Note that the agencies seem to only count domestic upstream emissions, and thus may significantly undercount upstream effects. For latest IPCC values, compare IPCC Working Group I, Fifth Assessment Report, Climate Change 2013: The Physical Science Basis, Chapter 8: Anthropogenic and Natural Radiative Forcing (2014) at 633, 711-712, 714 (Table 8.7), available at https://www.ipcc.ch/pdf/assessment-report/ar5/wg1/WG1AR5_Chapter08_FINAL.pdf (and see the adjustment identified in note B).

104 See Ctr. for Biological Diversity v. Nat’l Highway Traffic Safety Admin., 538 F.3d 1172, 1202 (9th Cir. 2008) (finding NHTSA’s decision to assign zero value to carbon reductions to be arbitrary and capricious).

106 See, e.g., Marten et al at 7 (describing eleven prior studies estimating the social cost or global damage potential associated with methane).

107 Alex L. Marten et al., Incremental CH4 and N2O Mitigation Benefits Consistent With the US Government’s SC--? CO2 Estimates, Climate Policy (2014).

110 Interagency Working Group on the Social Cost of Carbon, Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis, 12 (February 2010), available at https://www.whitehouse.gov/sites/default/files/omb/inforeg/for-agencies/Social-Cost-of-Carbon-for- RIA.pdf (“Impacts other than temperature change also vary across gases in ways that are not captured by GWP. For instance . . . damages from methane emissions are not offset by the positive effect of CO2 fertilization.”). Martin et al (2015) state that “A comparison across models further highlights the importance of CO2 fertilization impacts on the global damage potential. CO2 emissions, and the resulting increase in atmospheric concentration, have the potential to increase yields in the agriculture and forestry sector. This characteristic is not shared by other GHG emissions. Accordingly, the FUND model, which explicitly captures this effect, exerts downward pressure on the SC- CO2 that is not present for the SC-CH4 and SC-N2O, allowing for the possibility of substantially higher global damage potential estimates. The results based on the FUND model presented in this article exhibit this effect; however, the CO2 fertilization effect is not explicitly modelled in DICE and PAGE and therefore they are found to produce lower estimates of the global damage potential. For example, using the 3% discount rate, the global damage potential for CH4 as estimated by FUND ranges between 58 and 88 depending on the scenario, whereas it ranges from 19 to 28 for DICE and PAGE. As the DICE and PAGE models only consider two natural system impacts, temperature and sea level, if they do implicitly include potential CO2 fertilization benefits, they are included by using the temperature anomaly as a proxy for the increasing atmospheric CO2 concentration. Fertilization benefits would therefore be allowed to falsely accrue to perturbations of other GHG emissions besides CO2. It is not clear the degree to which these models try to incorporate CO2 fertilization effects and therefore the degree to which this issue is of concern.”

111 A study by Sarofim et al. (2015) finds that reductions in surface ozone levels from the mitigation of methane emissions would provide additional global health benefits from avoided cardiopulmonary deaths equal to 60 to 140% of climate benefits identified by Marten. Similarly, Shindell (2014) finds that the impact of methane on agriculture, via changes in surface ozone, are valued at $22 and $27 per ton, for 5% and 3% discounting respectively, in addition to his study’s estimates for climate and climate-health related damages.

113 IPCC Working Group I, Fifth Assessment Report, Climate Change 2013: The Physical Science Basis, Chapter 8: Anthropogenic and Natural Radiative Forcing (2014) at 633, 711-712, 714 (Table

116 E.g., EPA, 420-D-09-001, DRAFT REGULATORY IMPACT ANALYSIS: CHANGES TO RENEWABLE FUEL STANDARD PROGRAM 690 tbl. 5.3-4 (2009).

Response:

The EPA acknowledges this comments and agrees with the recommendation to use the Marten et al. approach in the final rulemaking analysis. Regarding the recommendations to improve the estimates, see response to Institute for Policy Integrity, Excerpt 7, in RTC Section 11.8, for complete discussion.

Regarding the recommendations to include a qualitative assessment of impacts omitted from the SC-CO₂ and SC-CH₄ estimates: EPA notes that it is not possible at this time to provide a precise list of each model’s treatment (i.e., included, excluded) of climate impacts. EPA further notes that the table referenced by the commenter,215 which was published in a May 2009 draft regulatory impact analysis that was issued prior to the interagency working group’s development of the 2010 SC-CO₂ estimates, itemizes some of the impacts omitted from only one model. Subsequent to the publication of this draft RIA, the interagency working group (IWG) developed SC-CO₂ estimates based on an ensemble of three models. The IWG’s 2010 SC-CO₂ Technical Support Document presents a robust discussion of this key analytical issue, e.g., how each model estimates climate impacts, the known parameters and assumptions underlying those models, and the implications of incomplete treatment of impacts (catastrophic and non-catastrophic) for the SC-CO₂ and SC-CH₄ estimates. Moreover, the discussion in the SC-CO₂ TSD underscores the difficulty in accurately distilling the treatment of impacts in table-form for all three models. Most notably, the use of aggregate damage functions—which consolidate information about impacts from multiple studies—in two of the models, which were not addressed in the table referenced by the commenter, poses a challenge in listing included impacts. For example, within the broad agricultural impacts category, some of the sub-grouped impacts are not explicitly modeled but are highly correlated to other subcategories that are explicitly modeled. Therefore, EPA continues to determine that it is more appropriate to rely on the qualitative discussion in the TSDs about uncertainty. EPA has also updated the RIA Section 4.3 discussion to reference several publications that identify and discuss some of the important, unquantified climate effects.

EPA agrees that it is important to update the SC-CO₂ and SC-CH₄ periodically to incorporate improvements in the understanding of greenhouse gas emissions impacts and will continue to follow

215 EPA, 420-D-09-001, DRAFT REGULATORY IMPACT ANALYSIS: CHANGES TO RENEWABLE FUEL STANDARD PROGRAM 690 tbl. 5.3-4 (2009).
and evaluate the latest science on impact categories that are omitted or not fully addressed in the IAMs. As previously noted, EPA and the other IWG members are seeking external expert advice on the technical merits and challenges of potential approaches to update the damage functions in future revisions to the SC-CO₂ estimates, which would likely inform updates to the SC-CH₄ estimates. Finally, the RIA also continues to discuss climate change impacts, specifically an overview of the 2009 Endangerment Finding and climate science assessments released since then (see RIA, Chapter 4).

Regarding the recommendation for regular updates, see response to Institute for Policy Integrity, Excerpt 8, in RTC Section 11.8.

**Organization:** Mannix, Brian

**Social Cost of Carbon**

The goal of the President’s Climate Action Plan is to reduce emissions of greenhouse gases. The proposed Phase 2 standards will primarily reduce emissions of carbon dioxide, although some other greenhouse gases are also covered, and are converted to their “carbon equivalent” for purposes of the analysis. The RIA uses a Social Cost of Carbon (SCC, or SC-CO₂) to assign benefits to the estimates of reduced emissions. There are numerous complexities and controversies surrounding the estimation of the SCC. Nonetheless, as we have argued elsewhere, it is correct, in principle, for agencies to use a uniform SCC in evaluating programs designed to reduce carbon emissions.⁸ [EPA-HQ-OAR-2014-0827-1222-A1 p.5]

In doing a sensitivity analysis, the RIA uses multiple estimates of the SCC – including one that is intended to explore the “fat tails” of the probability distribution. “The fourth value is the 95th percentile of the SC-CO₂ from all three models at a 3 percent discount rate. It is included to represent higher-than-expected impacts from temperature change further out in the tails of the SC-CO₂ distribution (representing less likely, but potentially catastrophic, outcomes).”⁹ Note, however, that only the hot tail is considered. We know from the geological record that very large climate risks exist on the cold side. A major glacial advance, which has happened dozens of times in the past, would wipe out much of North America and northern Europe. The RIA’s use of only one tail of the distribution is an indication of bias in the analysis. [EPA-HQ-OAR-2014-0827-1222-A1 p.5]

There is another flaw in the SCC used to calculate the climate benefits of the standards: the agencies are using an estimate that is global. That is, the SCC mostly (an estimated 80% to 93%) represents benefits that accrue to other countries, rather than to the United States. This is a useful exercise to go through as part of an international conversation on climate change and what to do about it. It is not, however, suitable for estimating the benefits of a unilateral domestic rulemaking.¹⁰ Imposing costs on U.S. businesses and consumers in order to deliver benefits to other countries cannot be characterized as a “big step to grow our economy.”¹¹ Nor is it clear that delivering foreign aid is consistent with the statutory authorities on which the agencies rely in this rulemaking. A domestic SCC would be a sounder basis for evaluating the benefits of the standards. [EPA-HQ-OAR-2014-0827-1222-A1 p.5-6]

**Response:**

The comments regarding the aggregation of the SC-CO₂ estimates and general application in a rulemaking context mirror those submitted to the Office of Management and Budget’s separate comment solicitation on the SC-CO₂ (78 FR 70586; November 26, 2013). As a member of the interagency working group (IWG) on SC-CO₂, EPA has carefully examined and evaluated comments submitted to OMB’s separate solicitation. EPA has also carefully examined and evaluated all comments.
received regarding SC-CO\textsubscript{2} through this rulemaking process and determined that the IWG responses to the comments on the OMB solicitation address the comments on the aggregation of SC-CO\textsubscript{2} estimates and use of the estimates in this RIA. Specifically, EPA concurs with the IWG’s response to these comments and hereby incorporates them by reference.\textsuperscript{216}

In addition, EPA and other members of the U.S. Interagency Working Group on the SC-CO\textsubscript{2} are seeking independent expert advice on technical opportunities to update the SC-CO\textsubscript{2} estimates from the National Academies of Sciences, Engineering, and Medicine. A committee convened by the Academies is reviewing the state of the science on estimating the SC-CO\textsubscript{2}, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. The Academies’ review will focus on the SC-CO\textsubscript{2} methodology, but recommendations on how to update many of the underlying modeling assumptions will also likely pertain to the SC-CH\textsubscript{4} estimates. Going forward, the EPA will evaluate its approach to estimating the SC-CO\textsubscript{2}, SC-CH\textsubscript{4}, and SC-N\textsubscript{2}O based upon any feedback received from the Academies’ panel.

After careful evaluation of the full range of comments and associated technical issues described in this RTC, EPA has determined that it will continue to use the SC-GHG estimates in the final rulemaking analysis. In particular, the current SC-CO\textsubscript{2} estimates and the Marten et al. SC-CH\textsubscript{4} and SC-N\textsubscript{2}O estimates represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental emissions changes into regulatory analysis. Therefore, EPA has presented these estimates in this rulemaking. EPA will continue to consider these comments and will share the recommendations with the IWG as it moves forward with the Academies process.

The remainder of this section elaborates on these comments in the context of this rulemaking.

EPA acknowledges the commenter’s endorsement of federal agencies in principle using harmonized SC-CO\textsubscript{2} estimates to evaluate programs designed to reduce carbon emissions. EPA has determined using the current SC-CO\textsubscript{2} figures to estimate the value to society of marginal reductions in CO\textsubscript{2} emissions in Regulatory Impact Analysis under Executive Order 12866 is appropriate both in principle and in practice.

EPA disagrees with the commenter’s statement that use of the 95\textsuperscript{th} percentile SC-CO\textsubscript{2} estimates introduces bias to the analysis. As the 2010 TSD discusses, the SC-CO\textsubscript{2} estimates derived from the three integrated assessment models have several significant limitations that could lead to a substantial underestimation of the SC-CO\textsubscript{2}. These limitations include the incomplete treatment and monetization of non-catastrophic damages, the incomplete treatment of potential "catastrophic" damages, and uncertainty in extrapolation of damages to high temperatures. The IPCC Fourth Assessment Report, which was the most current IPCC assessment available at the time of the IWG’s 2009-2010 review, discussed these limitations and concluded that it was "very likely that [SCC] underestimates" climate change damages. Based on the current scientific understanding of climate change and its impacts, and on the limitations of the IAMs in quantifying and monetizing the full array of potential "catastrophic" and non-catastrophic damages, EPA and the other members of the IWG concluded that the distribution of SCC estimates may be biased downwards. Since then, the peer-reviewed literature has continued to support this conclusion. For example, the IPCC Fifth Assessment report observed that SC-CO\textsubscript{2} estimates continue to omit various impacts that would likely increase damages. The 95\textsuperscript{th} percentile

\textsuperscript{216} Referred to as the "OMB Response to Comments on SC-CO\textsubscript{2}.” In particular, see pgs 25 to 28, 30-32 at https://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-response-to-comments-final-july-2015.pdf.
estimate was included in the recommended range for regulatory impact analysis to address these concerns.

In addition, as acknowledged in the 2010 TSD, the SC-CO\textsubscript{2} estimates derived from the three IAMs did not take into consideration the possibility of risk aversion. That is, individuals may have a higher willingness-to-pay to reduce the likelihood of low-probability, high-impact damages than they do to reduce the likelihood of higher-probability, lower-impact damages with the same expected cost. The inclusion of the 95\textsuperscript{th} percentile estimate in the SC-CO\textsubscript{2} values was also motivated by this concern. In contrast, EPA is not aware of systematic upward biases in the estimates comparable to the downward biases discussed above. For this reason, while EPA and other members of the IWG have been fully transparent regarding the entire range of uncertainty reflected in the probability distributions, EPA did not include a 5\textsuperscript{th} percentile estimate in the selected range for regulatory impact analysis.

EPA disagrees with the commenter’s statement that application of a global SC-CO\textsubscript{2} to calculate the benefits of domestic rulemaking is not appropriate. As discussed in the 2010 SC-CO\textsubscript{2} Technical Support Document (TSD), the IWG determined that a global measure of SC-CO\textsubscript{2} is appropriate in this context because emissions of most greenhouse gases contribute to damages around the world and the world’s economies are now highly interconnected.\textsuperscript{217} To reflect the global nature of the problem, the SC-CO\textsubscript{2} incorporates the full damages caused by CO\textsubscript{2} emissions and other governments are expected to consider the global consequences of their greenhouse gas emissions when setting their own domestic policies.

Carbon dioxide is a global pollutant with global consequences. Carbon dioxide, in addition to methane, N\textsubscript{2}O and other GHG emissions, contributes to warming of the atmosphere, which over time leads to increased air and ocean temperatures, changes in precipitation patterns, melting and thawing of global glaciers and ice, increasingly severe weather events, such as hurricanes of greater intensity, and sea level rise, among other impacts. Pursuant to Clean Air Act section 202(a), the EPA Administrator found that GHGs in the atmosphere threaten the public health and welfare of current and future generations. In particular, the Administrator found that the mix of six greenhouse gases (CO\textsubscript{2}, CH\textsubscript{4}, N\textsubscript{2}O, HFCs, PFCs, and SF\textsubscript{6}) is “global in nature because the greenhouse gas emissions emitted from the United States (or from any other region of the world) become globally well mixed, such that it would not be meaningful to define the air pollution as the greenhouse gas concentrations over the United as somehow being distinct from the greenhouse gas concentrations over other regions of the world” (74 FR 66517; December 15, 2009). Any pollutant with an atmospheric lifetime of greater than one or two years becomes well-mixed globally. One attribute of a well-mixed substance is that the location of emission has little impact on the consequences of those emissions, such that a ton of methane emitted in the US will have just as much an impact on global temperatures as a ton of methane emitted in Australia.

As stated in the OMB Response to Comments on SC-CO\textsubscript{2}, if all countries acted independently to set policies based only on the domestic costs and benefits of carbon emissions, it would lead to an economically inefficient level of emissions reductions which could be harmful to all countries, including the United States, because each country would be underestimating the full value of its own reductions. The same applies to methane emissions because methane is, as discussed in the previous paragraph, a well-mixed global pollutant with global consequences. This is a classic public goods problem because each country’s reductions benefit everyone else and no country can be excluded from enjoying the benefits of other countries’ reductions, even if it provides no reductions itself. In this situation, the only

\textsuperscript{217} 2010 SC-CO\textsubscript{2} TSD available in the docket and at https://www.whitehouse.gov/sites/default/files/omb/inforeg/for-agencies/Social-Cost-of-Carbon-for-RIA.pdf
way to achieve an economically efficient level of emissions reductions is for countries to cooperate in providing mutually beneficial reductions beyond the level that would be justified only by their own domestic benefits. By adopting a global estimate of the SC-CO$_2$ or the SC-CH$_4$ or the SC- N$_2$O , the U.S. government can signal its leadership in this effort. In reference to the public good nature of mitigation and its role in foreign relations, thirteen prominent academics noted that these "are compelling reasons to focus on a global [SC-CO$_2$]" in a recent article on the SC-CO$_2$ (Pizer et al., 2014). In addition, there is no bright line between domestic and global damages from greenhouse gas emissions, such as CO$_2$, methane, and N2O. Adverse impacts on other countries can have spillover effects on the United States, particularly in the areas of national security, international trade, public health and humanitarian concerns.

GHG emissions in the United States will have impacts abroad, some of which may, in turn, affect the United States. For this reason, a purely domestic measure is likely to understate actual impacts to the United States. Also, as stated above, the EPA and the other members of IWG believes that accounting for global benefits can encourage reciprocal action by other nations, leading ultimately to international cooperation that increases both global and U.S. net benefits relative to what could be achieved if each nation considered only its own domestic costs and benefits when determining its climate policies. As a party to the United Nations Framework Convention on Climate Change, the United States is actively engaging with the international community to find solutions and promote global cooperation on climate change. As of May 2016, over 170 nations have signed the Paris Agreement on climate change, signifying worldwide commitment to reduce GHG emissions.

Further, as explained in the 2010 TSD, from a technical perspective, the development of a domestic SC-CO$_2$ was greatly complicated by the relatively few region- or country-specific estimates of the SC-CO$_2$ in the literature, and impacts beyond our borders have spillover effects on the United States, particularly in the areas of national security, international trade, and public health. As a result, it was only possible to include an "approximate, provisional, and highly speculative" range of 7 to 23 percent for the share of domestic benefits in the 2010 TSD. This range was based on two strands of evidence: direct domestic estimates resulting from the FUND model, and an alternative approach under which the fraction of GDP lost due to climate change is assumed to be similar across countries.

Regarding the commenter’s criticism that the SCC does not consider the risks of cooling, there are no credible projections of future temperatures over the next century that include any appreciable probability that temperatures will decline. This is because the elevated concentrations of greenhouse gases already in the atmosphere are projected to lead to future warming even in the absence of future increases in concentrations until the Earth system returns to a radiative balance: future emissions of greenhouse gases (and in particular carbon dioxide due to its long lifetime) will lead to even more warming.

Finally, EPA notes that the commenter has not provided any basis for his assertion that an estimated 80 to 93 percent of the SC-CO$_2$ represents benefits that accrue to other countries. This figure is not presented in the Gayer and Viscusi paper referenced by the commenter.

10 Gayer and Viscusi note that “imposing a global perspective on benefits will increase the apparent desirability of the policy but will overstate the actual benefits to the American people.”

11 Remarks by the President on Fuel Efficiency Standards for Medium and Heavy-Duty Vehicles, February 18, 2014.

Organization: Michaels and Knappenberger

It is clearly inappropriate to relate unmeasurable and unverifiable impacts to economic gains. The EPA, nevertheless, does this through using the social cost of carbon (SCC), attributing $100 billion of economic savings through the alleviation of future climate change. [EPA-HQ-OAR-2014-0827-1206-A1 p.1]

EPA’s determination of the SCC is discordant with the best scientific literature on the equilibrium climate sensitivity and the fertilization effect of carbon dioxide—two critically important parameters for establishing the net externality of carbon dioxide emissions. It is based upon the output of Integrated Assessment Models (IAMs) which have little utility because of their great uncertainties. They provide no reliable guidance as to the sign, much less the magnitude of the social cost of carbon. Additionally, as run by the Interagency Working Group (IWG), whose results were incorporated by the EPA in this proposal, the IAMs produce illogical results that indicate a misleading disconnection between climate changes and the SCC value. Additionally, new research strongly suggests that the scientific research on the SCC is biased in favor of high SCC values, and that when this bias is accounted for, the SCC value used by the EPA is inflated. [EPA-HQ-OAR-2014-0827-1206-A1 p.1-2]

Considering the improprieties surrounding the determination of the SCC by the current Administration, their determination should never be used federal rulemakings. It is better not to use any value for the SCC in cost/benefit analyses, than to include one which is clearly improper, inaccurate and misleading. [EPA-HQ-OAR-2014-0827-1206-A1 p.2]

The combination of a lack of measurable climate impacts with the lack of logical cost estimates renders this proposed regulation unjustifiable. Consequently, we suggest that it should be withdrawn. [EPA-HQ-OAR-2014-0827-1206-A1 p.2]

And perhaps most remarkable of all, is that although the climate risks were not “formally estimated,” the EPA determines that the climate impacts resulting from the proposed regulation will lead to “net economic benefits exceeding $100 billion making this a highly beneficial rule” (Federal Register, Vol. 80, No. 133, pg 40169). [EPA-HQ-OAR-2014-0827-1206-A1 p.6]

Things that one can neither measure nor detect cannot be assigned any discrete cost. [EPA-HQ-OAR-2014-0827-1206-A1 p.6]
This occurs throughout the EPA’s ill-advised application of the ill-suited and ill-determined social cost of carbon (Federal Register, Vol. 80, No. 133, pg 40456). [EPA-HQ-OAR-2014-0827-1206-A1 p.6]

Comments on the Social Cost of Carbon

The EPA incorporates the social cost of carbon (SCC) value determined through a process conducted by the federal Interagency Working Group (IWG) that was initially established in 2010 and subsequently revised on several occasions. The EPA uses the SCC value established by the IWG in its May 2013 update. Therefore, our comments largely reflect the contents of the IWG 2013 SCC justifications and the EPA’s reliance upon them. We note that recently, in July 2015, the IWG, through the Office of Management and Budget (OMB) has reaffirmed the 2013 SCC value, and offered responses to criticism of that determination. However, the IWG (2015) response is inadequate to alleviate the concerns that we express in this set of comments. [EPA-HQ-OAR-2014-0827-1206-A1 p.6]

The IWG continues to ignore a large amount of relevant science such that the current SCC value (as incorporated by the EPA in this rulemaking) should be considered invalid and discarded. It is better not to include any value for the SCC in federal cost/benefit analyses such as this one, than to include one which is knowingly inaccurate and thus potentially misleading. [EPA-HQ-OAR-2014-0827-1206-A1 p.6]

Domestic vs. Global Costs

During the public comment period associated with new regulations such as this one which incorporate the SCC, a clear distinction should be made between domestic costs/benefits and foreign cost/benefits—and numerical calculations of each provided in all cost/benefit analyses included in the proposal (to be included in the main body of the proposal). In this way, the public can readily judge for itself (rather than have to defer on the judgement of the IWG) the value of the regulation. As it currently stands, the public likely has little idea as to how large a percentage of the benefits of the proposed EPA regulations on domestic activities are conferred upon foreign nations under the guise of the SCC. We recommend reporting the results of the domestic SCC calculation in the main body of the proposed regulation. As it stands presently, the situation is clearly not as “transparent” as it should be. [EPA-HQ-OAR-2014-0827-1206-A1 p.7]

Equilibrium Climate Sensitivity

In May 2013, the Interagency Working Group (IWG) produced an updated SCC value by incorporating updates to the underlying three Integrated Assessment Models (IAMs) used in its initial 2010 SCC determination. But, at that time, the IWG did not update the equilibrium climate sensitivity (ECS) employed in the IAMs. This was not done, despite there having been, since January 1, 2011, at least 14 new studies and 20 experiments (involving more than 45 researchers) examining the ECS, each lowering the best estimate and tightening the error distribution about that estimate. Instead, the IWG wrote in its 2013 report: “It does not revisit other interagency modeling decisions (e.g., with regard to the discount rate, reference case socioeconomic and emission scenarios, or equilibrium climate sensitivity).” [EPA-HQ-OAR-2014-0827-1206-A1 p.7]

This decision was reaffirmed by the IWG in July 2015. But, through its reaffirmation, the IWG has again refused to give credence to and recognize the importance of what is now becoming mainstream science—that the most likely value of the equilibrium climate sensitivity is lower than that used by the IWG and that the estimate is much better constrained. This situation has profound implications for the
determination of the SCC and yet continues to be summarily dismissed by the IWG. [EPA-HQ-OAR-2014-0827-1206-A1 p.7]

The earth’s equilibrium climate sensitivity is defined in the Interagency Working Group on Social Cost of Carbon 2010 (hereafter, IWG2010) report as “the long-term increase in the annual global-average surface temperature from a doubling of atmospheric CO$_2$ concentration relative to pre-industrial levels (or stabilization at a concentration of approximately 550 parts per million (ppm))” and is recognized as “a key input parameter” for the integrated assessment models used to determine the social cost of carbon. [EPA-HQ-OAR-2014-0827-1206-A1 p.7]

The IWG2010 report has an entire section (Section III.D) dedicated to describing how an estimate of the equilibrium climate sensitivity and the scientific uncertainties surrounding its actual value are developed and incorporated in the IWG’s analysis. The IWG2010, in fact, developed its own probability density function (pdf) for the ECS and used it in each of the three IAMs, superseding the ECS pdfs used by the original IAMs developers. The IWG’s intent was to develop an ECS pdf which most closely matched the description of the ECS as given in the Fourth Assessment Report of the United Nation’s Intergovernmental panel on Climate Change which was published in 2007. [EPA-HQ-OAR-2014-0827-1206-A1 p.7]

The functional form adopted by the IWG2010 was a calibrated version of Roe and Baker (2007) distribution. It was described in the IWG2010 report in the following Table and Figure (from the IWG2010 report): [EPA-HQ-OAR-2014-0827-1206-A1 p.8]

[Table 1, 'Summary Statistics for Four Calibrated Climate Sensitivity Distributions', and Figure 2, 'Estimates of the Probability Density Function for Equilibrium Climate Sensitivity', can be found on p.8 of docket number EPA-HQ-OAR-2014-0827-1206-A1]

The calibrated Roe and Baker functional form used by the IWG2010 is no longer scientifically defensible; nor was it at the time of the publication of the IWG 2013 SCC update, nor at the time of the July 2015 update. [EPA-HQ-OAR-2014-0827-1206-A1 p.8]

The figure below vividly illustrates this fact, as it compares the best estimate and 90% confidence range of the earth’s ECS as used by the IWG2010/2013/2015 (calibrated Roe and Baker) against findings in the scientific literature published since January 1, 2011. [EPA-HQ-OAR-2014-0827-1206-A1 p.8]

Whereas the IWG2010/2013/2015 ECS distribution has a median value of 3.0°C and 5th and 95th percentile values of 1.72°C and 7.14°C, respectively, the corresponding values averaged from the recent scientific literature are 2.0°C (median), 1.1°C (5th percentile), and 3.5°C (95th percentile). [EPA-HQ-OAR-2014-0827-1206-A1 p.9]

These differences will have large and significant impacts on the SCC determination. [EPA-HQ-OAR-2014-0827-1206-A1 p.9]

The IWG2010 report noted that, concerning the low end of the ECS distribution, its determination reflected a greater degree of certainty that a low ECS value could be excluded than did the IPCC. From the IWG2010 (p. 14): [EPA-HQ-OAR-2014-0827-1206-A1 p.10]
“Finally, we note the IPCC judgment that the equilibrium climate sensitivity “is very likely larger than 1.5°C.” Although the calibrated Roe & Baker distribution, for which the probability of equilibrium climate sensitivity being greater than 1.5°C is almost 99 percent, is not inconsistent with the IPCC definition of “very likely” as “greater than 90 percent probability,” it reflects a greater degree of certainty about very low values of ECS than was expressed by the IPCC.” [EPA-HQ-OAR-2014-0827-1206-A1 p.10]

In other words, the IWG used its judgment that the lower bound of the ECS distribution was higher than the IPCC 2007 assessment indicated. However, the collection of the recent literature on the ECS shows the IWG’s judgment to be in error. As can be seen in the chart above, the large majority of the findings on ECS in the recent literature indicate that the lower bound (i.e., 5th percentile) of the ECS distribution is lower than the IPCC 2007 assessment. And, the average value of the 5th percentile in the recent literature (1.1°C) is 0.62°C less than that used by the IWG—a sizeable and important difference which will influence the SCC determination. [EPA-HQ-OAR-2014-0827-1206-A1 p.10]

In fact, the abundance of literature supporting a lower climate sensitivity was at least partially reflected in the new IPCC assessment report issued in 2013. In that report, the IPCC reported: [EPA-HQ-OAR-2014-0827-1206-A1 p.10]

Equilibrium climate sensitivity is **likely** in the range 1.5°C to 4.5°C (**high confidence**), **extremely unlikely** less than 1°C (**high confidence**), and **very unlikely** greater than 6°C (**medium confidence**). The lower temperature limit of the assessed **likely** range is thus less than the 2°C in the AR4…[EPA-HQ-OAR-2014-0827-1206-A1 p.10]

Clearly, the IWG’s assessment of the low end of the probability density function that best describes the current level of scientific understanding of the climate sensitivity is incorrect and indefensible. [EPA-HQ-OAR-2014-0827-1206-A1 p.10]

But even more influential in the SCC determination is the upper bound (i.e., 95th percentile) of the ECS probability distribution. [EPA-HQ-OAR-2014-0827-1206-A1 p.10]

The IWG2010 notes (p.14) that the calibrated Roe and Baker distribution better reflects the IPCC judgment that “values substantially higher than 4.5°C still cannot be excluded.” The IWG2010 further notes that [EPA-HQ-OAR-2014-0827-1206-A1 p.10]

“Although the IPCC made no quantitative judgment, the 95th percentile of the calibrated Roe & Baker distribution (7.1 °C) is much closer to the mean and the median (7.2 °C) of the 95th percentiles of 21 previous studies summarized by Newbold and Daigneault (2009). It is also closer to the mean (7.5 °C) and median (7.9 °C) of the nine truncated distributions examined by the IPCC (Hegerl, et al., 2006) than are the 95th percentiles of the three other calibrated distributions (5.2-6.0 °C).” [EPA-HQ-OAR-2014-0827-1206-A1 p.11]

In other words, the IWG2010 turned towards surveys of the scientific literature to determine its assessment of an appropriate value for the 95th percentile of the ECS distribution. Now, more than five years hence, the scientific literature tells a completely different story. [EPA-HQ-OAR-2014-0827-1206-A1 p.11]

Instead of a 95th percentile value of 7.14°C, as used by the IWG2010, a survey of the recent scientific literature suggests a value of 3.5°C—more than 50% lower. [EPA-HQ-OAR-2014-0827-1206-A1 p.11]
And this is very significant and important difference because the high end of the ECS distribution has a large impact on the SCC determination—a fact frequently commented on by the IWG2010. [EPA-HQ-OAR-2014-0827-1206-A1 p.11]

For example, from IWG2010 (p.26):

“As previously discussed, low probability, high impact events are incorporated into the SCC values through explicit consideration of their effects in two of the three models as well as the use of a probability density function for equilibrium climate sensitivity. Treating climate sensitivity probabilistically results in more high temperature outcomes, which in turn lead to higher projections of damages. Although FUND does not include catastrophic damages (in contrast to the other two models), its probabilistic treatment of the equilibrium climate sensitivity parameter will directly affect the non-catastrophic damages that are a function of the rate of temperature change.” [EPA-HQ-OAR-2014-0827-1206-A1 p.11]

And further (p.30):

**Uncertainty in extrapolation of damages to high temperatures:** The damage functions in these IAMs are typically calibrated by estimating damages at moderate temperature increases (e.g., DICE was calibrated at 2.5 °C) and extrapolated to far higher temperatures by assuming that damages increase as some power of the temperature change. Hence, estimated damages are far more uncertain under more extreme climate change scenarios. [EPA-HQ-OAR-2014-0827-1206-A1 p.11]

And the entirety of Section V [sic] “A Further Discussion of Catastrophic Impacts and Damage Functions” of the IWG 2010 report describes “tipping points” and “damage functions” that are probabilities assigned to different values of global temperature change. Table 6 from the IWG2010 indicated the probabilities of various tipping points. [EPA-HQ-OAR-2014-0827-1206-A1 p.11]

[Table 6, ‘Probabilities of Various Tipping Points from Expert Elicitation’, can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1206-A1]

The likelihood of occurrence of these low probability, high impact, events (“tipping points”) is greatly diminished under the new ECS findings. The average 95th percentile value of the new literature survey is only 3.5°C indicating a very low probability of a warming reaching 3.5°C by 2100 as indicated in the 3rd column of the above Table and thus a significantly lower probability that such tipping points will be reached. This new information will have a large impact on the final SCC determination using the IWG’s methodology. [EPA-HQ-OAR-2014-0827-1206-A1 p.12]

The size of this impact has been directly investigated. [EPA-HQ-OAR-2014-0827-1206-A1 p.12]

In their Comment on the Landmark Legal Foundation Petition for Reconsideration of Final Rule Standards for Standby Mode and Off Mode Microwave Ovens, Dayaratna and Kreutzer (2013) ran the DICE model using the distribution of the ECS as described by Otto et al. (2013)—a paper published in the recent scientific literature which includes 17 authors, 15 of which were lead authors of chapters in the recent Intergovernmental Panel on Climate Change’s Fifth Assessment Report. The most likely value of the ECS reported by Otto et al. (2013) was described as “2.0°C, with a 5–95% confidence interval of 1.2–3.9°C.” Using the Otto et al. (2013) ECS distribution in lieu of the distribution employed by the IWG (2013), dropped the SCC by 42 percent, 41 percent, and 35 percent (for the 2.5%, 3.0%, 5.0% discount rates, accordingly). This is a significant decline. [EPA-HQ-OAR-2014-0827-1206-A1 p.12]
In subsequent research, Dayaratna and Kreutzer (2014) examined the performance of the FUND model, and found that it too, produced a greatly diminished value for the SCC when run with the Otto et al. distribution of the equilibrium climate sensitivity. Using the Otto et al. (2013) ECS distribution in lieu of the distribution employed by the IWG (2013), dropped the SCC produced by the FUND model to $11, $6, $0 compared with the original $30, $17, $2 (for the 2.5%, 3.0%, 5.0% discount rates, accordingly). Again, this is a significant decline. [EPA-HQ-OAR-2014-0827-1206-A1 p.12]

The Dayaratna and Kreutzer (2014) results using FUND were in line with alternative estimates of the impact of a lower climate sensitivity on the FUND model SCC determination. [EPA-HQ-OAR-2014-0827-1206-A1 p.13]

Waldhoff et al. (2011) investigated the sensitivity of the FUND model to changes in the ECS. Waldhoff et al. (2011) found that changing the ECS distribution such that the mean of the distribution was lowered from 3.0°C to 2.0°C had the effect of lowering the SCC by 60 percent (from a 2010 SCC estimate of $8/ton of CO$_2$ to $3/ton in $1995). While Waldhoff et al. (2011) examined FUNDv3.5, the response of the current version (v3.8) of the FUND model should be similar. [EPA-HQ-OAR-2014-0827-1206-A1 p.13]

Additionally, the developer of the PAGES model, affirmed that the SCC from the PAGES model, too drops by 35% when the Otto et al. (2013) climate sensitivity distribution is employed (Hope, 2013). [EPA-HQ-OAR-2014-0827-1206-A1 p.13]

These studies make clear that the strong dependence of the social cost of carbon on the distribution of the estimates of the equilibrium climate sensitivity (including the median, and the upper and lower certainty bounds) requires that the periodic updates to the IWG SCC determination must include a critical examination of the scientific literature on the topic of the equilibrium climate sensitivity, not merely kowtowing to the IPCC assessment. There is no indication that the IWG undertook such an independent examination. But what is clear, is that the IWG did not alter its probability distribution of the ECS between its 2010, 2013, and 2015 SCC determination, despite a large and growing body of scientific literature that substantially alters and better defines the scientific understanding of the earth’s ECS. It is unacceptable that a supposed “updated” social cost of carbon does not include updates to the science underlying a critical and key aspect of the SCC. [EPA-HQ-OAR-2014-0827-1206-A1 p.13]

We note that there has been one prominent scientific study in the recent literature which has argued, on the basis of recent observations of lower tropospheric mixing in the tropics, for a rather high climate sensitivity (Sherwood et al., 2014). This research, however, suffers from too narrow a focus. While noting that climate models which best match the apparent observed behavior of the vertical mixing characteristics of the tropical troposphere tend to be the models with high climate sensitivity estimates, the authors fail to make note that these same models are the ones whose projections make the worst match to observations of the evolution of global temperature during the past several decades. The figure below shows the observed global surface temperature history from 1951-2013 compared with the temperature evolution projected by the collection of models used in the new IPCC 2013 report. We broke the climate models down into two groups—those which have a climate sensitivity greater than 3.0°C (as suggested by Sherwood et al., 2014) and those with a climate sensitivity less than 3.0°C. The Figure shows that while neither model subset does a very good job is capturing evolution of global temperature during the past 15-20 years (the period with the highest human carbon dioxide emissions), the high sensitivity models do substantially worse than the lower sensitivity models. [EPA-HQ-OAR-2014-0827-1206-A1 p.13]
While Sherwood et al. (2014) prefer models that better match their observations in one variable, the same models actually do worse in the big picture than do models which lack the apparent accuracy in the processes that Sherwood et al. (2014) describe. The result can only mean that there must still be even bigger problems with other model processes which must more than counteract the effects of the processes described by Sherwood et al. After all, the overall model collective is still warming the world much faster than it actually is (see Figure below). In fact, for the observed global average temperature evolution for the past 30 years largely lies below the range which encompasses 95% of all climate model runs—an indication that the observed trend is statistically different from the trend simulated by climate models. And for periods approaching 40 years in length, the observed trend lies outside of (below) the range that includes 90% of all climate model simulations—and indication that the observed trend is marginally inconsistent with climate model simulations. [EPA-HQ-OAR-2014-0827-1206-A1 p.14]

We note that our statistics are based upon both the warm and the cold departures from predicted trends. In reality, the cold departure is what is of most interest from a policy perspective—for if warming is being demonstrably overpredicted, then policies based upon models that are in error are a substantial regulatory overreach. Our probability estimates are conservative as values at the .05 level are actually at the 2.5th percentile for warmth from the model ensemble. [EPA-HQ-OAR-2014-0827-1206-A1 p.14]

These results argue strongly against the reliability of the Sherwood et al. (2014) conclusion and instead provide robust observational evidence that the climate sensitivity has been overestimated by both climate models, and the IWG alike. [EPA-HQ-OAR-2014-0827-1206-A1 p.14]

Agricultural Impacts of Carbon Fertilization

Carbon dioxide is known to have a positive impact on vegetation, with literally thousands of studies in the scientific literature demonstrating that plants (including crops) grow stronger, healthier, and more productive under conditions of increased carbon dioxide concentration. A recent study (Idso, 2013) reviewed a large collection of such literature as it applies to the world’s 45 most important food crops (making up 95% of the world’s annual agricultural production). Idso (2013) summarized his findings on the increase in biomass of each crop that results from a 300ppm increase in the concentration of carbon dioxide under which the plants were grown. This table is reproduced below, and shows that the typical growth increase exceeds 30% in most crops, including 8 of the world’s top 10 food crops (the increase was 24% and 14% in the other two). [EPA-HQ-OAR-2014-0827-1206-A1 p.15]

Idso (2013) found that the increase in the atmospheric concentration of carbon dioxide that took place during the period 1961-2011 was responsible for increasing global agricultural output by 3.2 trillion dollars (in 2004-2006 constant dollars). Projecting the increases forward based on projections of the increase in atmospheric carbon dioxide concentration, Idso (2013) expects carbon dioxide fertilization...
to increase the value of agricultural output by 9.8 trillion dollars (in 2004-2006 constant dollars) during the 2012-2050 period. [EPA-HQ-OAR-2014-0827-1206-A1 p.16]

This is a large positive externality, and one that is insufficiently modeled in the IAMs relied upon by the IWG in determining the SCC. [EPA-HQ-OAR-2014-0827-1206-A1 p.16]

In fact, only one of the three IAMs used by the IWG has any substantial impact from carbon dioxide fertilization, and the one that does, underestimates the effect by approximately 2-3 times. [EPA-HQ-OAR-2014-0827-1206-A1 p.16]

The FUND model has a component which calculates the impact on agricultural as a result of carbon dioxide emissions, which includes not only the impact on temperature and other climate changes, but also the direct impact of carbon dioxide fertilization. The other two IAMs, DICE and PAGE by and large do not (or only do so extremely minimally; DICE includes the effect to a larger degree than PAGE). Consequently, lacking this large and positive externality, the SCC calculated by the DICE and PAGE models is significantly larger than the SCC determined by the FUND model (for example, see Table A5, in the IWG 2013 report). [EPA-HQ-OAR-2014-0827-1206-A1 p.16-17]

But even the positive externality that results from carbon dioxide fertilization as included in the FUND model is too small when compared with the Idso (2013) estimates. FUND (v3.7) uses the following formula to determine the degree of crop production increase resulting from atmospheric carbon dioxide increases (taken from Anthoff and Tol, 2013a): [EPA-HQ-OAR-2014-0827-1206-A1 p.17]

\[ A_{t,r}^f = \gamma_r \ln(CO_2_t/275) \] [EPA-HQ-OAR-2014-0827-1206-A1 p.17]

where

- \( A_{t,r}^f \) denotes damage in agricultural production as a fraction due to the \( CO_2 \) fertilization by time and region; [EPA-HQ-OAR-2014-0827-1206-A1 p.17]
- \( t \) denotes time; [EPA-HQ-OAR-2014-0827-1206-A1 p.17]
- \( r \) denotes region; [EPA-HQ-OAR-2014-0827-1206-A1 p.17]
- \( CO_2 \) denotes the atmospheric concentration of carbon dioxide (in parts per million by volume); [EPA-HQ-OAR-2014-0827-1206-A1 p.17]
- 275 ppm is the pre-industrial concentration; [EPA-HQ-OAR-2014-0827-1206-A1 p.17]
- \( \gamma \) is a parameter (see Table A, column 8-9). [EPA-HQ-OAR-2014-0827-1206-A1 p.17]

Column 8 in the table below shows the \( CO_2 \) fertilization parameter (\( \gamma_r \)) used in FUND for various regions of the world (Anthoff and Tol, 2013b). The average \( CO_2 \) fertilization effect across the 16 regions of the world is 11.2%. While this number is neither a really weighted, nor weighted by the specific crops grown, it is clear that 11.2% is much lower than the average fertilization effect compiled by Idso (2013) for the world’s top 10 food crops (35%). Further, Idso’s fertilization impact is in
response to a 300ppm CO₂ increase, while the fertilization parameter in the FUND model is multiplied by \( \ln(\text{CO}_2/275) \) which works out to 0.74 for a 300ppm CO₂ increase. This multiplier further reduces the 16 region average to 8.4% for the CO₂ fertilization effect—some 4 times smaller than the magnitude of the fertilization impact identified by Idso (2013). [EPA-HQ-OAR-2014-0827-1206-A1 p.17]

[Table, 'Impact of climate change on agriculture in FUND model', can be found on p.18 of docket number EPA-HQ-OAR-2014-0827-1206-A1]

Although approximately four times too small, the impact of the fertilization effect on the SCC calculation in the FUND model is large. [EPA-HQ-OAR-2014-0827-1206-A1 p.18]

According to Waldhoff et al. (2011), if the CO₂ fertilization effect is turned off in the FUND model (v3.5) the SCC increases by 75% from $8/ton CO₂ to $14/ton CO₂ (in 1995 dollars). In another study, Ackerman and Munitz (2012) find the effective increase in the FUND model to be even larger, with CO₂ fertilization producing a positive externality of nearly $15/ton CO₂ (in 2007 dollars). [EPA-HQ-OAR-2014-0827-1206-A1 p.18]

Clearly, had the Idso (2013) estimate of the CO₂ fertilization impact been used instead of the one used in FUND the resulting positive externality would have been much larger, and the resulting net SCC been much lower. [EPA-HQ-OAR-2014-0827-1206-A1 p.18]

This is just for one of the three IAMs used by the IWG. Had the more comprehensive CO₂ fertilization impacts identified by Idso (2013) been incorporated in all the IAMs, the three-model average SCC used by the IWG would be greatly lowered, and likely even become negative in some IAM/discount rate combinations. [EPA-HQ-OAR-2014-0827-1206-A1 p.18]

In its 2015 Response to Comments Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866, the IWG admits to the disparate ways that CO₂ fertilization is included in the three IAMs. Nevertheless, the IWG quickly dismisses this as a problem in that they claim the IAMs were selected “to reflect a reasonable range of modeling choices and approaches that collectively reflect the current literature on the estimation of damages from CO₂ emissions.” This logic is blatantly flawed. Two of the IAMs do not reflect the “current literature” on a key aspect relating to the direct impact of CO₂ emissions on agricultural output, and the third only partially so. [EPA-HQ-OAR-2014-0827-1206-A1 p.19]

CO₂ fertilization is a known physical effect from increased carbon dioxide concentrations. By including the results of IAMs that do not include known processes that have a significant impact on the end product must disqualify them from contributing to the final result. The inclusion of results that are known a priori to be wrong can only contribute to producing a less accurate answer. Results should only be included when they attempt to represent known processes, not when they leave those processes out entirely. [EPA-HQ-OAR-2014-0827-1206-A1 p.19]

The justification from the IWG (2015) that “[h]owever, with high confidence the IPCC (2013) stated in its Fifth Assessment Report (AR5) that ‘[b]ased on many studies covering a wide range of regions and crops, negative impacts of climate change on crop yields have been more common than positive ones.’” is completely irrelevant as CO₂ fertilization is an impact that is apart from “climate change.” And further, the IAMs do (explicitly in the case of FUND and DICE or implicitly in the case of PAGE) include damage functions related to the climate change impacts on agriculture. So not only is the IWG justification irrelevant, it is inaccurate as well. The impact of CO₂ fertilization on agricultural output and its impact on lowering the SCC must be considered. [EPA-HQ-OAR-2014-0827-1206-A1 p.19]
The Misleading Disconnect Between Climate Change and the Social Cost of Carbon in the Integrated Assessment Models

It is generally acknowledged, the results from IAMs are highly sensitive not only to the model input parameters but also to how the models have been developed and what processes they try to include. One prominent economist, Robert Pindyck of M.I.T. recently wrote (Pindyck, 2013) that the sensitivity of the IAMs to these factors renders them useless in a policymaking environment: [EPA-HQ-OAR-2014-0827-1206-A1 p.19]

Given all of the effort that has gone into developing and using IAMs, have they helped us resolve the wide disagreement over the size of the SCC? Is the U.S. government estimate of $21 per ton (or the updated estimate of $33 per ton) a reliable or otherwise useful number? What have these IAMs (and related models) told us? I will argue that the answer is very little. As I discuss below, the models are so deeply flawed as to be close to useless as tools for policy analysis. Worse yet, precision that is simply illusory, and can be highly misleading. [EPA-HQ-OAR-2014-0827-1206-A1 p.19]

…[A]n IAM-based analysis suggests a level of knowledge and precision that is nonexistent, and allows the modeler to obtain almost any desired result because key inputs can be chosen arbitrarily. [EPA-HQ-OAR-2014-0827-1206-A1 p.19]

Nevertheless, EPA has incorporated the IWG2013 determinations of the SCC into the cost/benefit analysis of this proposed regulation—ill-advisedly so in our opinion. Consider the following: the social cost of carbon should reflect the relative impact on future society that human-induced climate change from greenhouse gas emissions would impose. In this way, we can decide how much (if at all) we are willing to pay currently to reduce the costs to future society. It would seem logical that we would probably be more willing to sacrifice more now if we knew that future society would be impoverished and suffer from extreme climate change than we would be willing to sacrifice if we knew that future society would be very well off and be subject to more moderate climate change. We would expect that the value of the social cost of carbon would reflect the difference between these two hypothetical future worlds—the SCC should be far greater in an impoverished future facing a high degree of climate change than an affluent future with less climate change. [EPA-HQ-OAR-2014-0827-1206-A1 p.19-20]

But if you thought this, you would be wrong. [EPA-HQ-OAR-2014-0827-1206-A1 p.20]

Instead, the IAMs as run by the IWG2013 (and reflected in the July 2015 update) produce nearly the opposite result—the SCC is far lower in the less affluent/high climate change future than it is in the more affluent/low climate change future. Such a result is not only counterintuitive but misleading. [EPA-HQ-OAR-2014-0827-1206-A1 p.20]

We illustrate this illogical and impractical result using the DICE 2010 model (hereafter just DICE) used by the IWG2013 (although the PAGE and the FUND models generally show the same behavior). The DICE model was installed and run at the Heritage Foundation by Kevin Dayaratna and David Kreutzer using the same model set up and emissions scenarios as prescribed by the IWG2013. The projections of future temperature change (and sea level rise, used later in the Comment) were graciously provided to us by the Heritage Foundation. [EPA-HQ-OAR-2014-0827-1206-A1 p.20]

The figure below shows the projections of the future change in the earth’s average surface temperature for the years 2000-2300 produced by DICE from the five emissions scenarios employed by the IWG2013. The numerical values on the right-hand side of the illustration are the values for the social cost of carbon associated with the temperature change resulting from each emissions scenario (the SCC...
is reported for the year 2020 using constant $2007 and assuming a 3% discount rate—numbers taken directly from Table A3 of the IWG2013 report). The temperature change can be considered a good proxy for the magnitude of the overall climate change impacts. [EPA-HQ-OAR-2014-0827-1206-A1 p.20]

[Figure, 'Temperature Change (DICE)', can be found on p.21 of docket number EPA-HQ-OAR-2014-0827-1206-A1]

Notice in the figure above that the value for the SCC shows little (if any) correspondence to the magnitude of climate change. The MERGE scenario produces the greatest climate change and yet has the smallest SCC associated with it. The “5th Scenario” is a scenario that attempts to keep the effective concentration of atmospheric carbon dioxide at 550 ppm (far lower than the other scenarios) has a SCC that is more than 20% greater than the MERGE scenario. The global temperature change by the year 2300 in the MERGE scenario is 9°C while in the “5th Scenario” it is only 3°C. The highest SCC is from the IMAGE scenario—a scenario with a mid-range climate change. All of this makes absolutely no logical sense—and confuses the user. [EPA-HQ-OAR-2014-0827-1206-A1 p.21]

If the SCC bears little correspondence to the magnitude of future human-caused climate change, than what does it represent? [EPA-HQ-OAR-2014-0827-1206-A1 p.21]

The figure below provides some insight. [EPA-HQ-OAR-2014-0827-1206-A1 p.21]

[Figure, 'Global GDP (DICE)', can be found on p.22 of docket number EPA-HQ-OAR-2014-0827-1206-A1]

When comparing the future GDP to the SCC, we see, generally, that the scenarios with the higher future GDP (most affluent future society) have the higher SCC values, while the futures with lower GDP (less affluent society) have, generally, lower SCC values. [EPA-HQ-OAR-2014-0827-1206-A1 p.22]

Combining the results from the two figures above thus illustrates the absurdities in the IWG’s use of the DICE model. The scenario with the richest future society and a modest amount of climate change (IMAGE) has the highest value of the SCC associated with it, while the scenario with the poorest future society and the greatest degree of climate change (MERGE) has the lowest value of the SCC. A logical, thinking person would assume the opposite. [EPA-HQ-OAR-2014-0827-1206-A1 p.22]

While we only directly analyzed output data from the DICE model, by comparing Tables 2 and Tables 3 from the IWG2010 report, it can be ascertained that the FUND and the PAGE models behave in a similar fashion. [EPA-HQ-OAR-2014-0827-1206-A1 p.22]

This counterintuitive result occurs because the damage functions in the IAMs produce output in terms of a percentage decline in the GDP—which is then translated into a dollar amount (which is divided by the total carbon emissions) to produce the SCC. Thus, even a small climate change-induced percentage decline in a high GDP future yields greater dollar damages (i.e., higher SCC) than a much greater climate change-induced GDP percentage decline in a low GDP future. [EPA-HQ-OAR-2014-0827-1206-A1 p.22]

Who in their right mind would want to spend (sacrifice) more today to help our rich decedents deal with a lesser degree of climate change than would want to spend (sacrifice) today to help our relatively less-well-off decedents deal with a greater degree of climate change? No one. Yet that is what the SCC
would lead you to believe and that is what the SCC implies when it is incorporated into federal
cost/benefit analyses. [EPA-HQ-OAR-2014-0827-1206-A1 p.22]

In principle, the way to handle this situation is by allowing the discount rate to change over time. In
other words, the richer we think people will be in the future (say the year 2100), the higher the discount
rate we should apply to damages (measured in 2100 dollars) they suffer from climate change, in order to
decide how much we should be prepared to sacrifice today on their behalf. [EPA-HQ-OAR-2014-0827-
1206-A1 p.23]

Until (if ever) the current situation is properly rectified, the IWG’s determination of the SCC is not fit
for use in the federal regulatory process, such as this EPA regulation, as it is deceitful and misleading.

Sea Level Rise

The sea level rise module in the DICE model used by the IWG2013/2015 produces future sea level rise
values that far exceed mainstream projections and are unsupported by the best available science. The sea
level rise projections from more than half of the scenarios (IMAGE, MERGE, MiniCAM) exceed even
the highest end of the projected sea level rise by the year 2300 as reported in the Fifth Assessment
Report (AR5) of the Intergovernmental Panel on Climate Change (see figure). [EPA-HQ-OAR-2014-
0827-1206-A1 p.23]

[Figure, 'Sea Level Rise (DICE)', can be found on p.23 of docket number EPA-HQ-OAR-2014-0827-
1206-A1]

How the sea level rise module in DICE was constructed is inaccurately characterized by the IWG2013
(and misleads the reader). The IWG2013 report describes the development of the DICE sea level rise
scenario as: [EPA-HQ-OAR-2014-0827-1206-A1 p.23]

“The parameters of the four components of the SLR module are calibrated to match consensus results

However, in IWG2013 footnote “6” the methodology is described this way (Nordhaus, 2010): [EPA-

“The methodology of the modeling is to use the estimates in the IPCC Fourth Assessment Report

“Using estimates” and “calibrating” are two completely different things. Calibration implies that the sea
level rise estimates produced by the DICE sea level module behave similarly to the IPCC sea level rise
projections and instills a sense of confidence in the casual reader that the DICE projections are in
accordance with IPCC projections. However this is not the case. Consequently, the reader is misled.

In fact, the DICE estimates are much higher than the IPCC estimates. This is even recognized by the

“The RICE [DICE] model projection is in the middle of the pack of alternative specifications of the
different Rahmstorf specifications. Table 1 shows the RICE, base Rahmstorf, and average Rahmstorf.
Note that in all cases, these are significantly above the IPCC projections in AR4."

That the DICE sea level rise projections are far above the mainstream estimated can be further evidenced by comparing them with the results produced by the IWG-accepted MAGICC modelling tool (in part developed by the EPA and available from http://www.cgd.ucar.edu/cas/wigley/magicc/). Using the MESSAGE scenario as an example, the sea level rise estimate produced by MAGICC for the year 2300 is 1.28 meters—a value that is less than 40% of the average value of 3.32 meters produced by the DICE model when running the same scenario (see figure below). 

The justification given for the high sea level rise projections in the DICE model (Nordhaus, 2010) is that they well-match the results of a “semi-empirical” methodology employed by Rahmstorf (2007) and Vermeer and Rahmstorf (2009). However, subsequent science has proven the “semi-empirical” approach to projecting future sea level rise unreliable. For example, Gregory et al. (2012) examined the assumption used in the “semi-empirical” methods and found them to be unsubstantiated. Gregory et al. (2012) specifically refer to the results of Rahmstorf (2007) and Vermeer and Rahmstorf (2009).

The implication of our closure of the [global mean sea level rise, GMSLR] budget is that a relationship between global climate change and the rate of GMSLR is weak or absent in the past. The lack of a strong relationship is consistent with the evidence from the tide-gauge datasets, whose authors find acceleration of GMSLR during the 20th century to be either insignificant or small. It also calls into question the basis of the semi-empirical methods for projecting GMSLR, which depend on calibrating a relationship between global climate change or radiative forcing and the rate of GMSLR from observational data (Rahmstorf, 2007; Vermeer and Rahmstorf, 2009; Jevrejeva et al., 2010).

In light of these findings, the justification for the very high sea level rise projections (generally exceeding those of the IPCC AR5 and far greater than the IWG-accepted MAGICC results) produced by the DICE model is called into question and can no longer be substantiated. Given the strong relationship between sea level rise and future damage built into the DICE model, there can be no doubt that the SCC estimates from the DICE model are higher than the best science would allow and consequently, should not be accepted by the IWG as a reliable estimate of the social cost of carbon.

And here again, the IWG (2015) admits that these sea level rise estimates are an outlier on the high end, yet retains them in their analysis by claiming that they were interested in representing a “range” of possible outcomes. But, even the IWG (2015) admits that the IPCC AR5 assigned “a low confidence in projections based on such [semi-empirical] methods.” It is internally inconsistent to claim the IPCC as an authority for limiting the range of possibilities explored by the IAMs (which it did in the case of
equilibrium climate sensitivity) and then go outside the IPCC to justify including a wildly high estimate of sea level rise. Such inconsistencies characterize the IWG response to comments and weaken confidence in them. We thereby suggest that our comments should be considered independently from the IWG (2015) response. [EPA-HQ-OAR-2014-0827-1206-A1 p.26]

We did not investigate the sea level rise projections from the FUND or the PAGE model, but suggest that such an analysis must be carried out prior to extending any confidence in the values of the SCC resulting from those models—confidence that we demonstrate cannot be assigned to the DICE SCC determinations. [EPA-HQ-OAR-2014-0827-1206-A1 p.26]

High Social Cost of Carbon Estimates

A few papers have appeared in the recent scientific literature that have argued that the SCC should be considerably higher than that determined by the IWG. However, these papers suffer from serious flaws. [EPA-HQ-OAR-2014-0827-1206-A1 p.26]

For example, Van den Bergh and Botzen (2014) purport to make a “conservative” estimate of the SCC that is nearly four times larger than the central estimate made by the IWG. This estimate suffers from the many of the issues described previously—a low discount rate, high climate sensitivity, and little to no positive benefits from agriculture. By including all sorts of imagined bad climate outcomes—with high monetary damages—and being largely dismissive of positive impacts, high SCC values are readily created by the authors. [EPA-HQ-OAR-2014-0827-1206-A1 p.26]

Another recent analysis which arrived at an estimate of the social cost of carbon that was considerably higher than those made by the IWG was conducted by Moore and Diaz (2015). However, a careful examination shows that the assumptions made and methodologies employed therein produce a non-robust and ultimately unreliable result (McKitrick, 2015). Applying a better and more thorough methodology leads to results which are virtually opposite to those initially reported by Moore and Diaz (2015)—one in which the social cost of carbon is quite low and perhaps even positive. [EPA-HQ-OAR-2014-0827-1206-A1 p.26]

According to McKitrick (2015), the major underlying flaw in the Moore and Diaz paper is the reliance on the results of Dell et al. (2012) in which a warming climate was linked to economic declines in both rich and poor countries. Using a more up-to-date dataset, McKitrick shows that the negative economic linkage to a warming climate is statistically insignificant and “not a robust basis for a policy assertion.” [EPA-HQ-OAR-2014-0827-1206-A1 p.26]

Furthermore, McKitrick (2015) shows that if a the more standard methodology is applied, where the temperature changes are really-weighted rather than weighted by country-level population, the relationship between economic growth and temperature change reverses for rich countries and becomes statistically significant. According to McKitrick (2015), “each degree of warming significantly increases the annual income growth rate in rich countries by over 2 percentage points,” while in poor countries, the relationship “is statistically insignificant.” In conclusion, McKitrick (2015) finds: [EPA-HQ-OAR-2014-0827-1206-A1 p.27]

The fact that the relevant poor-country coefficients are statistically insignificant implies they should not have been relied upon in Moore and Diaz (2015). And since the rich country coefficient corresponding to the [integrated assessment model] IAM structure is positive and significant, Moore and Diaz (2015) should actually have reported an acceleration of economic growth in rich countries associated with rising temperatures and a correspondingly reduced SCC. Also, since the rich countries begin with a
larger GDP it is also likely that the overall global effect of warming on income growth would be positive, even applying the poor country coefficient. In any case the computations in Moore and Diaz (2015) are uninformative since they used coefficients from DJO based on an incomplete sample and a definition of temperature incompatible with their IAM. [EPA-HQ-OAR-2014-0827-1206-A1 p.27]

Bottom line is that the Moore and Diaz (2015) high SCC estimates as well as the Dell et al. (2012) results upon which they were based, do not stand up under careful re-analysis. In fact, when assessed properly, they produce a low SCC estimate, in support of our overall analysis. [EPA-HQ-OAR-2014-0827-1206-A1 p.27]

And finally, Havranek et al. (2015) reviewed the collective literature on the social cost of carbon estimates (809 estimates across 101 studies) and concluded that it suffers from selective reporting—with negative values (i.e., social benefits of carbon dioxide emissions) being largely downplayed or unreported. According to Havranek et al.: [EPA-HQ-OAR-2014-0827-1206-A1 p.27]

Our results are consistent with a situation when some authors of primary studies report preferentially estimates for which the 95% confidence interval excludes small values of the SCC, which creates an upward bias in the literature. In other words, we observe that small estimates of the SCC are associated with less uncertainty (expressed as the approximate standard error used to compute the lower bound of the confidence interval) than large estimates. The finding suggests that some small estimates with large uncertainty—that is, not ruling out negative values of the SCC—might be selectively omitted from the literature. Our results also indicate that selective reporting tends to be stronger in studies published in peer-reviewed journals than in unpublished manuscripts. [EPA-HQ-OAR-2014-0827-1206-A1 p.27]

After applying a correction for the selective reporting, Havranek et al., conclude that the upper bound for the SCC from the collective literature is close to the mean value determined by the IWG—an indication that the IWG mean value is inflated: [EPA-HQ-OAR-2014-0827-1206-A1 p.27]

The result is USD 39 (= 134 · 1.07/3.67), which suggests that the upper boundary for mean estimates reported in the literature and corrected for selective reporting is remarkably close to the central estimate of 40 used by the US Government’s Interagency Working Group on Social Cost of Carbon (IWGSCC, 2015). [EPA-HQ-OAR-2014-0827-1206-A1 p.27-28]

Further, and rather importantly, Havranek et al., note that selective reporting likely plagues other aspects of the climate change literature, further leading to an inflated SCC value as produced by the IWG: [EPA-HQ-OAR-2014-0827-1206-A1 p.28]

Moreover, other studies suggest that some of the parameters used for the calibration of integrated assessment models, such as climate sensitivity or the elasticity of intertemporal substitution in consumption, are likely to be exaggerated themselves because of selective reporting, which might further contribute to the exaggeration of the SCC reported in individual studies—including the results of the Interagency Working Group. [EPA-HQ-OAR-2014-0827-1206-A1 p.28]

Do the EPA and the IWG understand that they are contributing additional material and evidence that the Obama Administration is involved in clear and present scientific and economic mendacity? These new papers provide additional evidence. [EPA-HQ-OAR-2014-0827-1206-A1 p.28]

Conclusion on Social Cost of Carbon
The social cost of carbon as determined by the Interagency Working Group in their May 2013 Technical Support Document (updated in November 2013 and July 2015) and used by the EPA in its proposed Greenhouse Gas Emissions and Fuel Efficiency Standards for Medium- and Heavy-Duty Engines and Vehicles—Phase 2 is unsupported by the robust scientific literature, fraught with uncertainty, illogical, and thus completely unsuitable and inappropriate for federal rulemaking. As such, use of the SCC in cost/benefit analyses in this proposed rulemaking should be suspended and not revisited until the above-mentioned weaknesses are fully rectified. [EPA-HQ-OAR-2014-0827-1206-A1 p.28]

Given the uncertainties that are involved, the EPA should cease the use of the SCC in this and all regulatory analyses. [EPA-HQ-OAR-2014-0827-1206-A1 p.28]

---

Response:

The comments regarding the SC-CO$_2$ estimates and general application in a rulemaking context mirror those submitted to the Office of Management and Budget’s separate comment solicitation on the SC-CO$_2$ (78 FR 70586; November 26, 2013). As a member of the interagency working group (IWG) on SC-CO$_2$, EPA has carefully examined and evaluated comments submitted to OMB’s separate solicitation. EPA has also carefully examined and evaluated all comments received regarding SC-CO$_2$ through this rulemaking process and determined that the IWG responses to the comments on the OMB solicitation address this commenter’s statements about SC-CO$_2$ (use of global values, treatment of equilibrium climate sensitivity, CO$_2$ fertilization and sea level rise in the models, the validity of integrated assessment models used to develop the estimates) and use of the estimates in this RIA. Specifically, EPA concurs with the IWG’s response to these comments and hereby incorporates them by reference.

Furthermore, EPA disagrees with the commenter’s assertion that the OMB Response to Comments on SC-CO$_2$ does not address the commenter’s statements, which were submitted both to this rulemaking and to OMB’s separate comment solicitation on SC-CO$_2$ (78 FR 70586; November 26, 2013). The commenter has not provided evidence supporting their assertion they have not received a response that addresses their comments; the remainder of this response elaborates on this point.

Also, EPA and other members of the U.S. Interagency Working Group on the SC-CO$_2$ are seeking independent expert advice on technical opportunities to update the SC-CO$_2$ estimates from the National Academies of Sciences, Engineering, and Medicine. A committee convened by the Academies is reviewing the state of the science on estimating the SC-CO$_2$, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward. The Academies’ review will focus on the SC-CO$_2$ methodology, but recommendations on how to update many of the underlying modeling assumptions will also likely pertain to the SC-CH$_4$ and SC-N$_2$O estimates. Going forward, the EPA will evaluate its approach to estimating the SC-CO$_2$, SC-CH$_4$, and SC-N$_2$O based upon any feedback received from the Academies’ panel.

After careful evaluation of the full range of comments and associated technical issues described in this RTC, EPA has determined that it will continue to use the SC-GHG estimates in the final rulemaking analysis. In particular, the current SC-CO$_2$ estimates and the Marten et al. SC-CH$_4$ and SC-N$_2$O estimates represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental emissions changes into regulatory analysis. Therefore, EPA has presented these estimates in this rulemaking. EPA will continue to consider these comments and will share the recommendations with the IWG as it moves forward with the Academies process.

The remainder of this section elaborates on the points raised by the commenter in the context of this rulemaking.

---

Global and domestic values

See response to “Mannix, Brian,” in RTC Section 11.8.

Equilibrium Climate Sensitivity

The EPA strongly disagrees with the commenter’s assertion that the Interagency Working Group on the social cost of carbon (IWG) does not give credence to mainstream science, in particular for studies on equilibrium climate sensitivity (ECS). The EPA is aware that this is an active area of research and as stated in OMB’s Response to Comments on the SC-CO$_2$, the IWG remains committed to updating the SC-CO$_2$ estimates to incorporate new scientific information and accurately reflect the current state of scientific uncertainty regarding the ECS. While EPA acknowledges that the ECS distribution, along with other climate modeling inputs to the SC-CO$_2$ calculation, should be updated periodically to reflect the latest scientific consensus, care must be exercised in selecting an appropriate range of estimates for this important parameter. Many studies estimating climate sensitivity have been published, based on a variety of approaches (instrumental record, paleoclimate observations, models, etc.). These individual studies report differing values and provide different information. Picking a single study from the high or low end of the range, or even in the middle, will exclude relevant information. A valid representation of uncertainty regarding climate sensitivity should be obtained from a synthesis exercise such as that done by the IPCC that considers the full range of relevant studies.

As noted in the SC-CO$_2$ TSDs, the EPA and the other IWG members are committed to periodic updates in the estimates to reflect ongoing developments in our understanding of the science and economics of climate change. Moreover, the EPA has determined that the current SC-CO$_2$ estimates continue to represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental CO$_2$ emissions changes into regulatory analyses. As previously noted, the EPA and other members of the U.S. Interagency Working Group on the social cost of carbon are seeking independent expert advice on technical opportunities to update these estimates from the National Academies of Sciences, Engineering, and Medicine.

To date, the Committee has released an interim report, which recommended against doing a near term update of the SC-CO$_2$ estimates. In particular, the Committee concluded that the “equilibrium climate sensitivity (ECS) is only one parameter affecting the social cost of carbon (SCC). Each of the three SCC integrated assessment models also embodies a different representation of the climate system and its underlying uncertainties, including relationships and parameters beyond the ECS. Therefore, updating the ECS alone within the current SCC framework may not significantly improve the estimates.” (PDF page 56).

The Committee elaborated:

---

219 EPA notes that the 2013 update was based on new versions of each IAM. The 2013 update did not revisit the 2010 modeling decisions with regards to the discount rate, reference case socioeconomic and emission scenarios, and equilibrium climate sensitivity distribution. Rather, improvements in the way damages are modeled are confined to those that have been incorporated into the latest versions of the models by the developers themselves and published in the peer-reviewed literature.

“…there would not be sufficient benefit of modifying the estimates to merit a near-term update that would be based on revising a specific parameter in the existing framework used by the IWG to reflect the most recent scientific consensus on how global mean temperature is, in equilibrium, affected by CO₂ emissions. Furthermore, the committee does not recommend changing the distributional form used to capture uncertainty in the equilibrium CO₂ emissions-temperature relationship. Rather than simply updating the distribution used for equilibrium climate sensitivity—the link that translates CO₂ emissions to global temperature change—in the current framework, the IWG could undertake efforts toward the adoption or development of a common representation of the relationship between CO₂ emissions and global mean surface temperature change, its uncertainty, and its profile over time” (page 12).

For future revisions, the Committee recommended the IWG move efforts towards a broader update of the climate system module consistent with the most recent, best available science, and also offered recommendations for how to enhance the discussion and presentation of uncertainty in the SC-CO₂ estimates. Specifically, the Committee recommended that “the IWG provide guidance in their technical support documents about how [SC-CO₂] uncertainty should be represented and discussed in individual regulatory impact analyses that use the [SC-CO₂]” and that the technical support document for each update of the estimates present a section discussing the uncertainty in the overall approach, in the models used, and uncertainty that may not be included in the estimates. At the time of this writing, the IWG is reviewing the interim report and considering the recommendations. The EPA looks forward to working with the IWG to respond to the recommendations and will continue to follow IWG guidance on SC-CO₂.

EPA also notes that at the time the 2013 SC-CO₂ update was released, the most authoritative statement about ECS appeared in the IPCC’s AR4. Since that time, the IPCC issued a Fifth Assessment Report that updated its discussion of the likely range of climate sensitivity compared to AR4. The new assessment reduced the low end of the assessed likely range (high confidence) from 2°C to 1.5°C, but retained the high end of the range at 4.5°C. Unlike in AR4, the new assessment refrained from indicating a central estimate of ECS. This assessment is based on a comprehensive review of the scientific literature and reflects improved understanding, the extended temperature record for the atmosphere and oceans, and new estimates of radiative forcing.

Several of the post-AR4 studies highlighted by the commenter were cited in the AR5 assessment. In particular, both Aldrin et al. (2012) and Otto et al. (2013) were cited in both Chapter 10 and Chapter 12 of the AR5 Working Group I assessment. Eight of the authors of Otto et al. (2013), including the lead author, were authors of Chapter 12 for AR5’s Working Group I and one was a lead author for the chapter. Hence it is clear that the IPCC considered Otto et al. (2013) in its synthesis of literature on the ECS. More broadly, the AR5 climate sensitivity distribution likely incorporates much of the literature identified by the commenters. EPA will continue to follow and evaluate the latest science on the ECS.

As discussed in Section I.A.2 of the Preamble, the 2009 Endangerment Finding, and in the OMB Response to Comments on SC-CO₂, among other resources, the links between CO₂ and temperature are established beyond question by laboratory measurements, physical theory, paleoclimate observations, instrumental observations, and observations of other planets. Climate change and its impacts, such as sea level rise, have been exhaustively documented, and synthesized internationally by the IPCC and domestically by the U.S. National Climate Assessment. Based on the wide acceptance of these conclusions in the scientific community, EPA believes that: (1) anthropogenic emissions of greenhouse gases are causing atmospheric levels of greenhouse gases in our atmosphere to rise to levels unprecedented in human history; (2) the accumulation of greenhouse gases in our atmosphere is exerting a warming effect on the global climate; (3) there are multiple lines of evidence, including increasing average global surface temperatures, rising ocean temperatures and sea levels, and shrinking ice in
glaciers, ice sheets, and the Arctic, all showing that climate change is occurring, and that the rate of climate change in the past few decades has been unusual in the context of the past 1000 years; (4) there is compelling evidence that anthropogenic emissions of greenhouse gases are the primary driver of recent observed increases in average global temperature; (5) atmospheric levels of most greenhouse gases are expected to continue to rise for the foreseeable future; and (6) risks and impacts to public health and welfare are expected to grow as climate change continues, and that climate change over this century is expected to be greater compared to observed climate change over the past century.

While there are inherent uncertainties associated with modeling climate systems over long time spans, the general circulation models (GCMs) upon which estimates of ECS and other climate science research are based have been extensively evaluated. For example, since 1989 the DOE has had a large program (The Program for Climate Model Diagnosis and Intercomparison) dedicated to evaluating these models.

The ECS parameter is a useful parameter for summarizing the strength of the climate system’s response to accumulating GHG concentrations in the atmosphere. However, it is influenced by many highly complex and uncertain natural processes, some of which adjust over very long periods of time. Therefore, persistent uncertainty about the ECS is not surprising. Furthermore, persistent uncertainty does not suggest an absence of useful information. However, EPA does not agree that progress has not been made in reducing this uncertainty. Over the last 30 years the scientific community has elucidated many aspects of the climate system’s response to GHGs accumulating in the atmosphere. While the AR5 "likely" range is slightly larger than that of AR4, the assessment presented greater confidence in the tails. AR5 found that climate sensitivity is very unlikely to be greater than 6°C, whereas AR4 stated that the "lack of strong constraints limiting high climate sensitivities prevents the specification of a 95th percentile bound." Similarly, while the AR5 and the IPCC’s (2001) Third Assessment Report (TAR) bounds look similar, the TAR bounds were presented as a range without estimated probabilities.

**Comments on CO₂ Fertilization and on Sea Level Rise**

The commenter has misconstrued the IWG’s response to comments (in the OMB RTC on SC- CO₂) on carbon fertilization, also referred to as CO₂ fertilization. The commenter (Michaels and Knappenberger) has referenced text that responded to conflicting public comments, which were submitted to OMB’s separate solicitation, about damage functions. In particular, these public comments “disagreed about whether the IAMs overestimate or underestimate CO₂ fertilization effects in the agriculture and forestry sectors” (OMB Response to Comments on SC-CO₂, page 9). The IWG response, which is only partially quoted by this commenter, acknowledged uncertainty about climate change impacts on agriculture and quoted the IPCC’s observation that findings from the peer-reviewed literature of negative impacts of climate change on crop yields are more common than positive impacts. Specifically, the IWG stated on page 10:

“As a result there is uncertainty as to the magnitude of these impacts and the role of interactions between changes in the climate and other factors, such as CO₂ fertilization, temperature, precipitation, ozone, pests, etc. Additionally, these effects are likely to vary widely across regions and crops. However, with high confidence the IPCC (2013) stated in its Fifth Assessment Report (AR5) that "[b]ased on many studies covering a wide range of regions and crops, negative impacts of climate change on crop yields have been more common than positive impacts."

---

The distinction that the commenter draws here between CO2 and "positive impacts" mentioned in this passage from AR5 include primarily studies from high-latitude regions but do not exclude the effects of CO2 fertilization. In fact, the IPCC explicitly states that there are "stimulatory effects on crop yields" associated with CO2 fertilization and correctly identifies CO2 fertilization as one of multiple factors that interact with changes in the climate.222

The commenter’s misinterpretation of the IWG response and AR5 passage notwithstanding, EPA disagrees with the commenter’s assertion that models that exclude “known processes” should be omitted. To date, the EPA and other members of the IWG have accepted the models as currently constituted, and omitted any damages or beneficial effects that the model developers themselves do not include. The EPA recognizes that none of the three IAMs fully incorporates all climate change impacts, either positive or negative. Some of the effects (e.g., damages related to agriculture broadly and CO2 fertilization specifically) are explicitly modeled in the damage functions of one or more of the current models (although the treatment may not be complete), and the model developers continue to update their models as new research becomes available. The IWG undertook the 2013 revision because of updates to the models, which include new or enhanced representation of certain impacts, such as sea level rise damages. In addition, some of the categories are currently speculative or cannot be incorporated into the damage function for lack of appropriate data. Using an ensemble of three different models was intended to, at least partially, address the fact that no single model includes all of the impacts. We recognize that there may be effects that none of the three selected models addresses (e.g., impacts from ocean acidification) or that are likely not fully captured (e.g. catastrophic effects). However, EPA strongly disagrees with the commenter that models that do not include all known processes should therefore be omitted. The science underlying the assessment and valuation of climate change impacts is constantly evolving. In 2007 the Ninth Circuit Court remanded a CAFE fuel economy rule to DOT for failing to monetize the benefits of the CO2 emissions reductions in its regulatory impact analysis, noting that “the value of carbon emissions reduction is certainly not zero.”223 As discussed in this document and in the RIA, EPA has determined that the current estimates continue to represent the best scientific information on the impacts of climate change available in a form appropriate for incorporating the damages from incremental CO2 emissions changes into regulatory analyses.

EPA acknowledges the comments on the sea level rise projections in DICE and the Agency recognizes that sea level rise projections are an area of ongoing research. One key issue involves projections of melt from the Greenland and West Antarctic ice sheets. The IPCC AR5 report notes there is a possibility of sea level rise "substantially above" their best estimate of a likely range because of uncertainties regarding the response of the Antarctic ice sheet (AR5 Working Group I, Chapter 13). In AR5 the IPCC also discusses semi-empirical methods, stating a low confidence in projections based on such methods, which calibrate a mathematical model against observations rather than projecting individual processes. However, the IPCC did not entirely discount these methods. Further supporting the use of semi-empirical methods, the U.S. National Climate Assessment uses an average of the high end of semi-empirical projections in order to define their "Intermediate-High" Scenario (Parris et al., 2012). Additionally, recent NRC assessments have also produced higher sea level rise projections than the IPCC: the NRC Sea Level Rise assessment projects a global sea level rise of 0.5 to 1.4 meters (1.6 to 4.6 feet) by 2100, the NRC National Security Implications assessment suggests that “the Department of the

222 The paragraph in AR5 that elaborates on the observation about the frequency of studies finding negative impacts compared to positive impacts states, “CO2 has stimulatory effects on crop yields in most cases, and elevated tropospheric ozone has damaging effects. Interactions among CO2 and ozone, mean temperature, extremes, water, and nitrogen are non-linear and difficult to predict (medium confidence)” (WGII, AR5 Part A, pg 47).

Navy should expect roughly 0.4 to 2 meters [1.3 to 6.6 feet] global average sea-level rise by 2100,"34 and the NRC Climate Stabilization Targets assessment states that an increase of 3°C will lead to a sea level rise of 0.5 to 1 meter (1.6 to 3.3 feet) by 2100. Therefore, it is reasonable for one out of three models used by the IWG to include some reliance upon semi-empirical methods.

EPA continues to find this response, which was also presented by the IWG in the OMB Response to Comments on SC-CO$_2$, to be valid and relevant, and therefore disagrees with the commenter’s suggestion that EPA disregard it. In particular, the EPA disagrees with the commenter’s suggestion that the IWG has inconsistently used the IPCC to justify methodological decisions, such as the development of the ECS distribution, and the treatment of sea level rise in DICE. The IPCC is an authoritative assessment but it is not the only assessment of the peer-reviewed literature. The fact that the IPCC AR5 did not entirely discount semi-empirical methods and the fact that both the highly credible and extensively reviewed U.S. National Climate Assessment and assessments from the National Research Council projected higher rates of sea level rise than did the IPCC led EPA and other members of the IWG to conclude that this approach is reasonable for one of the three models.224

Moreover, the commenter has not demonstrated why or how this response lacks validity, particularly in light of the fact that EPA and the other members of the IWG are seeking independent expert advice on technical opportunities to update the SC-CO$_2$ estimates from the National Academies of Sciences, Engineering, and Medicine. EPA is aware that more sophisticated yet still relatively simplified climate models, such as MAGICC, could be used to replace the highly simplified climate science components of the three IAMs. However, given the range of climate models available and the technical issues associated with such a change, replacing the climate modules or other structural features of the IAMs requires additional investigation before it can be applied to SC-CO$_2$ estimation. A committee convened by the Academies is reviewing the state of the science on estimating the SC-CO$_2$, and will provide expert, independent advice on the merits of different technical approaches for modeling and highlight research priorities going forward.

Integrated Assessment Models Used to Estimate the SC-CO$_2$

EPA strongly disagrees that the estimates are “deceitful and misleading.” The SC-CO$_2$ TSDs fully document the methodology used to develop the estimates and the considerations that led the IWG to adopt this methodology. EPA acknowledges uncertainty in the SC-CO$_2$ estimates but disagrees that the uncertainty is so great as to undermine use of the SC-CO$_2$ estimates in regulatory impact analysis. The uncertainty in the SC-CO$_2$ estimates is fully acknowledged and comprehensively discussed in the TSDs and supporting academic literature. As noted in the SC-CO$_2$ TSDs, the EPA and the other IWG members are committed to periodic updates in the estimates to reflect ongoing developments in our understanding of the science and economics of climate change, including the treatment of uncertainty.

Regarding the models, DICE, FUND, and PAGE are the most widely used and widely cited models in the economic literature that link physical impacts to economic damages for the purposes of estimating the SCC. As stated in the 2010 TSD:

> These models are frequently cited in the peer-reviewed literature and used in the IPCC assessment. … These models are useful because they combine climate processes, economic

---

224 As stated in the 2014 National Climate Assessment, page 3, the NCA “draws from a large body of scientific, peer-reviewed research, as well as a number of other publicly available sources” that have been “carefully reviewed…to ensure a reliable assessment of the state of scientific understanding.” See http://nca2014.globalchange.gov/downloads.
growth, and feedbacks between the climate and the global economy into a single modeling framework. … Other IAMs may better reflect the complexity of the science in their modeling frameworks but do not link physical impacts to economic damages.

In addition, the National Academies of Science (NAS) identified these three models as "the most widely used impact assessment models" in a 2010 report (NAS, 2010). Furthermore, in a comprehensive literature review and meta-analysis conducted in 2008, the vast majority of the independent impact estimates that appeared in the peer-reviewed literature were derived from FUND, DICE, or PAGE (Tol, 2008).

While the development of the DICE, FUND and PAGE models necessarily involved assumptions and judgments on the part of the modelers, the damage functions are not simply arbitrary representations of the modelers’ opinions about climate damages. Rather they are based on a review by the modelers of the currently available literature on the effects of climate change on society. The conclusions that the modelers draw from the literature, and the bases for these conclusions are documented, and all three models are continually updated as new information becomes available. While EPA recognizes that there are limitations with these models, including some of those discussed in Pindyck (2013), IAMs nonetheless provide valuable information for regulatory impact analysis. In a recent article in the peer-reviewed literature, Weyant (2014) addressed this issue as follows:

While Pindyck’s observations about the empirical weaknesses of IAMs or calculations of the SCC are worthy of careful study, the conclusion that IAMs are therefore useless fundamentally misconceives the enterprise. IAMs and the [SC-CO$_2$] are conceptual frameworks for dealing with highly complex, non-linear, dynamic, and uncertain systems. The human mind is incapable of solving all the equations simultaneously, and modeling allows making "If…, then…" analyses of the impacts of different factors. The models have provided important insights into many aspects of climate-change policy.

EPA has thus determined that it was appropriate for the IWG to base the SC-CO$_2$ estimates on the DICE, FUND and PAGE models. Moving forward, EPA will continue to follow and evaluate the latest peer reviewed literature applying IAMs. As previously noted, EPA and all of the other IWG members will seek external expert advice on the technical merits and challenges of using additional models (e.g., CRED, ENVISAGE) to estimate the SC-CO$_2$ and/or removing existing models from the ensemble (DICE, FUND, and PAGE) used to estimate the SC-CO$_2$.

Regarding potential inconsistencies between scenarios and IAMs, given the nature of estimating the SC-CO$_2$ and available data/resources, a full harmonization along all possible dimensions of the three IAMs used to estimate the SC-CO$_2$ with the four models used to develop the scenarios was not possible. Therefore, the IWG chose to harmonize the models with respect to the scenario variables to which SC-CO$_2$ estimates are most sensitive (GDP, population, and emissions) using common techniques in the literature. The scenarios used were developed by highly respected international modeling groups and published in the peer-reviewed literature. In terms of potential inconsistencies across scenario variables past 2100, an effort was made to account for some basic correlations among scenario variables in the post-2100 extrapolation. For example, extrapolations were based on GDP per capita growth, which implicitly correlates population and GDP growth, rather than GDP levels or growth alone. Similarly, extrapolations were based on CO$_2$ emissions intensity with respect to GDP, which correlates emissions and GDP growth, rather than CO$_2$ emissions levels or growth alone.

Consistent with historical observations, it is expected that growth rates of rapidly developing economies will exceed those of already developed economies in the near term. Scenarios with projections of global economic growth that exceed recent trends in developed economies are consistent with this expectation.
The chosen scenarios capture a wide range of potential future states of the world, but were not intended to represent a comprehensive accounting of the full range of uncertainty, and therefore it is possible that future outcomes will fall outside of this range. EPA and the members of the IWG have acknowledged that the projection of the scenarios beyond 2100 has greater uncertainty than shorter-term projections and will continue to monitor the literature, including the development of extended RCP/SSP scenarios, for ways to improve the estimated trajectories and improve internal consistency.

11.8 Monetized Non-GHG Health Impacts

Organization: BYD Motors

The current version of the plan will have real benefits for public health and will provide total cost of ownership benefits for fleet operators over the life of the vehicles. [EPA-HQ-OAR-2014-0827-1182-A1 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.227.]]

Response:

We agree that the rulemaking will have real benefits for the public and have demonstrated these benefits in the regulatory impact analysis that accompanies this rulemaking.

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Scope of costs and benefits

The NPRM requests comment on whether any costs or benefits are omitted from the analysis. CARB staff supports the inclusion of all quantifiable impacts of reductions in GHG and non-GHG pollutants. Specifically, CARB staff suggests the inclusion of ecosystem benefits from reduced non-GHG pollutants including those to crops as outlined in Murphy et al. (1999). Changes in fugitive emissions from altered driving patterns on paved roads may also impact agriculture and ecosystem health. These impacts should be included in the analysis to the extent that they can be quantified.99 [EPA-HQ-OAR-2014-0827-1265-A1 p.182]

Comment on Topic Where NPRM Requests Comment

Comment – Economic value of reduction in criteria pollutants

The NPRM requests comment on the economic valuation of reductions in criteria pollutants resulting from the proposed rulemaking. CARB staff supports the inclusion of criteria pollutant emission reductions as well as consideration of the impacts on toxic air contaminants such as diesel PM. CARB staff also suggests the impact of local pollutants be based on source-specific estimates of marginal damage.86 CARB staff supports continued full-scale air quality modeling for the final rulemaking to capture local variability. [EPA-HQ-OAR-2014-0827-1265-A1 p.186]
Response:

EPA agrees with the commenter that the analysis would benefit from the full inclusion of all quantifyable impacts of reductions in GHG and non-GHG pollutants. EPA endeavors to include all of the human health and environmental impacts that can be quantified and monetized. However, the full complement of human health and welfare effects associated with PM, ozone, other criteria pollutants, and toxic air pollutants remain unquantified because of current limitations in methods or available data. We have not quantified a number of known or suspected health effects linked with ozone, PM, and other criteria pollutants for which appropriate health impact functions are not available or which do not provide easily interpretable outcomes (e.g., changes in heart rate variability). Regarding diesel PM, a toxic air pollutant, we do not estimate the change in health risk associated with reductions in diesel PM based on current limitations in methods and available data. However, we capture benefits related to reductions in diesel PM to the extent that diesel PM is included in measured PM$_{2.5}$. Additionally, we are unable to quantify a number of known welfare effects, including reduced crop damage, reduced acid and particulate deposition damage to cultural monuments and other materials, and environmental benefits due to reductions of impacts of eutrophication in coastal areas. As a result, the health benefits quantified in this section are likely underestimates of the total benefits attributable to the standards. Please refer to Appendix 8A (and Table 8A-2) for a full description of the health and welfare impacts EPA is currently able to quantify.

EPA had planned on including PM- and ozone-related health benefits based on full-scale photochemical modeling in its analysis for the FRM. However, as described in Chapter 8.6 of the RIA, we have not included the results from the primary analysis because, out of necessity, the air quality modeling was based on emissions inventories that reflected the form of the standards as they were proposed, not finalized (air quality modeling results are presented in Appendix 6A). The length of time needed to prepare the inventories and run the air quality model required EPA to make air quality modeling input decisions early in the analytical process, and therefore made it impossible to base the health impacts analysis on the emissions changes associated with the final rulemaking.

The chief limitation when using air quality inventories based on emissions from the proposal is that they can diverge from the estimated emissions of the final rulemaking. How much the emissions might diverge and how that difference would impact the air quality modeling and health benefit results is difficult to anticipate. For the FRM, EPA concluded that when comparing the proposal and final rule inventories, the differences were enough to justify moving the typical Calendar Year (CY) benefits analysis (based on air quality modeling) from the primary estimate of costs and benefits to a supplemental analysis presented in Appendix 8A. While we believe this supplemental analysis is still illustrative of the standard’s potential benefits, EPA has instead chosen to characterize the CY benefits in the primary analysis in a manner consistent with the Model Year (MY) lifetime analysis. That is, we

See Chapter 5 of the RIA for a presentation and discussion of the differences between the proposal inventories used to conduct the air quality modeling and the final rule inventories.
apply PM-related “benefits per-ton” values to the CY final rule emission reductions to estimate the PM-related benefits of the final rule.

**Organization:** Fuller, Tony

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 149.]

Also I was thinking given the larger role the Federal government has been taking in healthcare and the costs associated with it, the monetary savings for the government alone should be a factor that should be considered.

**Response:**

EPA agrees that avoided health care costs from improvements in air quality should be accounted for in our rulemaking analyses. We account for criteria pollutant-related health improvement benefits in our regulatory impact analysis that supports this rulemaking.

### 11.9 Energy Security Impacts

**Organization:** Achates Power, et al.

The rulemaking has the potential to secure an even safer future by saving up to 200,000 more barrels of oil per day by 2035.¹ [EPA-HQ-OAR-2014-0827-1762-A2 p.2]

---

**Organization:** California Air Resources Board (CARB)

**Comment on Topic Where NPRM Requests Comment**

**Comment – Energy security analysis**

The NPRM requests comment on the estimation of energy security benefits of the proposed rulemaking. CARB staff supports the estimation of energy security benefits and suggests that the benefit to national defense be included in the estimation. The National Research Council (2013) estimates that inclusion of the impact to national defense could impact the estimation of energy security benefit by 25 percent. CARB staff recommends additional analysis to determine methodologies to incorporate the impact of national defense in the analysis of energy security.⁸⁷ [EPA-HQ-OAR-2014-0827-1265-A1 p.186]

**Organization:** Competitive Enterprise Institute et al.
Although the ostensible purpose of the rule is to reduce greenhouse gas (GHG) emissions and oil imports, the climate and energy-security benefits of the rule are entirely speculative and vanishingly small at best. [EPA-HQ-OAR-2014-0827-1251-A2 p.2]

II. The rule’s climate and energy security benefits are vanishingly small at best and completely unverifiable.

The proposed standards, which phase in during model-years 2021–2027, apply to four types of HDVs: (1) combination tractors (semi-trucks), (2) trailers pulled by combination tractors, (2) heavy-duty pickups and vans, and (4) vocational trucks (a wide-ranging assortment of trucks and buses). The agencies estimate that the technologies needed to comply with the proposed standards will cost $25 billion but that the rule will generate $230 billion in net benefits over the lifetime of vehicles sold in the regulatory timeframe, including $170 billion in fuel savings. [EPA-HQ-OAR-2014-0827-1251-A2 p.5-6]

Although the ostensible objectives of the rule are to reduce GHG emissions and oil consumption, the climate and energy-security benefits, if any, are speculative and no one will actually experience them. [EPA-HQ-OAR-2014-0827-1251-A2 p.6]

Energy Security Impact The agencies argue that the “concentration” of global petroleum production in “potentially unstable” countries poses a significant energy-security risk to the U.S. economy. They worry that turmoil or conflict in those nations could cut global petroleum supply by as much as 10%, “leading to an unprecedented price shock.” They are also concerned that OPEC could use “monopoly power” to “restrict oil supply relative to demand.” [EPA-HQ-OAR-2014-0827-1251-A2 p.7]

While such risks are possible, their likelihood is small and diminishing. Despite ongoing warfare in Middle East, UN sanctions that cut Iran’s oil exports nearly in half, Russia’s invasion of Crimea, and continuing warfare in Ukraine, the price of crude oil is lower than at any time since February 2009. U.S. motorists enjoyed the lowest Labor Day gasoline prices in a decade. The decline in oil and gasoline prices, despite geopolitical tensions, is a testament to the ingenuity of U.S. producers, who have used directional drilling and hydraulic fracturing to increase domestic production every year since 2008. [EPA-HQ-OAR-2014-0827-1251-A2 p.8]

Rather than restrict output to raise prices, OPEC is following a “no production cuts” policy, with Saudi Arabia increasing output to a record 10.4 million barrels per day (MMBD) in the second quarter of 2015. Perhaps OPEC members simply don’t want to lose even more market share to North American producers. Or perhaps they want to drive oil prices below the U.S. fracking industry’s production costs. Whatever the case, the proposed rule would do nothing to diminish Russia and OPEC’s share of world oil production. [EPA-HQ-OAR-2014-0827-1251-A2 p.8]

Other policies would more effectively shift global production from Russia and OPEC to the United States and Canada. Those include repeal of the crude oil export ban, timely approval of major infrastructure projects such as the Keystone XL Pipeline, and allowing more oil and gas exploration in U.S. coastal waters and federal lands, such as the Alaska National Wildlife Refuge (ANWR). The White House recently declined to comment on an Energy Information Administration (EIA) study finding net economic benefits from oil exports, and the administration’s policies on Keystone and ANWR are counterproductive. [EPA-HQ-OAR-2014-0827-1251-A2 p.9]
NHTSA estimates its fuel economy standards will reduce U.S. oil imports by 0.16 MMBD in 2025, 0.37 MMBD in 2030, and 0.65 MMBD in 2040. So by 2040, the rule would avoid 10% of projected imports. [EPA-HQ-OAR-2014-0827-1251-A2 p.9]

[Table IX-23 can be found on p.9 of docket number EPA-HQ-OAR-2014-0827-1251-A2]

Imports as a share of total production declined from 60% in 2005,31 to 40% in 2012,32 to 27% in 2014.33 EIA expects the decline in import dependence to continue. The agency’s 2015 Annual Energy Outlook (AEO 2015) forecasts net U.S. oil and petroleum product imports in four cases. In the reference case, the net import share falls from 33% in 2013 to 17% in 2040.34 [EPA-HQ-OAR-2014-0827-1251-A2 p.9]

[Figure ES4 can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1251-A2]

If imports as a share of consumption fall to 17% in 2040, and the proposed rule cuts imports by 10%, it will reduce national consumption by 1.7%. Such a minor change would do little to ameliorate price shocks from major disruptions in global petroleum supply. [EPA-HQ-OAR-2014-0827-1251-A2 p.10]

16 80 FR 40465

17 U.S. Energy Information Administration, Under sanctions, Iran’s crude oil exports have nearly halved in three years, June 24, 2015, http://www.eia.gov/todayinenergy/detail.cfm?id=21792

Lifting the ban could increase U.S. petroleum exports by 5.7 million barrels per day by 2035 in EIA’s High Oil and Gas Resource Case if OPEC cuts output to raise crude oil prices. Charles Ebinger and Heather L. Greenley, Changing Markets: Economic Opportunities from Lifting the U.S. Ban on Crude Oil Exports, Policy Brief 14-02, Brookings Institution, September 2014, http://www.brookings.edu/~/media/research/files/reports/2014/09/09%208%20facts%20about%20crude%20oil%20production/crude%20oil%20exports%20web.pdf

Organization: Consumer Federation of America (CFA)

A number of other benefits round out the total. The largest component of this category is the national energy security benefits of reduced oil consumption and oil imports. Unlike past rulings that paid lip service to these benefits, EPA/NHTSA value the security benefits at a little over $11/barrel in 2020, rising to almost $18/barrel in 2040. [EPA-HQ-OAR-2014-0827-1336-A1 p.48]

Organization: Investor Network on Climate Risk

Lastly, strong standards will serve to mitigate the economic risks associated with our continuing dependence on oil as well as climate change. Strong standards would save an estimated 1.4 million barrels of oil per day by 2030.
In addition, climate change presents significant long-term risks to the global economy, and to investors across all asset classes. Strong standards will serve to mitigate that risk by providing significant GHG reductions; the standards we propose have the potential to save 270 million metric tons of GHG emissions annually by 2030.\footnote{NHTSA-2014-0132-0113-A1 p.2]

\footnote{Organization: Mass Comment Campaign sponsored by the Pew Charitable Trusts (web) - (4,452)}

In addition to financial benefits, vehicle efficiency has national security and environmental benefits. By using less petroleum, we can help reduce our imports. [EPA-HQ-OAR-2014-0827-1252-A1 p.1]

Burning less fossil fuel also means less pollution and related illnesses such as asthma [EPA-HQ-OAR-2014-0827-1252-A1 p.1]

\footnote{Organization: Operation Free}

I am a veteran of the United States Navy and a member of Operation Free, a nationwide coalition of more than 5,000 veterans who advocate for securing America with clean energy. I applaud the Obama administration for proposing standards that will make our trucks cleaner and more efficient. I joined the military because I care deeply about protecting our country. I am here today because along with a consensus of senior military and national security experts, I believe that we face a serious threat to our national security: dependency on oil. [EPA-HQ-OAR-2014-0827-1175 p.1] [These comments can also be found in EPA-HQ-OAR-2014-0827-1372, pp.191-192.]

Although trucks are only 7% of the total number of vehicles on the roads, they consume 25% of fuel often that same fuel that we had to protect going through the Strait of Hormuz. This marks a significant percent of emissions relative to the number of trucks on the road. With these new regulations, we will save 1.8 billion barrels of oil over the lifetime of the vehicles on the road an important step in combatting oil dependency. [EPA-HQ-OAR-2014-0827-1175 p.2] [These comments can also be found in EPA-HQ-OAR-2014-0827-1372, p.193.]

Currently, oil is essential for the military to defend us. Everything from tanks to fighter jets to Humvees use oil, and delivering it on the battlefield is a dangerous job. In Afghanistan, 1 in every 24 fuel convoys ended with a casualty; oil trade routes are slow, scheduled, and frequent, making them easy targets for the enemy. These rules benefit the military because trucks won’t have to refuel as frequently, which can be dangerous and costly in combat zones. Additionally, too much of our money for oil ends up in the hands of hostile countries and extremist fighters. [EPA-HQ-OAR-2014-0827-1175 p.2][These comments can also be found in EPA-HQ-OAR-2014-0827-1372, pp.192-193.]

While these new EPA regulations make great strides to mitigate the impacts of carbon emissions such as reducing GHG emissions by 1 billion metric tons over the life of vehicles on the road we must take further measures to reduce our oil dependency in the interest of national security. Analysis shows that with modern engineering capabilities, stronger standards could reduce trucks’ fuel use by 40% by 2025. Continued progress in environmental standards made by the EPA are vital to the well-being of our
In raising our standards for greenhouse gas emissions and fuel efficiency, we strengthen our national security by supporting the U.S. economy, increasing global stability, and sending fewer of our men and women into harm’s way. Once again, I applaud the administration for proposing standards to make our trucks more efficient. [EPA-HQ-OAR-2014-0827-1175 p.2] [These comments can also be found in EPA-HQ-OAR-2014-0827-1372, p. 196.]

Organization:  Securing America’s Future Energy

Additional revisions should be considered to enhance the immediate effectiveness of the proposed Phase 2 standards with regard to increasing national energy security through reductions in medium-and heavy-duty vehicle petroleum demand. These revisions would also eliminate the differential treatment of medium- and heavy-duty vehicle manufacturers relative to their light-duty counterparts, resulting in a more seamless, integrated policy for motor vehicle greenhouse gas and fuel economy regulation. [EPA-HQ-OAR-2014-0827-1282-A1 p.1]

The U.S. transportation sector relies on oil for 92 percent of its total energy consumption. This dependence leaves the U.S. economy vulnerable to volatile price conditions. Increasing vehicle fuel efficiency is one of the most effective tools for decreasing the oil intensity of the U.S. economy, and thereby enhancing economic and national security. [EPA-HQ-OAR-2014-0827-1282-A1 p.3]

Medium- and heavy-duty vehicles represent the fastest growing component of U.S. transportation oil demand. Strengthening fuel economy standards for these vehicles is a critical part of any efforts to enhance U.S. energy security. [EPA-HQ-OAR-2014-0827-1282-A1 p.3]

However, improvements in vehicle fuel efficiency alone will not insulate the U.S. economy from the volatile oil price conditions typical of the global oil market. Securing America’s Future Energy (SAFE) recommends multiple revisions to the proposed rule that if adopted will help strengthen U.S. energy security by achieving even greater oil savings over the long term through the wider use of medium and heavy-duty vehicles powered by alternative fuels. Specifically, SAFE recommends: (1) extending 49 USC 32905 manufacturing incentives into the medium- and heavy-duty sector and (2) implementing advanced technology credits for medium- and heavy-duty natural gas vehicles and reinstating them for technologies that qualify for the credit under Phase I. SAFE also provides comments on the agency's considerations related to upstream natural gas vehicle emissions. [EPA-HQ-OAR-2014-0827-1282-A1 p.3-4][This comment can also be found in section 12.3 of this comment summary]

The Energy Security Implications of Petroleum in Transport

Almost 40 percent of total U.S. primary energy demand is met by oil, giving it an economic significance unmatched by any other fuel. The transportation sector accounts for more than 70 percent of total U.S. oil consumption of approximately 19 mbd. This sector relies on oil for 92 percent of its total energy consumption-97 percent when including ethanol blending—and has no readily available substitutes. [EPA-HQ-OAR-2014-0827-1282-A1 p.4]

Between 2011 and 2014, the country's reliance on oil led to an average economy-wide spend of almost $880 billion per year on petroleum products, equivalent to more than 5 percent of U.S. gross domestic product. These high levels of spending—more than twice what they were in the early 2000s—strain the budgets of consumers, businesses, and governments alike. Higher oil prices also added $1.2 trillion to
the U.S. federal debt between 2002 and 2012, and every U.S. recession for the past 40 years has been preceded by, or coincided with, an oil price spike.\[EPA-HQ-OAR-2014-0827-1282-A1 p.4\]

Although oil prices, and thus U.S. spending on oil, are expected to be markedly lower in 2015—a forecast $54 per barrel versus $99 per barrel in 2014 and approximately $595 billion versus $850 billion in 2014, respectively—total U.S. spending on petroleum fuels exceeded a combined $3.5 trillion between 2011 and 2014.\[EPA-HQ-OAR-2014-0827-1282-A1 p.4\] Households are also expected to spend less on gasoline in 2015, at levels slightly below those last seen on an annual basis in both 2009 (during the Great Recession) and 2005.\[EPA-HQ-OAR-2014-0827-1282-A1 p.4\] Nevertheless, and despite rising domestic oil production, the United States still sends nearly $1 billion abroad each day to pay for oil, often to countries that are hostile to U.S. interests.\[EPA-HQ-OAR-2014-0827-1282-A1 p.4\]

The extreme economic importance of oil to the United States creates adverse national security challenges. Notably, more than 50 percent of daily oil supplies transit through seven major chokepoints in often unstable regions, particularly the Middle East.\[EPA-HQ-OAR-2014-0827-1282-A1 p.4\] The U.S. military is placed in harm's way to protect these maritime supply routes and vulnerable energy infrastructure across the globe. U.S. oil dependence also weakens the country's ability to address foreign policy challenges, including those with Iran. Effective sanctions on Iran's oil industry as far back as 2005 were undermined by the impact such sanctions would have on global oil prices.\[EPA-HQ-OAR-2014-0827-1282-A1 p.4\]

Uncertain events around the world also contribute to volatility in global oil markets and oil prices. For example, conflict in Yemen has affected oil prices despite Yemen's minimal oil production capacity, in part due to the country's strategic location adjacent to the Bab el-Mandeb strait and shared border with Saudi Arabia. Moreover, Russia's incursions into Ukraine and subsequent international sanctions, the emergence and expansion of Daesh (Islamic State of Iraq and the Levant, or ISIL) in Northern Iraq and Syria, and other developments increase concerns over the security and stability of global oil supplies.\[EPA-HQ-OAR-2014-0827-1282-A1 p.4-5\]

The global oil market is also frequently subject to unpredictable—and sometimes anti-competitive—behavior from oil-producing countries that supply it, most notably from members of the Organization of the Petroleum Exporting Countries (OPEC). For example, the organization's November 2014 decision not to reduce output despite a growing imbalance between global oil demand and supply helped to contribute to a more than 50 percent decline in oil prices between the summer of 2014 and January 2015, resulting in levels of oil price volatility not observed since 2009, among other impacts.\[EPA-HQ-OAR-2014-0827-1282-A1 p.5\]

Medium- and heavy-duty vehicles represent a sizable portion of U.S. transportation-related oil demand. In total, commercial trucks accounted for 2.8 mbd of U.S. oil consumption in 2013, equal to 20 percent of transportation-related oil consumption, a share that was second only to light-duty vehicles.\[EPA-HQ-OAR-2014-0827-1282-A1 p.5\] Long-haul heavy-duty trucks accounted for more than 70 percent of the oil consumed by trucks.\[EPA-HQ-OAR-2014-0827-1282-A1 p.5\]

In noticeable contrast to the light-duty vehicle segment, energy and oil use by medium- and heavy-duty vehicles is forecast to rise, not fall, over the next 25 years from 2.8 mbd today to approximately 3.4 mbd in 2040. This rise in demand is attributable to an increase in the number of medium- and heavy-duty vehicles on U.S. roads (and corresponding increase in total vehicle miles driven), plus only very gradual improvements in vehicle fuel economy. Without the Phase 2 rule, for example, the U.S. Department of Energy forecasts that the average fuel economy of diesel-powered heavy-duty vehicles will increase by 17 percent over the next 25 years, from 6.15 miles per gallon (mpg) to 7.21 mpg.\[EPA-HQ-OAR-2014-0827-1282-A1 p.5\]
Analysis commissioned by SAFE finds that achieving the improvements required by the Phase 2 rule are both technologically feasible and cost effective. Subsequent analysis of the potential fuel savings finds that demand attributable to medium and heavy-duty vehicles could decline by almost 0.5 mbd by 2030 (-13 percent) and by nearly 0.8 mbd (-20 percent) by 2040 due to the rule. As a result, total onroad fuel use could decline by 4.5 percent by 2030 and 7.5 percent by 2040, respectively. Reductions of this magnitude are good for the security and economic prosperity of the United States. As such, SAFE supports the rulemaking with the following recommendations aimed at strengthening the energy security aspects of the proposed rule and increasing the flexibility of the rule to facilitate real-world compliance. [EPA-HQ-OAR-2014-0827-1282-A1 p.5]

Before finalizing the Phase 2 fuel efficiency and greenhouse gas emissions standards, there are several issues SAFE believes that EPA and NHTSA could address to enhance their immediate effectiveness with regard to strengthening U.S. energy security through reductions in medium- and heavy-duty oil use. The suggested revisions would also eliminate the differential treatment of medium- and heavy-duty vehicle manufacturers relative to their light-duty counterparts, resulting in a more seamless integrated policy for motor vehicle greenhouse gas and fuel economy regulation. [EPA-HQ-OAR-2014-0827-1282-A1 p.6]

The United States depends on oil to power 92 percent of its transportation sector, a virtual monopoly. This strategic commodity is priced on an unfree, volatile global oil market, posing serious risks to our national and economic security—the government spends an estimated $67.5 billion annually just on protecting oil supply lines around the world, and consumers and businesses are forced to pay whenever conflict or supply disruptions cause an oil price spike. Reducing the nation's overall oil intensity is a critical step towards curtailing U.S. exposure to such volatility, thus improving energy security. [EPA-HQ-OAR-2014-0827-1462-A1 p.1]

Response:

In the proposal to this rule, the agency solicited comments on quantifying the military benefits from reduced U.S. imports of oil. Reduced U.S. imports of oil, particularly from potentially unstable areas, could reduce the need for the U.S. military to protect flows of oil from those areas. The California Air Resources Board (CARB) notes that the National Research Council (NRC) attempted to estimate the military costs associated with U.S. imports and consumption of petroleum. The NRC cited estimates of the national defense costs of oil dependence from the literature that range from less than $5 billion per year (GAO, 2006; Parry and Darmstadter, 2004) to $50 billion per year or more (Moreland, 1985; Ravenal, 1991; Kaufmann and Steinbruner, 1991; Copoulos, 2003; Delucchi and Murphy, 2008). Assuming a range of approximate range of $10 billion to $50 billion per year, the NRC divided national defense costs by a projected U.S. consumption rate of approximately 6.4 billion barrels per year (EIA, 2012). This procedure yielded a range of average national defense cost of $1.50 - $8.00 per barrel (rounded to the nearest $0.50), with a mid-point of $5/barrel (in 2009$). EPA acknowledges this NRC study, but has not included the estimates as part of its cost-benefit analysis for this rule.

The Competitive Enterprise Institute (CEI) and others argue that there are little, if any, energy security benefits associated with this rule. In large part CEI argues that oil supplies are plentiful and that current oil prices are low so that reduced consumption of petroleum products due to this rule would have no effect on energy security. However, the discussion of current low oil prices ("lowest Labor Day gasoline prices in a decade") does not assure the absence of future oil supply shocks or price shocks, or even speak to their reduced likelihood. CEI points out that the current low oil prices have been observed before as recently as a decade ago, as they have in more than one instance before that. For example, oil prices were even lower in 1999. But in the intervening periods, oil supply and price shocks have continued to recur, and the recent price record only amplifies oil's high historical price volatility. Also, sharply lower world oil prices do not clearly imply greater energy security for the U.S. Current low world oil prices may reduce the U.S. fracking industry's tight oil production (as CEI points out), or other sources of oil supplies around the world. Some have hypothesized that reduction in oil production outside of OPEC may be the objective of some OPEC producers. With low oil prices, the U.S. oil import share over time might be larger, increasing the U.S. dependence on imported oil.

Securing America’s Future Energy (SAFE), Operation Free and the Investor Network on Climate Risk agree that this rule does improve America’s energy security. SAFE goes on to state that several policy options should be included in this rule to further enhance energy security. The Agency agrees that this
rule enhances America’s energy security, but does not have information to evaluate the policy options that SAFE proposes.

11.10 Other Impacts

Organization: California Air Resources Board (CARB)

Comment on Topic Where NPRM Requests Comment

Comment – Accidents, congestion, and noise

The NPRM requests comment on the input metrics used in the analysis of accidents, congestion, and noise. CARB staff supports the holistic inclusion of these inputs and suggests that the inputs related to congestion, accidents, and noise be consistent with any anticipated changes in vehicle usage, including VMT, mode switching, and route modification, due to the rebound effect of the proposed rulemaking. Any modification to the rebound effect from continued research should be reflected in the estimation of accidents, congestion, noise, and increased travel. [EPA-HQ-OAR-2014-0827-1265-A1 p.187]

Response:

The agencies agree with the commenter that accidents, congestion and noise due to increased VMT from rebound driving should be quantified in the regulatory impact analysis. If net operating costs of a heavy duty vehicle decline, then we expect a positive rebound effect. Increased vehicle use associated with a positive rebound effect contributes to increased traffic congestion, motor vehicle crashes, and highway noise. Depending on how the additional travel is distributed throughout the day and on where it takes place, additional vehicle use can contribute to traffic congestion and delays by increasing traffic volumes on facilities that are already heavily traveled during peak periods. These added delays impose higher costs on drivers and other vehicle occupants in the form of increased travel time and operating expenses. Because drivers do not take these added costs into account in deciding when and where to travel, they must be accounted for separately as a cost of the added driving associated with the rebound effect.

Our approach in this final rule is identical to that used in the proposal. EPA and NHTSA rely on estimates of congestion, crash, and noise costs caused by pickup trucks and vans, single unit trucks, buses, and combination tractors developed by the Federal Highway Administration to estimate the increased external costs caused by added driving due to the rebound effect.226 The FHWA estimates are intended to measure the increases in costs from added congestion, property damages and injuries in traffic crashes, and noise levels caused by various classes of trucks that are borne by persons other than their drivers (or “marginal” external costs). EPA and NHTSA employed estimates from this source previously in the analysis accompanying the light-duty 2012-2016 vehicle rulemaking. Given the lack of alternative estimates in the literature, the agencies continue to find them appropriate for this analysis after reviewing the procedures used by FHWA to develop them and considering other available estimates of these values.

FHWA’s congestion cost estimates for trucks, which are weighted averages based on the estimated fractions of peak and off-peak freeway travel for each class of trucks, already account for the fact that

226 These estimates were developed by FHWA for use in its 1997 Federal Highway Cost Allocation Study; see http://www.fhwa.dot.gov/policy/hcas/final/index.htm (last accessed July 21, 2010)
trucks make up a smaller fraction of peak period traffic on congested roads because they try to avoid peak periods when possible. FHWA’s congestion cost estimates focus on freeways because non-freeway effects are less serious due to lower traffic volumes and opportunities to re-route around the congestion. The agencies, however, applied the congestion cost to the overall VMT increase, though the fraction of VMT on each road type used in MOVES range from 27 to 29 percent of the vehicle miles on freeways for vocational vehicles and 53 percent for combination tractors. The results of this analysis potentially overestimate the congestions costs associated with increased truck use, and thus lead to a conservative estimate of benefits.

**Organization:** California State Senator Ricardo Lara

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 56.]

In California, we understand that climate change is not just an abstract concept but a public health crisis that is disproportionately impacting our most vulnerable communities, namely the poor and communities of color.

**Response:**

We agree that elevated concentrations of GHG emissions in the atmosphere may reasonably be anticipated to endanger public health and welfare of current and future generations. We also agree that children, the elderly, and the poor are among the most vulnerable to these climate-related health effects. The impacts addressed by this action will reduce these adverse impacts within communities where the population may be especially vulnerable.

**Organization:** Walmart Transportation

Although perhaps not to be addressed within this rule, in the drive for greater fuel efficiency we encourage consideration of the significant impact of initiatives broader than equipment. Opportunities in congestion reduction, speed, payload efficiency, and infrastructure maintenance and upgrades will result in environmental, safety, and economic benefits far surpassing equipment innovations. A system view and approach will be essential to ensuring the vitality of the backbone of the U.S. economy. [NHTSA-2014-0132-0117-A1 p.2]

**Response:**

While the initiatives outlined by the commenter could very well result in beneficial impacts, they fall outside the scope of this rulemaking.

**11.11 Employment Impacts**

**Organization:** Achates Power, et al.

Our nation relies heavily on medium- and heavy-duty trucks and buses to keep our economy moving. The Phase 2 rulemaking has the potential to be a significant economic driver of jobs and prosperity, by rewarding innovative solution providers. [EPA-HQ-OAR-2014-0827-1762-A2 p.2]

**Organization:** American Council for an Energy-Efficient Economy (ACEEE)
The Phase 2 program also offers the potential of new jobs in the design and production of new vehicle technologies. [EPA-HQ-OAR-2014-0827-1280-A1 p.5] [This comment can also be found in section 1.1 of this comment summary]

**Organization:** BlueGreen Alliance

These standards will increase fuel efficiency and cut greenhouse gas emissions from long-haul trucks—along with full size pick-ups, other trucks, buses, and vocational vehicles. These standards can also continue America’s auto and manufacturing resurgence. [EPA-HQ-OAR-2014-0827-1246-A2 p.1] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.71.]]

The BlueGreen Alliance and its 15 labor and environmental partners recognize the importance of the proposed medium- and heavy-duty truck fuel efficiency and greenhouse gas emissions reduction rule. America’s economy depends on leadership in building the next generation of clean globally competitive energy and vehicle technology. These new standards can provide a critical opportunity to sustain jobs, further reduce the pollution driving climate change and foreign oil dependence while enhancing the competitiveness of U.S.-manufactured trucks in global markets. [EPA-HQ-OAR-2014-0827-1246-A2 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.71-72.]]

For the past decade, the auto industry (in the light-, medium- and heavy-duty sectors), and American workers—represented by the United Auto Workers, the United Steelworkers and others—have been on the front lines when it comes to rebuilding manufacturing jobs and building the world-leading technology needed to achieve deep cuts in carbon pollution and save consumers billions at the pump. Soon to be released research carried out by several of our partners finds more than 380 plants that are manufacturing fuel efficient medium- or heavy-duty vehicles or their components today in states all across the country. [EPA-HQ-OAR-2014-0827-1246-A2 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.71-72.]]

These companies include major assemblers—like Freightliner manufacturing long haul trucks in Cleveland, North Carolina and companies making key subsystems—like Volvo Mack Powertrain, with semi-truck powertrain manufacture and advanced engine test facilities in Hagerstown, Maryland. They also include large and small manufacturers of components, trailers, tires, and the steel and aluminum that goes into them, such as Nexteer in Saginaw, Michigan; Bridgestone, in Tennessee; and Eaton in California, Michigan, Minnesota, North Carolina, and Ohio. [EPA-HQ-OAR-2014-0827-1246-A2 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.72-73.]]

[Map of US manufacturers of fuel efficient medium- and heavy-duty vehicles are components can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-1246-A2]

Done right, this standard can spur investment, secure and grow jobs, and enhance U.S. competitiveness across these businesses and technologies—and the industry as a whole. With this rule EPA and NHTSA have the opportunity both to encourage continued investment in manufacturing more fuel-efficient trucks in the US and to ensure that these trucks can be designed and built without causing boom and bust cycles in vehicle purchasing and therefore employment. The final rule can and should do both. [EPA-HQ-OAR-2014-0827-1246-A2 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.73.]]

We greatly appreciate the thorough and systematic process EPA and NHTSA have undertaken in developing this proposal. It is critical that an effective final rule works for the environment, for the
economy and for the thousands of hard-working American women and men in the heavy truck, component and related industries. The auto industry and autoworkers have been at the forefront in proving that America can lead globally in combating climate change while rebuilding our manufacturing sector and creating and sustaining quality jobs. We urge the agencies to continue their thorough and deliberate process to ensure that the final truck rule will continue this trajectory. [EPA-HQ-OAR-2014-0827-1246-A2 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.73.]]

Together, the previous rounds of car and light-duty truck and medium- and heavy-duty truck standards achieve the largest greenhouse gas reductions ever undertaken in the U.S. and one of the largest globally. We thank EPA and NHTSA for their work to date and look forward to working with the agencies and all our partners to ensure that we keep on combating climate change by building great trucks. [EPA-HQ-OAR-2014-0827-1246-A2 p.3] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.73-74.]]

**Organization:** Ceres

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 201-202.]

Strict standards are also key to retaining the U.S. leadership position in efficient truck manufacturing and expanding job opportunities in that sector. We are currently the world leader in the development, production, and use of energy-efficient and hybrid trucks. Without strong standards in place, companies and investors will lack the requisite certainty to invest in the development and production of new technologies that will allow us to retain our primary position and increase job growth.

**Organization:** Environmental Defense Fund (EDF)

**C. Fuel efficiency standards have positive impact on truck industry and employment**

EDF preformed an extensive market analysis of heavy-duty vehicle purchases between 1992 and 2014 matched with the 2007 and 2010 engine standards. Appropriately controlling for macroeconomic trends, our analysis showed that there was smooth growth in vehicle demand prior to, and during, implementation of the 2014 Phase 1 fuel efficiency standards. As further evidence, model year 2014 heavy-duty trucks saw the highest sales since 2005. The results of our analysis support the premise that fuel savings provide an advantage in the competitive market. Lower freight costs drive higher demand for freight transport and demand for freight transport drives demand for new vehicles. [EPA-HQ-OAR-2014-0827-1312-A1 p.25][This comment can also be found in section 11.7 of this comment summary]

Our analysis also concluded that fuel efficiency standards insulate the heavy truck market from fuel price shocks – and that market stability translates into employment stability. In a marketplace without standards, not all manufacturers produce fuel-efficient models (e.g., the light-duty vehicle market pre-CAFE standards). When fuel prices spike, more fuel-efficient vehicles are in greater demand, shifting demand across manufacturers and disrupting sales and employment. Analysis by MIT and Northwestern economists found that for manufacturers on which CAFE standards are binding, marketing more fuel-efficient models reduces the impact of fuel-price shocks on aggregate new-vehicle demand and dampening the cross manufacturer impacts of fuel price shocks. Consistent with their results, we found that demand for heavy-duty vehicles becomes less sensitive to fuel price changes as fuel economy of new heavy-duty vehicles increases – and lower variability in demand for heavy-duty vehicles means
steadier sales and employment. Combining employment and wage with fuel prices and vehicle standards over the last 35 years, we found that over time fuel efficiency standards are associated with declining impacts of fuel price shocks on employment and wages in light-duty and heavy-duty vehicle manufacturing. [EPA-HQ-OAR-2014-0827-1312-A1 p.25]

Despite these findings with respect to the Phase I program, some have suggested that previous criteria pollutant standards have resulted in “boom and bust” purchasing. This comparison is inappropriate, however, and, in any event, our analysis shows that there was no meaningful adjustment in market purchasing due to those standards. [EPA-HQ-OAR-2014-0827-1312-A1 p.25]

120 Busse, et al., Who is Exposed to Gas Prices? How Gasoline Prices Affect Automobile Manufacturers and Dealerships, No. w18610, National Bureau of Economic Research (2012).

121 Fuel economy standards are not likely to impact new-vehicle sales, because, unlike criteria pollutant standards, the benefits of improved fuel-economy accrue directly to the vehicle purchaser. While improving the fuel-economy of new vehicles won’t be costless, fuel-savings will provide offsetting benefits directly to the consumer. They quickly pay back the up-front investment cost, lower the long-run cost of operating the vehicle, and provide a critical advantage in the highly competitive freight industry.

Organization:  
Gilroy, JD

A third thing I find praiseworthy about the proposed standards is that they seem to involve powerful economic benefits even aside from environmental and health benefits—all allegedly 124,000 jobs by 2030 and a ratio of benefits to costs of 10 to 1, or a savings for truckers of $160 billion after new technology upgrades are paid off. That is probably why the affected industries have been largely supportive of the new standards, some even meeting the standards before required to do so, and that is a fourth reason I like them. [EPA-HQ-OAR-2014-0827-0751 p.2]

Organization:  
International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

We reject the false calculus that environmental regulations always cost jobs. It is not a zero-sum equation. Thoughtful, well-constructed regulations crafted with input from stakeholders can protect the environment while simultaneously protecting existing jobs and creating jobs in new advanced technology sectors of the economy. This can be a win-win for the environment and the economy. [EPA-HQ-OAR-2014-0827-1248-A2 p.2]
We urge EPA and NHTSA to tread carefully in order to avoid creating economic insecurity for the hardworking men and women who toil in the industries affected by this proposal. Any new regulations should not negatively disrupt the economy or create a “pre-buy/no-buy” cycle that results in layoffs or job losses for American workers. [EPA-HQ-OAR-2014-0827-1248-A2 p.2]

A significant market disruption is not only bad for workers; it is bad for the overall economy, which is still recovering from the Great Recession. Layoffs, regardless of their duration, are obviously bad for the workers who lose their jobs. Surrounding communities are also negatively impacted as families suddenly have less to spend on housing, car payments, groceries, clothes and other essential and discretionary items. [EPA-HQ-OAR-2014-0827-1248-A2 p.2]

This is not a theoretical concern for UAW members. In mid-2006, there were almost 18,000 UAW members working at Freightliner, Navistar, Mack, Volvo and Peterbilt. By mid-2007, the number of active workers was down to just under 13,000 with over 4,000 workers laid-off. This occurred before the Great Recession and market disruptions caused by regulations were undoubtedly a major factor. [EPA-HQ-OAR-2014-0827-1248-A2 p.2]

In 2008, the number of laid-off workers increased to over 6,000 and in 2009, there were over 10,000 laid-off UAW members at those manufacturers. The chart below shows UAW membership in the industry from 2004 to 2014: [EPA-HQ-OAR-2014-0827-1248-A2 p.2]

[Chart can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1248-A2]

These are much more than statistics. UAW members not only lost their jobs, many of them lost their homes and the stress brought on by financial insecurity led to divorces and other family crises. We have no interest in repeating scenes of boarded up storefronts on our main streets or families losing their homes. [EPA-HQ-OAR-2014-0827-1248-A2 p.3]

We urge EPA and NHTSA to ensure that the new regulations do not create economic uncertainty for working families by creating significant market disruptions. In order to achieve this goal the final rule must be consistent with the following principles: [EPA-HQ-OAR-2014-0827-1248-A2 p.4]

- Regulations Cannot Disrupt the Market
- Single National Program
- Regulatory Certainty
- Accurate Technology Market Penetration, Cost and Reliability Assumptions and Testing Protocols
- Flexibility to meet stringency standards [EPA-HQ-OAR-2014-0827-1248-A2 p.4]

As previously mentioned engine regulations in the past have had adverse economic consequences and contributed to a pre-buy/no-buy boom and bust cycle. This proposal must guard against creating these conditions. Severe market disruptions would not only be bad for workers, they would also be bad for the environment and would undermine the regulation’s foundational goal of reducing harmful greenhouse gas emissions and increasing fuel efficiency. If fleets and other customers pull ahead truck purchases due to concerns about increased cost or unproven technology, the end result is more higher-polluting and less fuel efficient trucks on the road for a longer period of time. [EPA-HQ-OAR-2014-0827-1248-A2 p.4] [This comment can also be found in section 11.7 of this comment summary.]
UAW members in this industry suffered economic hardship caused by regulations during the last decade and we are sensitive to the potential impacts of Phase 2 regulations and are watching this process closely. The EPA established a comprehensive national program establishing emission standards in 2007 and 2010 for diesel engine emissions of oxides of nitrogen (NOx) and particulate matter (PM). The regulation’s intent was to reduce the harmful emissions of NOx and PM from the truck fleet by 90 and 95 percent respectively, dramatically reducing the threat those pollutants posed to public health. [EPA-HQ-OAR-2014-0827-1248-A2 p.5]

Many truck fleets and other customers, weary of increased costs and new and possibly problematic technology, pulled ahead truck orders prior to the implementation of the 2007 standard. The effect of this pre-buy was felt by the thousands of UAW members and other workers who worked overtime building as many legacy engines as they could prior to the standard and then were laid off once the standards took effect. [EPA-HQ-OAR-2014-0827-1248-A2 p.5]

Overall UAW membership in the medium and heavy-duty truck sector did not meaningfully recover until 2012. It would be an error to attribute the lay-off of 10,000 UAW members in 2009 solely to the pre-buy associated with the 2007 engine standards because clearly, the Great Recession and the closure of an assembly plant were also major contributors to the downturn in overall sector employment and UAW membership. However, it is important to understand that some of these workers only returned to work within the last few years. Truck makers are hiring new workers for the first time in many years and workers are concerned about the potential of the negative impact of regulations. [EPA-HQ-OAR-2014-0827-1248-A2 p.5]

Organization: International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

UAW members support an achievable and realistic Phase 2 standard that is good for the environment and manufacturing workers (Docket No. EPA–HQ–OAR–2014–0827; NHTSA–2014–0132). We reject the false argument that environmental protections and economic growth are not compatible. The final rule must be carefully crafted in order to avoid economic disruption of the medium- and heavy-truck, vocational, van, and heavy-duty pickup markets. [EPA-HQ-OAR-2014-0827-1895-A1 p.1]

UAW members and their families know first-hand the cyclical nature of the medium- and heavy-duty truck, vocational, van, and heavy-duty pickup markets. They have also experienced the pre-buy/no-buy disruption that can be caused by regulations. [EPA-HQ-OAR-2014-0827-1895-A1 p.2]

The Class 8 heavy-duty truck market was strong most of last year. However, in the latter part of 2015 and into 2016, heavy truck orders dropped significantly. In response, heavy truck manufacturers began laying off workers and cutting production. To date, Daimler and Volvo have announced the layoff of as many as 3,400 UAW members. Non-union PACCAR has also reduced their workforce in U.S. facilities. [EPA-HQ-OAR-2014-0827-1895-A1 p.2]

The following chart illustrates UAW membership in the medium- and heavy-duty truck sector since 2004: [EPA-HQ-OAR-2014-0827-1895-A1 p.2]

[Chart can be found on p.2 of docket number EPA-HQ-OAR-2014-0827-1895-A1]

This recent history warrants caution as we can’t predict the ups and down of the market during the term of the Phase 2 standards. However, we can work together to reduce the likelihood of the Phase 2
standards creating economic hardship for not only hardworking men and women who assemble and make parts for trucks, but also their neighbors and communities. [EPA-HQ-OAR-2014-0827-1895-A1 p.2]

Alternative Three proposes a 4% improvement in per vehicle fuel consumption and CO₂ improvement by MY 2027 compared to MY 2017 for diesel engines. According to the technology study, diesel engines can achieve this level of stringency without forcing problematic technologies like waste heat recovery. The study states, “Overall, diesel engines offer a potential for 2% to 5% improvement beyond the requirements of the Phase 1 GHG regulations.” The study lists the potential diesel engine improvement for long haul engines as 2-5%, medium-duty/vocational as 2-4% and pickup as 3-4% —all without waste heat recovery. [EPA-HQ-OAR-2014-0827-1895-A1 p.2]

We are concerned that increasing engine stringency to levels that require an unrealistic market penetration and forcing expensive and unproven technologies will significantly disrupt the market and create hardships for manufacturing workers and their families. [EPA-HQ-OAR-2014-0827-1895-A1 p.2]

Organization: Mannix, Brian

Employment Impacts

As required by President Obama’s Executive Order 13563 (January 18, 2011), the RIA includes an analysis of employment impacts of the proposed standards. President Obama’s message announcing the standards indicated that he believed they would “bring jobs back to America.” [EPA-HQ-OAR-2014-0827-1222-A1 p.6]

The RIA acknowledges the difficulty of the task, reviews the literature, and makes heroic efforts to develop a credible model that would allow it to forecast job impacts within the motor vehicle manufacturing sector. Ultimately it is not able to reach a definitive conclusion: [EPA-HQ-OAR-2014-0827-1222-A1 p.6]

The overall effect of these proposed rules on motor vehicle sector employment depends on the relative magnitude of the output effect and the substitution effect. Because we do not have quantitative estimates of the output effect, and only a partial estimate of the substitution effect, we cannot reach a quantitative estimate of the overall employment effects of these proposed rules on motor vehicle sector employment or even whether the total effect will be positive or negative. [EPA-HQ-OAR-2014-0827-1222-A1 p.6]

The RIA reaches similar conclusions about other sectors likely to be affected. One danger of this type of partial equilibrium analysis, which focuses primarily on the sectors directly affected by a rule, is that the analysis might have identified direct employment impacts while missing indirect impacts in sectors beyond the scope of the analysis. This is Bastiat’s classic “seen and unseen” problem, and the RIA appears to be sensitive to the danger: “In an economy with full employment, the primary employment effect of a rulemaking is likely to be to move employment from one sector to another, rather than to increase or decrease employment.” It might have added that the same is likely to be true in an economy that does not exhibit full employment, at least within the limits of our ability to analyze such effects. [EPA-HQ-OAR-2014-0827-1222-A1 p.6]

This does not mean that unemployment is not a serious and chronic problem, nor that regulation is not an important cause of it. Regulation may be especially harmful when it inhibits recovery from a recession, and there are good reasons to examine the effect of regulatory policy on employment more broadly. Nonetheless, unless the rule affects the terms of employment directly, a forecast of employment impacts is not likely to be reliable or informative for any particular regulatory decision.
The RIA is right to be cautious about generating such forecasts.\textsuperscript{15} [EPA-HQ-OAR-2014-0827-1222-A1 p.7]

\textsuperscript{12} RIA Section 8.11, p. 8-93 ff.

\textsuperscript{13} RIA, p. 8-101.

\textsuperscript{14} RIA, p. 8-103.

\textsuperscript{15} For a more complete discussion of this problem, see Brian F. Mannix, “Employment and Human Welfare: Why Does Benefit-Cost Analysis Seem Blind to Job Impacts?” Chapter 10 in Does Regulation Kill Jobs?, University of Pennsylvania Press, 2013; Cary Coglianese, Adam Finkel, and Christopher Carrigan, editors.

\textbf{Organization:} NAFA Fleet Management Association

Additionally, the proposed standards place greater strain on driver and technician resources (capability), which are two vocational areas where fleets are becoming more challenged to hire enough (and qualified) employees. [NHTSA-2014-0132-0111-A1 p.2-3] [This comment can also be found in section 11.2 of this comment summary.]

Many fleets have seen an increase in downtime, which has manifested itself in driver productivity issues, shop capacity concerns and an overall increase in the number of spare vehicles required to have on hand to ensure that enough units are available to serve customers. [EPA-HQ-OAR-2014-0827-1011 p.3] [This comment can also be found in section 11.2 of this comment summary.]

Lastly, fleets have had to increase training significantly to stay on top of the changes that have increased our technician counts across the country. [NHTSA-2014-0132-0111-A1 p.3] [This comment can also be found in section 11.2 of this comment summary.]

\textbf{Organization:} Natural Resources Defense Council (NRDC)

NRDC believes that the Phase 2 rule will protect existing manufacturing jobs in the medium- and heavy-duty industry and could potentially lead to job growth in the sector as tighter standards require the development, production and installation of technologies to improve efficiency and reduce emissions. Included in these comments is analysis conducted by NRDC with the BlueGreen Alliance that shows that more than 36,600 engineers, technicians and assembly workers are employed in over 380 facilities across 43 states to develop, design and build components and trucks that help haul goods using less fuel. The Phase 2 standards will play an important role in maintaining these jobs and positioning U.S. manufacturers to be global leaders in truck technology, especially as other nations implement their own truck fuel efficiency programs. [EPA-HQ-OAR-2014-0827-1220-A1 p.2]

\textbf{Employment Impacts}

NRDC believes that the Phase 2 heavy truck can have a positive impact on U.S. employment. We expect the standards to drive technology innovation that will increase labor intensity. We also expect the fuel savings that result from lower fuel consumption in shipping goods will be at least partially passed
on to consumers, providing the ability to inject more money into the broader economy and growing jobs. [EPA-HQ-OAR-2014-0827-1220-A1 p.10]

The Phase 2 standards are also likely to protect existing jobs. U.S. leadership in setting truck standards has encouraged U.S. vehicle and component manufacturers to establish engineering, development and manufacturing facilities in the U.S. to make world-leading truck technologies. As a result, the U.S. has a competitive edge for providing technologies that will be desired globally as more countries adopt more stringent truck standards. As noted in the proposed rule, EPA and NHTSA have “met with regulatory counterparts from several other nations who either have already or are considering establishing fuel consumption or GHG requirements, including outreach with representatives from the governments of Canada, the European Commission, Japan, and China.” A strong standard in the U.S. can help ensure fuel-efficient technologies are produced here to serve the domestic and international markets as they develop. [EPA-HQ-OAR-2014-0827-1220-A1 p.10-11]

i. More than 36,600 Jobs are Associated with Producing Cleaner, More Fuel Efficient Trucks

Working with the BlueGreen Alliance, NRDC is assessed the number of U.S. jobs associated with making and applying technologies that improve fuel efficiency in medium- and heavy-duty trucks. These are jobs represent private investment in the capabilities to meet necessary emissions and efficiency standards. By setting strong, long-term standards, the agencies provide continued market certainty to protect these existing investments and to encourage greater investment in jobs that produce additional fuel-saving technologies. [EPA-HQ-OAR-2014-0827-1220-A1 p.11] [[These comments can also be found in EPA-HQ-OAR-2014-0827-1372, pp. 44-45]]

Today, more than 36,600 engineers, technicians and assembly workers are employed in over 380 facilities across 43 states to develop, design and build components and trucks that help haul goods using less fuel. Below, the facility locations are placed on a map and employment is tabulated by state. [EPA-HQ-OAR-2014-0827-1220-A1 p.11] [[These comments can also be found in EPA-HQ-OAR-2014-0827-1372, p. 45]

[Map of U.S. Manufacturers of Fuel Efficient Medium- and Heavy-Duty Vehicles and Components and table of states and number of facilities and employment can be found on p.12-13 of docket number EPA-HQ-OAR-2014-0827-1220-A1]

ii. Methodology

The facilities captured in the table and map above are locations where components and vehicles are developed, designed, manufactured and/or assembled to improve fuel efficiency and lower carbon pollution in the on-road medium- and heavy-duty vehicle industry. The technologies produced by the facilities are expected to be deployed to meet standards through 2018 and will be important in achieving standards in subsequent years. [EPA-HQ-OAR-2014-0827-1220-A1 p.13-14]

The company facilities and employment included in this analysis are specifically involved in the medium and heavy-duty truck market including buses and vehicles used in a variety of commercial uses. Many of the researched companies also are involved in the light duty automotive industry (as well as other industries including off-road equipment), but those included must be directly involved in the medium and heavy-duty industry. The report includes components related to powertrain, the vehicles themselves (including trailers) and add-on componentry to adapt vehicles to various applications. We do not include componentry unless it is specifically related to fuel-saving activities. For example, companies that are involved in fuel saving activities including aerodynamic improvement are included,
while those producing structural components for these vehicles are not. [EPA-HQ-OAR-2014-0827-1220-A1 p.14]

This data should be viewed as a conservative estimate. We have not included facilities unless it could be specifically confirmed that the location provides products for medium- and heavy-duty trucks. In some cases the facilities (particularly of larger companies) have not been included because the information available could not provide that direct connection that is needed. It is likely that this requirement has significantly reduced the number of locations that are included, since in many cases it was difficult to obtain information on specific locations of companies that have multiple facilities. [EPA-HQ-OAR-2014-0827-1220-A1 p.14]

Employment estimates are conservative. We excluded employment figures for facilities where a no employment number was available. For facilities that serve both the automotive and medium- and heavy-truck markets, such as makers of turbochargers and plants assembling both light-duty and heavy-duty pickups, we counted only 5 percent of the total facility employment. The 5 percent is an approximation of the economic value of the medium- and heavy-duty market relative to the automotive market. [EPA-HQ-OAR-2014-0827-1220-A1 p.14]

The company, facility and employment database was developed by vehicle industry experts at Baum and Associates using a range of primary sources, including: [EPA-HQ-OAR-2014-0827-1220-A1 p.14]

- Available lists of major original equipment manufacturers and suppliers in the medium- and heavy-duty truck industry
- Membership directory of the NTEA-The Association for the Work Truck Industry,
- Databases including Hoovers and Lexis/Nexis,
- Internet research,
- Press reports from a wide variety of sources regarding fuel saving activities, and
- Direct contact with companies. [EPA-HQ-OAR-2014-0827-1220-A1 p.14]

Organization: Newell Coach Corporation

We also think it is worthy of consideration that the recreational vehicle industry is somewhat unique in that it offers products that are manufactured virtually exclusively by skilled labor in the United States. [EPA-HQ-OAR-2014-0827-1319-A1 p.2]

Organization: Recreational Vehicle Industry Association (RVIA)

There are presently thirty-four motorhome manufacturing sites in the United States employing 8,732 full-time employees. The annual employee payroll is over $619.7 million, and motorhome manufacturer revenues exceed $3.63 billion. [EPA-HQ-OAR-2014-0827-1261-A1 p.9]

Nearly 100% of motorhomes sold in the U.S. are made here. Roughly 66% of all motorhomes are produced in the state of Indiana, with many others manufactured in Iowa, Alabama, Texas and California. It is an industry dominated by small volume manufacturers. About half of all motorhome manufacturers produce fewer than one hundred motorhomes per year. [EPA-HQ-OAR-2014-0827-1261-A1 p.9]

The Proposed Rule will have negative impact on motorhome shipments and jobs RVIA contracted with John Dunham and Associates31 (Dunham) to assess the economic impact that compliance with the proposed Phase 2 standards could have on the motorhome industry. The methodology for this model is
available in Appendix C. In simplistic terms, Dunham’s model assumes that some change in price will have an impact on motorhome sales (shipments) and that this impact on sales will in turn impact industry jobs, wages, economic output, government tax revenue, etc. RVIA asked Dunham to estimate the economic impacts for the following four scenarios: [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.7 of this comment summary]

**Scenario 1:** Motorhomes buyers factor 100% of fuel savings into their purchase decision (8.5 years of discounted fuel savings were subtracted from estimated incremental cost increases; costs based on EPA ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.7 of this comment summary]

**Scenario 2:** Motorhomes buyers factor 100% of fuel savings into their purchase decision (8.5 years of discounted fuel savings were subtracted from estimated incremental cost increases; costs based on motorhome industry ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.7 of this comment summary]

**Scenario 3:** Motorhome buyers do not factor fuel savings into their purchase decision (costs based on EPA ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.7 of this comment summary]

**Scenario 4:** Motorhome buyers do not factor fuel savings into their purchase decision (costs based on motorhome industry ICMs were used) [EPA-HQ-OAR-2014-0827-1261-A1 p.20][This comment can also be found in section 11.3 and 11.7 of this comment summary]

The results of Dunham’s assessment for 2021MY, 2024MY and 2027MY are found in the following three tables below. Additional details are located in Appendix D. [EPA-HQ-OAR-2014-0827-1261-A1 p.21][This comment can also be found in section 11.3 and 11.7 of this comment summary]

[Charts, economic impacts, can be found on p.21-22 of docket number EPA-HQ-OAR-2014-0827-1261-A1]

In RVIA’s view, Scenario 4 represents the most likely outcome. Scenario 4 reflects costs based on an ICM that is more representative of actual practice in the motorhome industry which, as we have already discussed, is distinctly different from other vocational vehicle segments (largely because motorhomes are not purchased for commercial purposes). [EPA-HQ-OAR-2014-0827-1261-A1 p. 22][This comment can also be found in section 11.3 and 11.7 of this comment summary]

Scenario 4 also reflects the fact that the average motorhome buyer, unlike the commercial vehicle fleet manager, likely places little value on future fuel savings when purchasing a motorhome. These are not vehicles purchased for daily driving or commercial purposes. Rather, the purchaser generally focuses on cost, features and other factors. [EPA-HQ-OAR-2014-0827-1261-A1 p. 22] [This comment can also be found in section 11.7 of this comment summary]

Looking at Scenario 4 and 2024MY standards, we estimate that a total of 1,553 jobs would be lost. Of these, 460 would be motorhome manufacturing jobs. This is over 5% of the existing 8,732 motorhome manufacturing jobs that exist today in the thirty-four motorhome manufacturing sites in the United States. With motorhome manufacturing jobs located in a handful of rural communities in a small number of states, applying the proposed standards will have serious negative impact on these communities. The rule would negatively impact not just motorhome manufacturing employees (460 lost jobs) but also motorhome dealers and component part suppliers (144 and 404 lost jobs, respectively).
Also negatively impacted would be persons outside the industry who live in these manufacturing communities. Lost wages are estimated at nearly $118 million. Federal, state and local governments will also have about $34 million fewer tax dollars to invest in social programs, and infrastructure. [EPA-HQ-OAR-2014-0827-1261-A1 p.22][This comment can also be found in section 11.7 of this comment summary]

Regardless of the scenario and the extent to which our industry and the communities that manufacture motorhomes are affected, the negative impacts for our industry cannot be ignored. We have concrete evidence showing what happens when motorhome shipments decline. It has been only six years since 2009 when nearly two-thirds (64%) of all direct motorhome manufacturing employees lost their jobs. As of 2013, the latest year for which data is available, there are 43% fewer motorhome manufacturer businesses and still 59% fewer motorhome manufacturer employees than pre-recession. [EPA-HQ-OAR-2014-0827-1261-A1 p.22-23][This comment can also be found in section 11.7 of this comment summary]

While the estimated job losses associated with this rule do not approach the numbers experienced just a few years ago during and after the recession, they will still result in much pain and suffering, particularly for a handful of low-income rural communities that are only now just starting to recover from the recession. At the very least, EPA must consider these economic costs and impacts under the Regulatory Flexibility Act and Executive Orders 12866, 13563 and 12898. [EPA-HQ-OAR-2014-0827-1261-A1 p.23][This comment can also be found in section 11.7 of this comment summary]

11 Statistical Surveys, Inc.

31 John Dunham & Associates (JDA) is an economic specialist in regulatory analysis. JDA generates economic and fiscal impact studies from a national level down to geographic regions, municipalities, marketing areas or Federal and state legislative districts. See http://guerrillaeconomics.com/

32 According to John Dunham and Associates, the base elasticity for motorhomes is -0.905, suggesting that a 10 percent change in prices will reduce demand by 9 percent (see Appendix C).

Response:

Comments from Achates Power, ACEEE, BlueGreen Alliance, Ceres, EDF, NRDC, and JD Gilroy expressed support for the standards’ potential positive effect on the labor market.Comments included arguments that the standards will drive new jobs, reward organizations that innovate with respect to fuel efficiency, and help solidify and maintain the U.S. position as a leader in industries related to HD vehicle manufacturing and fuel efficiency technology.

Both NRDC and BlueGreen Alliance point to joint research that estimates that there are currently more than 36,600 jobs at over 380 facilities in the United States that are involved in the manufacturing process for fuel efficient medium- or heavy-duty vehicles or their components. They argue that the standards will help to sustain and add to those jobs as investment in the industry increases.
The agencies discuss employment impacts in Preamble Section IX.L and RIA Chapter 8.11. Although we are unable to quantify all possible pathways in which the standards can affect employment, our analysis suggests that employment effects in the regulated sector (the motor vehicle, trailer, and parts manufacturing sectors) are likely to be modest. We do not quantify changes in employment that result from the output effect (changes in demand for fuel efficient vehicles), which is part of the argument that NRDC and BlueGreen Alliance allude to in their comments. We agree that increases in employment are associated with the increased use of efficiency technologies; the estimates for substitution-effect employment in Preamble IX.L.2.b and RIA Chapter 8.11.2.2 aims to approximate employment impacts for those employers due specifically for the need for additional technologies. Thus, our analysis agrees with the comment from UAW that environmental regulations need not cost jobs, as well as with the BlueGreen Alliance that the standards may promote investment that contributes to jobs, and with Ceres that the U.S. can be an international leader on efficiency technology. Comments from Brian Mannix point out the difficulty associated with generating complete employment forecasts that include all direct and indirect effects. He concludes that the agencies are correct to be careful about estimating a definitive forecast.

Additional comments from UAW urge EPA and NHTSA to exercise caution in a general sense to ensure that the standards avoid market disruptions or “pre-buy/no-buy” boom and bust cycles. UAW suggests that in the past, market disruptions caused by pre-buy in anticipation of the 2007 and 2010 NOx and PM standards contributed to the lay-off of 10,000 UAW workers in 2009, which was also partly driven by the Great Recession. As pointed out in the comments from EDF and discussed in Preamble Section IX.F.2, RIA Chapter 8.4.2, and Chapter 11.7.2 of this Response to Comments, fuel economy standards are less likely to cause disruptions to vehicle purchasing trends since increases in costs for new technology are offset by fuel savings that accrue to the vehicle owner. This makes the standards fundamentally different from the past standards discussed in UAW’s comments.

NAFA Fleet Management Association expressed concern that the standards would make it more difficult to hire qualified drivers and technicians, and would require additional employee training. EPA expects that normal market forces will help alleviate labor shortages, should they occur. If the rule increases demand for skilled labor, economic theory suggests that there should eventually be increased wages and job opportunities as companies comply with the standards. Without evidence on increased costs for employee training or wage increases, we have not included them in our regulatory analysis. The rule may provide the regulatory certainty necessary for companies to make investments in new technology, additional employee training, or higher wages for qualified technicians.

Newell Coach Corporation and the Recreational Vehicle Industry Association (RVIA) note that the recreational vehicle (RV) industry is unique in offering products made “virtually exclusively” in the U.S. RVIA cites contracted analysis with John Dunham & Associates that estimates the effects of the standards on the RV industry. As discussed in Section 11.7 of this Response to Comments, the concern is that the RV industry is at risk to suffer significant negative effects due to the rule, based, in part, on the question of whether RV consumers will factor fuel savings into their purchase decisions. If consumers do not consider fuel savings, then increases in RV price due to complying with the rule could reduce sales, eventually leading to job losses. The RV industry was disproportionately hurt during the Great Recession and has only recently experienced a recovery. As RVIA itself notes, the employment

---

impacts due to the recession were much larger than even their high-level estimates of employment impacts due to the standards: while RVIA’s estimate of the maximum impact of the standards on employment is about 5 percent of current employment levels, it notes that nearly two-thirds of direct manufacturing employees lost their jobs in the recession. Preamble Section IX.L and RIA Chapter 8.11 discuss evidence that macroeconomic conditions appear to have a much more significant effect on employment than does environmental regulation. We also note, again, that the final rule provides optional standards for custom chassis vocational vehicles, including motorhomes, which are less stringent than the main standards, and which may satisfy many of this commenter’s concerns with the proposal. (The custom chassis standards were developed, in part, in response to this and similar comments).

The analysis by John Dunham & Associates also provides indirect and induced effects – that is, effects beyond the direct manufacturing sector – of their estimated sales and employment changes. As discussed in Preamble IX.L and RIA Chapter 8.11, these effects are likely to be small in the scope of the national economy when the economy is near full employment; at such times, environmental regulation is more likely to move employment from one sector to another rather than to have a major effect on total employment. In times of significant unemployment, those impacts are likely to be larger. Because we do not know the state of the macroeconomy at the time that these standards will come into effect, the agencies focus our employment analysis on the directly regulated sector, with qualitative assessment of closely related sectors.

As also discussed in Preamble Section IX.L and RIA Chapter 8.11, employment effects of regulation are due not only to the output effect, the effect on sales of vehicles, but also to the substitution effect, the increased labor costs associated with complying with the standards: part of the increased costs due to meeting the standards goes into labor involved with designing, producing, and installing fuel-saving technologies. The analysis by John Dunham & Associates does not take into account the employment increases associated with this “substitution effect,” and thus is very likely to overstate the decrease in employment associated with the standards. For these reasons, as with overall employment impacts in the HD sector, we expect modest impacts on employment in the RV sector.

11.12 Cost of Ownership and Payback Analysis

Organization: Allison Transmission, Inc.

In the RIA on page 7-45 under section 7.2.4 “Payback Periods,” Table 7-47 shows a payback period for MHs for additional new technology (via a MOVES calculation), that exceeds 23 years. The next closest “long” payback period on the chart is for school buses at 11 to 18 years (at both a 3% or 7% discounted rate and dependent on the fuel choice). This highlights the large difference in the use patterns of MHs versus the other vocational vehicle classes. In other words, as noted above, MHs are seldom driven over the course of a full year. Thus, when compared to most of the other vocational classes, MHs simply do not generate operational costs on par with vocational vehicles from which significant cost savings could occur (e.g., through more mpg). Indeed, the operational savings per year created through increasing the efficiency of MHs would be comparatively miniscule when compared with vocational vehicles that may be driven long distances every day or standard delivery or service routes. Given a “payback period” in excess of 23 years, consumers would literally have no incentive to purchase a more efficient vehicle.

[EPA-HQ-OAR-2014-0827-1284-A1 p.49][This comment can also be found in section 6.4 of this comment summary]

Response:

The agencies considered potential payback as part of the consideration of the rule’s costs, and have concluded that payback is one reason for finding the costs of the Phase 2 standards to be reasonable. We disagree with the assertion that consumers do not care about fuel savings and do not consider fuel savings when purchasing a new vehicle. Allison is claiming here that it is an important and, perhaps, the primary consideration in making a new vehicle purchase, at least for purchases of motor homes. We acknowledge that the payback metric for motor homes is not attractive due to fewer miles travelled and may not entice buyers into showrooms to get the more efficient motor homes. Importantly, the final rules contain custom chassis provisions meant to result in a simpler, less costly set of vehicle technologies than the primary standards would otherwise require.

Organization:  American Trucking Associations (ATA)

Technology Costs Remain Suspect

ATA believes the agencies underestimated the costs of various technologies making the payback period on these technologies much longer than is stated in the proposed rule. A fleet owner typically demands an 18-month payback on technology purchases. If the actual payback extends beyond 24 months, it will likely lead to the risk of increased fleet pre-buy, low-buy, and no-buy scenarios. The Phase 2 Rule currently envisions a maximum 24-month payback period. If variables such as predicted technology costs, MPRs, and fuel costs are not accurate, fleet payback periods for equipment may not be recognized during the period of equipment ownership. Moreover, likely additional costs for maintenance and downtime for new technologies need to be wholly accounted for under the rule. If payback on equipment purchases is pushed beyond ownership periods, there is little or no incentive for fleets to make the initial investments in technologies under Phase 2. [EPA-HQ-OAR-2014-0827-1243-A1 p.10]

To further expand upon this point, let’s focus on one payback period variable. The table below is an abbreviated version of the fuel pricing forecasts contained in the June 2015 Phase 2 Draft Regulatory Impact Analysis (with an additional line added for present-day fuel pricing comparisons). [EPA-HQ-OAR-2014-0827-1243-A1 p.10]

[Table, '2014 Early Release Reference Case Fuel Prices 92012$/gallon', can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1243-A1]

If diesel fuel costs are indeed more than 50% higher than present day fuel pump prices, it is logical to assume that estimated payback periods are reduced (assuming the agencies have accurately forecasted future technology pricing). Moreover, likely additional costs for maintenance and downtime for new technologies need to be wholly accounted for under the rule. If these assumptions are incorrect or lacking and payback on equipment purchases is pushed beyond typical ownership periods (oftentimes 36-48 months), there is little or no incentive for fleets to make investments in technologies under Phase 2. [EPA-HQ-OAR-2014-0827-1243-A1 p.10]

Increased Warranty, Maintenance, and Downtime Costs Should be Included

The proposed Phase 2 standards represent a more technology-forcing approach than Phase 1, predicated on use of both off-the-shelf technologies and emerging technologies that are not yet in widespread use. Past experience with emerging technologies in heavy-duty engines has shown that warranty claims, where an operator takes a vehicle out of service to a maintenance facility to have a part under warranty
replaced, tend to be higher during the initial years of introduction. [EPA-HQ-OAR-2014-0827-1243-A1 p.12]

As shown in Appendix 3, based on warranty claims data required to be submitted to CARB, particulate filter-related warrantee claims were at 35% during their initial year of introduction (2007), decreased to 18% during the second year and fell to 4% during the fifth year (2011, the last year of data provided). Similarly, SCR-related warranty claims were at 20% during their initial year of introduction (2010) and decreased to 10% during the second year (2011). Also of note is how other technologies were affected during the introduction of a new technology. For example, warranty claims for engine/ECM/other components increased from 22% prior to the introduction of particulate filters to 90% during the first year this technology was introduced. [EPA-HQ-OAR-2014-0827-1243-A1 p.12]

This data highlights the fact that additional warranty, maintenance and downtime costs result when new or significantly altered technologies are introduced. It appears the proposed rule only includes increased maintenance costs associated with tires. Based on operational cost data collected from motor carriers, the cost of repair and maintenance accounts for 6-9% of the marginal cost of operating a truck.\textsuperscript{10} This is 3 to 4 times more than tire costs. ATA requests the agencies to further examine the warrantee claims and operational cost data to develop an algorithm that accounts for additional warranty, maintenance and downtime costs as part of the final rule. [EPA-HQ-OAR-2014-0827-1243-A1 p.12-13]

\textsuperscript{10} American Transportation Research Institute, An Analysis of the Operational Cost of Trucking: 2015 Update (September 2015).

**Response:**

We respond to comments regarding pre-buys in Section 11.7.2 of this Response to Comments. Further, we do not believe that extending paybacks beyond 24-months will result in pre-buys/low-buys/no-buys. We have included many more maintenance items in our maintenance cost estimates for the final rules. Please see RIA 7.2.3 for more details. Comments regarding the 2007/2010 criteria pollutant rule are addressed in Section 15.10.4 of this Response to Comments.

**Organization:** Amy's Kitchen et al.

Strong standards will be good for businesses, the trucking industry and American consumers. Importantly, the financial benefits of strong standards will be significantly greater than the costs. These lower life cycle costs will start accruing as soon as the first new trucks enter into service. In fact, trucking will see lower life cycle costs right away and these savings will grow to $0.21 cents a mile in 2040;\textsuperscript{x} that is an annual savings potential of more than $25 billion.\textsuperscript{xi} [NHTSA-2014-0132-0232-A1 p.2]

Organization: Association for the Work Truck Industry (NTEA)

Fuel Efficiency Payback
With regard to Alternative 3, in 2027 when the standard is fully phased in, heavy-duty vehicles across all classes would achieve up to the following CO₂ emissions and fuel use reductions.

- 24 percent for combination tractors designed to pull trailers and move freight when compared to Phase 1 standards
- 8 percent for trailers when compared to an average model year 2017 trailers
- 16 percent for pick-up trucks and light vans when compared to Phase 1 standards [EPA-HQ-OAR-2014-0827-1187-A1 p.3]

Further, the proposal calculates figures for expected payback periods based on the additional costs associated with the proposed standards and the economic savings based on the increased fuel efficiency expected with Alternative 3. The proposal estimates “Reasonable Payback Periods for the Trucking Industry In model year 2027,” for the buyer of a new vehicle. The notice states that the buyer would recoup the extra cost of technology used to achieve the standard (Alternative 3) within:

- 2 years for a tractor/trailer combo
- 3 years for pick-ups and vans

The expected payback periods for tractor/trailer combinations and pick-ups/vans seems reasonable. Most companies would look towards a 2-3 year payback period for moderate fuel efficiency gains. [EPA-HQ-OAR-2014-0827-1187-A1 p.4]

Thank you for your comments.

Organization: CALSTART

Vocational Vehicles. As we shared at the Long Beach workshop, CALSTART recently published a report, titled “Higher Fuel Efficiency: Working for Fleets,” which assessed the business case for fleets from higher fuel efficiency trucks that might be driven by a new fuel economy rule. This report has highlighted two core issues: that there are achievable technologies that can provide higher efficiency on the rule timeline, and that these technologies on whole can be cost-effective and provide reasonable payback to fleets using them. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.1.2 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.152.]]
To understand the payback issue we took a different approach from the Agencies. We worked with a cross section of fleets representing various applications and truck types nationwide to validate the key components of a fleet business case assessment model, collaborating with the NAFA Fleet Management Association and its fleets. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.1.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.152.][This comment can also be found in section 6.1.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.152-153.]

In developing the model, we also surveyed fleets on their support for and concerns about increased fuel efficiency. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.1.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.152-153.]

- Interestingly, we found 87-percent of fleet managers responding supported rules driving higher fuel efficiency. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.1.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.152-153.]

- Their primary concern was cost; though 89-percent said they would be willing to pay more up front for fuel efficient trucks if they knew they would pay back over their life. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.1.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

- They also expressed concern about reliability and maintenance costs. This does have relevance for the rule duration. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.1.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

Using the life cycle cost model we validated with fleets we assessed business cases in seven specific truck use profiles: [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.1.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

- Class 8 Over the Road; [EPA-HQ-OAR-2014-0827-1190-A1 p.2][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

- Class 8 Regional Haul; [EPA-HQ-OAR-2014-0827-1190-A1 p.2][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

- three medium duty use profiles: Urban, rural/intra-city and work site support; and [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

- Class 2B pickups and vans. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

While structured before your draft rules were released, the categories are very similar to the three vocational segments you are proposing and which we do support. [EPA-HQ-OAR-2014-0827-1190-A1 p.2][This comment can also be found in section 6.2 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.153.]

Page 1687 of 2127
We looked at different technology packages that were most applicable to each use profile, assembling packages that could achieve up to a 40 percent reduction of fuel use over 2010 baseline trucks. These packages, and their projected costs, were adapted from National Research Council and Transportation Research Board studies. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.154.]]

Our top level findings were these: [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary]

- We found there is a reasonable business case payback, based on fleet-validated cost assessment tools, for higher fuel economy trucks at levels proposed in the rules. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.154.]]

- The stringency levels we modeled in the report were, in most cases, actually higher than those proposed in the Alternative 3 language. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.154.]]

- We saw the potential for higher fuel economy targets than those proposed in several use profiles – particularly urban trucks, regional trucks and those vehicles with high work site idle time. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.154.]]

- The biggest variables for payback were utilization – the mileage and fuel used – and the upfront cost of the technology. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, pp.154-155.]]

- Fleets have suggested that modeling payback sensitivity to maintenance cost would be helpful and we encourage the Agencies to develop this information to address fleet concerns. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.155.]]

As mentioned, the report used different – and generally higher – assumptions for stringency than those recommended in the Agencies’ preferred Alternative 3. Below we highlight the comparisons between the segments we studied, the corresponding segment in the rule (where there is one), and the stringency proposed in the draft rules compared with those studied in the report. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary]

[Table of segments studied and results can be found on p.3 of docket number EPA-HQ-OAR-2014-0827-1190-A1][This comment can also be found in section 6.2 of this comment summary]

More can be done in Class 8, particularly as concerns advanced engines such as being developed by innovative firms and work being done at the existing OEM levels. However, we believe the Class 8 segment stringency appears both achievable and drives GHG reductions close to the reduction path needed to achieve climate stability. In contrast, we are concerned that the vocational segments as proposed do not meet the same level of reduction path and we believe they could, while still providing
fleet users with the functionality they need and a payback they can afford. [EPA-HQ-OAR-2014-0827-1190-A1 p.3][This comment can also be found in section 6.2 of this comment summary]

In shaping the final rule, we believe the Agencies’ payback projections from efficiency are reasonable and real. Indeed, we see a strong case for higher efficiency targets than those currently called for particularly in several vocational segments. We also see the ability to further push improvements in engine technology than proposed while still making sure those engines are a component of a full vehicle strategy. [EPA-HQ-OAR-2014-0827-1190-A1 p.9][This comment can also be found in section 6.1 of this comment summary][These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.155.]

**Response:**

Thank you for your comments.

**Organization:** Ceres

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 201.]

Despite higher up-front costs, advanced fuel-efficient trucks will more than pay for themselves over a typical ownership period due to fuel cost savings. In fact, a joint analysis by Ceres and the Environmental Defense Fund found these standards would reduce freight costs by 3 percent in 2030 and 7 percent in 2040, an estimated $34 billion annual saving potential.

**Response:**

Thank you for your comments.

**Organization:** City of West Hollywood

Setting a strong second-phase standard will help fleets save more money on fuel. For example, manufacturers could improve the efficiency of transit buses, school buses, utility trucks and other ‘vocational’ vehicles by almost a third by 2025, with technology that would pay for itself in fuel savings in less than 4 years (compared to an average life of 15 years for an average transit bus, for example). [NHTSA-2014-0132-0056-A1 p.2]

Payback times for heavy-duty pickups and vans would be less than three years. And for tractor-trailers, efficient technology could pay for itself completely in only 13 months. [NHTSA-2014-0132-0056-A1 p.2]

**Response:**

Thank you for your comments.

**Organization:** Clean Fuels Ohio (CFO)

In addition to class 8 trucks, the phase two rules will apply to vocational vehicles as well as pickup trucks and vans. Compliance with the rules will raise initial vehicle costs in all market segments. However, savings on fuel will pay for these increased initial costs. The EPA estimates payback periods
will be 2 years for class 8 tractors/trailers, three years for pickups, and 6 years for vocational vehicles. 
Clean Fuels Ohio appreciates the need and value for these rules despite increased up-front costs. 
Assuming EPA estimates are correct, payback periods for tractors, trailers and pickups fall within a 
reasonable timeframe for most commercial users. We do have concerns about the 6-year estimated 
payback for vocational vehicles, since this timeframe falls outside of planned ownership duration for 
many companies who buy vocational vehicles. [EPA-HQ-OAR-2014-0827-1192-A1 p.2]

Clean Fuels Ohio is hopeful that advancements in vehicle efficiency technologies will shorten this 
payback period to lessen the hardship on this industry sector. Clean Fuels Ohio also applauds the EPA 
for suggesting creative approaches, such as "delegated assembly," that leverage innovation in the work 
truck industry by smaller-scale technology developers and third-party installers. [EPA-HQ-OAR-2014-
0827-1192-A1 p.2]

Response:

Vocational vehicle payback periods are difficult to estimate given the variety of duty cycles and vehicle 
types in the vocational vehicle sector. We provide our estimates in a table in final RIA Chapter 7.2.4. 
We do not believe that the payback periods we have estimated will result in pre-/low-/no-buy outcomes.

Organization:  Consumer Federation of America (CFA)

Early in the PHASE II NOPR, the agencies offer a fundamental observation about the proposed rule that 
is highlighted in Figure VI-1. "The standards will result in significantly lower operating costs for 
vehicle owners (unlike the 2007 standard, which increased operating costs).” Unlike many 
environmental regulations, this joint fuel economy/environmental regulation produces so much fuel 
savings that it pays for itself. Two-thirds of the benefits come in the form of fuel savings and these 
benefits are over five times as large as the costs. [EPA-HQ-OAR-2014-0827-1336-A1 p.47]

[Figure VI-1 can be found on p.47 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

Response:

Thank you for your comments.

Organization:  Edison Solar Inc.

Finally, we know that improving truck fuel efficiency can is achievable and can be done affordably: 

• In model year 2027, a new tractor-trailer owner would recoup the extra cost of technology used to 
achieve the standards within 2 years. [EPA-HQ-OAR-2014-0827-1176-A1 p.2]

Response:

Thank you for your comments.

Organization:  First Industries Corporation

(2) EPA underestimates technology costs, meaning that payback periods will be longer than EPA 
estimates [EPA-HQ-OAR-2014-0827-1145-A2 p.2]
EPA Underestimates the Costs of Various Technologies

Because EPA underestimates the costs of various technologies, the payback period on these technologies is actually much longer than is stated in the proposed rule. This is especially of importance as the agencies present the 'average' cost per truck of this rule, whereas customers must pay the actual costs at time of purchase; therefore, actual costs not 'average costs' should be estimated by the rule. Our customers typically demand an 18-month payback on technology. If the actual cost payback extends beyond two years, it will lead to a pre-buy/no-buy situation. [EPA-HQ-OAR-2014-0827-1145-A2 p.4]

The estimated costs of the following technologies as presented in the proposed rule are too low: [EPA-HQ-OAR-2014-0827-1145-A2 p.4]

Warranty Costs and Downtime: The EPA must consider warranty costs and downtime in making its calculations of costs and pay back periods. This is especially important, and difficult to do, when the technology needed to meet the proposed rule is not yet adopted. However, such costs are critical in a customer's purchasing decision and will not be insignificant for a rule that pushes new technology into the market. [EPA-HQ-OAR-2014-0827-1145-A2 p.5]

Response:

Unfortunately, we do not understand the comment about our use of “average” costs rather than “actual” costs. Presumably the comment is meant to differentiate between cost estimates and price impacts. It is true that we do not attempt to estimate prices. Warranty costs are included in our markups estimating indirect costs. Downtime is not expected for the technologies projected for use. Downtime associated with prior EPA regulations should not be seen as an indication that downtime will occur in association with this regulation.

Organization: Gilroy, JD

A third thing I find praiseworthy about the proposed standards is that they seem to involve powerful economic benefits even aside from environmental and health benefits---allegedly 124,000 jobs by 2030 and a ratio of benefits to costs of 10 to 1, or a savings for truckers of $160 billion after new technology upgrades are paid off. That is probably why the affected industries have been largely supportive of the new standards, some even meeting the standards before required to do so, and that is a fourth reason I like them. [EPA-HQ-OAR-2014-0827-0751 p.2][This comment can also be found in section 11.12 of this comment summary]

Response:

Thank you for your comments.

Organization: Hoosier Environmental Council

From an economic perspective, we support this rule as it will lead to net savings for Indiana truck owners, for whom fuel accounts for 40% of their operating cost (American Trucking Associations) and for which payback periods is projected to be as short as two years for later model year tractor-trailers. This is especially important for Indiana, which has made logistics a growth priority, as Indiana ranks in the top 10 in more than 40 logistics-related metrics (Indiana Economic Development Corporation). [EPA-HQ-OAR-2014-0827-1245-A1 p.1]
Thank you for your comments.

Organization: NAFA Fleet Management Association

Trucking fleets can better absorb cost increases associated with the purchase of fuel efficiency technologies if they deliver reasonable payback periods. We are concerned that the actual costs of Phase 2 technologies for model year 2017-2027 vehicles will greatly exceed the agencies’ estimates. Fleets look at the total cost of ownership (TCO) — acquisition costs, fuel, personnel, maintenance, overhead, road charges, insurance, residual values, and taxes, to name a few components of TCO [NHTSA-2014-0132-0111-A1 p.2]

Fleet managers are responsible for the entire capital budget for new and replacement vehicles. Multi-year capital forecasts are done annually. The capital approval and release for spending is an annual exercise and depends on the organization’s resources. [NHTSA-2014-0132-0111-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.179.]]

When deciding to purchase or lease a vehicle, a fleet manager looks first at the cost of the vehicle and how that cost affects the annual vehicle replacement budget. The initial cost of the vehicle is always a concern. The projected lifecycle costs and the payback period do factor in to making the business case for a vehicle; and no variable cost is more important than fuel. The projected payback periods in the proposal are based on fuel savings, but after cost, a fleet’s primary focus is on making sure that the vehicle and drivetrain features meet the specific work and duty-cycle needs, before considering fuel savings. [NHTSA-2014-0132-0111-A1 p.2] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.179.]]

A review of the American Trucking Research Institute analysis data find that the operational costs have increased about 8-9% year over year. (See Table below) [NHTSA-2014-0132-0111-A1 p.2]

[Table can be found on p.2 of docket number NHTSA-2014-0132-0111-A1]

There are also indirect costs related to excessive warranty repair recovery, as well as the external work required because vehicles increasingly need to be sent to the dealers due to complexity of the new technology. The latter causes increases in downtime, as the dealers are overwhelmed and ill equipped at times to handle the capacity and capability issues. [NHTSA-2014-0132-0111-A1 p.13]

Response:

We have made every effort to put forth what we believe to be the best cost estimates available to us. Realize that we do not attempt to estimate price impacts because so many factors go into eventual pricing, but we have attempted to estimate the increased costs necessary to comply with the standards. As such, we do not believe that the actual costs will greatly exceed our estimates.

Organization: Odyne Systems LLC

Return on Investment Projections

Odyne has constructed basic payback models for medium and heavy-duty truck systems to assist the EPA in its market penetration and cost assumptions for Phase Two final rule development. The figures
included here are best estimates using available industry and Odyne-specific data. Projections made here are based on plug-in hybrid systems for vocational trucks with PTOs that are able to attain full workday duty cycle GHG reductions of up to 50% or better. [EPA-HQ-OAR-2014-0827-1239-A1 p.10]

Response:

Organization: Owner-Operator Independent Drivers Association (OOIDA)

Cost of Trucks

The agencies claim an owner of a new truck designed under the proposal will be able to recoup costs in “less than two years” due to fuel savings, however, the agencies have yet to show a direct connection between specific technologies and specific costs savings. The GEM model that the agencies utilized to make these estimates does not reflect all types of operations or geography. Moreover the OEMs have unmistakably declared that such a payback period is unrealistic considering the actual costs of the rule. Again, the agencies estimated that a new MY 2027 tractor will cost roughly between $10,000 and $13,000 more due to the Phase II standards. Nevertheless, this is based on the false assumption that typical heavy-duty truck costs $100,000. According to the OOIDA Foundation’s Owner-Operator Member Profile Survey, the average price of a new truck today is $123,351. [EPA-HQ-OAR-2014-0827-1244-A1 p.41-42]

While a $10,000 increase, which is an underestimation of actual costs, does not seem to be a large sum to the agencies proposing the rule, this cost is quite substantial for an owner-operator who takes home a net revenue of approximately $30,000 per year. If an individual were to purchase a new 2016 Kenworth T660 and a new 2016 Reitneour Dropdeck flatbed trailer for $164,593 and $49,500, respectively, before taxes and fees. This price does not include the additional costs for chains, tarps, nylon straps, ratchet binders, etc., which are necessary in order to secure a load to the trailer. Even with a promise of a return on their investment via improved fuel economy, which again, is not realistic, the investment must be attainable in order to receive any positive benefits from the technology. An increase of $10,000 can easily put the purchase of a new truck out of reach for an owner-operator or small fleet. Simply stated, if the cost of the equipment exceeds the point where a person can attain credit in order to purchase it, an owner-operator will not buy it. This is an increasingly likely scenario with the Phase 2 NPRM, thus the opportunity for safe and experienced drivers to become an owner-operator will be reduced. It is important for the agencies to also include as part of their cost and benefit analysis, the increased purchase price of used trucks in response to the uptick in demand for vehicles without Phase II technologies. [EPA-HQ-OAR-2014-0827-1244-A1 p.42-43]

Warranty, Maintenance, and Downtime Costs

The proposed rule will force new technologies into the market and with new technologies will come increased warranty costs, maintenance costs, and costs associated with increased downtime. The proposed rule only counts some of the increased maintenance costs associated with tires. In doing so, the agencies are greatly underestimating the overall impact of new technology. The agencies should calculate in the analysis additional warranty, maintenance and downtime costs. In an April 2014 Board Meeting, OOIDA Board Member Lewie Pugh presented to the EPA a 7-foot long printout of everything that had gone wrong with the MaxxForce engine truck that he had purchased in 2011. He said, “When
the truck breaks down, the mechanics don’t even know what’s wrong. They don’t know how to work on them. The dealership I go to is packed with trucks with emission problems. [EPA-HQ-OAR-2014-0827-1244-A1 p.45]

If an Alternative that forces new technologies is chosen by the agencies, the impact of increased repairs beyond traditional warranty coverage needs to be taken into account. Small business owners and fleets cannot continue to bear the cost of forced technologies and the ensuing repairs. The irony with this situation is that any increased warranty coverage would increase the purchase price of a new truck. Additionally, this will negatively impact the resale value of the truck. For example, the trucks subject to the Phase I standards, such as the MaxxForce engine which caused large amounts of downtime, will be passed along to the new consumer, without an extended warranty, many owner-operators could be placed out of business. According to the OOIDA Foundations Member Profile Survey, 74 percent of owner-operators purchase used trucks. Any unreliable or problematic truck produced as a consequence of the Phase II standards will eventually be placed on the used market, thus adversely impacting owner-operators who purchase them several years into the future. [EPA-HQ-OAR-2014-0827-1244-A1 p.45-46]

48 “EPA takes notes on OOIDA concerns.”

Response:

The commenter states that, “the agencies have yet to show a direct connection between specific technologies and specific costs savings.” We respond to comments regarding GEM in Section 2 of this Response to Comments, the effectiveness of engine technologies in Section 3 of this Response to Comments, and the effectiveness of tractor technologies in Section 4 of this Response to Comments.

Our cost estimate for tractors is not in any way based on a false assumption that the cost of a tractor is $100,000. We take a bottom up approach to estimating our tractor cost by first estimating individual technology costs, then estimating their adoption rates, then estimating the resulting cost impact. That estimate is independent of the total cost or price of a tractor. We mentioned the $100,000 tractor only as a means of providing some scale. Most readers of our regulatory documents are far more familiar with light-duty vehicle prices in the $25,000 to $40,000 range. So it was seen as important to provide some scale when presenting a cost impact on the order of $10,000 to $13,000. If a tractor is more like $123,000, that simply means the cost impact of the new standards is a lower percentage than we suggested when we used the $100,000 value. As for increased warranty, we include these in our indirect cost markups. As for downtime, we do not foresee any increased downtime associated with the technologies expected in response to the new standards.

Organization: PepsiCo

[The following comments were submitted as testimony at the Long Beach, California public hearing on August 18, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1420, p. 43.]

The EPA and NHTSA’s approach to evaluate current and future technology adoption into the heavy-duty truck industry with an average two-year payback is a fair assumption and creates a standard built on facts and grounded in logic.
Response:

Thank you for your comments.

Organization:  Quasar Energy Group

Finally, we know that improving truck fuel efficiency can is achievable and can be done affordably: [EPA-HQ-OAR-2014-0827-1335-A1 p.2]

In model year 2027, a new tractor-trailer owner would recoup the extra cost of technology used to achieve the standards within 2 years. [EPA-HQ-OAR-2014-0827-1335-A1 p.2]

Response:

Thank you for your comments.

Organization:  Truck Renting and Leasing Association

The economic savings touted by the agencies, to the extent they materialize, will not be seen by the renting and leasing industry. The agencies’ economics are premised on the notion that increased up-front costs due to the addition of expensive fuel-economy technologies will be made up later, in whole or in part, through future savings via reduced fuel consumption and thus fuel expenditures. Proposed Standards, at 40483. In the vehicle leasing context, whatever benefits may accrue from reduced fuel expenditures will be reaped by the vehicle operator/lessee, not the lessor. That scenario, in turn, may tend to favor vehicle ownership over leasing – an outcome that could result in negative environmental and economic outcomes to society overall given the benefits provided by the leasing industry.3 [EPA-HQ-OAR-2014-0827-1140-A1 p.4]

Response:

The new standards are not intended to provide benefits or costs to any individual stakeholder out of line with any other stakeholder. In fact, the new standards are meant to result in net benefits to society, which they do. We do not believe that the current market will undergo any meaningful disruption due to the new standards.

Organization:  Werner Enterprises

There are several key areas the Agencies need to address: [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

- Accurately reflect operators’ total cost of ownership [EPA-HQ-OAR-2014-0827-1236-A1 p.2]

- Correct underestimated costs of technology and maintenance costs meaning the payback periods will be longer than estimated. [EPA-HQ-OAR-2014-0827-1236-A1 p.2]
Response:

The commenter has not provided sufficient detail for us to consider possible improvements to our estimates. We have made changes as discussed throughout the final RIA in an effort to improve every aspect of our analysis.

Organization: Recreational Vehicle Industry Association (RVIA)

If the standards for work trucks (e.g., Ford F-250 or Ram 2500 pickups) are finalized as proposed, these vehicles that are used for RV towing would need to become more fuel efficient during the 2021-2027 timeframe. The fuel economy standards would reduce fuel consumption by 2.5% each year such that by 2027 these vehicles would consume 16% less fuel than pre-2021 vehicles. [EPA-HQ-OAR-2014-0827-1261-A1 p.26]

According to agency estimates, these improvements will cost an estimated $493 in 2021 to $1,366 in 2027. Thus, for a $40,000 work truck, the price increase would range from 1.2% to 3.4%. [EPA-HQ-OAR-2014-0827-1261-A1 p.26]

Although EPA finds that the savings at the pump may eventually offset the increase in cost associated with the fuel savings technology required for compliance with work truck standards, we are concerned that the cost increase associated with this regulation, when coupled with cost increases relating to a number of other regulatory requirements coming from CARB and NHTSA, will cause harm to the RV industry. [EPA-HQ-OAR-2014-0827-1261-A1 p.26]

If the cost of purchasing a towable RV, such as a travel trailer, fifth-wheel, folding camping trailer, or truck camper and the vehicle needed to tow the RV is no longer cost-competitive with other recreation alternatives, consumers will leave ‘RV'ing’ for a more affordable alternative such as boating. This could have a devastating impact on the RV industry and more specifically the same small rural communities that produce motorhomes (see Section VIII). EPA should more carefully consider the impact of this regulation in conjunction with other regulations. In fact, this is required by Section 1(b) of Executive Order 13563 (Improving Regulations and Regulatory Review) which states that, when issuing new regulations, agencies shall tailor their regulations to impose the least burden on society, consistent with obtaining regulatory objectives, taking into account, among other things, and to the extent practicable, the costs of cumulative regulations.” (emphasis added). [EPA-HQ-OAR-2014-0827-1261-A1 p.26-27]

Operating in a vacuum can have dangerous consequences and EPA should carefully consider the cost impact of not just this regulation on tow vehicles but other regulations that are in development or likely to be put into effect in the next decade by either NHTSA or EPA that could affect these vehicles. As EPA is conducting this rulemaking jointly with NHTSA and closely coordinating with CARB, there is no reason why these three agencies, the primarily regulators of the auto industry in the U.S., should not be able to undertake this very important task of looking at what future regulatory requirements are on the horizon and what will be the cumulative costs associated with them in the aggregate. [EPA-HQ-OAR-2014-0827-1261-A1 p.27]

Response:

RVIA has raised concerns that the increased price for pickups hauling recreational vehicles (RVs) might reduce interest in RVs, and people might switch to another activity, such as boating. We note that, for HD pickups generally used for hauling RVs, the savings outweigh the costs within the third year of ownership (see RIA Chapter 7.2.4). We are unaware of evidence on the combined effects of higher up-front costs and lower operating costs on the purchase or use of pickups for hauling RVs: the lower
operating costs might encourage use, even if the higher up-front costs might discourage purchase. We are also unaware of evidence that people interested in “RVing” might choose instead to do something so different, such as boating, based on the increased cost of the pickup needed to tow the RV.

RVIA would also like the agencies to consider the costs of future regulations as well as current ones in its estimates. We include in the reference case the costs of all existing regulations on vehicles. Because it is impossible to know the requirements or costs of future regulations before they are finalized, it is not possible to include the costs of future regulations in this analysis.

11.13 Safety Impacts

Organization: American Chemistry Council (ACC)

Lightweight plastic and composite materials have the ability to reduce vehicle weight without compromising safety, and Congress has taken steps to recognize that fact. Over the last 9 years, Congress has directed NHTSA to create a safety roadmap for lightweight Plastic and Composite Intensive Vehicles (PCIVs) through the THUD Appropriations bills. The report, titled “A Safety Roadmap for Future Plastics and Composites Intensive Vehicles” and published in 2007, evaluates the potential safety benefits of PCIVs to enable their deployment by 2020. [EPA-HQ-OAR-2014-0827-1147-A2 p.4]

In support of the Roadmap’s implementation, NHTSA conducted a study to lightweight a 2008 Silverado by approximately 20% utilizing plastic and polymer composites. The lightweight study vehicle was shown to maintain equivalent safety based upon NCAP test results. The study, entitled “Investigation of Opportunities for Lightweight Vehicles Using Advanced Plastics and Composites” was finalized and published by NHTSA in 2012. As in comments submitted in 2011 in response to the Phase I, ACC continues to urge EPA/NHSTA to make full implementation of the PCIV safety roadmap, because it not only exhibits the full performance potential that PCIVs hold, but also recognizes the importance of ensuring safety at each phase of product development. ACC stands ready to assist the agencies in this regard. [EPA-HQ-OAR-2014-0827-1147-A2 p.4]

The high strength and energy absorption of structural polymer composites can also improve crash safety by strengthening vehicle compartments to help protect passengers during crashes. [EPA-HQ-OAR-2014-0827-1147-A2 p.5]

NHTSA Should Continue to Review and Analyze Potential Safety Impacts of Fuel Efficiency Technologies

In June 2015, NHTSA published its Review and Analysis of Potential Safety Impacts of and Regulatory Barriers to Fuel Efficiency Technologies and Alternative Fuels in Medium- and Heavy-Duty Vehicles.\(^\text{12}\)

This report undertook a safety analysis of medium- and heavy-duty vehicles equipped with fuel efficiency technologies and/or using alternative fuels (i.e., CNG, LNG, propane, biodiesel, and power train electrification). This peer-reviewed study included a comprehensive literature review, complemented with inputs from subject matter experts, and a scenario-based hazard analysis. Specific fuel efficient technologies examined included: Intelligent Transportation Systems and telematics, speed limiters, idle reduction devices, tire technologies (single-wide tires, TPMS and ATIS), aerodynamic components, longer-combination vehicles, and light-weighting materials. Federal and state safety regulations and voluntary technical standards affecting fleet adoption rates of fuel efficient technologies and alternative fuels were discussed, as were potential regulatory barriers. The findings, while based on literature reviews up though 2013 and prior to the implementation of Phase 1, suggest that potential safety hazards identified can be prevented or mitigated by complying with safety regulations, voluntary standards, and industry best practices. The study did not identify any major regulatory barriers to rapid adoption of fuel efficient technologies and alternative fuels by both medium and heavy-duty fleets.\[EPA-HQ-OAR-2014-0827-1243-A1 p.17\]

ATA is pleased that NHTSA has undertaken such a study and asks that DOT’s Volpe National Transportation Systems Center continue to assess and evaluate potential safety impacts that may be attributed to the use of fuel efficiency devices. ATA recommends that regular updates and publication of results be undertaken on an established schedule as determined by NHTSA but not less frequent than once every three years. Such analysis should build upon the technologies already identified under the 2015 report and should be expanded to include warranty claim reviews as well as fleet interviews and surveys.\[EPA-HQ-OAR-2014-0827-1243-A1 p.17\]

---

Organization: Diesel Technology Forum

We believe these are also important considerations for EPA in developing a final Phase 2 rules, as follows: [EPA-HQ-OAR-2014-0827-1171-A2 p.5]

- That it is mindful of the other requirements placed on industry relative to environmental and safety requirements of commercial vehicles: Unlike passenger cars, commercial trucks must adhere to a number of additional federal and state safety and operational requirements. Provisions that impact fuel economy must not compromise safety or utility of the vehicle. [EPA-HQ-OAR-2014-0827-1171-A2 p.6]

Organization: Optimus Technologies

Biodiesel
Regarding the comment at 80 FR 40486 (Column 3, Paragraph 5) about issues with biodiesel specifically that biodiesel has “presented some operational safety concerns dependent on blending fraction, such as material compatibility, bio-fouling sludge accumulation, or cold-weather gelling.” Optimus Technologies would like the EPA and NHTSA to be aware of Optimus’ biodiesel conversion system which is retrofitted onto diesel vehicles (for which Optimus has achieved EPA compliance) and eliminates the problems with material compatibility and cold-weather gelling. [EPA-HQ-OAR-2014-0827-1276-A1 p.3]

Response:
Thank you the comment. The conversion systems would need to be considered by the manufactures as an alternative technology as they have internal vehicle requirements for packaging, quality, serviceability and other factors. Safety and legal requirements of this technology would need to be addressed during complete system testing. The testing methods of each manufacturer are proprietary and provisioned to different vehicle applications.

11.14 Consumer Impacts

Organization: Amy's Kitchen et al.

Strong standards will be good for businesses, the trucking industry and American consumers. Importantly, the financial benefits of strong standards will be significantly greater than the costs. These lower life cycle costs will start accruing as soon as the first new trucks enter into service. In fact, trucking will see lower life cycle costs right away and these savings will grow to $0.21 cents a mile in 2040;\(^x\) that is an annual savings potential of more than $25 billion.\(^{xi}\) [NHTSA-2014-0132-0232-A1 p.2]

Organization: Business for Innovative Climate & Energy Policy

In turn, these benefits would accrue to consumers and the greater economy; under stricter standards, the average U.S. household stands to save $250 per year in lower priced goods.\(^3\) [NHTSA-2014-0132-0095-A1 p.1-2]

Organization: Clean Fuels Ohio (CFO)

EPA also has suggested that the proposed rule will help bring down the costs of transporting goods, with the average household saving $150 a year by 2030, assuming the savings and costs are passed through to consumers. [EPA-HQ-OAR-2014-0827-1192-A1 p.2]
As discussed below, the fuel consumption of medium and heavy duty trucks is an important consumer issue and the performance standard approach taken by the agencies is exactly the right approach. Our technical expertise is not in the design and construction of these consumer durables, it is in the design and implementation of minimum energy standards focusing on their impact upon consumers. We believe that knowing how to build an effective standard is at least as important to arriving at a successful energy saving outcome as knowing how to build a consumer durable. Moreover, although we do not claim expertise in the technical design of consumer durables, we do claim expertise in the economic analysis of technologies. Our analysis combines a review of the technical economic studies prepared by others and evidence on the market performance of heavy duty trucks to determine whether there are significant potential consumer savings that would result from a higher standard. [EPA-HQ-OAR-2014-0827-1336-A1 p.7-8]

B. APPROACH AND OUTLINE

We approach the setting of standards from a uniquely consumer point of view, always starting from a series of basic questions: [EPA-HQ-OAR-2014-0827-1336-A1 p.8]

- Will a standard save consumers money? If there appears to be potential savings, we ask: [EPA-HQ-OAR-2014-0827-1336-A1 p.8]

- Why is there an efficiency gap that appears to impose unnecessary costs on consumers? If we find market imperfections that prevent the efficiency gap from being closed and cost savings from being realized, we then ask: [EPA-HQ-OAR-2014-0827-1336-A1 p.8]

- Is a standard an appropriate policy and, if so, how can the standard be best designed to achieve the goal of lowering consumer cost? If a standard seems to be a good option, we then ask: [EPA-HQ-OAR-2014-0827-1336-A1 p.8]

- Does the proposed standard do a good job? Here we evaluate the standard EPA/NHTSA has proposed against the answers to the first three questions. [EPA-HQ-OAR-2014-0827-1336-A1 p.8]

These comments are divided into five sections. We answer the first question above in two steps. First, in Section II, we estimate the amount and cost of fuel consumed by the medium and heavy duty trucks subject to the proposed rule compared to the amount of money households pay for gasoline and electricity, which is the second largest home energy cost. [EPA-HQ-OAR-2014-0827-1336-A1 p.8]

Then, in Section III, we show that consumers are very likely to “Pay the Freight. Household budgets bear the burden of truck fuel costs indirectly in the cost of goods and services they buy. As a result, the Phase II rule deserves close attention from the consumer point of view. [EPA-HQ-OAR-2014-0827-1336-A1 p.9]

II. THE CONSUMER STAKE IN THE FUEL USE OF HEAVY DUTY TRUCKS

Over the past decade public opinion polling by the Consumer Federation of America and other organizations has revealed strong and widespread support for energy efficiency standards for consumer durables including automobiles and households appliances. Because gasoline and electricity bills are such a large part of household annual expenses – currently about $2,600 for gasoline and over $1400 for electricity — it is not surprising that polls consistently elicit this support. Consumers clearly feel the
pain in their pocketbooks and understand the economic impact of those energy costs on their household budgets. [EPA-HQ-OAR-2014-0827-1336-A1 p.9-10]

Economic analysis has shown that there is a sound basis for consumer support of energy efficiency standards. Although energy saving technologies require an investment, when they lower energy bills by more than their cost, the result is ultimately net savings to consumers. [EPA-HQ-OAR-2014-0827-1336-A1 p.10]

While direct household expenditures on personal energy consumption are significant, they are only part of the consumer’s expenditures on energy. Consumers also pay indirectly for the energy consumption in the commercial and industrial sectors through the prices of goods and services. As shown in Figure I-1, the total residential energy consumption represents just over one-third of total national energy consumption. In other words, almost two thirds of the nation’s energy consumption takes place in the production and distribution of goods and services and the costs incurred are recovered in the prices of those goods and services. [EPA-HQ-OAR-2014-0827-1336-A1 p.10]

[Figure 1-1, 'Energy consumption in the residential, commercial and industrial sectors' can be found on p.10 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

In fact, these comments show that indirect freight truck fuel costs passed on to consumers are about half as large as direct gasoline expenditures and almost equal to household electricity bills. [EPA-HQ-OAR-2014-0827-1336-A1 p.11]

Consumers recognize that when fuel prices rise, so does the cost of consumer goods due to the cost of transporting those goods. Conversely, because of competition, a reduction in transportation costs will result lowering the cost of goods and services for consumers. Reducing the energy consumption of medium and heavy duty trucks will reduce household expenditures by lowering the cost of all goods and services. Therefore, the rulemaking currently underway regarding medium and heavy duty truck fuel consumption deserves close scrutiny and support from consumers and consumer advocates. This section examines the costs of energy used by medium and heavy duty trucks and the positive impact increased truck fuel efficiency can have on America’s households. [EPA-HQ-OAR-2014-0827-1336-A1 p.11]

In this section we estimate the potential size of the indirect consumer expenditure. In the next section, we discuss the evidence that the costs are passed through to consumers and survey evidence that shows the public understands the impact of transport costs on their pocketbooks and the role of truck fuel economy standards in alleviating the burden. [EPA-HQ-OAR-2014-0827-1336-A1 p.11]

A. HOUSEHOLD EXPENDITURES FOR MEDIUM AND HEAVY DUTY TRUCK FUEL

Expenditures for transportation fuels, whether direct or indirect, are the result of the amount of energy consumed and the price of that energy. [EPA-HQ-OAR-2014-0827-1336-A1 p.11]

To estimate the potential consumer savings from improvements in the fuel economy of trucks, we first estimated the fuel used by the three main vehicle categories (household light duty, commercial light duty, and medium-heavy duty trucks). We undertake this analysis because different organizations that analyze energy use slightly different categorizations of energy use by different types of vehicles, and we want to make clear how we arrived at our figures. However, because light duty vehicles, which make up the vast majority of households vehicles, are already covered by CAFE standards, we do not include them in our analysis. We have been careful not to double count energy light duty consumption in our
estimate of indirect household expenditures on medium and heavy duty transportation fuel. [EPA-HQ-OAR-2014-0827-1336-A1 p.12]

Table II-1 (below) shows three different approaches to estimating household gasoline consumption. We used several data sources to build our estimate: EIA Residential Consumption Survey, the Department of Transportation’s, National Household Transportation Survey; the Energy Information Administration’s Annual Energy Outlook; the Bureau of Labor Statistics’ Consumer Expenditure Survey; and the U.S. Department of Transportation’s, Bureau of Transportation statistics each of which estimates fuel usage by types of vehicles. [EPA-HQ-OAR-2014-0827-1336-A1 p.12]

[Table II-1, 'three methodologies for estimating the indirect, aggregate, annual household consumption of transportation energy', can be found on p.12 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

The 2009 calculation compares an estimate based on the Bureau of Labor Consumer Expenditure Survey to an estimate based on the National Household Transportation Survey, both for 2009. Using each of the estimates, we divided the household expenditure by the average price per gallon to arrive at the number of gallons per household. We then multiplied the household consumption by the total number of households. The National Household Transportation Survey estimates the total number of vehicle miles traveled by households. We divided this by the average miles per gallon of the light duty vehicle fleet to arrive at the amount of gasoline consumed. These two estimates are quite close. [EPA-HQ-OAR-2014-0827-1336-A1 p.13]

The 2010 estimate is based on EIA data that identifies the amount of energy consumed by automobiles and light duty vehicles, medium duty vehicles and heavy duty trucks. The EIA data does not separate out household and commercial use of light duty vehicles, so we used the Consumer Expenditure Survey from the Bureau of Labor Statistics to estimate the gasoline consumed by households. We subtracted this from the total for light duty vehicles, as reported in the Annual Energy Outlook, to determine the amount of energy consumed by light duty vehicles that is not consumed by households. We call this commercial light duty. [EPA-HQ-OAR-2014-0827-1336-A1 p.13]

As shown in Table II-1, this approach provides an estimate that is consistent with the Department of Transportation data, which categorizes vehicles by axle length and the number of tires. Again, the estimates are quite close, although they are lower than the estimate for 2009. There was a decrease in consumption between 2009 and 2010 in the aggregate consumption. The consistency of this data provides us with a substantial level of confidence in the amount of medium and heavy duty truck fuel we use for our calculations. [EPA-HQ-OAR-2014-0827-1336-A1 p.13]

Table II-2 applies the BLS/EIA approach from Table II-1 to the data for 2013 and 2014. We prefer this approach since it can be updated easily. As a result, for 2013, we estimate 92 billion gallons of household gasoline consumption and 43 billion in medium and heavy duty truck consumption. We reduce the freight truck consumption by 11% to account for exports, since their cost burden would not fall on consumers. [EPA-HQ-OAR-2014-0827-1336-A1 p.14]

[Table II-2, 'Household expenditures', can be found on p.14 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

This confirms the conclusion we reached in our earlier analysis. We estimate 730 direct gallons per household and 300 indirect gallons of diesel fuel consumption. Keeping in mind that diesel prices were 10% higher than gasoline prices in 2013, for every dollar that consumers spend on household gasoline, they spend about $0.47 on freight transport fuel consumption. At an annual cost of nearly $1,200,
households spend almost as much on freight truck fuel as they do on electricity. [EPA-HQ-OAR-2014-0827-1336-A1 p.15]

B. FUTURE HOUSEHOLD EXPENDITURE TRENDS

Any cost/benefit analysis of a proposed standard must be forward looking and factor in expected costs at the time of implementation. As shown in Figure II-2, the EIA projects lower prices for both gasoline and diesel in 2020, followed by a steady increase in prices to 2030. The Figure shows both “real” prices, which are adjusted to compensate for inflation and actual expected prices. The EIA, which is the primary source that government agencies use for future pricing, projects diesel prices to rise slightly faster than gasoline prices, which has been the trend for the past decade. [EPA-HQ-OAR-2014-0827-1336-A1 p.15]

[Figure II-2, 'future prices, real and discounted', can be found on p.15 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

Figure II-2 also shows the effect of “discounting” future prices. The reason to discount is that the use of money has value. It could have been put to other uses and earned a return. The standard discount rates established by the Office of Management and Budget (OMB) for regulatory analysis are 3% for the consumer discount rate and 7% for the producer discount rate. In our analysis of the proposed rule, we use the consumer discount rate of 3%. [EPA-HQ-OAR-2014-0827-1336-A1 p.16]

As large as current household spending is on transportation fuel used by medium and heavy duty trucks, it will become even larger in the future. Going forward, the new CAFE requirements will lower the household impact of fuel costs associated with consumer and commercial light duty vehicles. On the other hand, without some controls, the burden on households due to medium and heavy duty truck fuel costs will only increase both absolutely and relative to their direct expenditures on gasoline. Figure II-3 shows that, historically, the fuel economy of medium-heavy duty trucks has not increased. [EPA-HQ-OAR-2014-0827-1336-A1 p.16]

[Figure II-3, 'motor economy 1949-2011', can be found on p.16 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

The most recent Annual Energy Outlook from the EIA, incorporating the new fuel economy standard for light duty vehicles, projects a substantial decline in fuel consumption as a result of increasing fuel economy standards, as shown in the top graph of Figure II-4. [EPA-HQ-OAR-2014-0827-1336-A1 p.17]

[Figure II-4, 'Trends in fuel economy and consumption mileage by vehicle type expected mpg', can be found on p.17 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

As shown in the bottom graph of Figure II-4, fuel consumption of light duty vehicles (and therefore household gasoline) is projected to decline because the increase in fuel economy is larger than the expected increase in miles driven. On the other hand, in spite of the recently adopted truck standard (2014), the EIA projected MPG for these vehicles to remain flat. As the use of these vehicles increases, the lack of MPG improvement and rising fuel prices will significantly increase fuel costs. [EPA-HQ-OAR-2014-0827-1336-A1 p.18]

Without long-term standards for freight trucks, fuel consumption of trucks is projected to increase because fuel economy improvements will not keep up with increasing demand for freight services.
Within 20 years, taking the price difference between gasoline and diesel into effect, the gap between direct and indirect household expenditures on transportation energy will narrow considerably. As shown above, today, the burden imposed indirectly on household budgets by truck fuel consumption equals about half the burden imposed directly by gasoline consumption. Without stronger fuel economy standards for trucks, that burden will grow to 80% of the future gasoline burden because the current light duty standard will drive down consumption. [EPA-HQ-OAR-2014-0827-1336-A1 p.18]

This analysis of the indirect cost burden that medium and heavy duty trucks place on household budgets indicates that consumers have a big stake in the Phase II rule. [EPA-HQ-OAR-2014-0827-1336-A1 p.18]

III. COMMERCIAL FUEL COSTS ARE PASSED THROUGH TO HOUSEHOLDS

A. A COST OF DOING BUSINESS

While we have calculated the size of fuel expenditures on a per household basis, we must ask, “do households actually pay these costs?” To a large degree, the answer is “Yes.” These costs are just like any other commercial costs in the economy. When a farmer pays for fertilizer or the delivery driver gets his paycheck, these business costs are recovered in the price of the related goods and services. The same is true with fuel costs. In fact, the Mid-Atlantic Freight Coalition confirms the pass-through of transportation costs in a report on how transportation and logistics consume a significant portion of household budgets. According to the report, [EPA-HQ-OAR-2014-0827-1336-A1 p.19]

“This freight logistics system costs nearly $4,500 per person, which is spent moving and warehousing goods. This $4,500 factors into the cost of every product we buy. Anything that industry or government can do to make the logistics system more efficient will return benefits in terms of lower cost and greater global competitiveness.”[14] [EPA-HQ-OAR-2014-0827-1336-A1 p.19]

Although this estimate of the size of the expenditure on freight logistics includes all transportation modes (truck, rail, barge, etc.) and all costs, (equipment, maintenance, salaries, etc.), it acknowledges the importance of transportation costs to the economy which includes truck fuel costs. In addition to the pass-through of these costs to consumers, there is the significant dependence on foreign sources for this fuel. Imported petroleum now makes up just under half (48%) of the total U.S. product supplied,[15] which is a drain on the U.S. economy. [EPA-HQ-OAR-2014-0827-1336-A1 p.19]

While the recognition that transportation costs are paid by consumers is obvious, the concept is reinforced by two observations: First, although transportation costs are a small part of the total economy (just under 3%), they are as large or larger, than several other sectors, including agriculture, mining, utilities and construction (see Figure III-1). It is widely recognized that those costs are passed on to consumers. [EPA-HQ-OAR-2014-0827-1336-A1 p.19]

[Figure III-1, 'gross domestic product by sectors', can be found on p.19 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

Second, fuel costs are the single largest component of transportation costs, representing over one-third of the total transportation costs (see Figure III-2). Fuel costs are slightly larger than driver pay and three times as large as the cost of owning and insuring the truck. As transportation costs are passed through to consumers, fuel is the largest component of that pass through. There is certainly no reason to believe that fuel costs are less likely to be recovered from consumers than drivers’ wages or owners’ capital costs. [EPA-HQ-OAR-2014-0827-1336-A1 p.20]
B. ECONOMETRIC MODELS DEMONSTRATE THE PASS-THROUGH NATURE OF TRANSPORTATION FUEL COSTS

The economic reality of the flow through to consumers of transportation fuel costs is reflected in the way econometric models describe the growth of the economy. Such models are built on input/output tables, and transportation costs are a significant input in the models. In building these models, the pass-through of transportation costs is assumed, since transportation plays a fundamental role in the overall cost of production. [EPA-HQ-OAR-2014-0827-1336-A1 p.21]

Transportation is an economic factor of production of goods and services, implying that relatively small changes can have substantial impacts on costs, locations and performance…[EPA-HQ-OAR-2014-0827-1336-A1 p.21]

Transport also contributes to economic development through job creation and its derived economic activities. According to a large number of direct (freighters, managers, shippers) and indirect (insurance, finance, packaging, handling, travel agencies, transit operators) employment are associated with transport. Producers and consumers make economic decisions on products, markets, costs, location, prices which are themselves based on transport services, their availability, costs and capacity. 16 [EPA-HQ-OAR-2014-0827-1336-A p.21]

The importance of transportation in these economic models is reflected in the high multiplier it is given. In order to build a model of the economy, analysts study the places where a sector purchases inputs and sells output. Typically, the more places that are touched by a sector, the larger its multiplier. Because most economic models are built on the flow of goods and services through the economy, they depend on the geographic scope and nature of activity within the economy being modeled. Transportation is generally seen as a central input to measuring broader economic activity. To further reinforce the impact of transportation costs on consumer pocketbooks, Figure III-3 presents the sector multipliers for the state of California. [EPA-HQ-OAR-2014-0827-1336-A1 p.21]

Transportation has the 20th largest multiplier, in a study of 60 California sectors. Not only is the transportation cost multiplier above average, but it is substantially larger than the multipliers related to petroleum production. [EPA-HQ-OAR-2014-0827-1336-A1 p.22]

In modeling the impact of higher fuel economy with these econometric models, it is important to understand certain market factors. As the cost of transportation declines, demand for transportation increases because the demand for goods and services increases due to their lower costs. In addition, as the population and economy grows, the need for commercial transportation increases as well. Nevertheless, the fuel savings from greater efficiency are much larger than the increase in consumption. The net effect is to reduce expenditures on fuel as a percent of total output. In fact, the reduction in energy consumption may be so large that the absolute level of consumption is lowered. This has a positive effect on the economy. We consume less petroleum products and more of other goods and services. Because those other goods and services have bigger multipliers, the economy expands. So it is clear that the passthrough to consumers of truck fuel costs is important for both energy policy and economic policy. [EPA-HQ-OAR-2014-0827-1336-A1 p.22]
C. PUBLIC OPINION

Since we have been able to demonstrate that these fuel costs are considerable and, in fact, likely to be passed on as indirect costs to households, we should not be surprised to find that consumers understand that fact (see Figure III-4). [EPA-HQ-OAR-2014-0827-1336-A1 p.23]

Two recent Consumer Federation of America surveys, found that the vast majority of consumers (over 90%) understand that “some, most, or all” of the fuel costs of heavy-duty trucks, which transport virtually every consumer good, are passed on to consumers, as shown in the upper graph of Figure III-4. In fact, over 55 percent believe that “all or most” of these costs are passed on to the consumer. [EPA-HQ-OAR-2014-0827-1336-A1 p.23] [[These comments can also be found in Docket Number EPA-HQ-OAR-2014-0827-1420, p.237.]]

In both of the CFA surveys, consumers clearly understood the possibility of these savings as nearly three quarters of the respondents favored requiring truck manufacturers to increase the fuel economy of large trucks (see the lower graph in Figure III-4). [EPA-HQ-OAR-2014-0827-1336-A1 p.23]

[Figure III-4, 'Consumer Attitudes about freight fuel costs and standards', can be found on p.23-24 of docket number EPA-HQ-OAR-2014-0827-1336-A1]

2. Pass-through

A second theoretical explanation that played an important part in the earlier analysis and was addressed by EPA/NHTSA is the question of the pass-through of cost savings to consumers. [EPA-HQ-OAR-2014-0827-1336-A1 p.51] [This comment can also be found in section 11.5 of this comment summary.]

As a result of this proposed rulemaking, it is anticipated that trucking firms will experience fuel savings. Fuel savings lower the costs of transportation goods and services. In a competitive market, some of the fuel savings that initially accrue to trucking firms are likely to be passed along as lower transportation costs that, in turn, could result in lower prices for final goods and services. Some of the savings might also be retained by firms for investments or for distributions to firm owners. Again, how much accrues to customers versus firm owners will depend on the relative elasticities of supply and demand. Regardless, the savings will accrue to some segment of consumers: Either owners of trucking firms or the general public, and the effect will be increased spending by consumers in other sectors of the economy, creating jobs in a diverse set of sectors, including retail and service industries. [EPA-HQ-OAR-2014-0827-1336-A1 p.51-52] [This comment can also be found in section 11.5 of this comment summary.]

The pass-through issue also turns up in another key aspect of the overall analysis, the rebound effect. The increase in consumption associated with the rebound effect occurs because consumers have more money to spend. The first effect is through the reduction of the cost of travel, but there is a second effect through the increase in disposable income available for other consumption. [EPA-HQ-OAR-2014-0827-1336-A1 p.52] [This comment can also be found in section 11.5 of this comment summary.]

Elasticities with respect to fuel price and fuel cost can provide some insight into the magnitude of the HDV VMT rebound effect…. Freight price elasticities measure the percent change in demand for freight in response to a percent change in freight prices, controlling for other variables that may influence freight demand such as GDP, the extent that goods are traded internationally, and road supply and capacity. This type of elasticity is only applicable to the HDV subcategory of freight trucks (i.e., combination tractors and vocational vehicles that transport freight). One desirable attribute of such
measures for purposes of this analysis is that they show the response of freight trucking activity to changes to trucking rates, including changes that result from fuel cost savings as well as increases in HDV technology costs. Freight price elasticities, however, are imperfect proxies for the rebound effect in freight trucks for a number of reasons. For example, in order to apply these elasticities we must assume that our proposed rule’s impact on fuel and vehicle costs is fully reflected in freight rates. This may not be the case if truck operators adjust their profit margins or other operational practices (e.g., loading practices, truck driver’s wages) instead of freight rates. It is not well understood how trucking firms respond to different types of cost changes (e.g., changes to fuel costs versus labor costs).42 [EPA-HQ-OAR-2014-0827-1336-A1 p.52] [This comment can also be found in section 11.5 of this comment summary.]

These observations make it clear that there is a significant level of pass-through of cost savings. Given the competitiveness of the trucking industry and its importance, we believe it is substantial. EPA/NHTSA conclude that there will be pass-through, but they do not provide an estimate. Their estimate of the rebound effect is moderate – 10% – based on a variety of factors. We have discussed this earlier. Given the very large economic benefits, the magnitude of the rebound effect does not significantly affect the bottom line of the analysis. Without specifying the precise level, it is clear that pass-through is significant and has important macroeconomic benefits. [EPA-HQ-OAR-2014-0827-1336-A1 p.52-53] [This comment can also be found in section 11.5 of this comment summary.]

VII. STRIKING THE BALANCE BETWEEN FUEL SAVINGS AND FEASIBILITY

In this section we examine the challenge of striking a balance between achieving the maximum energy savings/emissions reductions and the constraints of feasibility. Failing to achieve the maximum economically beneficial savings imposes a direct and significant harm on consumers – they are forced to pay too much for the goods and services that they consume. Mandating technologies that are infeasible will drive up costs and ultimately cause the performance standards to fail. These two considerations deserve equal weight, particularly in a sector where efficiency improvements have been largely flat, while the rest of the economy has been improving dramatically. The “burden of proof” established by the underlying statutes does not favor one concern over the other and leaves the agencies a great deal of discretion. [EPA-HQ-OAR-2014-0827-1336-A1 p.58]

6 Mark Cooper, 2013, Energy Efficiency Performance Standards: The Cornerstone of Consumer-Friendly Energy Policy, Consumer Federation of America, presents an extensive bibliography of survey analysis by the Consumer Federation of America and other consumer groups.

7 Based on Bureaus of Labor statistics, Consumer Expenditure Survey, for 2013 and 2013-2014

8 Cooper, 2013
9 For the purposes of simplicity, in this paper, we will refer to medium and heavy duty trucks as ‘freight trucks’.

10 We estimate 2014 based on total products supplied and average price for the year, assuming a 1% increase in the number of households and constant consumption per household. This is consistent with the difference between the 2013 Consumer Expenditure Survey and the mid-year 2014 Consumer Expenditure Survey. While price is down 3% between 2014 and 2013, expenditures are down 1.5% in the year July 2013-July 2014. By the end of the year we would expect the increase in consumption stimulated by declining prices to be offset by the decrease in consumption reflecting more fuel efficient vehicles and the underlying trend. For diesel, we divide the total expenditures by the estimated number of households.

11 Mark Cooper and Jack Gillis, Paying the Freight: The Consumer Benefits of Increasing the Fuel Economy of Medium and Heavy Duty Trucks, Consumer Federation of America, February 2014.

12 EPA/NHTSA, PHASE II NOPR, p. 40434, PHASE II RIA, p.8-1. The benefits and costs of these rules are analyzed using 3 percent and 7 percent discount rates, consistent with current OMB guidance. These rates are intended to represent consumers’ preference for current over future consumption (3 percent), and the real rate of return on private investment (7 percent) which indicates the opportunity cost of capital. However, neither of these rates necessarily represents the discount rate that individual decision-makers use. The program may also have other economic effects that are not included here.

13 Population growth will increase vehicles on the road and overall miles driven.

14 Mid-America Freight Coalition “The Economic Importance of Freight,” p. 2.

15 EIA, Monthly Energy Review, August 2015, Table 3.1.

16 Transportation and Economic Development Authors: Dr. Jean-Paul Rodriguez and Dr. Theo Notteboom, http://people.hofstra.edu/geotrans/eng/ch7en/conc7en/ch7c1en.html . A regional analysis reinforces this observation, Oregon, Transportation, Plan Update, Transportation and the Economy Manufacturing is dependent on transportation to receive raw materials and to deliver its products. Manufacturing is usually a highly competitive activity. Unless an area has other low cost attributes, high transportation costs will cause manufacturers to leave or avoid that area.

17 Both surveys were conducted by ORC International, and in each poll ORC surveyed over a thousand Americans with an error rate of +/- 3%.

Because truck fuel consumption is so great (and growing), the benefits of improving truck fuel efficiency are also great (and growing): [EPA-HQ-OAR-2014-0827-1176-A1 p.2]
• Fuel savings will help bring down the costs of transporting goods, with the average household saving $150 a year by 2030, assuming the savings and costs are passed through to consumers. [EPA-HQ-OAR-2014-0827-1176-A1 p.2]

**Organization:** Environmental Defense Fund (EDF)

Consumers also stand to benefit from a strong rule. The average United States household pays more than $1,100 a year to fuel heavy trucks as companies pass some of their fuel costs on to customers. The Consumer Federation of America found that more robust Phase 2 standards could deliver as much as $400 in savings to an average household annually on services and goods by 2035. [EPA-HQ-OAR-2014-0827-1312-A1 p.18]

**Organization:** Hoosier Environmental Council

Furthermore, such savings (at the aggregate) will inevitably translate into savings for Indiana residents in terms of the cost of their goods. [EPA-HQ-OAR-2014-0827-1245-A1 p.1]

**Organization:** Illinois Public Interest Research Group (PIRG)

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 254.]

Strong emission standards for heavy duty vehicles will save consumers money. According to the National Resource Defense Council and their partner organizations that have researched these standards, consumers will save more money by the decrease of the use of oil and the use of efficiency technology.

**Organization:** International Union, United Automobile, Aerospace and Agricultural Implement Workers of America (UAW)

**Importance of the Motor Vehicle Sector**

The United States' motor vehicle sector is large, profitable and competitive. The domestic motor vehicle industry is vital to the U.S. economy and it is imperative that we remain strong and competitive. Nearly 900,000 people worked in auto and auto-parts manufacturing alone. When jobs from other sectors that are dependent on the industry are included, the auto industry is responsible for 7.25 million jobs nationwide, or about 3.8% of private-sector employment. The industry generates tens of billions in tax revenues across the country. [EPA-HQ-OAR-2014-0827-1248-A2 p.3]

The motor vehicle industry is in many ways the cornerstone of our manufacturing sector. The economic impact of the standards on the entire supply chain must be taken into account when analyzing the proposed regulations. [EPA-HQ-OAR-2014-0827-1248-A2 p.3]
The current proposal is expansive and complex. The impact of costs associated with development and production costs should be taken into account while drafting the final rule, including any costs associated with disruption of program and capital cycles. It also covers a lengthy period of time as the proposed regulations would be in effect until 2027. Regulatory certainty is an essential part of the industry’s ability to develop and market new advanced technologies and maintain product cycles meeting stringency requirements. [EPA-HQ-OAR-2014-0827-1248-A2 p.7]

**Organization:** Investor Network on Climate Risk

Furthermore, strong standards would also benefit consumers and the economy; as operating costs come down due to more fuel-efficient trucks, consumers will see cost savings, which in turn will be reinvested in the broader economy. Under strong standards, the average U.S. household stands to save $250 per year in lower-priced goods.³ [NHTSA-2014-0132-0113-A1 p.2]

**Organization:** Mass Comment Campaign sponsored by the Pew Charitable Trusts (web) - (4,452)

When businesses spend more on fuel, the cost is passed along to consumers through purchased goods and services. According to the Consumer Federation of America, goods and services delivered by medium- and heavy-duty trucks cost each U.S. household $1,100 in 2010. Assuming the fuel savings from the new standards were passed along to consumers through the reduced cost of transported goods, American families could save an extra $150 a year by 2030. [EPA-HQ-OAR-2014-0827-1252-A1 p.1]

**Organization:** Midwest Truckers Association

[The following comments were submitted as testimony at the Chicago, Illinois public hearing on August 6, 2015. See Docket Number EPA-HQ-OAR-2014-0827-1372, p. 267.]

we look forward to the next step in this rulemaking process and have been encouraged to see a rule that can not only be an improvement for the environment, but also result in potential cost savings for these truck operators. And, of course, then that's passed onto the consumer, who could benefit from the fact that lower fuel consumption means less overhead costs. [This comment can also be found in section 1.1 of this comment summary]

**Organization:** National Ready Mixed Concrete Association (NRMCA)

NRMCA holds concerns with a number of specific issues in the joint EPA/NHTSA proposal. NRMCA believes more attention should be placed on costs that inevitably will filter to downstream consumers of new heavy-duty trucks. [EPA-HQ-OAR-2014-0827-1146-A1 p.2]

**Organization:** Quasar Energy Group

Because truck fuel consumption is so great (and growing), the benefits of improving truck fuel efficiency are also great (and growing): [EPA-HQ-OAR-2014-0827-1335-A1 p.1]
Fuel savings will help bring down the costs of transporting goods, with the average household saving $150 a year by 2030, assuming the savings and costs are passed through to consumers. [EPA-HQ-OAR-2014-0827-1335-A1 p.2]
