B. Cost Impacts

1. CAFE Model Results

The technology application algorithm implemented with the CAFE Model was used as the basis for estimating costs for the fleet. Here, costs refer to costs or civil penalties to manufacturers relative to NHTSA's MY 2022-2025 augural standards and the MY 2022-2025 EPA standards finalized in 2012. In each of these tables, costs are shown incremental to a technology baseline that represents the technology that the CAFE Model assumes would proceed the new technology application.

Table VII-190 through Table VII-199 show the direct unit costs of the various CAFE technologies that are examined in the CAFE Model lumped by general technology category. These direct costs were marked up to retail level using the Retail Price Equivalent (RPE) multiplier and adjusted for learning effects to produce the aggregate cost impacts that are illustrated in Table VII-200 through Table VII-271. A full discussion of the indirect cost and learning curve impacts is provided in later sections of this section.

Monetized aggregate cost impacts are presented for Passenger Cars, Light Trucks, and Combined Light-Duty. Also, 3% and 7% discounts rates are shown; undiscounted values are also presented where applicable. Lastly, results have been produced for both CAFE and CO_2 standards. The following is a brief description of the tables presenting aggregate cost impacts:

Table VII-200 through Table VII-217 show lifetime societal costs, by model year, under the preferred alternative. Table VII-218 through Table VII-229 show incremental lifetime societal costs for MYs 1977-2029 for each alternative. Costs are included for advanced vehicle technologies, consumer surplus/loss, and costs due to increased crashes, fatalities, congestion, and noise.

Table VII-230 through Table VII-241 show incremental total costs by societal perspective under each alternative, by vehicle model year.

Table VII-242 through Table VII-247 show average incremental technology cost and civil penalties per vehicle by model year. Average costs are presented for each alternative and without a discount rate.

Table VII-248 through Table VII-259 show per-vehicle net present value of ownership costs, by model year, under the preferred alternative. Table VII-260 through Table VII-271 show MY 2030 per-vehicle net present value of ownership costs under each alternative. Owner costs include vehicle price increase and additional ownership costs.

Section Cost Impacts discusses indirect costs to manufacturers, which are estimated as a mark-up to direct manufacturing costs for the various technologies manufacturers are expected to use to meet future CAFE and CO_2 standards. Section Cost Impacts discusses retail price equivalent (RPE), which is a method of estimating indirect costs based on an examination of historical financial data contained in 10-K reports filed by manufacturers with the Securities and Exchange Commission (SEC). In Section Cost Impacts, the indirect cost multiplier (ICM) is discussed as another method for estimating indirect costs, which is more specific to technology in terms of level of complexity.

Cost impacts due to learning in manufacturing are discussed in Section Cost Impacts. Learning curves reflect the effect of experience and volume on the cost of production, which generally results in better utilization of resources, leading to higher and more efficient production.

C. Benefits

This section presents estimates of societal benefits, both at the aggregate and component levels. Part A provides estimates of impacts on lifetime societal benefits, incremental lifetime societal benefits, energy consumption, refueling time, petroleum market externalities, emissions, and mobility. Part B provides estimates of impacts on emissions, and a discussion of health effects associated with changes in emissions. Changes in emissions represent changes in benefits due to the corresponding changes in health quality.

1. Benefit Estimates

Monetized aggregate benefits were estimated separately for passenger cars and light trucks, as well as both combined. The negative values in these tables indicate that net reductions in fuel consumption or emissions and their resulting economic impacts (i.e., benefits) are less than the associated changes to congestion, noise or crash severity costs. Benefit levels parallel the differences in stringency among the alternatives that were examined.

Discount rates used are 3% and 7%, while undiscounted values are also presented where applicable. Lastly, results have been produced for both CAFE and CO_2 standards. The following is a brief description of the tables presenting aggregate benefits:

Table VII-272 through Table VII-289 show lifetime societal benefits, by model year, under the preferred alternative. Lifetime societal benefits generally decrease at the model year level for passenger cars and light trucks; lifetime societal benefits are estimated to increase slightly for pre-MY 2019 passenger cars and pre-MY 2018 light trucks.

Table VII-290 through Table VII-301 show incremental lifetime societal benefits for MYs 1977-2029 for each alternative. Monetized benefits estimates are listed separately for fuel savings, reduced refueling time, petroleum market externalities, and reduction of CO_2 and related emissions. Incremental societal benefits are estimated to be negative across all alternatives.

Table VII-302 through Table VII-313 show incremental present the estimated discounted lifetime societal benefits across the range of alternative CAFE and CO_2 standards evaluated in this analysis. The tables present results across model year; the results vary by vehicle and discount rate, with positive estimates for pre-MY 2020 vehicles in some cases, and negative estimates for all other vehicles.

Table VII-314 through Table VII-325 show per-vehicle net present value of ownership benefits, by model year, under the preferred alternative. Table VII-326 through Table VII-337 show MY 2030 per-vehicle net present value of ownership costs and benefits under each alternative. Estimates of owner benefits are listed separately as fuel savings, increased mobility, and reduced refueling time.

Table VII-338 through Table VII-343 summarize the fuel savings, in gallons, from all alternatives for passenger cars and light trucks, by model year. Similarly, Table VII-344 through Table VII-349 present the net change in electricity consumption from all alternatives for passenger cars and light trucks, by model year.

c) Health Effects of Other Pollutants

This section presents results of the analysis showing health effects associated with exposure to some of the criteria and air toxic pollutants impacted by the new final vehicle standards. As discussed above, the health impacts presented here are subject to a number of uncertainties, some of which arise from the less complex benefits-per-ton approach relied on in this analysis, and some of which arise from the uncertainty surrounding many of the assumptions and other inputs relied on in the agencies' analysis. As the agencies conclude above, although it may seem that the agencies' estimates of increases in premature mortality resulting from the final standards are more likely to be too high than too low, it is extremely difficult to anticipate whether this is actually the case.

d) Health Effects and Benefits Modeling Results from Photochemical Air Quality Modeling

As indicated in the Notice of Intent to Prepare an Environmental Impact Statement for Model Year 2022–2025 Corporate Average Fuel Economy Standards (NHTSA 2017)[2554] and the Draft Environmental Impact Statement (EIS)[2555] (NHTSA 2018), NHTSA performed photochemical air quality modeling based on the inputs and emissions forecasts used in the Draft EIS. As discussed in detail in Appendix E of the FEIS, NHTSA used the Community Multiscale Air Quality (CMAQ) model and the Environmental Benefits Mapping and Analysis Program (BenMAP) tool to quantify and compare the air quality and health-related benefits of the NPRM Proposed Action and alternatives.[2556]

NHTSA also used BenMAP-CE to estimate monetized health-related benefits (based on VSL studies, lost wages, health care expenses, and "willingness-to-pay") associated with the health impacts. These estimates are derived using a set of monetary surrogates for the various health effects developed by EPA and public health researchers. BenMAP-CE also tracks changes over time in willingness to pay for reductions in health risks and includes adjustment factors that incorporate the effect of inflation on health-care costs. The following section presents estimates of monetized health-related benefits based on photochemical air quality modeling and BenMAP-CE analysis for the NPRM No Action Alternative and the eight NPRM action alternatives, Alternatives 1 through 8.

As explained in Appendix E of the FEIS, NHTSA projected small net decreases in nationwide adverse health effects based on the inputs and emissions forecasts used in the Draft EIS, resulting in net health and monetized benefits compared to the No Action Alternative. These decreases in health effects were driven primarily by decreases in tailpipe emissions of oxides of nitrogen (NO_X) and $PM_{2.5}$ due to the vehicle miles traveled (VMT) rebound effect and, because large populations are located near roadways, the relatively high level of population exposure to tailpipe emissions. Although upstream emissions increased under the Draft EIS alternatives and CAFE Model projections, the associated increases in health effects were not as large as the decreases due to decreased tailpipe emissions. As a result, the net changes in adverse health effects estimated in this appendix were predicted to be decreases.

For the Final EIS, both tailpipe and upstream emissions of NO_X and $PM_{2.5}$ are predicted to increase under the action alternatives, as described in FEIS Chapter 4, *Air Quality*. Tailpipe emissions of sulfur dioxide (SO_2) are predicted to increase under the action alternatives while

[2554] Notice of Intent to Prepare an Environmental Impact Statement for Model Year 2022–2025 Corporate Average Fuel Economy Standards, 82 FR 34740 (July 26, 2017).

[2555] To accommodate the substantial time required to complete the air quality modeling analysis, NHTSA initiated air quality modeling before the inputs and emissions forecasts for the Final EIS were finalized. Therefore, NHTSA used the inputs and emissions forecasts for the Proposed Action and alternatives as stated in the Draft EIS for the analysis in this report.

[2556] The NPRM included the No Action Alternative and eight action alternatives; the final rule included the No Action Alternative and seven action alternatives, which are discussed further in preamble Section V.

upstream emissions of SO_2 are predicted to decrease by greater amounts, yielding decreases in total SO_2 emissions under the action alternatives.

Although the photochemical air quality modeling described in FEIS Appendix E does not reflect the health effects that would be associated with the Final EIS alternatives and CAFE Model projections, it documents how the analysis is performed, and how the spatial distributions of emissions sources and populations influence the results. The analysis illustrates how predicted health effects change with different assumptions and indicates the magnitudes of predicted changes in health effects to be expected from changes in emissions. If the photochemical air quality modeling was repeated with the Final EIS data, the results likely would show very small increases in adverse health effects associated with the changes in tailpipe emissions, as well as small increases in adverse health effects associated with the changes in upstream emissions. Overall, the increases in adverse health effects likely would be greater than described in the analysis below, and likely would be of the same order of magnitude as the health effects reported in the Draft EIS (Table 4.2.3-1). For example, the increase in mortality might be tens to a few hundred cases per year.

The analysis presented here is not considered as part of either agency's cost-benefit analysis, as the agencies estimated changes in the aggregate value of health damage costs using per-ton damage costs that apply to unit values to the increased frequency of each health effect, representing the dollar costs or estimated willingness-to-pay to avoid its occurrence, and combined the results to estimate total damage costs. As discussed further in preamble Section VI, those values represent estimates of the nationwide incidence or frequency of selected health impacts and their collective or aggregate economic damage costs per ton of additional emissions of selected criteria pollutants. In contrast, as discussed above, the estimates presented here are intended to represent the estimated health impacts resulting from population exposure to changes in atmospheric accumulations of various pollutants that result from the actual geographic distribution of changes in emissions attributable to potential regulatory alternatives. Accordingly, the following estimates of monetized health-related benefits are presented here to illustrate the effects valuation associated with different assumptions across a range of changes in emissions, including a geographic distribution of changes in emissions that could result from this rule.

(1) Valuation Metrics

The assessment of monetized health-related benefits involves assigning monetary values to each health endpoint and totaling all benefits associated with changes in pollutant exposures. Different valuation methods are used for the various health endpoints. The monetary surrogate value for mortality is derived using a VSL approach; that is, the additional cost that individuals would be willing to bear for reductions in risks that, in the aggregate, reduce the expected number of fatalities by one.[2557] The VSL used for this analysis is identified in BenMAP-CE as $8.7 million (in 2015-equivalent dollars).

Valuation methods for morbidity endpoints (non-fatal health effects) include approaches referred to as cost of illness (COI), willingness to pay (WTP), and lost wages or productivity.[2558] COI estimates comprise a range of approaches that account for the costs of medical care and in some cases lost wages. WTP approaches refer to methods in which voluntary payments to avoid disease are directly or indirectly estimated and used to estimate monetized health-related benefits. Finally, lost-productivity methods value the time lost to illness using wage rates or the estimated value of leisure or school time.[2559] For all endpoints, the total monetized health-related benefit for a given endpoint is estimated by multiplying the monetary values for that endpoint by the estimated change in the number of "cases" of the endpoint. For most studies, morbidity values are small compared to the mortality values. Therefore, the specific valuation methods used for morbidity have only a small effect on the overall monetized health-related benefits estimates.

Table VII-375 and Table VII-376 list the endpoints and methods used for the valuation portion of the analysis for ozone and $PM_{2.5}$, respectively. The endpoints include monetized health-related benefits associated with changes in mortality, and a range of morbidity endpoints. All monetized health-related benefits results for this analysis are presented in 2010-equivalent dollars.

In the aggregation and valuation step, the results were aggregated for the national scale. Default options were applied in the aggregation and pooling of the results. Similarly, EPA standard health care inflation values (defaults) were used for the valuation. The results are given in 2010-equivalent dollars.

(2) BenMAP-CE Results

NHTSA used BenMAP-CE to estimate the reduction in the incidence of various health-related endpoints and to develop a monetized estimate of the health-related benefits for each action alternative. This section provides the valuation results, which reflect both an income growth adjustment and a time lag between exposure and $PM_{2.5}$ mortality.

The income growth adjustment accounts for expected growth in real income over time. Economic theory suggests that WTP for most goods and services (such as environmental protection) will increase if income increases. To account for growth in income through 2035, the

BenMAP-derived reductions were multiplied by 1.2 for long-term mortality, 1.23 for chronic health impacts, and 1.07 for minor health impacts.

The valuation results for $PM_{2.5}$ assume that there is a time lag between changes in $PM_{2.5}$ concentration and changes in $PM_{2.5}$ mortality. To account for this, monetized health-related benefits occurring in the future are discounted. For this analysis, the BenMAP-derived reductions were multiplied by 0.91 to achieve a 3 percent discount rate and by 0.82 to achieve a 7 percent discount rate. There are no similar adjustments for ozone or for the morbidity endpoints. All of the valuation results are rounded to two significant figures.

Table VII-377 lists BenMAP-CE valuation results for ozone mortality (reduction in millions of U.S. dollars/year) under the action alternatives. The monetized health-related benefits represent nationwide changes in millions of U.S. dollars (2010-equivalent). No discount rate was applied for ozone mortality. Estimates of monetized health-related benefits under Alternative 1 range from $40 million to $274 million for the ozone-related mortality valuation. The estimated benefits under Alternative 2 and 3 are slightly smaller than those under Alternative 1. Alternative 4 and 5 are similar and less than Alternatives 1 through 3. Alternative 7 and 8 shows the least benefit, at less than half of Alternative 1.

Table VII-377 – BenMAP-Derived Nationwide Monetized Health-Related Benefits for Ozone-Related Mortality: Estimated Monetized Benefits (millions 2010 U.S. dollars/year) Related to Premature Mortality, Direct and Indirect Impacts

Epidemiology Study	**Reduction (Millions 2010 U.S. Dollars/Year)**							
	Alt 1	**Alt 2**	**Alt 3**	**Alt 4**	**Alt 5**	**Alt 6**	**Alt 7**	**Alt 8**

Table VII-381 lists BenMAP-CE valuation results for other $PM_{2.5}$-related health effects (reduction in millions of U.S. dollars/year) and associated endpoints (morbidity) for the direct and indirect impact analysis. For the endpoints considered here, the monetized health-related benefits are smallest under Alternative 7, about the same for Alternatives 2, 3 and 4, and largest for Alternative 1. The largest reductions in monetized health-related benefits are associated with fewer incidences of upper respiratory symptoms and work loss days.

Table VII-381 – BenMAP-Derived Nationwide Monetized Health-Related Benefits for PM2.5-Related Morbidity: Estimated Monetized Benefits (millions 2010 U.S. dollars/year) Related to Various Morbidity Endpoints, Direct and Indirect Impacts

Epidemiology Study	Reduction (Millions 2010 U.S. Dollars/Year)

PM2.5 = particulate matter with diameter equal to or less than 2.5 microns

Figure VII-1 and Figure VII-2 graphically display the nationwide monetized health-related benefits associated with selected health endpoints for ozone and $PM_{2.5}$. For both ozone and $PM_{2.5}$, the monetized health-related benefits (cost savings) are displayed for mortality and combined respiratory symptoms. For ozone, the combined symptoms include emergency room visits for asthma, asthma exacerbation (one or more symptoms), and hospital admissions for respiratory symptoms. For $PM_{2.5}$, the combined symptoms include acute bronchitis, asthma exacerbation, emergency room visits for asthma, lower and upper respiratory symptoms, and hospital admissions for respiratory symptoms. Again, to accommodate differences in the results, the scales are different for each plot.

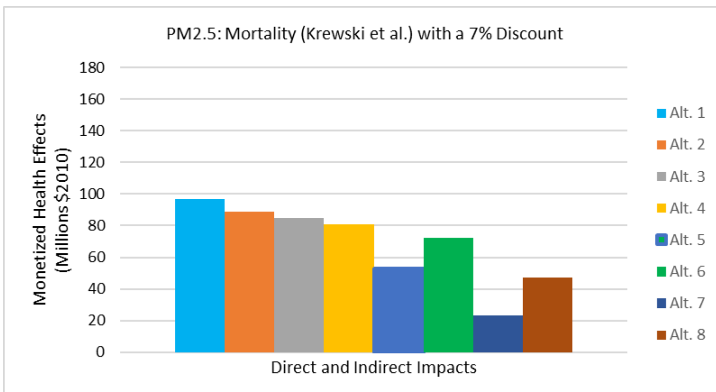
Mortality with 7 Percent Discount



Combined Respiratory Symptoms

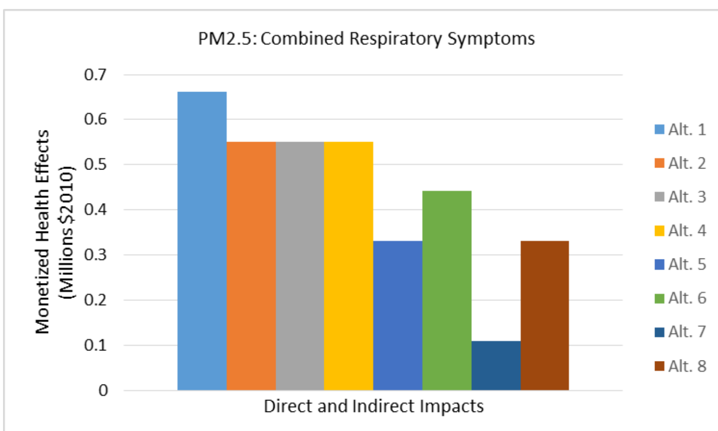


Figure VII-2 – BenMAP-Derived Monetized Health-Related Benefits for the Direct and Indirect Impacts Analyses: $PM_{2.5}$ (Reduction in Millions of 2010 U.S. Dollars/Year)

In summary:

- The relative changes in monetized health-related benefits are consistent with the changes in emissions for the action alternatives described in Appendix E of the FEIS. Because they are driven by the CMAQ modeling results, the BenMAP-CE results are also affected by the emission changes, their spatial distributions in relation to population, and the complex (and often non-linear) chemical reactions in the atmosphere throughout each of the different regions during the course of the annual simulation period.
- Alternative 7 is associated with the smallest monetized health-related benefits. Alternative 1 is associated with the largest monetized health-related benefits. Alternatives 2 through 6 and Alternative 8 fall between the least and most stringent.

(3) Uncertainty in Valuing Mortality and Mortality Risks

The BenMAP-CE tool incorporates a wide variety of studies that can be used to quantify and monetize health effects resulting from reductions in air pollutant concentrations. The epidemiological studies address a variety of different health endpoints and, in some cases, multiple studies (involving different populations or concentration-response functions) allow for some comparison. BenMAP-CE includes up-to-date valuation methods and data for the monetization of health impacts. BenMAP-CE also incorporates advanced statistical methods for aggregating and weighting the results to obtain both mean values and information about the likelihood (probability) that the value will be within a given range. A primary advantage of BenMAP-CE is that it can incorporate the change in air quality directly from air quality model output files. Therefore, BenMAP-CE accounts for spatial and temporal differences in the changes in air quality and relates these to population. For this analysis, selection of the health effects studies and valuation methods were based on the BenMAP-CE (configuration and aggregation, pooling and valuation) input files (which reference the studies and methods EPA considers the most relevant and applicable to the United States population as a whole).

Nevertheless, there are uncertainties associated with the estimation of changes in health effects and monetized health-related benefits associated with changes in ozone and $PM_{2.5}$ air quality. For the health incidence calculations, BenMAP-CE includes an option to generate an average incidence estimate and range of results that assume variability in the inputs to the health impact functions. Variability is incorporated into most of the BenMAP-CE exposure-response algorithms by prescribing a dose-response parameter that assumes a Gaussian (bell-shaped) distribution about the mean value. In calculating the health effects, BenMAP-CE samples this distribution to develop a probability distribution of effect. The result is expressed as the mean value of the distribution. For the $PM_{2.5}$ mortality expert elicitation functions, variability is accounted for in a variety of ways.

For the valuation calculation, the valuation function is also specified as a probability distribution, accounting for different methods of estimating health costs and WTP. BenMAP-CE samples from probability distributions from single or multiple cost estimation models and combines the results through Monte Carlo simulation. The valuation function for morbidity used for this analysis is a Weibull distribution with a mean of $8.7 million (in 2015 dollars).

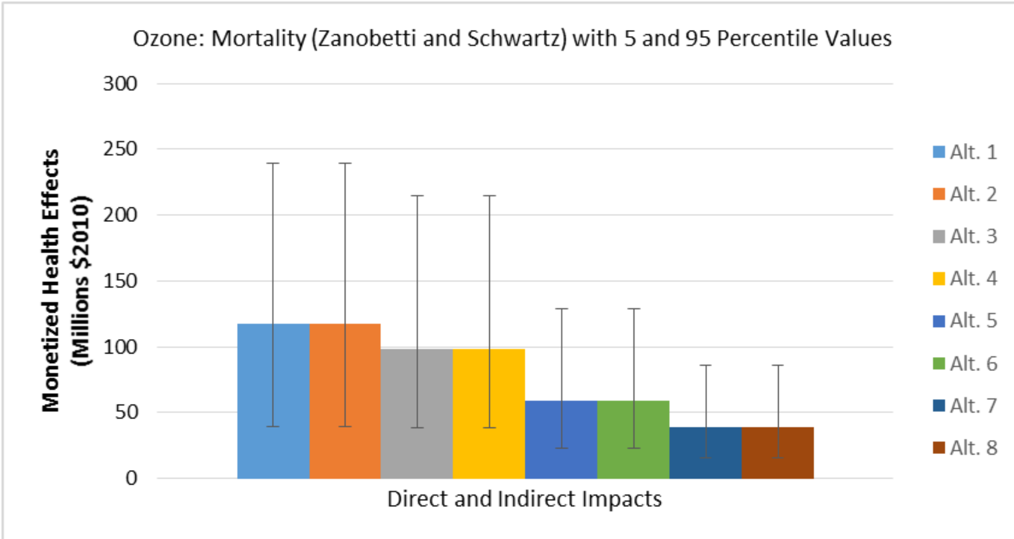
Therefore, the resulting monetized benefit distributions include contributions both from the uncertainty in the exposure-response relationships and in the valuation functions. The previous section presented the expected value (mean) estimates generated by BenMAP-CE.

Figure VII-3 presents the BenMAP-generated overall distributions in monetized health-related benefits (represented by 5th- and 95th– Percentile intervals) for mortality for ozone, as determined by Zanobetti and Schwartz[2560] and $PM_{2.5}$, as determined by Krewski et al.[2561] Mortality is used here to illustrate the uncertainty because most monetized health-related benefits are associated with mortality.

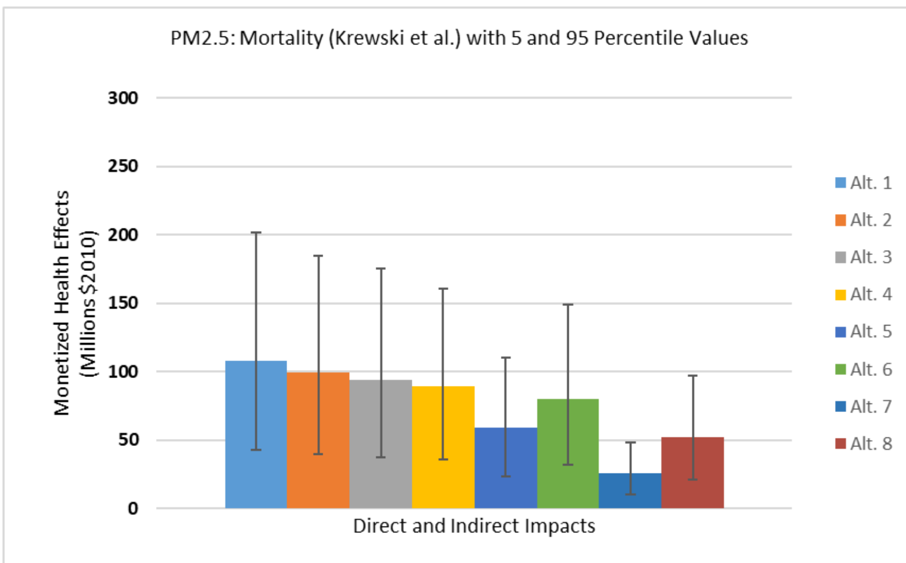
[2560] Zanobetti A. and Schwartz, J. 2008. Is there adaptation in the ozone mortality relationship: A multi-city case-crossover analysis. Environmental Health 7-22. Available: http://ehjournal.biomedcentral.com/articles/10.1186/1476-069X-7-22. [hereinafter Zanobetti A. and Schwartz, J. 2008].

[2561] Krewski, D., M. Jerrett, R. Burnett, R. Ma, E. Hughes, Y. Shi, M. C. Turner, C. A. I. Pope, G. Thurston, E. Calle and M. J. Thun. 2009. Extended follow-up and spatial analysis of the American Cancer Society study linking particulate air pollution and mortality. HEI Research Report, 140, Health Effects Institute, Boston, MA. [hereinafter Krewski et al. 2009].

(a) Ozone Mortality



(b) $PM_{2.5}$ Mortality with 3 Percent Discount



(c) $PM_{2.5}$ Mortality with 7 Percent Discount

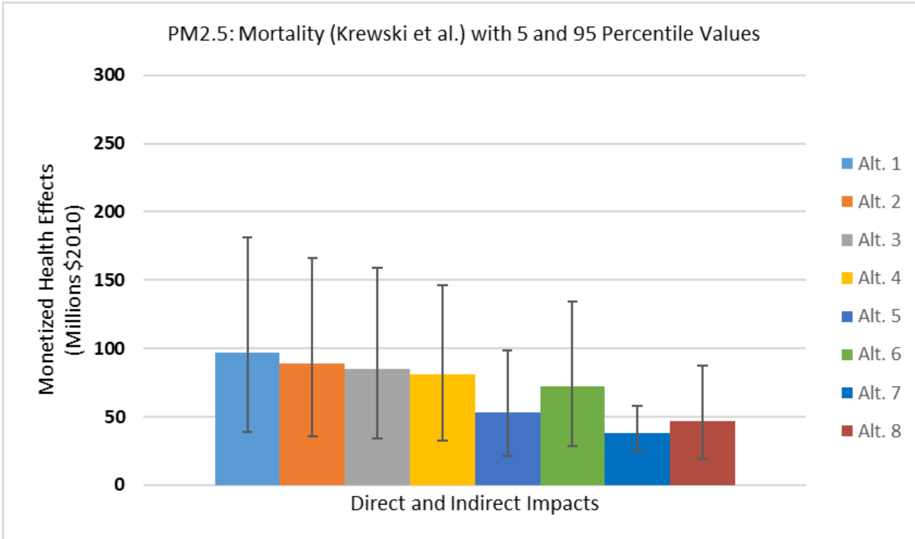


Figure VII-3 – BenMAP-Derived Monetized Health-Related Benefits for the Direct and Indirect Impacts Analyses, with 5th- and 95th-Percentile Ranges (Reduction in Millions of 2010 U.S. Dollars/Year)

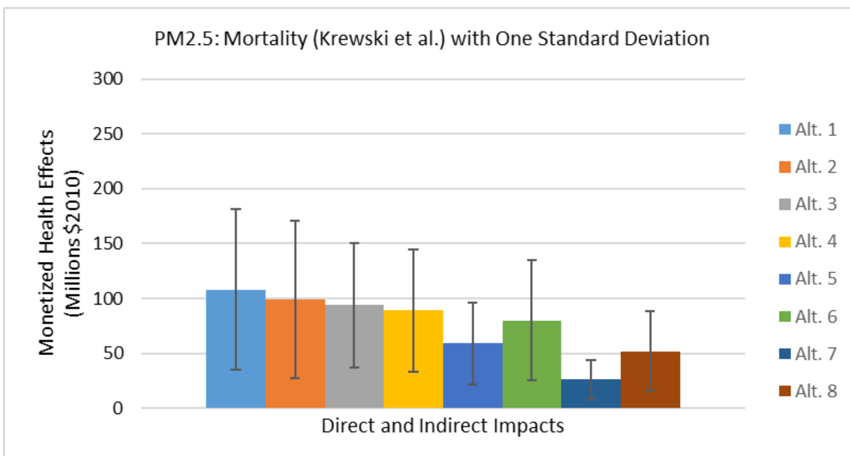
In general, the 5th- and 95th-percentile values indicate a large range in values compared to the mean value. For example, results under Alternative 1 for $PM_{2.5}$ with a 7 percent discount rate indicate that the mean value is $97 million. The 5th- and 95th-percentile values are $39 million and $181 million, respectively. Therefore, there is a 90 percent probability that the monetized health-related benefits would be between $39 million and $181 million.

Figure VII-4 presents the BenMAP-generated mean and standard deviations in monetized health-related benefits for mortality for ozone, as determined by Zanobetti and Schwartz,[2562] and $PM_{2.5}$, as determined by Krewski et al.[2563]

[2562] Zanobetti A. and Schwartz, J. 2008.
[2563] Krewski et al. 2009.

(a) Ozone Mortality

(b) PM2.5 Mortality with 3 Percent Discount



(c) PM2.5 Mortality with 7 Percent Discount

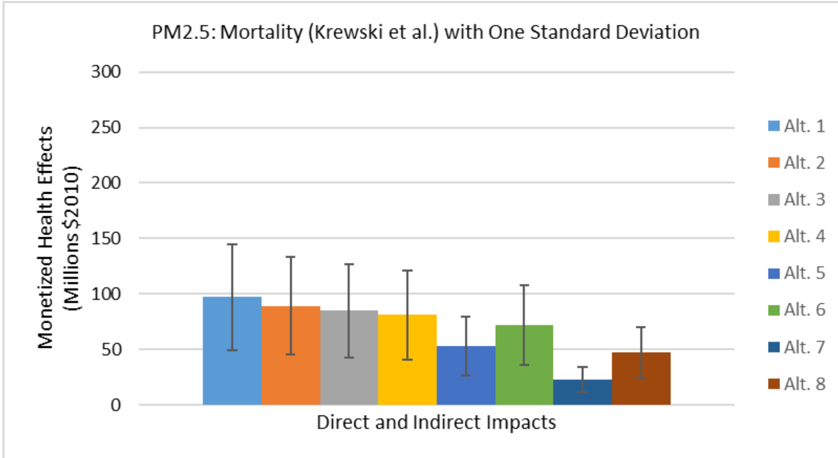


Figure VII-4 – BenMAP-Derived Monetized Health-Related Benefits for the Direct and Indirect Impacts Analyses, with One Standard Deviation (Reduction in Millions of 2010 U.S. Dollars/Year)

he standard deviation values indicate variability in the distributions, leading to uncertainty in the results. For example, under Alternative 1 for $PM_{2.5}$ with a 7 percent discount rate, the results show that the mean value is $97 million but with a standard deviation of $48 million.

Regarding the uncertainty with mortality risks, higher confidence is found for the magnitude of the risks for simulated $PM_{2.5}$ concentrations that coincide with the bulk of the observed $PM_{2.5}$ concentrations in epidemiological studies that are used to estimate the benefits. Less confidence is found in the risk for simulated $PM_{2.5}$ concentrations that fall below the bulk of the observed $PM_{2.5}$ concentration data used in these studies. There are uncertainties inherent in identifying any point at which the confidence in reported associations decreases appreciably, and the scientific evidence provides no clear dividing line.

One approach that has been used to illustrate the relative confidence is the concentration benchmark approach (also referred to as the Lowest Measured Level [LML] analysis), which has been used in several EPA regulatory impact analyses[2564,2565] and EPA's Policy Assessment for

[2564] EPA. Regulatory Impact Analysis for the Repeal of the Clean Power Plan, and the Emission Guidelines for Greenhouse Gas Emissions from Existing Electric Utility Generating Units, U.S. EPA Office of Air Quality Planning and Standards, Research Triangle Park, NC, June 2019, EPA-452/R-19-003.
[2565] EPA. Regulatory Impact Analysis for the Proposed Emission Guidelines for Greenhouse Gas Emissions from Existing Electric Utility Generating Units; Revisions to Emission Guideline Implementing Regulations; Revisions to New Source Review Program. U.S. EPA Office of Air Quality Planning and Standards, Research Triangle Park, NC. August 2018.

Particulate Matter[2566] by reporting the estimated $PM_{2.5}$-related premature deaths according to alternative concentration cutpoints.

LML analysis allows a reader to determine the portion of population exposed to annual mean $PM_{2.5}$ levels at or above different concentrations, which provides insight into the level of uncertainty in the estimated $PM_{2.5}$ mortality benefits. These concentration benchmarks should not be viewed as concentration thresholds below which NHTSA and EPA would not quantify health benefits of air quality improvements.[2567] Rather, the benefit estimates are appropriate estimates because they reflect the full range of air quality concentrations associated with the emissions changes being evaluated. The Integrated Science Assessment for Particulate Matter[2568] concluded that the scientific evidence is sufficient to determine that there is a causal relationship between long-term $PM_{2.5}$ exposures and mortality, and that overall, the studies support the use of a no-threshold log-linear model to estimate mortality attributed to long-term $PM_{2.5}$ exposure.

Modeling results from each scenario are stratified by estimated $PM_{2.5}$ premature deaths according to the concentration at which they occurred: below the LML, between the LML and the NAAQS, and above the NAAQS for each of the eight alternatives (Table VII-382). The estimated number of deaths above and below the LML varies considerably according to the epidemiology study used to estimate risk. Table 4.3.1-10 identifies the LML for the two cohort studies used in this analysis. For Krewski et al.,[2569] the LML is 5.8 $\mu g/m^3$ and for Lepeule et al.,[2570] the LML is 8 $\mu g/m^3$. For Krewski, most of the mortalities are above the LML, while the majority of the Lepeule mortality is below the LML. Table VII-382 also shows that a very small percentage of $PM_{2.5}$-related premature deaths occurs above the NAAQS using either of these two studies. These results are sensitive to the annual mean $PM_{2.5}$ concentration predicted by the air quality model in each 36-by-36-kilometer grid cell. The results should be viewed in the context of the air quality modeling technique used to estimate $PM_{2.5}$ concentrations. In general, higher confidence is placed in the ability of CMAQ to estimate changes in annual mean $PM_{2.5}$ concentrations than in the ability to estimate absolute $PM_{2.5}$ concentrations.

Notes:
[a] The LML of the Krewski study is 5.8 μg/m^3 and 8 μg/m^3 for Lepeule study.
Values less than 0.05 have been rounded to zero.
Sum of individual values may not equal total due to rounding.

LML = Lowest Measured Level

Table VII-383 and Table VII-384 show the estimated dollar values for a 3 and 7 percent discount rate of changes in $PM_{2.5}$-related premature deaths calculated using the two different cohort studies to help in understanding the fraction of $PM_{2.5}$-related dollar value occurring at lower ambient concentration levels. The results summarize the dollar value of these impacts relative to the No Action Alternative across all $PM_{2.5}$ premature deaths. When estimating benefits at or above the $PM_{2.5}$ NAAQS, the percentage of dollar value to reducing $PM_{2.5}$ exposure ranges from 0 to 4 percent. However, the bulk of the benefit at or above the LML ranges from 76 to 92 percent for Krewski, but only 3 to 29 percent for Lepeule. The 3 percent discount rate shows about 11 percent higher dollar values benefit over the 7 percent discount rate.

D. Net Impacts

This section compares the costs of technologies needed to make improvements in fuel economy with the potential benefits, expressed in total costs (millions of dollars) from a societal perspective for each model year. The costs do not include CAFE civil penalties estimated to be paid by manufacturers to NHTSA, since these are transfer payments. Thus, the total costs shown in this section do not match the total costs shown earlier in this section. These are incremental costs and benefits compared to the adjusted baseline of MY 2016. The incremental costs and benefits are followed by sales and labor utilization impacts. This section concludes with an evaluation of cumulative impacts across multiple fuel economy standards.

Payback periods are not reported in this section. Unlike previous CAFE analyses, in this analysis there is no incremental fuel-saving technology added to vehicles in the alternatives. Rather, technologies are removed from vehicles across the alternatives relative to the baseline. In turn, rather than facing upfront investment costs that are paid back throughout vehicle ownership (yielding a breakeven point that represents the end of a payback period), consumers receive immediate, upfront cost savings across all alternatives.

1. Net Impacts Across Alternative Fuel Economy and CO_2 Standards

Table VII-385 and Table VII-386 present total costs, benefits and net benefits for the light-duty vehicle fleet across alternative fuel economy standards. Costs decrease under all alternatives, ranging from -$123 billion to -$331 billion at a three-percent discount rate, and from -$87 billion to -$234 billion at a seven-percent discount rate. Benefits also decrease under all alternatives, ranging from -$131 billion to -$347 billion at a three-percent discount rate, and from -$81 billion to -$216 billion at a seven-percent discount rate. The net benefits straddle zero, and for all alternatives are very small relative to the scale of the costs and the scale of the benefits. The net benefits range from $0.3 billion to -$31 billion at a three-percent discount rate, and from $4.4 to $18.4 billion at a seven-percent discount rate. Table VII-387 through Table VII-398 provide the present value of net benefits. Table VII-399 through Table VII-410 present estimates of societal costs, benefits and net benefits under the CAFE Model. Table VII-411 through Table VII-422 present societal costs, benefits and net benefits, consumer impacts and net consumer benefits for MY 2030 vehicles relative to MY 2017 vehicles under the CO_2 Program are presented.

This analysis does not explicitly identify "co-benefits" from its proposed action to change fuel economy standards, as such a concept would include all benefits other than cost savings to vehicle buyers. Instead, it distinguishes between private benefits – which include economic impacts on vehicle manufacturers, buyers of new cars and light trucks, and owners (or users) of used cars and light trucks – and external benefits, which represent indirect benefits (or costs) to the remainder of the U.S. economy that stem from the proposal's effects on the behavior of vehicle manufacturers, buyers, and users. In this accounting framework, changes in fuel use and safety impacts resulting from the proposal's effects on the number of used vehicles in use represent an important component of its private benefits and costs, despite the fact that previous analyses have failed to recognize these effects. The agency's presentation of private costs and benefits from its proposed action clearly distinguishes between those that would be experienced by owners and users of cars and light trucks produced during previous model years, and those that would be experienced by buyers and users of cars and light trucks produced during the model years it would affect. Moreover, it clearly separates these into benefits related to fuel consumption and those related to safety consequences of vehicle use. This is more meaningful and informative than simply identifying all impacts other than changes in fuel savings to buyers of new vehicles as "co-benefits."

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

2. Net Impacts Under the Preferred Alternative

This section reviews impacts under the preferred alternative.

Table VII-423 - Preferred Alternative, Summary of Impacts, CAFE Program

Regulatory Class	Light Truck	Passenger Car	Combined Fleet
Required MPG for MY 2026+	34.1	47.7	40.5
Achieved MPG for MY 2026+	36.0	50.3	42.7
Achieved MPG for MY 2020	31.9	44.2	37.5
Per Vehicle Price Increase	-1360	-823	-1083
MY 2030 Lifetime Fuel Savings (per vehicle), Discounted at 3%	-2046	-1181	-1423
MY 2030 Lifetime Fuel Savings (per vehicle), Discounted at 7%	-1580	-927	-1110
Consumer Per Vehicle Savings, Discounted at 3%	-903	-577	-499
Consumer Per Vehicle Savings, Discounted at 7%	-343	-253	-110
Payback Period Relative to MY 2016 (Years), Values Discounted at 3%	5	6	6
Payback Period Relative to MY 2016 (Years), Values Discounted at 7%	6	8	7
Total Lifetime Fuel Savings (bGallons)	-38.3	-46.0	-84.4
Total Lifetime CO_2 Reductions (million metric tons)	-408.8	-513.7	-922.5
Fatalities (Scrappage)	-2455	2000	-455
Fatalities (Change in Curb Weight)	62	-331	-269
Fatalities (Rebound Miles)	-1390	-1230	-2620
Total Technology Costs ($b), Discounted at 3%	-85.2	-40.7	-126.0
Total Technology Costs ($b), Discounted at 7%	-68.4	-32.3	-100.6
Total Net Societal Benefits ($b), Discounted at 3%	115.2	-128.3	-13.1
Total Net Societal Benefits ($b), Discounted at 7%	85.7	-69.6	16.1

The estimated impacts under the CO_2 Program model are consistent with the estimated impacts under the CAFE Model, as presented in Table VII-424. The primary differences between the two model outputs are higher estimated per vehicle price decreases and a greater reduction in fatalities under the CAFE Program Model:

Table VII-424 – Preferred Alternative, Summary of Impacts, CO_2 Program

Regulatory Class	Light Truck	Passenger Car	Combined Fleet
Required MPG for MY 2026+	34.1	48.9	41.0
Achieved MPG for MY 2026+	35.2	50.4	42.2
Achieved MPG for MY 2020	31.4	43.9	37.1
Per Vehicle Price Increase	-1098	-856	-977

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

[1] This value includes both the value of the fuel spent to drive rebound miles, and the consumer surplus representing the additional amount consumers would have, but did not spend to drive the additional miles.

[2] It is assumed that consumers that drive rebound miles fully internalize fatal and non-fatal crash costs. The miles are driven because they receive an equal and offsetting benefit from driving the miles. These cells report the magnitude of the offsetting benefits.

3. Sales and Labor Utilization Impacts

Higher vehicle prices resulting from CAFE technologies will reduce new vehicle sales, which will in turn affect labor utilization associated with those sales. Conversely, production of new technologies used to improve fuel economy will create new demand for production.

The results of these estimates are shown below in Table VII-463, which lists the average vehicle price change each year for the preferred alternative that is associated with the sales impacts, and the labor utilization impacts associated with these sales impacts. While values for labor utilization impacts are reported as thousands of labor-years, changes in labor utilization would not necessarily involve the same number of changes in actual jobs, as auto industry employers may use a range of strategies (e.g., shift changes, overtime) beyond simply adding or eliminating jobs.

Note that labor utilization impacts represent a net effect of labor years associated with changes in new vehicle sales and changes in labor years required to produce new technologies that improve fuel economy in order to achieve required standards. This estimate assumes that jobs that would have been created to achieve more-stringent standards would remain in the United States and would not be outsourced as a result of increased costs. Overall, relative to the baseline augural standards, the proposal would produce small increases in sales and small net decreases in labor requirements for MYs 2017-2030.

*The change in MSRP may not match the change in technology costs reported in other tables. The change in MSRP noted here will include shifts in the average value of a vehicle, before technology application, due to the dynamic fleet share model (more light trucks are projected under the augural standards than the final standards, and light trucks are on average more expensive than passenger cars), in addition to the price changes from differential technology application and civil penalties, reported elsewhere.

4. Cumulative Impacts

Section 1(b) of Executive Order 13563, Improving Regulatory Planning and Review, requires the consideration, to the extent practicable, of "the costs of cumulative regulations." To adhere to this requirement, costs of all NHTSA light vehicle safety final rules (i.e., Federal Motor Vehicle Safety Standards) with an expected full compliance date of MY 2016 or later were examined. In addition, proposed rules, which have been published in the Federal Register for light vehicles, are also identified, and preliminary cost estimates are provided. Furthermore, cost estimates from the MY 2021-2026 CAFE rule were analyzed. The baseline for cost estimates for this final rule is the 2017 baseline to estimate costs associated with the MY 2021-MY 2026 standards.

The costs being considered include manufacturing cost per vehicle for safety standards that often increase weight, possible other operational costs, and costs for meeting fuel economy requirements. Manufacturing cost estimates are not discounted because they occur at the time the vehicle is purchased; therefore, no discounting is necessary. For calculating costs related to meeting fuel economy standards, costs equal per-vehicle technology costs plus costs of fines. The CAFE-related consumer costs provided in this analysis are those resulting from the current CAFE Model results for costs manufacturers would incur to achieve the MY 2021-2026 CAFE standards. The costs estimated in this analysis are based on an assumption that the 2020 standards would have been extended to apply to MYs 2021-2026 if the agency had not proposed higher standards.2571 For fuel economy, the cost is based on updated estimates of costs of technologies in MY 2016. All costs from previous years are adjusted to 2018 dollars using the implicit price deflator for gross domestic product (GDP).[2572] For safety standards, the cost per average vehicle includes the estimated cost from a range of costs and countermeasures that any vehicle might incur, and also considers voluntary compliance with the rule. In other words, vehicles that already complied with the rule at the time of estimating the average cost for vehicles needing to meet the rule were not considered.

Results of this analysis show that compared to the MY 2016 baseline, safety standards that are already final rules and have been proposed are estimated to add costs to the average passenger car and light truck. For CAFE, when compared to MY 2020, this final rule is also estimated to add costs to these vehicles, as shown in Table VII-464 through Table VII-456. Based on the final safety rules and the final CAFE rule, the average cost of a passenger car will decrease by $286 to $446 and the average cost of a light truck will decrease by $793 to $953 in MY 2026 (with respect to MY 2016 for the safety standards and MY 2020 for this final CAFE rule).[2573]

[2571] The consumer costs associated with the preferred alternative are lower than the costs associated with the augural standards. For example, the average price of a MY 2026 vehicle under this rule is projected to be $34,700, which is a reduction of $1,450 from the corresponding projected average price under the augural standards ($36,150).

[2572] Bureau of Economic Analysis, NIPA Table 1.1.9 Implicit Price Deflators for Gross Domestic Product. https://apps.bea.gov/iTable/index_nipa.cfm

[2573] The preferred alternative, Alternative 3, was used in the discussion.

Table VII-467 through Table VII-469 provide a breakdown of those costs by model year, by vehicle type, and equipment costs for safety and CAFE rules.

Table VII-464 – Summary of Estimated Average Vehicle Increases in Total Consumer Cost for Safety Rules and CAFE Rule (2018$)

	Standards			Total (millions)	
	Safety, with respect to MY 2016 vehicles[2574] (millions)		CAFE, with respect to MY 2020 vehicles[2575] (millions)		
	Low	High		Low	High
Passenger Cars and Light Trucks, Combined	$3,008	$3,809	-$2,501	$507	$1,308

Table VII-465 – Costs of Passenger Car and Light Truck Safety Final Rulemakings that Take Effect in MY 2016 or Later (GVWR of 10,000 lbs. or less, in 2018$)

Final Rule	Effective Model Year	Average Cost Per Vehicle		Total Industry Cost (millions)	
		Low	High	Low	High
FMVSS No. 111, Rear Visibility[2576]	2018	$49	$163	$627	$712
FMVSS No. 141, Minimum Sound Requirements for Hybrid and Electric Vehicle[2577]	2020	$84	$86	$45.7	$45.7

Table VII-466 – Costs of Passenger Car and Light Truck Safety Proposed Rulemakings that Take Effect in MY 2016 or Later (GVWR of 10,000 lbs. or less, in 2018$)

	Average Cost Per Vehicle[2578]		Total Cost (millions)	
	Low	High	Low	High
FMVSS No. 150, Vehicle-To-Vehicle Communication Technology for Light Vehicles	$144	$188	$2,335	$3,051

2025	-$432	-$272	-$1,028	-$868
2026	-$446	-$286	-$953	-$793

Table VII-470 – Total Safety and CAFE Costs of Passenger Cars and Light Trucks Combined, by Model Year with Respect to MY 2020 (2018$)

MY	Total Consumer Cost (millions)	
	Low	High
2021	$2,430	$3,231
2022	$1,523	$2,324
2023	$1,232	$2,033
2024	$450	$1,251
2025	$431	$1,232
2026	$507	$1,308

E. Sensitivity analysis

Results presented today reflect the best judgments regarding many different factors. Based on analyses in past rulemakings, the agencies recognize that some analytical inputs are especially uncertain, some are likely to exert considerable influence over specific types of estimated impacts, and some are likely to do so for the bulk of the analysis. Alternative values were used to explore a range of potential inputs and the sensitivity of estimated impacts to changes in model inputs. The large collection of sensitivity cases in this analysis spans assumptions related to technology applicability and cost, economic conditions, consumer preferences, externality values, and safety assumptions, among others. In contrast to an uncertainty analysis, where many assumptions are varied simultaneously, the sensitivity analyses included here vary a single assumption and provide information about the influence of each individual factor, rather than suggesting that an alternative assumption would have justified a different preferred alternative. This analysis contains hundreds of assumptions and most of them are uncertain – particularly several years in the future. However, assumptions are a necessity of analysis and a sensitivity analysis can identify two critical pieces of information: how big an influence does each parameter exert on the analysis, and how sensitive are the model results to that assumption?

For example, if the cost of battery packs for BEVs learn down at a faster or slower rate than the agencies have projected, technology costs are affected slightly but net benefits, very little. However, if fuel prices are either higher or lower than the projections in the central case (represented by the EIA high and low oil price cases in AEO2019), the set of alternatives considered today produce significantly different results across a variety of metrics, including net social benefits. In that respect, it might be said that the learning rate for batteries exerts relatively little influence on the analysis, as technology costs, the primary metric affected by application of BEV technology for the model years in question, are not much affected by the alternative assumptions. By contrast, the fuel price cases demonstrate that many different metrics are affected by alternative fuel price projections – market adoption of fuel economy improving technologies, the value of gallons saved, buyer payback periods for fuel economy investments, and vehicle miles traveled. The sensitivity analysis demonstrates that fuel prices can have significant impacts on a number of relevant metrics (i.e., model results are sensitive to this assumption), and alternative assumptions can change the sign on measures like net benefits and consumer costs (i.e., this assumption significantly influences the analysis).

This is not to suggest that any one of these sensitivity cases is more likely than the collection of assumptions that represent the central analysis (the "reference case" in the tables that follow). The central analysis still represents our best estimate of each individual assumption used to inform today's decision. Nor is this sensitivity analysis intended to suggest that only one of the many assumptions made is likely to prove unsound with the passage of time or new observations. It is likely that, when assumptions are contradicted by future observation (as previous fuel price projections have been subsequent to the 2012 final rule), there will be collections of assumptions, rather than individual parameters, that simultaneously require updating. For this reason, readers should not interpret the sensitivity analysis as justification for alternative regulatory scenarios to be preferred. Rather, the analysis provides an indication of which assumptions are most critical, and the extent to which future deviations from central analysis assumptions could affect costs and benefits of this rule.

Results of this sensitivity analysis are summarized below, and detailed model inputs and outputs are available on NHTSA's web site.[2579] These are reported as incremental values for the final rule relative to the baseline augural standards. They compare to the measures presented in the central analysis, above, using the reference case assumptions. The reference case values are also reported in the tables for easier comparison. It is important to note that the values of both the augural and the final rule change for each sensitivity case; the incremental changes are not due solely to a change in the absolute outcomes of the final rule, but also due to changes in the absolute outcomes of the augural standards. This can sometimes lead to counterintuitive incremental impacts of changing some of the reference assumptions.

Where the incremental results are counterintuitive, the agencies attempted to offer additional explanation about how the incremental values were reached. For example, the change in fleet size from the augural to final rule standards is smaller under both the low and high GDP cases

[2579] The CAFE Model and all inputs and outputs supporting today's proposal are available at https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system. .

than the reference cases, which immediately seems like a counterintuitive result. However, Table I-16, in the description of the GDP sensitivity cases, shows the fleet size under the augural and final rule regulatory alternatives for the low, reference, and high GDP cases. The absolute fleet size increases with the GDP under both regulatory alternatives (as expected), but because they do so by different absolute amounts in the augural and final rule alternatives, the incremental fleet size impacts are not guaranteed to follow the same rank order. For any incremental impacts reported that appear curious, readers are urged to review the estimated absolute values under both the augural standards and final rule.

The regulatory alternatives used to determine the reported incremental impact values are identical across all cases, except for a subset of alternative policy cases that use the reference assumptions. In the alternative policy cases, three include changes in the way the analysis modeled manufacturer responses to NHTSA's civil penalty rate for noncompliance starting in MY 2019 (in all cases, manufacturers are assumed to prefer fine payment to technology application), and alternative civil penalty rates of $5 and $14 are evaluated; NHTSA may consider changing the civil penalty rate in a separate regulatory action, and depending on the timing of any such action, the final rule to follow today's proposal could reflect the change.[2580] The other policy cases consider a regulatory scenario in which no standards exist after MY 2017, and three cases intended to force technology application at the highest possible rates. The following table lists, and briefly describes, the cases included in the sensitivity analysis.

[2580] 83 FR 13904 (Apr. 2, 2018).

Table VII-471 – Cases Included in Sensitivity Analysis

Sensitivity Case	Description
Reference Case	Reference case
Implicit Value Loss	Consumer value loss offsetting fuel savings beyond payback period
Consumer Benefit at 50%	Assume 50% loss in consumer surplus – equivalent to the assumption that consumers will only value the calculated benefits they receive at 50 percent of the analysis estimates
Consumer Benefit at 75%	75% loss in consumer surplus
12 Month Payback Period	12-month payback period (i.e., voluntary application of technologies paying back within first year of vehicle ownership)
24 Month Payback Period	24-month payback period
36 Month Payback Period	36-month payback period
High Oil Price	High fuel price estimates
High Oil Price with 60 Month Payback Period	High fuel price estimates and a 60-mo. payback period
Low Oil Price	Low fuel price estimates
Low Oil Price with 12 Month Payback Period	Low fuel price estimates and a 12-mo. payback period
High GDP	High economic growth, AEO2019
Low GDP	Low economic growth, AEO2019
High Social Cost of Carbon	High social cost of carbon
Low Social Cost of Carbon	Low social cost of carbon
Global Social Cost of Carbon with 3% Discount Rate	Global Social Cost of Carbon with 3% Discount Rate
Global Social Cost of Carbon with 7% Discount Rate	Global Social Cost of Carbon with 7% Discount Rate
Nonzero Valuation of CH_4 and N_2O	Applies values for CH_4 and N_2O developed by EPA (see page 1064)
No Impact on Domestic Refining	US refining share – US consumption changes have no impact on domestic refining
Maximum Impact on Domestic Refining	US refining share – All changes in US consumption are refined domestically
Scrappage, Sales, and Fleet Share Models Disabled	Keeps average new vehicle prices at MY 2016 levels within the scrappage model throughout the model simulation; this disables the effect of slower scrappage when new vehicle prices increase across more stringent scenarios.
Elasticity of Scrappage to New Vehicles Varies with Age	Scrappage price effect varies with age
High Sales and Scrappage Response to New Vehicle Prices	Price elasticity of -1.25, scrappage model at 95% CI values

Sensitivity Case	Description
Low Sales and Scrappage Response to New Vehicle Prices	Price elasticity of -0.75, scrappage model at 5% CI values
Rebound Effect at 10%	Rebound effect, the increase miles traveled as the cost of travel decreases, is set to 10%
Rebound Effect at 30%	Rebound effect set to 30%
On Road Gap 0.30	On-road gap is set to 30%
Safety Coefficient at 5th Percentile	Lower bounds of confidence interval of safety coefficients
Safety Coefficient at 95th Percentile	Upper bounds of confidence interval of safety coefficients
Low Crash Avoidance Technology Effectiveness	Lower range effectiveness estimates for all 6 crash avoidance technologies
High Crash Avoidance Technology Effectiveness	Higher range effectiveness estimates for all 6 crash avoidance technologies
Technology Cost Markup 1.10	Technology retail price equivalent (RPE) of 1.10 (i.e., 10% markup of direct costs)
Technology Cost Markup 1.24	Technology retail price equivalent (RPE) of 1.24 (i.e., 24% markup of direct costs)
Technology Cost Markup 2.00	Technology retail price equivalent (RPE) of 2.00 (i.e., 100% markup of direct costs)
Higher Battery Direct Costs and Reference Case Learning	15% higher direct manufacturing cost (DMC)
Lower Battery Direct Costs and Reference Case Learning	10% lower DMC
Reference Case Battery Direct Costs and Faster Learning	Learning 6.0% early
Higher Battery Direct Costs and Faster Learning	15% higher DMC and learning 6.0% early
Lower Battery Direct Costs and Faster Learning	10% lower DMC and learning 6.0% early
Reference Case Battery Direct Costs and Slower Learning	Learning 3.5% early
Higher Battery Direct Costs and Slower Learning	15% higher DMC and learning 3.5% early
Lower Battery Direct Costs and Slower Learning	10% lower DMC and learning 3.5% early
Unconstrained BEV adoption	No caps on BEV adoption
Slower BEV adoption	Tighter caps on BEV300 penetration
Exclude Strong Hybrids	Additional strong hybrids are excluded from the analysis
HCR0 and HCR1 Available Except in Pickups	HCR0 and HCR1 is included in the analysis for all non-pickup vehicles.

Sensitivity Case	Description
HCR2 Available	HCR2 engine applicable for all OEMs and technology classes
VCR Available for All Vehicles	VCR engine applicable for all OEMs and technology classes
Skip Peripheral Technologies	Disable LDB, SAX, EFR, ROLL20, AERO20, DSLI
Low Initial Road Load Reduction	Set initial level of body-level technologies to zero (ROLL0, AERO0, MR0)
Long Fleet Redesign Cadence	Redesign cadence (schedule of major technology upgrades for vehicles, engines, etc.) is extended to 1.2 times that of the reference case (rounded to nearest MY)
Short Fleet Redesign Cadence	Redesign cadence shortened to a 0.8 times that of the reference case (rounded to nearest MY)
1-Year Redesign Cadence	Vehicles redesigned every year
NPRM effective cost metric	Run NPRM version now that central version uses cost/credit
NPRM effective cost metric w/High Oil Price	NPRM version with high fuel price estimates
NPRM effective cost metric w/Low Oil Price	NPRM version with low fuel price estimates
Fewer Off-Cycle Credits	Maximum at 7 g/mi
More Off-Cycle Credits	Maximum at 15 g/mi
No Credit Carry-Forward	Disables credit carry-forward
Maximum technology scenario	Apply technology at fastest possible rate (very high stringency)
No CAFE/CO_2 standards	
Perfect Trading of CO_2 Credit Trading	Entire fleet treated as being produced by a single manufacturer. CO_2 program only.
No AC Leakage Credits	Add alternative with final standards that would apply without AC credits. CO_2 program only.

The remaining tables in the section summarize various estimated impacts as estimated for all of the cases included in the sensitivity analysis.

Table VII-472 – Average Required and Achieved CAFE Levels, and Technology Penetration Rates Under Final CAFE Standards (MY 2030 Combined Fleet)

	MY 2030		Technology Penetration Rate for Total MY 2030 Fleet						
Sensitivity Case	**Required CAFE - (mpg)**	**Achieved CAFE - (mpg)**	**Percent CW Reduction (from MY 2017)**	**HCR Engines**	**Turbo. Gasoline Engines**	**Dynamic Cylinder Deac.**	**SHEVs**	**PHEVs**	**BEVs**

Payback periods

The market for new vehicles reveals that buyers have a variety of preferences for attributes like seating capacity, interior volume, drive type, performance, and fuel efficiency (among others). Today's analysis characterizes buyers' preference for fuel economy improvements by the number of years required to offset the initial technology investment with avoided fuel costs – the payback period. While the central analysis uses a 30-month payback period to quantify the average preference for fuel economy improvements in the new vehicle market, the sensitivity analyses consider alternative values (12 months, 24 months, and 36 months). The amount of fuel economy demanded by the market affects both the achieved industry fuel economy level and the amount of fuel economy improvement that is attributable to a given standard. If manufacturers are applying more technology without regulatory pressure, then the cost of technology attributable to an alternative and the resulting fuel savings produced by those technologies both decrease. The sensitivity cases demonstrate that effect, with fuel economy increasing as the payback period increases, but both technology cost savings (relative to the baseline) and foregone fuel savings decreasing as well. The net effect of longer payback periods is an increase to the net benefits associated the preferred alternative (i.e. it becomes less negative as the payback period increases). The results also show that differences of 6 months in either direction are insufficient to measurably impact technology costs, fuel savings, or net benefits under the preferred alternative.

The current sales and scrappage modules do not respond to changes in the payback period. As such, cases with payback periods shorter than 30 months likely overestimate fleet size—and the associated benefits and costs—and, conversely, underestimate those measurements in cases with longer payback periods. The agencies intend to make the sales and scrappage modules responsive to changes in payback periods in future iterations of the model.

Oil Prices

The most impactful uncertainty for determining costs and benefits is the cost of fuel, both in the years that new vehicles are produced and in the subsequent years when they are used. In the central analysis, the rising price of fuel over time creates fuel savings (in dollars) above and beyond the anticipated savings at the time of purchase. Under the high fuel price case, this phenomenon is exacerbated. Under the high fuel price case (based on the AEO2019 high oil price case), consumers demand more fuel economy in the new vehicle market because each gallon fuel saved during the 30-month payback period is worth more. The savings in technology cost under the preferred alternative reflect the higher level of technology, though the value of foregone fuel savings also increases under the high fuel price case, despite the smaller difference in fuel efficiency between the baseline and preferred alternative. However, the higher fuel price also depresses rebound VMT, which serves to reduce annual fuel consumption in all alternatives. Under higher fuel prices, net benefits increase for higher stringencies. Conversely, the low oil price case reduces the amount of fuel economy technology demanded in the new vehicle market. It increases the difference in fuel economy between the baseline and preferred alternative, but decreases the value of (the higher number of) gallons saved. Either of these alternatives has the ability to produce meaningful changes in net social benefits associated with the preferred alternative. The values used to represent fuel price uncertainty appear in Figure VII-5. As the figure shows, the cases are not symmetrical. There is a greater difference between the reference case and the high case, than the reference and low case. However, there is also no period in the historical series that represents sustained real prices as high as the high oil case.

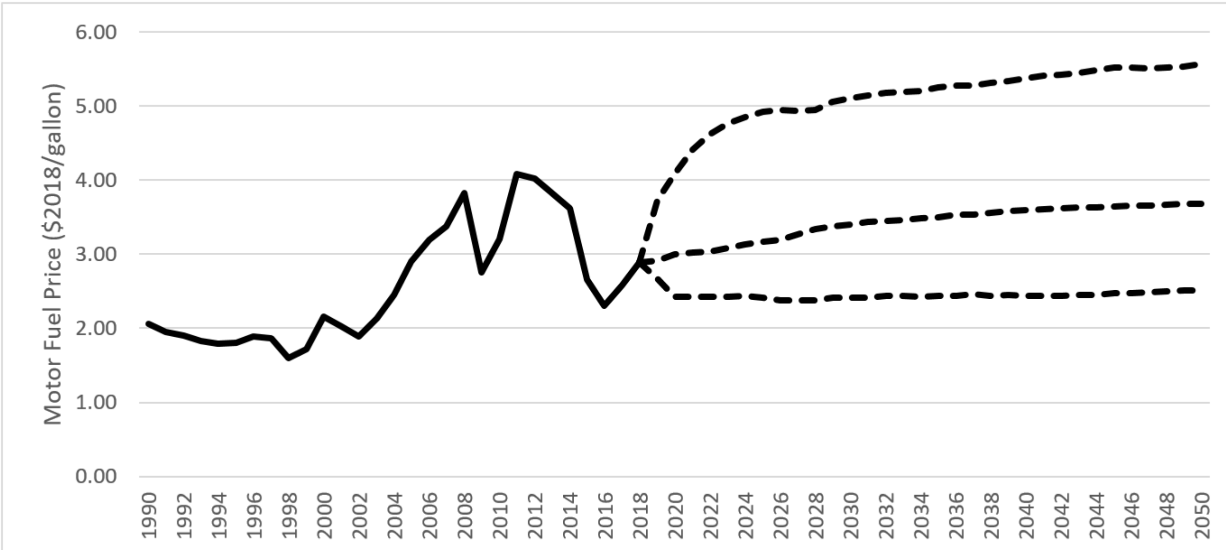

Figure VII-5 – Fuel Price Sensitivity Cases

In addition to varying the fuel price in the analysis, alternative payback periods were simultaneously considered—here manufacturers assume consumers would demand even greater amounts of fuel economy than the central analysis under high fuel prices, and lower amounts under low fuel prices. It is reasonable to suspect that under sustained, historically high fuel prices, consumers would demand higher levels of fuel economy than assumed in the central analysis. Similarly, if fuel prices erode relative to today's levels, preferences could shift toward other attributes. Each of these cases magnifies the impacts of the higher/lower fuel price case relative to the central analysis assumption of the 30-month payback period and the relevant fuel price scenario. The combination of high fuel prices and somewhat longer payback period serves to almost eliminate the difference between the baseline and the preferred alternative – where per-vehicle costs differ by less than $100 by MY 2030. While net social benefits are lower (more negative) than the reference case, the achieved fuel efficiency (and CO_2 emissions) are nearly identical to the baseline scenario. The achieved fuel economy in the preferred alternative rises to over 56 MPG by 2030 and the total number of gallons saved between the alternatives plummets over time as market forces, rather than regulation, drive outcomes. Under the low fuel price and low payback period case, the fuel gallons saved under the baseline, while larger in number, are worth less. This difference in the value of fuel savings is sufficient to change the sign on net benefits to a larger degree than the low fuel price case accomplishes without the shorter payback period.

Measuring Fuel Savings

The procedure the agencies use to estimate fuel consumption assumes that all vehicle models of the same body type—cars, SUVs and vans, and light trucks—and age are driven identical amounts each year. Under this assumption, the agencies' estimates of fuel consumption from increasing the fuel economy of each individual model depend only on how much its fuel economy is increased, and do not reflect whether its actual use differs from other models of the same body type. Neither do the agencies' estimates of fuel consumption account for variation in how much vehicles of the same body type and age are driven each year, which appears to be significant.

This assumption may cause the agencies' estimates of fuel consumption from imposing stricter CAFE and CO_2 standards to be too large. Because the distribution of annual driving is wide using its mean value to estimate fuel savings for individual car or light truck models may overstate the fuel consumption likely to result from tighter standards, even when the fuel economy of different models are correctly averaged.[2581] This will be the case even when increases in fuel economy can be estimated reliably for individual models, as the agencies' analysis does, because the reduction in a specific model's fuel consumption depends on how much it is actually driven as well as on the increase that stricter standards require.

To illustrate, the agencies estimate that new automobiles are driven about 17,000 miles on average during their first year. If the 17,000 mile figure represents the average of two different models that are driven 14,000 and 20,000 miles annually, and the two initially achieve, respectively, 30 and 40 miles per gallon—thus averaging 35 miles per gallon—they will consume a total of 967 gallons annually.[2582] Improving the fuel economy of each model by 5 miles per gallon will reduce their total fuel use to 844 gallons, thus saving 123 gallons annually.[2583] In contrast, the agencies' would estimate total fuel consumption for the two vehicles using the 17,000 mile average figure for both, thus yielding estimated fuel savings of 128 gallons per year, about 5% above the correct value.[2584]

The magnitude of this potential overestimation of fuel savings increases with any association between annual driving and fuel economy, which seems likely to be strong. Acting in their own economic interest, car and light truck buyers who anticipate driving more should be more likely choose models offering higher fuel economy, because the number of miles driven directly affects their fuel costs and thus the savings from driving a model that features higher fuel economy.[2585] Conversely, buyers who anticipate driving less are likely to purchase models with

---

[2581] The correct average fuel economy of vehicles whose individual fuel economy differs is the harmonic average of their individual values, weighted by their respective use; for two vehicles with fuel economy levels MPG_1 and MPG_2 that are assumed to be driven identical amounts (as in the agencies' analysis), their harmonic average fuel economy is equal to $2/(1/MPG_1 + 1/MPG_2)$.

[2582] Calculated as 14,000 miles / 30 miles per gallon + 20,000 miles / 40 miles per gallon = 467 gallons + 500 gallons = 967 gallons (all figures in this calculation are rounded to whole gallons).

[2583] Calculated as 14,000 miles / 35 miles per gallon + 20,000 miles / 45 miles per gallon = 400 gallons + 444 gallons = 844 gallons (again, all figures in this calculation are rounded to whole gallons).

[2584] The agencies estimate of their combined initial fuel consumption would be 17,000 miles / 30 miles per gallon + 17,000 miles / 40 miles per gallon, or 567 gallons + 425 gallons = 992 gallons. After the 5 mile per gallon improvement in fuel economy for each vehicle, the agencies' estimate would decline to 17,000 miles / 35 miles per gallon + 17,000 miles / 45 miles per gallon = 486 + 378 = 863 gallons, yielding an estimated fuel savings of 992 gallons - 863 gallons = 128 gallons (as previously, all figures in this calculation are rounded to whole gallons).

[2585] For example, some businesses, rental car firms, taxi operators, and ride sharing drivers are likely to anticipate using their vehicles significantly more than the average new car or light truck buyer. Furthermore, their choices among competing models are likely to be more heavily influenced by economics than by the preferences for other lower fuel economy. Such behavior—whereby buyers who expect to drive more extensively are likely to select models offering higher fuel economy—cannot be fully accounted for in today's analysis, because that analysis is necessarily based on empirical estimates of average vehicle use. To the extent it occurs, the agencies are likely to consistently overstate actual fuel savings from requiring higher fuel economy, as well as to overstate increases in fuel consumption resulting from lower standards. Thus, the agencies' central analysis is likely to overestimate the final rule's impact on consumer benefits such as reduced fuel consumption and increased refueling time, as well as on the resulting environmental impacts of fuel production and use

A similar phenomenon may cause the agencies to overstate the *value* of fuel savings resulting from requiring higher fuel economy as well. As with miles driven, the agencies' analysis assumes all vehicle owners pay the national average fuel price at any time. However, fuel prices vary substantially among different regions of the U.S., and one would expect buyers in regions with consistently higher fuel prices to purchase vehicles with higher fuel economy, on average. To the extent they actualy do so, evaluating the savings from requiring higher fuel economy identically in all regions using nationwide average fuel prices is likely to overstate their actual dollar value; similarly, assessing the increased fuel costs likely to result from lower standards using national average fuel prices is likely to overstate their true value insofar as car and light truck buyers facing above-average fuel prices choose higher-mpg models.

As an illustration, suppose gasoline averages $3.00 per gallon nationwide, but a buyer who expects to drive a new car 17,000 miles during its first year (the same value used in the example above) faces a local price of $4.00 per gallon, and chooses a model that achieves 40 mpg. That driver's cost of fuel during the vehicle's first year will total $1,700 (calculated at 17,000 miles / 40 miles per gallon x $4.00 per gallon). A buyer who plans to drive the same number of miles but faces a lower price of $2.00 per gallon and thus chooses a vehicle that offers only 30 mpg will have first-year fuel costs of $1,133 (calculated as 17,000 miles / 30 miles per gallon x $2.00 per gallon), so total annual fuel costs for these two vehicles will be $1,700 + $1,133 = $2,633. If the fuel economy of both vehicles increases by 5 mpg, their actual fuel savings will be $189 and $162, or a total savings of $351. However, evaluating total fuel savings using the national average price of $3.00 per gallon yields savings of $382, thus overstating actual savings by about 10%. This same phenomenon would cause the agencies to overestimate of costs of increased fuel use when standards are relaxed, as with this rule.

Alternative Discount Rates for Consumer Benefits

There are several reasons to believe that buyers of new cars and light trucks are likely to discount future fuel savings (or increases in future fuel costs) using rates higher than the 3 and 7 percent values that OMB prescribes for use in regulatory analysis. First, the 3 percent rate OMB recommends for discounting a regulation's economic effects on consumers is intended to apply in situations where those effects are foreseeable rather than uncertain. This is decidedly not the case with the investments in higher fuel economy that higher standards would compel consumers to make, because car buyers' returns on those investments depend critically on future fuel prices,

---

attributes that motivate many other buyers, making them more likely to select vehicles with higher fuel economy in order to improve their economic returns.

the number of miles they will drive, and the actual fuel economy that the models they purchase achieve under real-world driving conditions.

Each of these determinants of car buyers' actual savings in fuel costs is highly uncertain at the time they choose among competing models, making the "payoff" to choosing a model that features higher fuel economy extremely uncertain in contrast to its immediately apparent higher purchase price, and raising the distinct possibility of a financial loss. In the face of such extreme uncertainty, rational buyers may discount future cost savings from purchasing models that offer higher fuel economy at rates well above 3 percent, and perhaps even above 7 percent.

Second, buyers' investments to purchase models offering higher fuel economy are extremely "illiquid," because it is costly and time-consuming to convert those outlays back to cash. And while some of additional costs for more-efficient vehicles may be recouped when selling or trading-in the vehicle, the extent to which such costs may be recovered is uncertain. Because of these costs, investors routinely demand rates of return to justify making illiquid investments. Fuel economy is no exception, and rational car buyers may apply higher discount rates than included in the analysis to future savings in fuel costs than anticipated when paying higher prices for more fuel-efficient models.

There is also extensive empirical evidence that consumers discount future energy savings from energy-efficient durable goods at rates well above the "social" discount rates normally used in regulatory analysis. For example, Hausman (1979) estimated that consumers discount future savings from purchasing more energy-efficient household appliances at rates as high as 20 percent.[2586] More recently, Newell and Siikimaki (2015) estimated that the median discount rate that a sample of U.S. homeowners applied to future payoffs was 11 percent.[2587] On the more specific question of investments in higher fuel economy, Leard *et al.* (2017) estimate that consumers discount future fuel costs at approximately 12 percent, while Busse *et al.* (2013) estimate that new- and used-car buyers apply discount rates averaging about 9 percent and 17 percent to future fuel savings from purchasing higher-mpg models.[2588]

In response to the likelihood that car and light truck buyers discount future fuel savings at rates higher than the 3 and 7 percent rates used in their primary analysis, the agencies also examined the effects of higher discount rates on their estimates of benefits and costs from adopting the final standards. As the table below indicates, the social costs of the final standards exceed its social benefits at a 3 percent discount rate, while the reverse is true when both are discounted at a 7 percent rate. Since most costs and benefits of the final standards are borne by

Evidence from New and Used Car Purchases." American Economic Review Vol. 103 no. 1 (February 2013), at 220–256.

consumers, this indicates that as long as consumers discount the future at rates toward the upper end of the 3 to 7 percent range, the final rule's net social benefits will be positive.

In contrast, the table shows that private costs resulting from the final standards exceed its private benefits at both 3 percent and 7 percent discount rates, although by a much smaller margin at the latter rate. As the table also shows, consumers would have to discount future benefits and costs a much higher discount rate—apparently just above 15 percent—for the final standards to yield private benefits that exceed the private costs it imposes. This result reflects the importance of private impacts of the final standards other than savings in vehicle purchase prices and fuel costs. As the bottom line of the table suggests, however, if buyers of new cars and light trucks focus exclusively on these two impacts of the final standards—arguably its most visible and direct effects—they will experience net savings even if they discount the future at rates as low as approximately 5 percent, which the preceding discussion suggests is very likely.

Table VII-486 – Effect of Alternative Discount Rates on Benefits and Costs of Final Standards

Consumer Discount Rate	**3%**	**7%**	**10%**	**15%**
Social Discount Rate	**3%**	**7%**	**3%**	**3%**
Reduced Purchase Prices	$126	$101	$86	$68
Other Private Benefits	$48	$29	$21	$13
Total Private Benefits	$174	$130	$107	$81
Increased Fuel Costs	-$185	-$115	-$84	-$54
Other Private Costs	-$99	-$61	-$44	-$28
Total Private Costs	-$284	-$176	-$128	-$82
Net Private Benefits	-$110	-$46	-$21	-$1
External Benefits	$107	$70	$107	$107
External Costs	-$10	-$8	-$10	-$10
Net External Benefits	$97	$62	$97	$97
Social Benefits	$280	$200	$214	$188
Social Costs	-$294	-$184	-$138	-$91
Net Social Benefits	-$13	$16	$76	$96
Reduced Purchase Prices minus Increased Fuel Costs	-$12	$15	$23	$27

How Widespread Would Benefits from Lower Standards Be?

The estimates of benefits and costs from the standards this final rule establishes are based on the expected or average lifetimes and average annual usage of cars and light trucks, but both the actual lifetimes and annual use of individual vehicles vary widely around these expected values. This means that not all buyers of new cars and light trucks will benefit on balance from the combination of the expected reduction in new vehicles' sales prices and the increase in their lifetime fuel costs due to their lower fuel economy, even if buyers do so *on average*. The fraction who do benefit depends on how the actual lifetimes and use of individual cars and light trucks are distributed around their average values.

If current patterns of vehicle use prevail into the future, only some buyers (and subsequent owners) of new cars and light trucks are likely to drive enough that the fuel savings from higher fuel economy levels required by the augural standards would have repaid the higher prices they initially paid to purchase their new vehicles. These buyers will be worse off under the final standards, because their savings from lower purchase prices for new cars and light trucks will not be enough to offset the higher fuel costs they (and subsequent owners of vehicles they purchase new) will pay over those vehicles' lifetimes. In contrast, buyers who do not drive enough for the savings in fuel costs with the augural standards in effect to have repaid their higher purchase prices for new cars and light trucks will be better off financially under the less demanding standards the agencies are adopting.

Table VII-487 uses the estimates of price reductions and changes in fuel economy for new cars and light trucks from replacing the augural standards with the final standards to calculate the number of miles new cars and light trucks would need to be driven for their higher lifetime fuel costs to offset buyers' savings in their initial purchase prices. These mileage estimates differ between cars and light trucks because the changes in their purchase prices and fuel economy levels differ, and they also vary slightly among model years, because of the differing fuel prices vehicles from each model year will face over their lifetimes.

Table VII-487 – Llifetime Mileage Required for Higher Fuel Costs to Offset Savings in Purchase Prices of New Cars and Light Trucks

Model Year	Cars						
	Price Reduction	Baseline MPG	Preferred Alternative MPG	MPG Reduction	Average Fuel Price	Increase in Fuel Cost per Mile	Breakeven Lifetime Miles
2021	$279	45.3	43.5	1.8	$3.41	$0.004	72,000
2022	$422	47.0	44.2	2.8	$3.44	$0.006	73,000
2023	$538	48.2	44.5	3.6	$3.46	$0.007	73,000
2024	$753	49.6	45.0	4.6	$3.49	$0.009	83,000
2025	$857	50.6	45.2	5.3	$3.51	$0.010	84,000
2026	$871	50.9	45.5	5.4	$3.53	$0.010	85,000
2027	$861	51.0	45.6	5.5	$3.55	$0.010	83,000
2028	$846	51.2	45.7	5.5	$3.56	$0.010	81,000

Model Year	Light Trucks						
	Price Reduction	Baseline MPG	Preferred Alternative MPG	MPG Reduction	Average Fuel Price	Increase in Fuel Cost per Mile	Breakeven Lifetime Miles
2021	$651	33.2	31.2	1.9	$3.41	$0.008	82,000
2022	$1,221	35.1	31.7	3.4	$3.44	$0.013	93,000
2023	$1,331	35.6	31.9	3.7	$3.46	$0.014	94,000
2024	$1,725	36.7	32.1	4.6	$3.49	$0.017	102,000
2025	$1,636	37.3	32.7	4.7	$3.51	$0.017	98,000
2026	$1,561	37.6	33.0	4.6	$3.53	$0.016	96,000
2027	$1,519	37.7	33.1	4.6	$3.55	$0.016	93,000
2028	$1,468	37.9	33.3	4.6	$3.56	$0.016	91,000

As Table VII-487 shows, cars would only need to be driven 72,000-85,000 miles for higher fuel costs to offset buyers' savings in their initial purchase prices, while light trucks would need to be driven somewhat more (82,000-102,000 miles). Because buyers discount future fuel savings, the *discounted* mileage they expect to accumulate over future years would need to exceed these thresholds for the present value of higher lifetime fuel costs to offset the savings in purchase prices. Conversely, buyers of new cars and light trucks who expect to drive less than these thresholds—again, discounting miles that will be driven in future years—will save more on their initial purchases than they will pay in higher lifetime fuel costs.

There is some uncertainty in converting the lifetime mileage thresholds derived in Table VII-487 to average yearly miles over vehicles' lifetimes, because it is unknown whether a specific vehicle owner drives a constant number of miles each year or if their use of that vehicle declines gradually as the vehicle ages—as is observed for the average vehicle. Presumably, each of these patterns occurs to some extent, and tabulations of vehicle use at any specific age include a combination of vehicles that have experienced constant and declining use up to that age.[2589] Because the pattern of a vehicle's use as it ages affects the discounted value of the total mileage and fuel costs it accumulates over its lifetime, different assumptions about the pattern of use produce slightly different estimates of average annual mileage and discounted fuel costs. The assumption that annual use of cars and light trucks declines gradually with increasing age produces somewhat lower estimates of the annual mileage they must be driven for their higher fuel costs to offset the savings in their purchase prices, while assuming that they are driven the same number of miles each year throughout their lifetimes produces slightly higher estimates of their annual "breakeven" mileage.[2590] These estimates derived under these alternative assumptions bound the plausible range of the annual mileage at which the savings in initial purchase prices and increases in lifetime fuel costs resulting from the final standards would offset each other.

Figure VII-6 and Figure VII-7 display the distributions of average annual use of cars and light trucks of all ages owned and leased by U.S. households during 2017.[2591] As these figures show, the median number of miles cars are driven is approximately 9,000, while median annual use of light trucks is somewhat higher, at just under 10,000 miles. Figure VII-6 also displays the range of estimates of average annual mileage for cars corresponding to the "breakeven" mileage estimates defined as above, and shows how these compare to cars' median actual use. Figure VII-7 presents the same comparison for household-owned light-duty trucks.

[2589] Either of these (or any combination of them) would produce the observed fleet-wide distribution of annual car and light truck use by age, which shows average use for new vehicles in the range of 15-17,000 miles and annual use declining in an S-shaped pattern with increasing age.

[2590] This is because the discounted present value of mileage that occurs earlier in a vehicle's lifetime is larger than that of mileage that occurs later in its lifetime. For consistency with the agencies' sensitivity analysis examining the effect of higher consumer discount rates, the estimates of discounted mileage used in this analysis assume that buyers (and subsequent owners) of new cars and light trucks discount future fuel costs at 10%. At a 7% discount rate, the ranges for "breakeven" annual mileage shown in the figures below would span the median annual mileage of both cars and light trucks, although at least one-third – and perhaps as many as half – of both cars and light trucks would still be driven less than their breakeven mileage.

[2591] These distributions were tabulated from the vehicle file of the 2017 National Household Travel Survey conducted by the Federal Highway Administration; see https://nhts.ornl.gov/ Annual use is calculated from each vehicle's odometer reading on the day the household was surveyed, divided by its age in years.

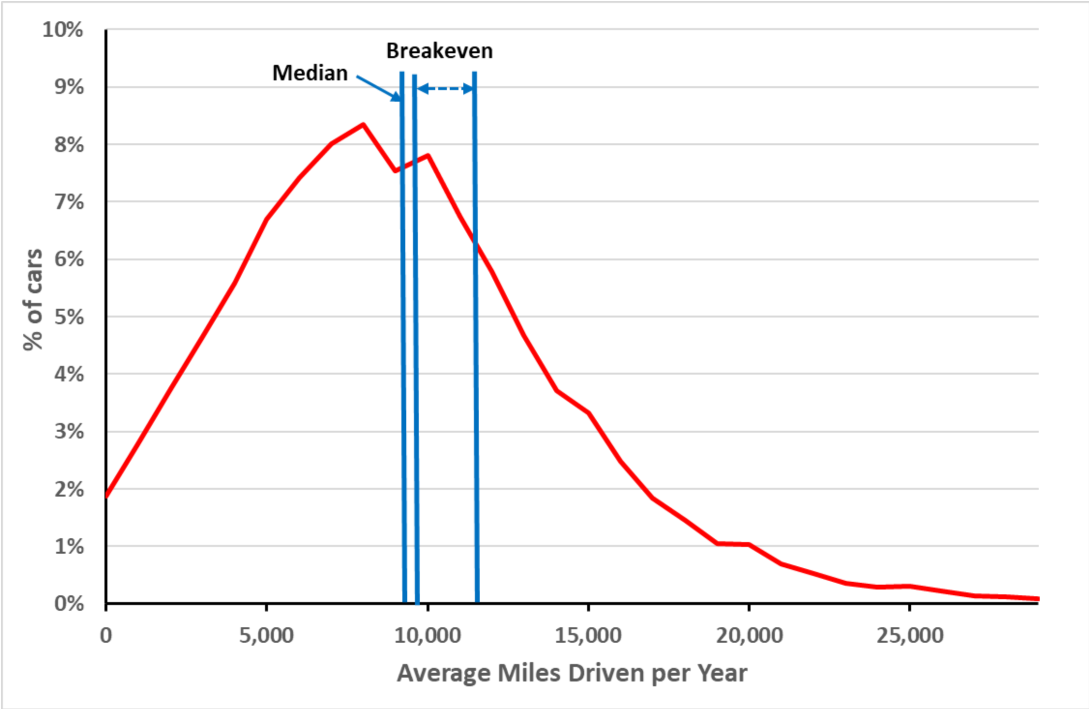

Figure VII-6 – Distribution of Average Annual Use of Household Automobiles

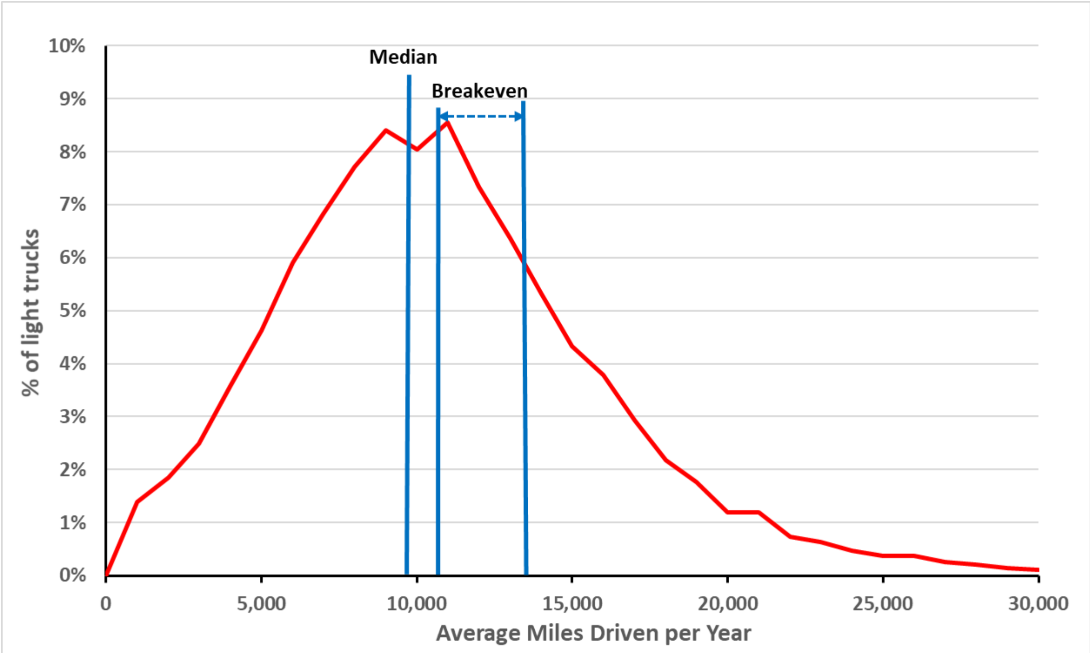

Figure VII-7 – Distribution of Average Annual Use of Household Light Trucks

As these comparisons illustrate, the annual mileage required to breakeven– estimated to be 9,400-11,700 miles per year, depending on the specific assumption about the pattern of vehicle use with age – is well above the median annual use of cars. This means that most new-car buyers will be financially better off under the more lenient standards this final rule establishes than they would have been with the augural standards remaining in effect, because they will save more from the lower prices to purchase new vehicles than they will pay in additional fuel costs (with future fuel costs discounted to their present value). Depending on the estimate of annual car use, 55 percent to 70 percent of household-owned cars were driven less during 2017 than the annual mileage that would be necessary for higher fuel costs to offset purchase price savings, meaning that the final standards will resulting in net financial savings for a significant number of American households.

For light trucks, the level of annual use necessary for higher fuel costs to offset lower purchase prices is higher – 10,400-13,300 miles, again depending on the assumption about how vehicle use varies with age – and considerably farther above median annual use of household-owned light trucks in 2017. As a consequence, at least 55 percent—and perhaps as many as 75 percent—of household light truck owners would on balance experience cost savings from the combination of lower purchase prices and higher fuel costs anticipated to result from this final rule.

Of course, a significant fraction—typically 15-20 percent of new vehicles – is purchased by businesses for the use of their employees, rental car firms, taxi operators, and government agencies. Statistics on the use of these vehicles are difficult to obtain, but annual use of corporate-owned cars and light trucks is reported to average 26,000-27,000 miles, while annual use of rental cars and light trucks appears to be only slightly lower.[2592] Cars and minivans used in taxi service appear to be driven more than 100,000 miles annually, while use of government-owned cars and light trucks appears to average 8,000-11,000 miles annually.[2593] If the owners and users chose to purchase vehicles near the new required MPG, most of these vehicles are likely to experience cost increases as a consequence of adopting these final standards instead of the augural standards, as their higher fuel costs exceed savings in their purchase prices—significantly so, in the case of corporate fleet, rental, and taxi vehicles. However, it seems likely that these purchasers are cognizant of their heavy vehicle use and capable of performing a cost-benefit analysis of their new vehicle purchase—either formally or informally—which will likely lead them to purchasing a vehicle with a MPG significantly higher than mandated by the standards.

Impacts on Petroleum Refining

[2593] Use of taxis was estimated from Automotive Fleet, U.S. Fleet Statistics by Industry Segment, http://www.automotive-fleet.com/statistics/statsviewer.aspx?file=http%3a%2f%2fwww.automotive-fleet.com%2ffc_resources%2fstats%2faffb12-9-fleetstats.pdf&channel= Use of cars and light trucks owned by government agencies was estimated from Government Fleet Fact Book 2012 (http://www.government-fleet.com/fileviewer/1556.aspx), "Fleet Size by Unit Type," p. 28, and "State, County, and Municipal Vehicle Totals," p. 30; and 2012 Federal Fleet Report (http://www.gsa.gov/portal/category/102859), Tables 2-5, 2-6, and 4-2.

The reference case analysis assumes that for each additional gallon of gasoline or diesel consumed, U.S. refinery output would increase by half a gallon. The sensitivity analysis includes a case, labeled "No Impact on Domestic Refining", that assumes U.S. refinery output would remain unchanged. This could occur if U.S. refineries adjust to the increased domestic demand by reducing exports and increasing imports of petroleum products. The sensitivity analysis also includes a case, labeled "Maximum Impact on Domestic Refining", that assumes U.S. refinery output would increase by a gallon for each additional gallon of gasoline or diesel consumed. Accounting for both upstream and tailpipe emissions, the analysis indicates that if refinery output changes on a gallon-for-gallon basis, emissions of pollutants other than CO are higher under the new standards than under the baseline/augural standards. These cases show small impacts on incremental changes in emissions CO and N_2O, and no changes in emissions of CO_2 and CH_4. Impacts on incremental total VOC emissions are larger, but not large enough to change the direction of these incremental emissions. However, the analysis also shows that if refining output remains unchanged, total NO_X and SO_2 emissions decrease under the new standards. These cases correspondingly show small impacts on total social benefits. If refining output remains unchanged, foregone benefits are about 3 percent smaller than in the reference case. If refining output changes on a gallon-for-gallon basis, foregone benefits are about 3 percent larger than in the reference case.

Emissions Costs

The effects of climate change are uncertain in both the magnitude and timing of their impacts on the natural environment. The sensitivity analysis considers both higher and lower estimates of the domestic social cost of carbon and two cases using the global SCC. Climate change impacts are largely external to the decisions of vehicle buyers, so these sensitivity cases do not affect any of the metrics associated with CAFE/CO_2 compliance, fuel consumption, or consumer benefits. They merely scale up (or down) the social cost associated with the metric tons of CO_2 emitted in the reference case. As one would expect, a higher domestic SCC increases costs and thus reduces net benefits, while a lower domestic SCC has the opposite effect. Similarly, the case where emissions of CH_4 and N_2O are valued increases the social cost associated with higher emissions of CH_4 and N_2O under the preferred alternative. However, the case also demonstrates that these emissions shifts have little impact on either costs or benefits.

Opportunity Costs

As in RIAs supporting past joint rulemakings regarding CAFE and CO_2 standards, today's sensitivity analysis includes cases examining the potential that consumers will ultimately realize benefits smaller than indicated by a simple actuarial accounting of avoided outlays for fuel. Like the RIA's for 2012-2016 and 2017-2025 standards, today's analysis includes cases that assume consumers would realize 50 percent or 75 percent of these benefits. Additionally, as discussed in today's *Federal Register* notice, today's analysis includes a case that assumes that buyers will face an opportunity cost equal to the value of outlays for fuel beyond the payback period assumed to represent buyers' willingness to pay for fuel economy. The reference case estimates that the market will behave as if buyers are willing to pay for fuel economy improvements expected to repay their initial costs during the first 30 months of vehicle operation. The implicit opportunity cost sensitivity case assumes that if standards cause manufacturers to apply technologies that produce fuel economy improvements with payback periods greater than 30 months, buyers forego an opportunity cost equal in value to the costs of achieving these improvements, net of the value of fuel savings they produce during the first 30 months a new vehicle is driven. The logic underlying this measure is that if consumers do not value fuel savings beyond 30 months but are forced to incur the costs of achieving them (in the form of higher prices to purchase new vehicles that comply with stricter standards), they must be compensated by improvements in vehicles' other attributes (e.g., higher performance, more space, etc.) that they view as at least as valuable as those additional but unvalued discounted lifetime fuel savings. Avoiding the imposition of this opportunity cost on new car and light truck buyers thus represents an additional benefit of adopting CAFE and CO_2 emission standards that are less demanding than the augural standards. Because these other improvements are not directly observable, they are accounted for implicitly and in aggregate rather than itemized and valued explicitly and in detail. For this case in today's sensitivity analysis, reported total costs (from the consumer and societal perspectives) thus include an entry identified as "implicit opportunity cost" in reported outputs from the CAFE Model.

The case including the estimated implicit opportunity cost is most consistent with the reference case estimates of buyers' willingness to pay for fuel economy improvements (i.e., as represented by a 30-month payback period). However, including the implicit opportunity costs increases the decline in private costs accounted for when standards relax. This changes the sign on per vehicle net benefits for purchasers of new vehicles under both discount rates of the CAFE program, and for the 7 percent discount rate of the CO_2 standards. At a 3 percent discount rate the per vehicle net benefits for new vehicle buyers changes from -$499 in the reference case to $69 in the sensitivity case that includes the implicit opportunity costs; at a 7 percent discount rate net benefits change from -$110, in the reference case, to $369, in the sensitivity case. At a 3 percent discount rate the reference case for the CO_2 standards has per vehicle net benefits of -$678; including the implicit opportunity costs decrease the magnitude of net benefits to -$87. At a 7 percent discount rate (more consistent with OMB guidance on private cost and benefit accounting), including the implicit opportunity costs changes per vehicle net benefits from -$280 to $219.

As can be seen, the sign of the net benefits of relaxing the standards from the augural standards to the final standards established in this rule, depends on assumptions about opportunity costs. Including the implicit opportunity costs also changes the sign of the societal net benefits for the 3 percent discount rate—they go from -$13b to $45b and from -$22b to $35b for the CAFE and CO_2 standards, respectively. At a 7 percent discount rate, including the implicit opportunity costs, increases the magnitude of the positive societal net benefits—they go from $16b to $55b and from $6b to $45b for the CAFE and CO_2 standards, respectively.

Vehicle Demand (Sales/Scrappage) Alternatives

The sensitivity cases that excludes the demand (sales, scrappage and dynamic fleet share) models show no incremental change in vehicles sales or fleet size (by design). Including the sales, scrappage and dynamic fleet share models in the reference case increases sales by 2.7 million and the fleet size (in vehicle years) by 35 million for the remaining lifetime of vehicles through model year 2029 in the preferred case relative to the augural. Including the dynamic fleet share allows the relative cost per mile of travel of light trucks and passenger cars to determine their share of the market. Because of the diminishing returns of incremental improvements in fuel economy, the cost per mile of light trucks and passenger cars converge when both classes improve in fuel economy, and the light truck share will generally increase with more stringent fuel economy standards. Under the preferred scenario, turning off the dynamic fleet share model results in a higher light truck share (49 percent) than in the reference case (47 percent). In net, including the sales, scrappage and dynamic fleet share models increases expected fatalities attributed to the remaining lifetime of vehicles through MY 2029 by 500 to 600, or about 20 percent, depending on the program, as a higher share of miles are driven by older, less safe vehicles. Shifts in the proportion of miles driven by vehicles of different ages and regulatory class, also change the expected changes in fuel consumption, CO_2, and pollutant emissions.

Recent work in economics literature estimates that the combination of the decline in new vehicles sales and lower scrappage rates may result in a 13 to 16 percent reduction in the estimated fuel savings from increases to fuel economy standards.[2594] By disabling the sales, scrappage, and dynamic fleet share models, estimates of fuel savings leakage can be compared to the literature estimate. This measure is calculated as the percent difference of the incremental fuel consumption for reference case relative to the case where the sales, scrappage, and dynamic fleet share models are disabled. The estimated leakage for the final CAFE standards is 7.0 percent and 11 percent for the final CO_2 standards. This is slightly smaller than the literature estimate, but importantly relies on a constraint for total VMT added in response to comments on the NPRM. Given that the literature example does not have the same constraint, the agencies take this sensitivity case as further evidence that the final sales, scrappage and dynamic fleet share models provide sensible estimates for the leakage between the new and used vehicle markets as prices of new vehicle change with CAFE/CO_2 standards.

Carbon dioxide, methane, and nitrous oxide scale approximately in proportion to fuel consumption so that the leakage of emissions abatement of these emissions is of a similar rate to fuel leakage. However, older vehicles are not only less efficient per mile, but also release certain pollutants at a higher per mile (and on average per gallon) rate. The result is that the total incremental change in key pollutants does not just scale with fuel consumption, but looks notably different when the sales and scrappage effects are excluded. The estimated reduction in carbon monoxide is 10 and 20 percent of the reference case when the sales and scrappage models are excluded for the CAFE and CO_2 programs, respectively. Incremental emission changes of VOC and NO_x increase by 36 to 39 percent and 72 to 79 percent when the sale and scrappage models are excluded for the CAFE and CO_2 programs, respectively. Finally, sulfur dioxide emissions decline by 7,200 metric tons under the reference CAFE assumptions, but actually increase by 4,100 metric tons when the demand models are excluded; they follow a more expected pattern under the CO_2 program, increasing by 16 percent relative to the reference case when the demand models are excluded. Depending on the calendar year, the sulfur dioxide emission rate per BTU is 15 to 20 times higher for electricity than it is for gasoline. Thus, the results for sulfur dioxide

[2594] Jacobsen, Mark R., and Arthur A. van Benthem. 2015. "Vehicle Scrappage and Gasoline Policy." *American Economic Review*, 105 (3): 1312-38.

can be explained by the change in penetration rates of battery powered vehicles (a result of the higher light trucks share when the dynamic fleet share is disabled).

As shown, modelling the sales, scrappage and dynamic fleet share changes the prediction of fuel savings, CO_2 and pollutant abatement, and fatality impacts of changing fuel economy and CO_2 standards. Taking all of these factors together, excluding these impacts would result in a one percent decrease and a 2 percent increase in the estimated total cost reduction of implementing the final rule for the CAFE and CO_2 programs, respectively. It would also result in an 8 percent and 10 percent increase in the estimated reduction in total benefits for the CAFE and CO_2 programs. The result is that including these models can have important impacts on the implied net benefits of the rule. Since few commenters argued that these were not real effects, the agencies take this as further evidence that their inclusion is essential to accurately understanding the costs and benefits of the rulemaking.

In addition to a case which excludes the sales, scrappage and dynamic fleet share models three other sensitivity cases which vary the scrappage and/or sales effects are included. Two cases model high and low estimates of the sales and scrappage impacts—because these effects are linked the agencies believe it is reasonable to vary them together. These cases do not change achieved and required CAFE and CO_2 standards nor do they alter the technology solutions simulated to meet the standard. They mostly act as a range on changes to total fatalities, new vehicle sales, fleet size, fuel consumption, and CO_2 and pollutant emissions. For example, the high sales/scrappage case increases total fatalities by approximately 3 percent and the low cases decreases total fatalities by approximately 3 percent, while barely changing the average vehicle age. These cases change fuel consumption, CO_2 emissions, and the total societal costs and benefits by less than 1 percent for both programs. However, since total societal costs and benefits move in opposite directions, these cases do put a 15 to 38 percent uncertainty range on total net benefits depending on the program and discount rate.

An estimate of the scrappage model that allows the elasticity of scrappage rates to new vehicle prices to vary by the age of the vehicle is also included. All reported social and consumer costs are within 1 percent and the total fatalities are within 2 percent of the reference case values. Further, all of the reported measures for the case that allows the scrappage elasticity to vary by age fall within the reported values for the high and low sales/scrappage effect cases except for one. The average age of the fleet in calendar year 2040 is slightly lower than the low, reference, and high sales/scrappage effect cases when the scrappage elasticity is allowed to vary with age. This suggests that the elasticity of the scrappage rates of younger used vehicles is more responsive to changes in new vehicle prices, as expected. Overall, varying the elasticity of scrappage to new vehicle prices by vehicle age produces less uncertainty in key measures and the overall costs and benefits of the program than does using the 5 and 95 percent confidence intervals of the adjusted new vehicle price coefficient in the central model. This further justifies the agencies decision to exclude the interaction terms between adjusted new vehicle prices and vehicle age.

GDP Alternatives

Assumptions about GDP affect three factors in the CAFE modelling: total non-rebound VMT, sales, and scrappage. A higher GDP will generally result in more VMT, higher new vehicle sales, and higher scrappage rates. Because rebound VMT is a percentage change over baseline levels, when baseline VMT is lower in the low GDP case, the change in rebound VMT is lower in magnitude. Similarly, when it is higher in the high case, the change in rebound VMT is higher in magnitude. For both programs, the high GDP case does not increase the estimated incremental new vehicle sales for the final rule (rounded to the nearest 100,000 units). For both programs, the low GDP case decreases the incremental new vehicles sales by 100,000 units, relative to the reference case. For the CO_2 program, the cumulative change in fleet size through MY 2029 is the same for the high and reference GDP cases, and is 1 million vehicle years smaller for the low GDP case; these results are not surprising. However, for the CAFE program, the incremental change in fleet size is smaller in both the high and low GDP cases, which is not an intuitive result, but can be explained by more detailed results from the table, below.

Table VII-488 – Fleet Size Metrics for Final and Augural CAFE Standards (Million Vehicle-Years), Cumulative through the Remaining Lifetime of Vehicles Through MY 2029

GDP Case	**Low**			**Ref**			**High**		
Scenario	**Final Rule**	**Augural Standards**	**Change**	**Final Rule**	**Augural Standards**	**Change**	**Final Rule**	**Augural Standards**	**Change**
Legacy Fleet[1] Years	2,367	2,372	-4.9	2,323	2,328	-4.9	2,299	2,304	-4.9
Analysis Fleet[2] Years	3,479	3,442	37	3,519	3,480	40	3,533	3,494	39
Total Fleet Years	5,847	5,814	33	5,843	5,808	35	5,831	5,798	34
New Vehicle Sales (millions)	207.4	204.9	2.6	214.6	211.8	2.7	218.2	215.4	2.7

[1] The legacy fleet is defined as vehicles model years 1978 to 2016. This portion of the fleet is affected by the scrappage model, but not the sale model.
[2] The analysis fleet is defined as vehicles model years 2017 to 2019. This portion of the fleet is affected both the sales and scrappage models.

As Table VII-488, above, shows, the legacy fleet size is largest for both the final standards and the augural standards for the low GDP case, and smallest for the high GDP case. This portion of the fleet is only affected by the scrappage model. When GDP is lower, consumers are expected to delay purchasing new vehicles and retain their existing vehicles longer, growing the legacy fleet, as shown. The analysis fleet and combines both the effects of the sales and scrappage models. The analysis fleet is highest under the low GDP case and lowest under the high GDP case. This suggests that in net, a lower GDP will result in a longer expected lifetime for vehicles affected by the MY 2021-2026 standards than a higher GDP. Still, the difference between the final and augural standards, suggests that the difference in million vehicle years is smallest for the low GDP case and highest for the reference case. This is true also of the total expected fleet lifetime in million vehicle years, as shown in the table above and the main sensitivity tables.

For both programs, the total foregone costs and benefits are lowest under the low GDP case and highest under the high GDP case. However, because total costs decline by more than total benefits under the low GDP case, the net benefits decrease slightly. They remain negative for all GDP cases for the 3 percent societal discount rate, and positive for all GDP cases for the 7 percent discount rate. The pollutant impacts are mostly bound around the reference case. The one exception is SO_2 emissions, where the additional fuel consumption under the high GDP case outweighs the additional tailpipe emissions from additional miles driven on electricity, and the incremental impact of changing the standards goes from slightly negative in the low and reference GDP cases to slightly positive in the high GDP case. The GDP cases change the total consumer costs and benefits by less than 3 percent.

Rebound Alternatives

The rebound assumption does not affect compliance with the CAFE/CO_2 programs, but does significantly change some key impacts. The incremental fleet size and sales remain the same as the reference case, but the incremental VMT for the central (20 percent) rebound case falls exactly in the middle of the lower (10 percent) and upper (30 percent) cases. This puts a range around how the elasticity of demand assumption will affect fuel consumption and CO_2 emissions (plus or minus 8 percent, for the high and low assumptions, respectively) and total fatalities (plus or minus 36 percent, for the high and low assumptions, respectively). The rebound assumption also acts as a range on carbon monoxide, VOC and PM emissions. It does not, however, act as a range on NO_x and S_2O emissions.

The rebound effect disproportionately affects vehicles that have a higher percentage change in cost per mile, so that rebound miles are disproportionately driven by PHEV and BEV vehicles. Under a low rebound assumption, the number of rebound miles is smaller. The tailpipe emission rate per BTU of electricity is notably higher for both NO_x and S_2O emissions, so that the overall tailpipe emissions decline in the final rule relative to the augural standards. For the CAFE program, the increase in upstream emissions of these pollutants from lowered fuel consumption outpaces the decrease in upstream emissions from lower rebound miles under the final rule relative the augural standards. Under the central case the sign flips for NO_x, but not for S_2O, emissions. Under high rebound assumption, the sign flips for both pollutants, and the final rules shows a reduction in both pollutants relative to the augural case. For the CO_2 program, the increase in upstream emissions outpaces the decrease in downstream emissions for S_2O emissions under all rebound assumptions. Only for the high rebound case does the decrease in tailpipe emissions outpace the increase in upstream emissions for NO_x.

All costs and benefits related to usage are affected by the rebound cases. The total consumer costs are unaffected by the rebound assumption, but the total consumer benefits are similarly bound the reference case (as the foregone mobility benefit, fuel savings, and refueling time are all affected by usage). The per vehicle lifetime expected consumer net benefits remain negative for all rebound assumptions, but are close to zero (-$60) for a 7 percent discount rate using the low rebound assumption. As expected, the low and high rebound cases bound the total societal costs and benefits and the resulting expected net benefits of the rule. The net benefits are positive at the high rebound assumption even at a 3 percent discount rate, and are positive for all rebound assumptions at a 7 percent discount rate (the low rebound net benefits at 7 percent are nearly exactly zero—$300 million).

On-Road Gap

For purposes of determining compliance with CAFE and CO_2 standards, manufacturers measure the CO_2 emissions rate of any given vehicle by testing the vehicle under test procedures defined by EPA, and use the measured CO_2 emissions rate to calculate the vehicle's fuel economy rating for CAFE. These procedures include "coast down" testing (observing the vehicle's speed as—in neutral, without application of the brakes—it decelerates from a defined initial speed), as well as testing on a chassis dynamometer (akin to a treadmill for a car) under driving cycles (speeds to be driven during a specific amount of time) intended to represent typical urban and highway driving. For more than three decades, evidence from a range of sources has demonstrated that fuel economy (as determined by measuring CO_2 emission rates) is generally lower under real-world driving conditions than under these regulatory test procedures.

The agencies' analysis represents this difference as a "gap" between laboratory and real-world fuel economy levels (and, correspondingly, CO_2 emission rates). The CAFE Model applies this gap when calculating fuel consumption, both in the portion of the model that simulates manufacturers' responses to standards, fuel prices, and consumer demand for fuel economy, and in the portion of the model that calculates national-scale fuel consumption and CO_2 emissions.

Prior to 2008, NHTSA applied EPA estimates that this "gap" was 15 percent. Starting in 2008, NHTSA increased this value to 20 percent. For operation on gasoline, diesel, or natural gas, the agencies' current reference case analysis continues to apply this 20 percent estimate. For operation on electricity or hydrogen, the agencies' reference case analysis applies a 30 percent estimate introduced in 2011 (in the notice proposing standards for MYs 2017-2025). As discussed in the accompanying *Federal Register* notice, some of the comments on the proposed standards suggest that the "on road gap" has likely increased as vehicles' fuel economy levels have increased with the application of various fuel-saving technologies. The agencies consider this to be plausible, and have included a sensitivity analysis case that extends a 30 percent value to operation gasoline, diesel, or natural gas.

With a 30 percent on-road gap, the analysis shows small shifts in the types and amounts of technologies applied in response to the final standards, slightly higher overall average fuel economy levels, and slightly lower overall average CO_2 emission rates. Differences (between the baseline/augural and final standards) in national-scale fuel consumption and CO_2 emissions are less than 1 percent smaller in magnitude when the larger gap is applied. Changes in incremental total benefits and costs to consumers and society are also small. However, these incremental benefit and costs are so closely balanced that corresponding changes in net benefits to consumers and society appear larger on a relative basis.

Vehicle Safety

Today's analysis accounts for the potential that changes in a vehicle's mass will change the risk that crashes involving that vehicle will result in fatalities. These changes could be positive (because, mass reduction in heavier vehicles tends to reduce overall societal fatalities) or negative (because, mass reduction in lighter vehicles tends to increase overall societal fatalities). The agencies' underlying statistical analysis involves uncertainty, and today's sensitivity analysis includes two cases with coefficients at, respectively, the 5 percent and 95 percent confidence intervals.

Today's analysis also accounts for the potential that crash risks will tend to be reduced as the market continues to more widely adopt new safety technologies (in particular, technologies aimed at avoiding crashes), and as those technologies become increasingly effective. The agencies' underlying estimates of the improvements involves uncertainty, and today's sensitivity analysis includes two cases under which resultant improvements in reducing risks are, respectively, lower or higher than in the reference case.

Today's analysis also accounts for the potential impact on safety of rebound driving on VMT, and thus added exposure to driving risk. The agencies adopted a central value for this rebound effect of 20 percent, but here the impact of 10 percent and 30 percent rebound effects are also examined.

Among these cases, those involving the estimated impacts of vehicle mass on safety, and those stemming from the rebound effect are much more impactful than those involving the impact of safety technologies. For vehicle mass impacts, at the 5 percent and 95 percent confidence intervals, the number of highway fatalities estimated to be avoided under the new standards changes by 40-50 percent. For the rebound effect, the impact of the 10 percent and 30 percent rebound assumptions change the number of highway fatalities avoided by roughly 36 percent. The cases involving lower or higher impacts of safety technologies change estimates of avoided highway fatalities by less than 1 percent. This difference is likely attributable to the gradual phase-in of these safety technologies in the on-road vehicle fleet during the MY 2029 timeframe examined in these tables.

Some other cases included in the sensitivity analysis also show significant relative changes in incremental VMT and fatalities. For example, the case that combines high oil prices with a 60-month payback period shows the size of the on-road fleet increasing (between the baseline/augural and final standards) by somewhat less than in the reference case, shows VMT decreasing by about as much as with a 10 percent rebound effect, and shows a smaller incremental change in fatalities than with a 10 percent rebound effect. On the other hand, the case that excludes strong hybrid electric vehicles shows the size of the on-road fleet increasing (between the baseline/augural and final standards) by somewhat more than in the reference case, shows VMT decreasing by about as much as with a 30 percent rebound effect, and shows a larger incremental change in fatalities than with a 30 percent rebound effect.

Of course, while these differences in estimated changes in VMT and fatalities between some of these cases appear significant, they are differences of differences that are, in turn, small relative to total VMT and fatalities. As demonstrated below, in the reference case analysis, the new standards never impact annual VMT or fatalities by more than 2 percent.

Table VII-489 – Reference Case VMT and Fatalities, CAFE Standards

Calendar Year	Annual VMT (b. mi.)				Annual Fatalities

BEV Adoption Rates

As discussed in the Preamble, the agencies excluded the additional application of BEV and FCV technology for the CAFE standard-setting analysis because of the statutory requirement to do so. ICCT commented "the agencies prevented their fleet compliance model from allowing battery electric vehicles from being applied in their analysis of the augural standards."[2595] The agencies conducted several sensitivity analyses, in response to these comments, to show the potential impacts if the statutory requirements were not followed. NHTSA did consider alternative fueled vehicles in the sensitivity case—but, again, is prohibited from considering the availability of such technologies when setting maximum feasible standards.

Given the compliance incentives contained in the CAFE and CO_2 programs for BEVs and FCVs, significant increases in BEV and/or FCV adoption beyond current levels would dramatically alter most manufacturers' compliance positions and, over time, would steadily shift energy consumption away from petroleum-based fuels. The market success of electrified vehicles will depend, in part, on the cost of such vehicles, and today's sensitivity analysis includes several cases, discussed below, exploring various costs of batteries for electric vehicles. However, from production to operation to eventual scrappage, BEVs and FCVs vehicles are sufficiently different from gasoline vehicles that their market adoption will likely depend on factors—such as component supply chains and the availability of fast charging (and, for FCVs, hydrogen fueling) stations—factors that are well beyond vehicle costs.

While the CAFE Model does not attempt to account explicitly for all factors that might impact the market adoption of BEVs and FCVs, the model does accommodate a variety of inputs that influence which technologies may be applied to which vehicle models/configurations in any given model year, and over time. Reflecting EPCA's requirements regarding analyses supporting decisions regarding maximum feasible CAFE standards, the reference and other cases presented for CAFE standards in this FRIA set aside the application of additional BEVs (and FCVs) until MY 2030. The CAA specifies no requirements for BEVs and FCVs regarding CO_2 standards, so all cases involving CO_2 standards allow that additional BEVs may be applied in any model year (after MY 2017). For both CAFE and CO_2 standards, the reference case analysis limits additional BEV penetration of the new vehicle market to 0.13 percent, 5 percent, and 0.018 percent additional penetration in each year for 200-mile BEVs, 300-mile BEVs, and FCVs, respectively through MY 2050. For example, these inputs reflect the potential that, within a decade, 300-mile BEVs could capture half of the market for new passenger cars and light trucks.

In addition to cases involving the cost of batteries for electrified vehicles, this sensitivity analysis includes a "Slower BEV Adoption" case that limits additional adoption of 300-mile BEVs to 0.5 percent annually, reflecting the potential that, within a decade, 300-mile BEVs might capture 5 percent of the market for new passenger cars and light trucks. The sensitivity analysis also includes an "Unconstrained BEV Adoption" case that allows both 200- and 300-

mile BEVs to increase as quickly as product redesign schedules are estimated to be able to accommodate.

The “Slower BEV Adoption” case evaluates a lower rate of deployment for higher range (BEV300) battery electric vehicles. Fundamentally, these constraints, for the purposes of modeling, would come in the form of market pressures such as cost, be it monetary or utility based, or the market availability of these vehicle types. This case provides a basis to understand how slower fleet penetration of higher range BEVs could impact future compliance pathways. On one hand, the reference case assumption that BEVs could potentially capture half the market within a decade departs radically from the slow progress BEVs have made since, for example, GM’s introduction of the EV1. On the other hand, Tesla’s rapid rise and other manufacturers’ recent public statements and product announcements support the potential for such an acceleration. The “Slower BEV Adoption” case therefore represents a plausible case wherein market adoption is more consistent with past trends and even the current market (e.g., calendar year 2019 sales information suggests battery electric vehicles most recently held a 1.4 percent market share)—a case the agencies nevertheless consider less likely than the reference case.

Through MY 2030, the technology and compliance-related impacts of this case under the CAFE program are minimal, if any, when fewer battery electric vehicles are deployed in the fleet. There would be no anticipated changes in the penetration levels of HCR engines, turbocharged engines, cylinder deactivation, and strong or mild hybrid propelled vehicles. In fact, the modeling indicates there would be no differences. This result is the same under the CO_2 program as well. This also holds fundamentally true for all other measures the agencies evaluate for rulemaking analyses.

The unconstrained BEV adoption case provides projected impacts of an approach where there are no limiting factors to potential production or consumer adoption of battery electric vehicles (BEV). These constraints could include component supply, limits on capital and/or engineering resources, range, charging time, cost, or other, similar factors that may inhibit the production and/or purchase of these vehicle types. The agencies evaluated this case to show the potential compliance paths that may be taken if nothing limits BEV production and consumers are willing to purchase battery electric vehicles in parity with non-BEV counterparts, when considering utility, infrastructure, price, and availability. Especially given sufficiently ubiquitous infrastructure, some aspects of this case could foreseeably come to fruition in a future marketplace, in particular consumer acceptance of future potential BEV utility characteristics.

Overall, under the CAFE program the case results show that technology impacts through MY 2030 are minimal when removing any battery electric vehicle related modeling constraints. Of course, not all of the fleet is redesigned in MY 2030, and because of EPCA constraints on assumptions to be reflected in analyses supporting decisions regarding CAFE standards, all of the cases in this sensitivity analysis for CAFE standards sets aside the additional application of BEVs and FCVs until MY 2030. There would be no anticipated changes in the penetration levels of HCR engines, turbocharged engines, cylinder deactivation, and strong or mild hybrid propelled vehicles. Two notable changes under this scenario are the increase of MY 2030 BEV penetration to 2.9 percent from 1.7 percent, most likely contributing to the achieved CAFE of one-half of one mile per gallon. This leads to increased credit generation as there is no change in the required CAFE mpg in this scenario. Technology application when viewed from a CO_2

program perspective in MY 2030 yields a reduction in turbocharged engines of 0.3 percent, decreases strong hybrids by 0.2 percent, reduces plug-in hybrids penetration to zero, and increases BEV deployment by 0.6 percent. Consistent with these small impacts on technology application and achieved CAFE and CO2 levels through MY 2030, these cases also involve relatively small changes in other impacts through MY 2030, as indicated in the above tables.

Beyond MY 2030, however, these cases are more impactful, because under the other reference case inputs, gasoline prices continue to rise (exceeding $3.50/gallon after 2030) as BEV costs continue to fall (e.g., falling nearly 50 percent by MY 2030), such that during the late 2030s, BEV begin to become more attractive (i.e., when the incremental change in vehicle price is weighed against the corresponding change in outlays for fuel) than conventional gasoline vehicles, even setting aside CAFE and CO_2 standards. This is reflected in the CAFE and CO_2 levels projected to be achieved after MY 2030. Showing impacts under CO_2 standards, as in the table appearing below, illustrates the trends. Under the reference and "Slower BEV Adoption" cases, average achieved CO_2 levels decline only slightly during the early 2030s (as would be expected given continued technology cost learning effects and fuel price increases), and then decline more rapidly through MY 2050, by which time the even the baseline/augural MY 2025 standards are clearly no longer binding. The decline is slower in the "Slower BEV Adoption" case, but not dramatically slower. However, under the "Unconstrained BEV Adoption" case, average achieved CO_2 levels after the early 2030s decline much more rapidly than in the reference case, largely erasing differences between the baseline/augural and final standards by 2050.

Table VII-491 – Slower and Unconstrained BEV Adoption Cases – CO_2 Standards

Model Year	Baseline/Augural CO_2 Standards						Final CO_2 Standards					
	Average Required CO_2 (g/mi)			Average Achieved CO_2 (g/mi)			Average Required CO_2 (g/mi)			Average Achieved CO_2 (g/mi)

Battery Costs

The agencies performed sensitivity runs with lower and higher battery direct costs with faster and slower learning rates relative to the reference case. Relative to the reference case, the cases involving lower and higher direct costs adjusted these costs downward by 10 percent and upward by 15 percent, respectively. Cases involving faster learning rates represent annual cost reduction of 6 percent during earlier MYs (2021-2032), as compared to 4.5 percent in the reference case. Cases involving slower learning rates represent a 3 percent annual rate during these model years. Using 300-mile BEVs as a reference point, resultant battery costs under each of these cases are shown below, in all cases relative to the MY 2018 reference case value. The reference case is shown in black. The case with higher direct costs and slower learning produces the highest costs, and is shown in green. The case with lower direct costs and faster learning produces the lowest costs, and is shown in red.

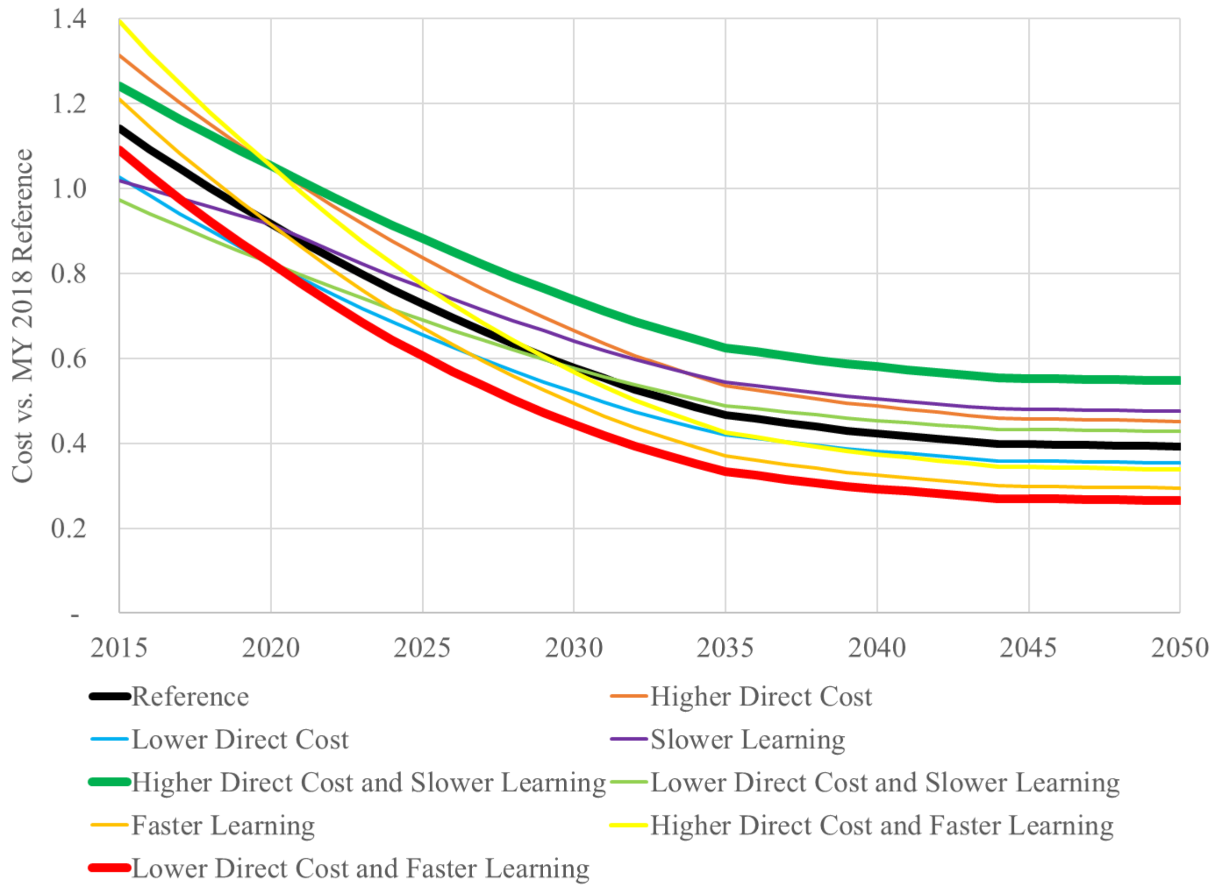

Figure VII-8 – Battery Costs vs. MY 2018 Reference Case

The agencies observed that with higher battery costs with either faster learning rate or slower learning rate, there is minimal impact on BEV adoption rate, and it has virtually no effect on adoption rate of engine technologies such as HCR engines, Turbo-Gasoline engines and in Dynamic Cylinder DEAC engines. Similarly, higher batter costs with either slow or faster learning rate has virtually no effect in adoption rate of regular hybrid or plug in hybrid technologies in both the CAFE compliance and in CO_2 compliance program. With regards to consumer costs, the agencies observed that there is marginal increase in per vehicle price as a consequence of higher battery costs. Because of higher battery costs, there is a marginal decrease in net consumer benefit. The agencies observed that only in the case of faster learning even with higher battery costs, the payback period is reduced by 6 months.

With regards to fleet impact, there is a 100,000 to 200,000 units increase in sales and this results in marginally higher VMT and in total fatalities. However, at the fleet level, there are virtually no change in the total fuel consumption.

With regards to pollutants, there is marginal variation in the cumulative changes in emissions attributed to lifetime usage of vehicles through MY 2029. In terms of net benefits, there is a decline in net benefits in the case of higher battery costs with reference learning and in slower learning. There is small increase in net benefits in the case of higher battery costs with faster learning under both CAFE program and CO_2 program

While the cost sensitivity cases demonstrate only small changes to the results through MY 2030, the long-term impacts of these uncertainties are significant. As Table VII-492 illustrates, while the required CO_2 levels move very little, if at all, after MY 2030 across all battery cost assumptions, the levels of achieved CO_2 diverge from the reference case assumptions – particularly in the case of lower costs and faster learning. This bounding case illustrates the significant potential for battery cost breakthroughs to influence transportation energy consumption from light-duty vehicles in the future. In just ten years, by MY 2040, the differences in achieved CO_2 levels between the baseline/augural standards and the preferred alternative are not only nearly eliminated, each is only about one third of the required level in MY 2025. It is impossible to know, at this point, how realistic the low cost/fast-learning assumptions are. However, the two cases represent a useful bounding exercise. In the most pessimistic case, where battery costs are higher and learn down slower, achieved CO_2 levels are comparable to the reference case through MY 2040 but fail to decline as fast in subsequent model years. This suggests that cost parity with internal combustion engines is not reached in the MY 2050 timeframe. Should this state of the world come to pass, the agencies have ample opportunity to take additional regulatory actions to consider changes in CAFE and CO_2 standards over that time period. However, if the more optimistic battery cost case were to be realized, the rapid transition to electric vehicles in the new car market could dwarf the impact of any actions taken today – an emissions reduction greater than 60 percent over a decade, from levels that will already be considerably lower than today's market.

Exclude Strong Hybrids

The agencies also conducted sensitivity cases using different strong hybrid assumptions. The "Exclude Strong Hybrids" sensitivity case takes an alternative approach to better understand how the absence of continued deployment of one electrification technology may impact potential compliance pathways. This sensitivity case imposes limits on future strong hybrid application but does not remove any existing strong hybrids that are already offered in the MY 2017 new vehicle market.

The agencies evaluated this case to gain a better understanding of what may be impacted if strong hybrids were supplanted by both plug-in hybrid electric vehicles and battery electric vehicles as the preferred electrification technology for a compliance pathway, or the consequences of manufacturers' pessimism about their ability to sell strong hybrids to new car buyers at expected fuel prices. Manufacturers have expressed concern about the degree to which potential standards rely on their ability to market strong hybrid systems to consumers. There is a strong relationship between consumer demand for strong hybrids and the price of fuel.

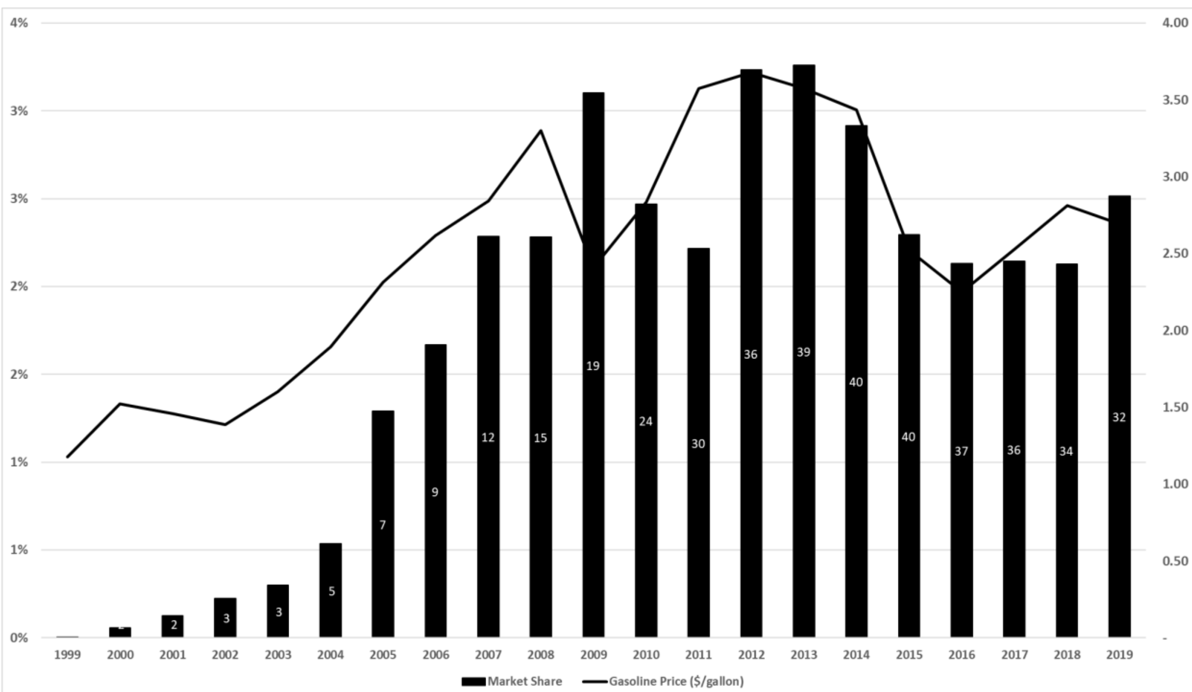

Figure VII-9 – Strong Hybrid Market Share and Fuel Prices

As Figure VII-9 illustrates, the market share of strong hybrids in the new vehicle market has mostly tracked fuel prices. The bars represent the market share (left axis) and the line tracks the price of fuel (on the right axis). The light numbers inside of each bar represent the number of unique strong hybrid models offered for sale in that year. Initially, we see rapid growth that continues during the fuel price increases of the mid-2000's and peaking at around 3.5 percent market share. Despite a doubling of the number of models offered for sale in subsequent years, market share continued to track fuel price closely, and fell dramatically as prices fell in 2015 and 2016. At fuel prices at or above $3.50/gallon, strong hybrids were able to capture additional market share. However, the current projection doesn't show prices returning to those levels for quite some time – leaving manufacturers uncertain about their ability to sell strong hybrids in the numbers estimated to be needed to comply with CAFE and CO_2 standards before MY 2026. As we discuss below, in the absence of strong hybrids, compliance pathways tend toward a greater reliance on advanced engines and transmissions, and more aggressive exploitation of opportunities to reduce vehicles' mass.

It is also possible that vehicle manufacturers may adopt electrification strategies that rely on selling smaller volumes of plug-in electric vehicles rather than relying on strong hybrids in the future. The modeling results for this case indicate no material changes in the required or achieved CAFE values but do indicate substantive increases in engines with HCR, turbochargers, and cylinder deactivation as well as additional reliance on curb weight reductions. The penetration of PHEVs and BEVs decreases by one and three-tenths of percent, respectively. Generally, this indicates manufacturers may choose to rely on non-electrification technologies to close any compliance gaps that may reside in fleet performance absent the ability to deploy strong hybrids. Conversely, there are no notable differences for this sensitivity case under the CO_2 program, a one-tenth of a percent increase on curb weight reduction withstanding. This is a consequence of favorable credit provisions for PHEVs and BEVs that allow manufacturers to treat BEVs as if they achieve 0 grams per mile CO_2 emissions for compliance, and sales multipliers through MY 2021. In higher stringency alternatives, the modeling results already prefer smaller numbers of BEV to higher volumes of SHEV in the CO_2 program.

In the CO_2 program, consumer costs increase slightly in the baseline and that increases the technology cost savings of the preferred alternative. The result of this is that net benefits un the preferred alternative increase by about $8 billion However, under the CAFE program, where battery electric vehicles are not a compliance option (due to statutory restrictions on their consideration for rulemaking), the additional cost of advanced engine technology in the baseline increases baseline technology cost by about $800 per vehicle, and increases the cost savings under the preferred alternative, which has a much smaller reliance on strong hybrids to achieve compliance, by about $600 per vehicle. This difference is sufficient to change the sign on net social benefits for the preferred alternative to being slightly negative, to being very positive (nearly $80 billion at a 3 percent discount rate). The magnitude of this impact is comparable to the impact of varying fuel price projections.

When evaluating measures attributed to vehicle lifetime, inhibiting the additional deployment of strong hybrids has a substantial increase in vehicle sales but no material impact to the amount of fuel consumed as VMT decreases under the CAFE program, also yielding a substantive reduction in fatalities. For the CO_2 program, and like the lack of technology impacts, it appears there are no material changes to these measures when inhibiting the additional deployment of strong hybrids, except for an indicated increase in fatalities.

Under the CAFE program, the potential emissions impacts vary significantly, increasing emissions and social damage costs which is most likely a result of greater reliance on conventional ICEs compared to the reference case. The variances in technology mix are not present under the CO_2 program and, therefore, emissions remain fundamentally aligned with the reference case.

Advanced Engine Technology Availability

Three sensitivity cases were performed to examine the effects of constraining the adoption of some advanced engine technologies. While the constraints in the central analysis are both necessary and reasonable, the sensitivity cases included here help to quantify the impact of those constraints. For more discussion on the constraints placed on the advanced engine technologies in the central analysis see Section VI.C.1.e).

The sensitivity runs expand the availability of HCR0 and HCR1 engines (one case enables HCR0 and HC1 technologies for all vehicles except pickups, and another case enables HCR technologies for all body styles, including the application of HCR2) and allows the VCR technology for all manufacturers and body styles. All of these cases primarily affect the cost of complying with standards, and impact few other metrics as achieved fuel economy and CO_2 levels are comparable to the central analysis. Achieved fuel economy was identical between the sensitivity cases and the reference case, and achieved CO_2 was nearly identical between the cases, with only the HCR0 and HCR1 case seeing a 0.3 percent reduction over the reference case. The largest departure from the reference case is in net consumer benefits. As a result of reduced per-vehicle compliance costs in the baseline (by $300 per vehicle in the case that allows all HCR engines, by about $200 per vehicle in the more restrictive HCR case, and by negligible amounts in the VCR case), the incremental savings in technology costs under the preferred alternative shrink by about $200 per vehicle. The two cases that consider alternative degrees of HCR engine availability have the larger departures from the central analysis. While the purchase cost savings under the proposal shrink, the foregone fuel savings remain similar. This results in lower net social benefits in both cases. The VCR case produces little impact on compliance costs in either the baseline or preferred alternative, and similarly small impacts on the net benefits of the preferred alternative. The results of these sensitivity analyses were in line with anticipated consequences for applying the constraints on these engines. For more discussion about the input constraints see Section VI.C.1.e)(3) and Section VI.C.1.e)(6).

The case that allowed HCR2 engines resulted in an increase in HCR technology penetration by 27 percent, predicting the market would consist of 47 percent HCR engines, under the CAFE standards, and a similar increase under the CO_2 standards. The increase in HCR technology resulted in a reduction in turbo technology, advanced DEAC technology and SHEV technology penetrations. The large influence of the HCR2 model on the calculated cost of compliance underscores the need for scrutiny of the model's creation and validation. The sensitivity case study supports the high level of review applied to the model and re-enforces the need for clear evidence, at least a working example of prototype operation, to consider the model for application in the rule making time frame. For discussion on the HCR2 model see Section VI.C.1.e)(3).

Skip Peripheral Technologies

The NPRM and this final rule analysis assessed pathways manufacturers could use to comply with CAFE and CO_2 standards considering the availability of over 50 different fuel economy improving technologies. Most of these technologies' effectiveness was determined using Autonomie full vehicle simulation and as discussed in Section P06 B. The analysis included several technologies that could be adopted assuming a high level of advancement or that the technologies are not widely present in the MY 2017 analysis fleet. These technologies include low drag brakes (LDB), secondary axle disconnect (SAX), engine friction reduction (EFR), 20 percent reduction in rolling resistance (ROLL20), 20 percent improvement in aerodynamic drag (AERO20), advanced diesel engine improvements (DSLI) and advanced diesel engines paired with advanced cylinder deactivation (DSLIAD). There is some uncertainty over these assumptions and whether some of these technologies are already present in the fleet, or whether these technologies may not necessarily be able to be adopted as widely as assumed in the real world due impacts on performance, customer satisfaction, increased complexity or lack benefits due to fuel efficiency synergetic of other fuel savings technology. This sensitivity case shows the impacts for not allowing these technologies to be applied.

For the sensitivity case "Skip Peripheral Technologies", the CAFE market input file was updated to skip LDB, SAX, EFR, ROLL20, AERO20, DSLI, and DSIAD. The CAFE Model results show that these technologies have minimal impact on the achieved CAFE and CO_2 in MY 2030. The Reference Case achieved 42.7 mpg and 197.2 g/mi versus sensitivity case of 42.1 mpg and 198.7 g/mi, respectively. Both these compliance levels are within 1.4 percent of the reference case.

When these technologies are not available other technologies are applied at slightly higher rates, specifically advanced engines and electrification. For example, for the CAFE analysis, strong hybrid penetration changed from 4.8% to 5.6% and plug-in hybrids penetration changed from 1.7% to 2.3% in the overall MY 2030 fleet. For the CO_2 analysis, strong hybrids changed from 2.2 percent for the reference case to 2.8 percent for the sensitivity case, plug-in hybrids changed from 0.2% to 0.3%, and BEVs changed from 3.7% to 4.3%. These results indicate that even with more peripheral technologies in the analysis, manufactures would still have to depend other advanced technologies for compliance. The availability of these technologies has small impact on overall technology costs, but a more measurable impact on absolute cost of compliance. Relative to the central case, compliance costs in the baseline increase by about $200 per vehicle when the technologies in this sensitivity are removed from compliance pathways. However, the preferred alternative faces the same technology restrictions, and the incremental savings associated with the preferred alternative are slightly smaller (about $150 per vehicle). While these restrictions on technology application produce measurable impacts on absolute compliance costs, the incremental cost is less dramatic and produces a minimal impact on net benefits.

Low Initial Road Load Reduction

ICCT commented to suggest that the agencies consider the impact of the road load assignments for the MY 2017 fleet on estimated technology costs and fuel efficiency. While the agencies have clearly described the methods by which initial road load technologies are assigned, we considered a sensitivity case that assumed no mass reduction, rolling resistance, or aerodynamic improvements had been made to the MY 2017 fleet (i.e., setting all vehicle road levels to zero - MRO, AERO and ROLL0), While this is an unrealistic characterization of the initial fleet, the agencies conducted a sensitivity analysis to understand any affect it may have on technology penetration along other paths (e.g. engine and hybrid technology).

Under the CAFE program, the sensitivity analysis shows a slight decrease in reliance on engine technologies (HCR engines, Turbo Gas Engines, and Cylinder DEAC engines) and hybridization (strong hybrids and plug-in hybrids) in the baseline (relative to the central analysis). The consequence of this shift to reliance on lower-level road load technologies is a reduction in compliance cost in the baseline of about $300 per vehicle (in MY 2026). As a result, cost savings in the preferred alternative are reduced by about $200 per vehicle. Under the CO_2 program, the general trend in technology shift is less dramatic (though the change in BEV is larger) than the CAFE results. The cost change is also comparable, but slightly smaller ($200 per vehicle in the baseline) than the CAFE program results. Cost savings under the preferred alternative are further reduced by about $100. With the lower technology costs in all cases, the consumer payback periods decreased as well. These results are consistent with the approach already taken by manufacturers who have already deployed many of the low-level road load reduction opportunities to improve fuel economy.

Redesign Cadence

As discussed in Section VI.1.b).(5) Characterizing Production Design Cycles], vehicle manufacturers establish redesign cadence considering market needs, the sale volume and payback periods for each of the manufacturer's vehicle models, the availability of capital and other resources, and regulatory requirements. As discussed in the preamble and elsewhere in this RIA, the agencies used an informed, historical review of redesign and refresh intervals to estimate future redesign and refresh intervals. However, the nature of automotive refresh and redesign cycles is not always consistent and can vary by model type, segment competitiveness, or a manufacturer's capital availability, among other factors.

The agencies conducted a series of sensitivity analyses related to vehicle redesign cadences to estimate the impacts of increasing or decreasing redesign intervals on compliance pathways, associated costs, and other variables the agencies evaluate as part of an informed rulemaking analysis. The agencies evaluated increasing the time between redesigns by 20 percent, reducing that interval by 20 percent, and an extreme case where vehicles would be redesigned every year. The first two cases have a level of plausibility, but the yearly redesign case is not sustainable or realistic due to the lack of a sufficient number of model years produced with each vehicle design to recoup costs, as well as capital and resource constraints. Manufacturers have and may reduce or increase redesign intervals for some vehicles in the future.

Importantly, the agencies note that for these sensitivity cases, the analyses do not account for the costs of potential stranded capital that would occur for more frequent redesign intervals, nor the increased capital that might be generated for less frequent redesign intervals.

The impacts of simulating varying redesign intervals within the CAFE Model depends on, among other factors, the compliance program being considered, each manufacturer's initial fleet, and the cadence assumptions employed within the reference case. For example, when simulating compliance under the CAFE program, manufacturers that have historically had longer redesign schedules may be able to improve compliance and reduce technology costs with shortened cadence intervals by distributing the application of cost effective technologies over a greater number of vehicle models and model years, rather than applying a greater amount of less cost-effective technology on fewer vehicles earlier in order to enable compliance in later years. Conversely, lengthening cadence for the same manufacturers may lead to postponing the application of cost-effective technology until much later model years, therefore not achieving compliance nor the associated benefits and costs within the years analyzed for the rulemaking. In both cases, these manufacturers could end up with lower achieved CAFE levels, and accordingly reduced costs and benefits. However, manufacturers that begin analysis with different starting conditions (e.g., shorter reference cadence intervals), may respond differently under the two cases, producing, for example, higher achieved CAFE levels and benefits, but possibly at lower cumulative technology costs. Again, importantly, these sensitivity cases do not account for the costs of potential stranded capital that would occur for more frequent redesign intervals, nor the increased capital that might be generated for less frequent redesign intervals. These impacts could be significant.

For the annual vehicle redesign case, there is a significantly greater pool of vehicle and technology combinations available to each manufacturer, increasing the likelihood of more optimal technology solutions being selected in each model year. This, in turn, would lead to a more optimal overall solution, producing higher consumer and social benefits, while at the same time lowering technology costs. As noted earlier, however, the high-frequency case is not realistic, and the CAFE Model does not presently attempt to account for the additional capital constraints mentioned above.

In terms of technology application, for the CAFE program, lengthening the cadence interval increases the penetration of high compression ratio and turbocharged gasoline engines and doubles the penetration of plug-in hybrid electric vehicles, with the increases being offset by decreases in strong hybrids and battery electric vehicles. This is intuitive, as manufacturers faced with fewer redesign opportunities must accomplish more fuel economy improvement at each opportunity. Shortening the reference redesign interval yields an increase of five percent in turbocharged gasoline engines which is offset by reductions in PHEVs and BEVs. Increasing redesign frequency to an annual rate leads to an increase in cylinder deactivation application by nearly ten percent, BEVs to nearly double, and HCR engines increase by nearly two percent; with a corresponding elimination of PHEVs and a 75 percent reduction in the penetration of the strong hybrids in the fleet. The overall fleet required and achieved CAFE mpg values appear to not be materially impacted by any of the three cadence variations.

For the CO_2 program, it appears the only meaningful impacts of varying the redesign cadence is a three and five percent increase in turbocharged gasoline engines and nearly one percent reductions in BEVs that occur under the reduced and annual redesign cadence cases, respectively. Under the CAFE program, the consumer impacts of adjusting the redesign cadence show reduced incremental net benefits relative to the augural standards when the cadence is lengthened or shortened by 20 percent. For the CO_2 program, incremental net consumer benefits in MY 2029 relative to the baseline standards are increased by either lengthening or shortening the redesign cadence by 20 percent. However, the series of changes to model years leading up to MY 2029 are relevant. And, as one would expect, total technology costs between MY 2017 and MY 2029 are higher in the baseline when redesign cadence is lengthened – increasing the technology cost savings in the preferred alternative from $108 billion in the reference case, to $133 billion in the sensitivity case (discounted at 3 percent). Similarly, the shorter cadence *decreases* the cost savings associated with the preferred alternative by $6 billion over the same model years. As a result of the more aggressive technology actions required when cadences are longer, vehicle efficiency is increased over the model years in that period, leading to an increase in foregone fuel savings under the preferred alternative (by about $25 billion). The shorter cadence sensitivity produces the opposite result, decreasing foregone fuel savings by about $14 billion.

Incremental fatalities and sales relative to the augural CAFE standards, show smaller sales impacts for the shorter cadence and larger sales impacts for the longer cadence. Based on the technology cost changes associated with each, this is both expected and appropriate. Naturally, the yearly redesign case further reduces the difference in sales between the baseline and preferred alternative, but doesn't completely eliminate it. The CAFE Model estimates new vehicle sales based on the differences in incurred technology costs and the associated fuel savings realized by the industry with respect to the augural standards. Thus, the changes in vehicle sales are proportional and a direct response to the achieved CAFE (or CO_2) levels and the associated technology costs. The magnitude and direction of change in cumulative vehicle sales under each case would also directly influence the subsequent measures attributed to lifetime vehicle use.

Technology Cost Markup

Estimates of indirect costs are applied within the model as a multiplier to the learned direct costs for each technology in each year. As such, they have a direct impact on the predicted costs and net impacts that this model estimates. As noted in Section 6 of this FRIA, we apply a RPE multiplier of 1.5 based on cost relationships obtained from financial statements and records filed by manufacturers with the SEC and compiled in previous literature, as well as a recent study conducted for EPA during their research into ICMs. Also as discussed in Section 6, an alternate method of measuring indirect costs (ICMs) has been considered but not applied at this time due to uncertainty regarding its valuation basis. To illustrate the impacts of alternate indirect cost multipliers, we have examined RPEs of 1.1, 1.24, and 2.0. The 1.1 and 2.0 multipliers were chosen to demonstrate a maximum range of likely impacts. As noted in Section 6, the 1.24 markup represents a derived estimate of the RPE equivalent value that would result based on the current research into ICMs. Because these assumptions affect the cost, and thus the price of vehicles, they influence the mix of technologies the model predicts that manufacturers select. This, together with the more direct impact of higher costs, combine to impact costs, benefits, and net benefits of the rule in a fairly straightforward fashion, with lower RPEs predicting lower technology costs, and concurrently, lower benefits from reducing those costs, while higher RPEs predict the opposite.

"Effective Cost" Metric

As for past rulemakings the NPRM version of the CAFE Model used an "effective cost" metric when simulating manufacturers' potential application of technology in response to a range of inputs such as estimated technology efficacy and cost, estimated future fuel prices, and estimates of the market's willingness to pay for fuel economy improvements. When simulating compliance with CAFE standards, this metric accounts for the rate at which civil penalties are levied for failures to comply with CAFE standards. When simulating compliance with CO_2 standard, this metric uses inputs estimating the value of CO_2 compliance credits, and the NPRM applied inputs that assumed CO_2 credits would be valued at rates roughly equivalent to the CAFE program's civil penalty rate.

In response to comments on the NPRM, the agencies have added a "cost per credit" metric to the CAFE Model. For a given potential application of some combination of technologies to some set of vehicles, this metric involves subtracting the value of avoided fuel outlays from the cost of the technologies, and then dividing the result by the corresponding change in compliance credits earned (in gallons and tons, respectively, for CAFE and CO_2 compliance). For today's reference case analysis, and for most of the cases included in the sensitivity analysis, the agencies selected this new "cost per credit" metric when running the CAFE Model. The agencies also included some sensitivity analysis cases running the CAFE Model with the same "effective cost" metric used for the NPRM analysis.

As discussed in the current notice, and in past notices, the CAFE Model's purpose is to estimate how manufacturers realistically could respond to new standards (and other factors, such as fuel prices), not to predict how manufacturers will actually respond, much less dictate how manufacturers should respond. Either of these metrics therefore amounts to part of a proxy for manufacturers' processes for making decisions about the application of fuel-saving technology. There is no way for the agencies to know exactly how manufacturers make such decisions and, therefore, no unambiguously "correct" means of simulating them, and no a priori basis to favor one of these metrics over the other.

Differences between the metrics vary with stringency, among manufacturers, from model year to model year, and with other model inputs. However, compared to the NPRM's "effective cost" metric, the new "cost per credit" metric appears to more frequently result in lower costs than in higher costs. Even at the industry level, though, there are exceptions, as illustrated below. For example, under the new CAFE standards, the "cost per credit" metric shows moderately higher costs than the "effective cost" metric, given reference case or low fuel prices. Also, as discussed below, the "cost per credit" metric appears to perform less intuitively than the "effective cost" metric when using the CAFE Model to simulate "perfect" trading of CO_2 compliance credits.

Differences between the metrics are sometimes considerably more significant for specific manufacturers. For example, under the new CAFE standards, using the "cost per credit" metric shows FCA applying $1,000 more technology than when using the "effective cost" metric:

Table VII-495 – Manufacturer-Level Comparison of "Cost per Credit" and "Effective Cost" Metrics (Final CAFE Standards)

	Average Required CAFE		**Ave. Achieved CAFE**		**Ave. Technology Cost**	
	Cost per Credit	**Effective Cost**	**Cost per Credit**	**Effective Cost**	**Cost per Credit**	**Effective Cost**

TOTAL	**40.5**	**40.5**	**42.7**	**42.3**	**894**	**819**

This may relate to the fact that the "cost per credit" metric considers only technology costs and the value of avoided fuel costs, while the "effective cost" metric also considers avoided civil penalties.

With high fuel prices, the "cost per credit" metric tends to show slightly higher ultimate (i.e., by MY 2050—the last model year analyzed here) technology costs under the least stringent CO_2 standards than the "effective cost" metric, although as shown below, these differences tend to be very small, and to occur well beyond model year 2030:

Table VII-496 – Comparison of "Cost per Credit" and "Effective Cost" Metrics (with High Oil Prices and "Alternative 1" CO_2 Standards)

“Perfect” Trading of CO_2 Compliance Credits

By modifying model inputs to tread all manufacturers as single entity, the CAFE Model can be exercised in a manner that simulates “perfect” trading of CO_2 compliance credits among manufacturers (though not CAFE compliance credits, as this method would mean ignoring EPCA/EISA’s statutory limits on trading of CAFE compliance credits). Theoretically, doing so should lead the model to show lower costs than when manufacturers are treated as separate entities that do not trade. The sensitivity analysis includes a case that exercises the CAFE Model in this manner. As shown below, for the baseline/augural standards, and comparing to the reference case, this “perfect trading” case shows higher average CO_2 levels through MY 2023 and lower costs through MY 2024. However, starting in MY 2025, the “perfect trading” case shows considerably higher costs, even though average achieved CO_2 levels are very similar in some model years (although CO_2 levels after MY 2023 are consistently lower under the “perfect trading” case). For example, in MY 2036, the “perfect trading” case shows costs about $200 greater than the reference case, even though average achieved CO_2 levels under the two cases are within 1 g/mi:

Table VII-497 – Impact of "Perfect" Trading of CO_2 Compliance Credits (Baseline/Augural Standards)

Model Year	Average Required CO_2 (g/mi)		Average Achieved CO_2 (g/mi)		Average Technology Cost ($)

2046	175	175	144	134	1,705	2,034
2047	175	175	142	131	1,731	2,081
2048	175	175	140	129	1,744	2,094
2049	175	175	135	125	1,829	2,150
2050	175	175	131	123	1,884	2,189

Undiscounted technology costs (relative to continued application of MY 2017 technology) accrued through MY 2029 total $230B under the reference case, and $236B under the "perfect trading" case. These counterintuitive results appear at least partially attributable to the new "cost per credit" metric. With the NPRM's "effective cost" metric, the "perfect trading" case shows consistently higher average CO_2 levels and lower costs than the case that modifies the reference case only by using the "effective cost" metric, as shown below. Also, costs accrued through MY 2029 total $268B in the (modified) reference case, and $239B in the case that simulates "perfect trading" while also applying the "effective cost" metric.

Table VII-498 – Impact of "Perfect" Trading of CO_2 Compliance Credits (Baseline/Augural Standards) When Applying "Effective Cost" Metric

On the other hand, while the "effective cost" metric leads the "perfect trading" case to show the expected directional effects (higher CO_2 levels and lower costs) than the reference case (as modified by applying the "effective cost" metric), both the reference and "perfect trading" cases show lower costs when applying the "cost per credit" metric than when applying the "effective cost" metric.

Off-Cycle and Air Conditioner Leakage Credits

For the reference case, the agencies assumed manufacturers would steadily increase the amount of credit (i.e., adjustments to achieved CAFE and CO_2 levels) for "off cycle" technologies (i.e., technologies producing benefits not observed on regulatory "two bag" CO_2 and fuel economy test procedures) to 10 grams per mile (g/mi) by MY 2023, with some manufacturers (e.g., JLR) doing so more rapidly than others (e.g., Mazda). The agencies also considered side cases involving manufacturers earning lesser or greater quantities of such credits. For the "Fewer Off-Cycle Credits" and "More Off-Cycle Credits" cases, the agencies assumed most manufacturers would eventually earn at most 7 g/mi or 15 g/mi, respectively, of such credit. As shown above, compared to the reference case, the "Fewer Off-Cycle Credits" case results in slightly greater application of technologies for which impacts do not depend on off-cycle crediting. Under the "More Off-Cycle Credits" case, slightly less technology is required than in the reference case.

The agencies also considered a case in which CO_2 standards under each of the alternatives would, in MY 2021, stop incorporating credit for reductions of HFC emissions through changes to mobile air conditioners and use of alternative refrigerants with lower GWPs (global warming potential), and in which the mathematical functions defining each of the action alternatives are adjusted accordingly. The preferred alternative, compared to the reference case, shows higher average required CO_2 and average achieved CO_2 levels, with similar levels of technology. However, as shown below, under the baseline/augural CO_2 standards, electrification (SHEV and BEV) is applied more widely by MY 2030, as are the more significant levels of aerodynamic improvements (AERO20) and mass reduction (MR4). This leads the difference in cost between the baseline/augural and final standards to more than double, underscoring the likelihood that given sufficient supply of low-GWP refrigerants, manufacturers are likely to find it cheaper to obtain AC leakage credits than to actually achieve lower tailpipe CO_2 emissions levels. For today's final rule, the agencies did not consider regulatory alternatives that would reduce or eliminate credits for technologies projected to reduce AC leakage emissions.

Compliance Credit Banking

As discussed above and in the Preamble, EPCA/EISA requires that, for purposes of determining the maximum feasible stringency of new CAFE standards, NHTSA set aside the potential the manufacturers could apply CAFE compliance credits for the model years for which NHTSA is considering new standards. The CAA imposes no such constraints on the analysis supporting the consideration of potential new CO_2 standards, and today's analysis exercised the CAFE Model in a way that simulates manufacturers' potential transfer of CO_2 compliance credits (between the passenger car and light truck fleets), and manufacturers' potential application of "banked credits" (i.e., the application of compliance credits carried forward from earlier model years). Regarding the analysis presented in the NPRM, some commenters argued that EPA had given undue consideration to "legacy" credits. As documented above and in Federal Register notice, the agencies have updated model inputs defining these credits.

To explore the role of credit banking CO_2 in the analysis, the agencies have included a sensitivity case that excludes the use of banked CO_2 compliance credits. This case, labeled "No Credit Carry-Forward" in the summary tables shown above, deletes the CO_2 compliance credit banks from the CAFE Model inputs, and also sets CAFE Model inputs to not "carry credits forward into future model years".

Differences between the "No Credit Carry Forward" and reference cases vary among manufacturers, across model years, and among regulatory alternatives. For example, the following two charts show differences for Toyota. Without credit banking, Toyota's modeled achieved CO_2 levels under the baseline/augural CO_2 standards are increasingly lower than in the reference case, and Toyota's modeled per-vehicle technology costs are, correspondingly, significantly greater than in the reference case, reaching a difference of nearly $1000 in MY 2025 before gradually declining through MY 2050.

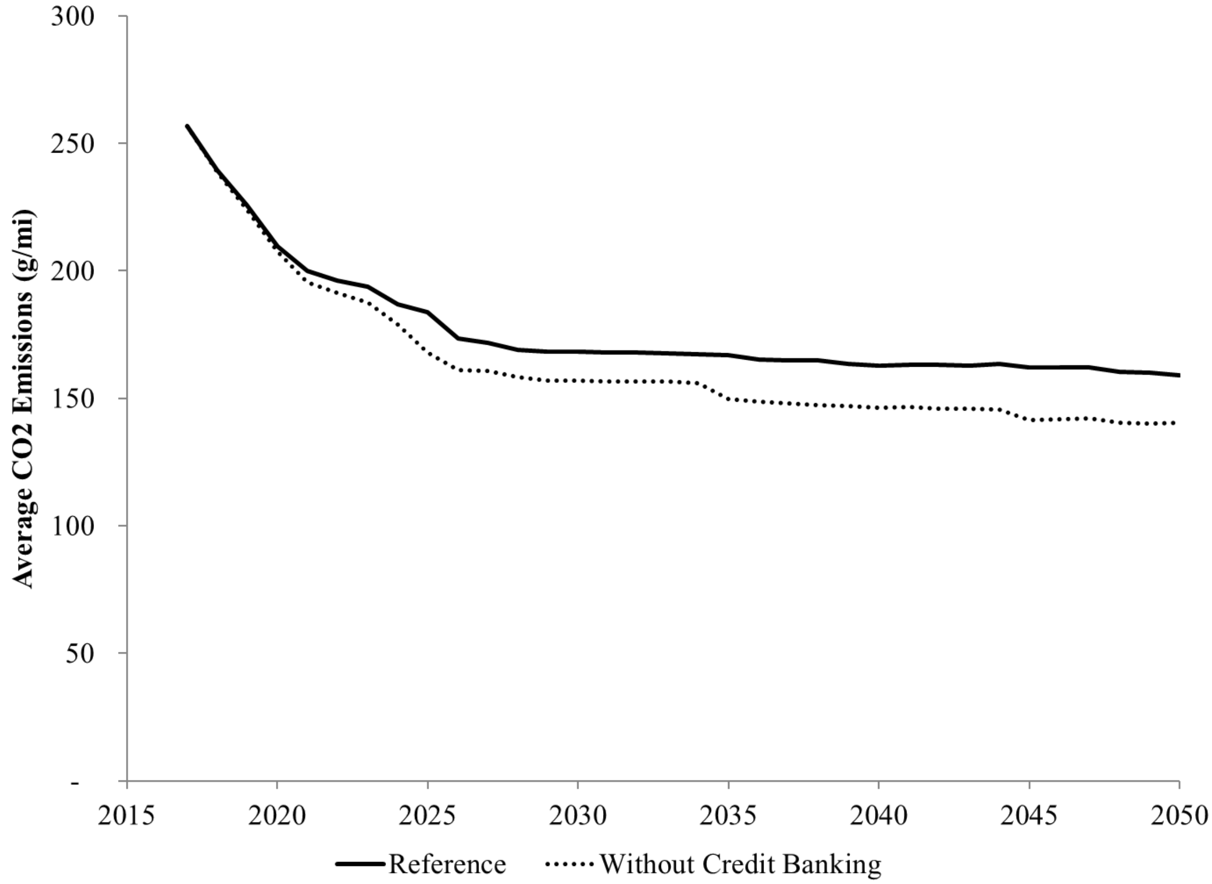

Figure VII-10 – Average Achieved CO_2 Levels under Baseline/Augural CO_2 Standards – Toyota

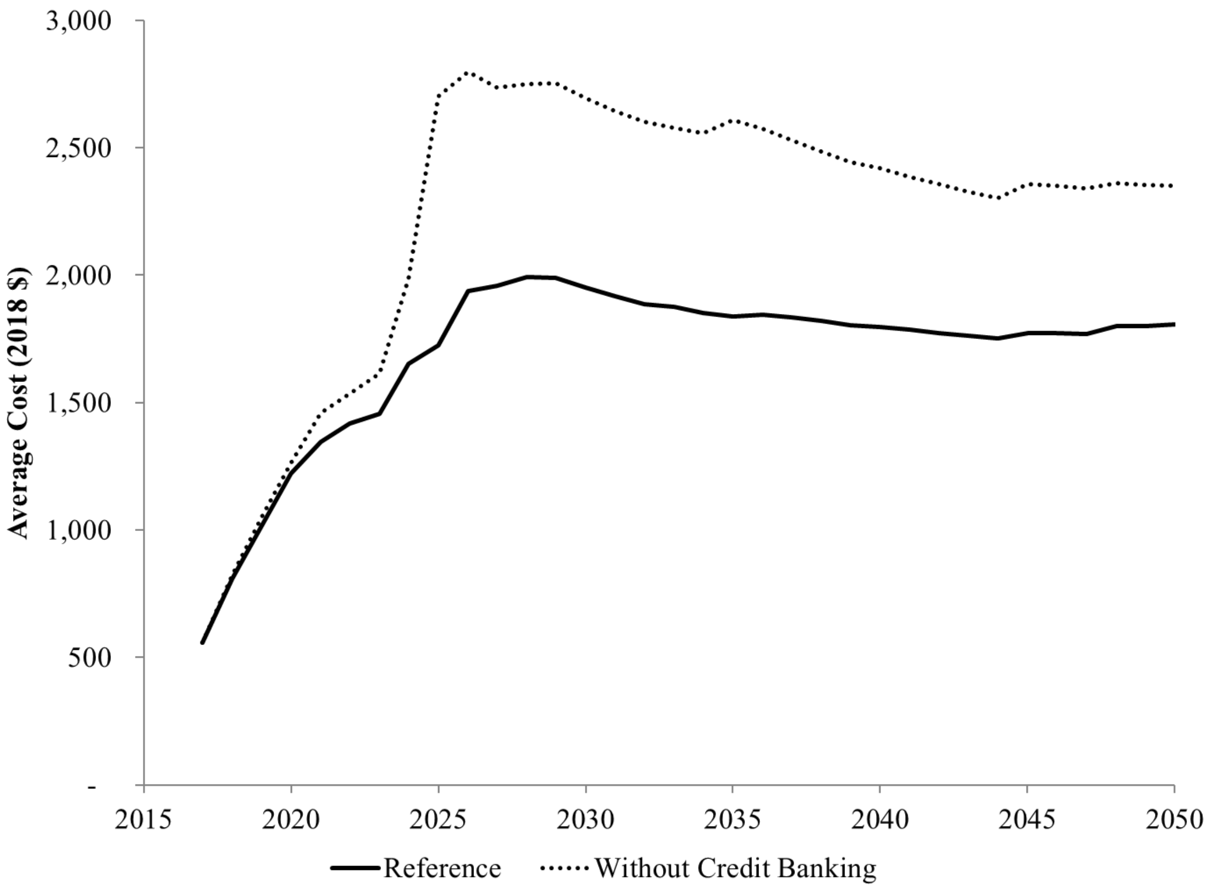

Figure I-VII-11 – Average Technology Cost under Baseline/Augural CO_2 Standards - Toyota

On an industry-wide average basis, differences are smaller, but still notable, as illustrated by the following two charts. Under the augural standards, industry-wide average achieved CO_2 levels are 2-5 percent lower than in the reference case, and average per-vehicle costs in MY 2025 are about $475 higher than in the reference case (the difference steadily declining through 2050).

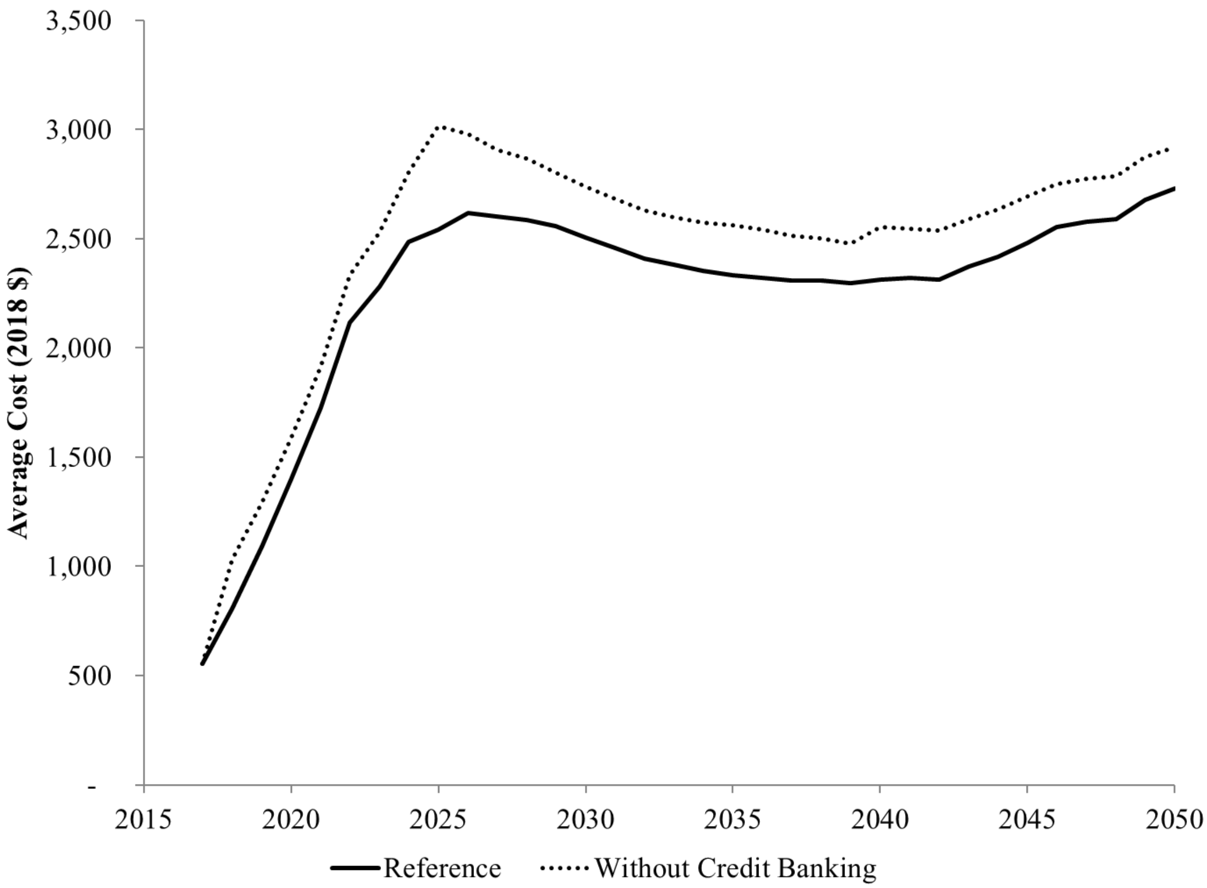

Figure VII-14 – Average Technology Cost under Baseline/Augural CO_2 Standards – Industry-Wide

High Stringency Alternatives

In addition to the set of regulatory alternatives considered in the central analysis, the agencies considered a set of high stringency alternatives in the sensitivity analysis in order to estimate the impacts of rapid technology deployment. The 2012 final rule central analysis included alternatives as high as 7 percent per year growth in stringency (with resulting fuel economy standards as high as 70 MPG in MY 2025). While today's central analysis contains no alternatives as stringent as that, the sensitivity analysis spans a broad range of stringencies from 60 MPG to over 200 MPG in MY 2025. As a result of the later starting year (MY 2021 in today's analysis, compared to MY 2017 in the 2012 final rule analysis), the year-over-year stringency increases must be more dramatic to reach comparable levels of required fuel economy. This sensitivity analysis uses year-over-year increases of 10, 20, and 30 percent to simulate the maximum rate of technology deployment.

Because the CAFE analysis does not consider the possibility that manufacturers can comply with standards by building dedicated alternative fuel vehicles (a restriction imposed by statute), and the CO_2 analysis allows these vehicle technologies, the results of the high stringency sensitivity cases diverge for the two programs in a way that most other cases do not. Under the

CAFE program (which prohibits the introduction of BEVs until MY 2030), MY 2026 compliance costs reach $3,700 per vehicle, $11,250 per vehicle, and over $20,000 per vehicle for the 10, 20, and 30 percent alternatives, respectively. The two highest stringencies include the cost of civil penalties for noncompliance (significant costs in the most stringent case). The smallest of these increases is comparable to the 7%/year case that was part of the central analysis in the 2012 final rule (which required 70 MPG in MY 2025, rather than 70 MPG in MY 2026 as the 10%/year sensitivity does). However, unlike the alternative in the 2012 final rule, the $3,700 per vehicle cost increase has consequences beyond increasing fuel economy. For example, new vehicle sales are nearly 20 million vehicles fewer (about 4 percent total) under the 10%/year alternative between 2017 and 2050 (compared to the baseline). This trend continues with increasing stringency, as the 20%/year alternative reduces sales over that period by 85 million vehicles (about 15 percent of the new market). Even the 10%/year alternative produces large-scale hybridization by MY 2026, with nearly 40 percent of the new vehicle market some type of strong hybrid, and another 35 percent some type of plug-in hybrid. While this scenario isn't intended to represent a real option for this rule, it does serve to demonstrate the consequences of achieving the highest range of alternatives considered in the 2012 final rule using updated technical inputs. Naturally, the two alternatives with even higher stringency (20%/year and 30%/year) continue this trend and push nearly all vehicles into the most aggressive technology available – with a PHEV share of almost 100 percent by 2026. The costs and benefits associated with these alternatives, nearly all of which accrue to the buyers of new vehicles, show higher costs than benefits over the model years considered in the central analysis and that trend increases along with stringency. However, once the model allows BEV to be applied, starting in MY 2030, all three scenarios aggressively shift from PHEVs to more cost effective BEVs, with the two highest stringency cases producing fleets that are nearly all electric by 2040.

The fleetwide impacts are also considerably different than the results produced by the range of alternatives in the central analysis. The 10%/year scenario produces an on-road fleet that is about five percent smaller than the baseline at its peak. However, the two more stringent alternatives produce fleet sizes that are twenty and thirty percent smaller, respectively. This forces demand for travel to be met by older vehicles to a greater extent than in the less stringent alternatives, which increases average per-vehicle emissions and degrades the safety of the on-road fleet.

In contrast, the CO_2 analysis of the high stringency alternatives lacks the expensive transition that occurs in the CAFE analysis between internal combustion and fully electric powertrains. As a consequence, while the general trends across the stringency increases are similar, the magnitude of the impacts is smaller. While the two lower stringency alternatives have costs that are comparable to the CAFE program sensitivities (within a few hundred dollars per vehicle), the most stringent alternative is closer to $12,000 per vehicle, compared to $20,000 per vehicle in the CAFE analysis. The primary reason for the difference is the access to compliance pathways that rely on BEVs – the 10%/year stringency already has 25 percent BEV by MY 2026 and the 20%/year is at 85 percent BEV. The 30%/year stringency is comparable. However, at those levels of BEV market share, the achieved CO_2 ratings are negative. While the average fleet requirement is 50 g/mi and 13 g/mi, for the two highest stringency cases in MY 2026, there is no path to compliance at those levels that does not leverage significant penetration of BEV. The lower compliance cost in the highest stringency scenario also represents a cap on the fleetwide impacts.

Rather than a gap in the size of the on-road fleet that continues to scale with stringency, the 20%/year and 30%/year cases produce on-road fleets that are at most 20 percent smaller than the baseline. And in both cases this difference erodes somewhat as technology costs learn down and the incremental cost of the more stringent alternatives decreases over time. While these alternatives are not considered in the central analysis, they represent stress tests for both the possible compliance pathways in the technology set, and the relationships in the model that determine demand response to price increases, retirement rates, and usage patterns. Unlike earlier iterations of agency models, the model used to support today's analysis responds to stressing scenarios that are likely to impact the light-duty vehicle fleet, both new sales and existing vehicles, in ways that are consistent with the characteristics of the scenario.

VIII. How do the Final Standards Fulfill the Agencies' Statutory Obligations?

A. How does the Technical Assessment Support the Final CO_2 Standards as Compared to the Alternatives that EPA has Considered?

1. Introduction

Title II of the Clean Air Act provides for comprehensive regulation of mobile sources, authorizing EPA to regulate emissions of air pollutants from all mobile source categories. Under Section 202(a) and relevant case law, as discussed below, EPA considers such issues as technology emission reduction effectiveness, its cost (both per vehicle, per manufacturer, and per consumer), the lead time necessary to implement the technology, and based on this the feasibility of potential standards; the impacts of potential standards on emissions reductions of both GHGs and non-GHGs; the impacts of standards on oil conservation and energy security; the impacts of standards on fuel savings by consumers; the impacts of standards on the auto industry; other energy impacts; as well as other relevant factors such as impacts on safety.

EPA is afforded considerable discretion under section 202(a) when assessing issues of technical feasibility and availability of lead time and in weighing these factors. In light of its consideration of the relevant factors, EPA has concluded, for the reasons discussed below, that the previous standards (which increase stringency at a rate of about 5% per year) are not appropriate, and the action is to revise the standards to increase stringency by 1.5% per year.Beginning in 2009, EPA and NHTSA have worked together jointly to establish fuel economy and tailpipe CO_2 emission standards for light duty vehicles. The first rulemaking, finalized in 2010, established standards for the 2012 through 2016 model years. Shortly thereafter, in 2012, the agencies established standards for the 2017 through 2025 model years—but given the limitation in EPCA that only allows for standards to be set five years at a time, the 2022-2025 model year standards were only final for EPA's tailpipe CO_2 emissions regulation. This rapid period of rulemaking to establish standards over a decade in advance may have marked a departure for NHTSA, but it followed EPA's longstanding approach when regulating vehicular criteria pollutant emissions to provide a significant period of time for the industry to develop technologies to achieve standards.

While EPA had decades of experience regulating light duty vehicle emissions, it did not previously have experience regulating tailpipe CO_2 emissions. And regulating CO_2 emissions is quite different from regulating criteria pollutant emissions. With criteria pollutants, technological emission controls exist primarily in the form of engine controls and catalytic conversion. Today's emission controls for criteria pollutants have only a de minimis effect on performance or functionality of the vehicle.

Controlling tailpipe CO_2 emissions for an internal combustion engine requires controlling the amount of energy used to propel the vehicle. All else being equal, better performance (in acceleration or passing speed) requires more energy. Similarly, vehicles with more storage capacity tend to be larger, and moving an object with larger mass requires more energy than objects with smaller mass. Vehicles with greater towing performance likewise require more energy. Maintaining utility and performance requires sophisticated and expensive technological solutions, such as reducing mass through advanced materials, changing engine combustion cycles, increasing compression ratios, or turbo-charging the engine. Consumers often can feel the difference in vehicle performance as a result of these controls, and as will be discussed herein.

As discussed when issuing the 2012 Final Rule, the economic and market assumptions underlying the standards the agencies finalized were crucial, and long-term projections are inherently uncertain. Upon review of those assumptions, such as the price of gas and the sales mix of pick-up trucks and sport-utility vehicles as compared to passenger cars, the agencies have now concluded that many of these assumptions have not proven to be accurate and therefore have been updated. Given the uncertainty about the 2012 assumptions at the time of that rulemaking, the agencies incorporated a mid-term evaluation process for EPA's 2022-2025 model year standards that would be "collaborative, robust and transparent," and "based on information available at the time of the mid-term evaluation and an updated assessment of all the factors considered in setting the standards and the impacts of those factors on the manufacturers' ability to comply."[2596]

While that process was expected to take place throughout 2017, and a final determination issued in the Spring of 2018, this process was expedited. On July 27, 2016, the agencies published a federal register notice making the public aware of the availability of a draft Technical Assessment Report, with comments due at the end of September 2016. On December 6, 2016, EPA published a notice in the federal register making the public aware of its proposed Final Determination and extensive Technical Support Document to keep the standards set in 2012 in place through the 2025 model year without change. The public was given until December 30, 2016 to comment on the proposed determination. Less than two weeks later, on January 12, 2017, EPA finalized its determination.

Industry commenters stated that the 2017 Final Determination "is the product of egregious procedural and substantive defects and EPA should withdraw it," that EPA had "fail[ed] to provide an adequate period for meaningful notice and comment," that EPA had "acknowledg[ed] that the Proposed Determination adjusted a number of EPA assumptions in response to commenters who pointed out errors at earlier stages" while stating that "there was no

[2596] 77 FR at 62633.

need for more time because [it] did not include much new material," and that "EPA [had] underestimated the burden [of the standards]," "EPA [made] cursory assertions that downplayed the impact of its mandate on auto sales and employment," and "EPA refused to consider many of the [industry's] technical concerns even when supported by an outside consultant, asserted [industry] provided insufficient data, and then refused further meetings for clarification."[2597]

In light of commenters' concerns about EPA's 2017 final determination, in March 2017, EPA announced its intent to reconsider the final determination in order to allow additional opportunity to hear from the public, and additional consultation and coordination with NHTSA in support of a national harmonized program. In August 2017, EPA published a notice in the Federal Register requesting comment on its reconsideration of the initial determination, and held a public hearing on the matter in September 2017. Then, in April 2018, EPA issued a revised final determination finding that the 2022-2025 model year GHG standards set in 2012 were not appropriate and a rulemaking should be initiated to revise the standards, as appropriate.

In this proceeding, in order to determine what standards are appropriate, EPA and NHTSA sought comment on a wide range of potential standards—ranging from holding the 2020 standards flat through the 2026 model year to retaining the standards finalized in 2012. Similar to the 2012 rulemaking, EPA considered a number of different alternatives—ranging from the standards finalized in 2012, to holding the 2020 MY standards flat through MY 2026. As in 2012, the manner in which different factors are weighed can yield very different result—more stringent standards would improve CO_2 emissions, reduce energy consumption, and save consumers fuel. Less stringent standards would reduce technology costs for manufacturers and save consumers in upfront purchase prices, enabling the fleet to turnover more quickly. While weighing these factors, EPA has considered compliance results that have been observed throughout the fleet. While the agencies have seen extraordinary reductions in tailpipe CO_2 emissions since EPA has begun regulation in this area, manufacturers are increasingly falling short of meeting their performance targets, and are increasingly using acquired or earned credits to comply with requirements. For the 2016 model year, the overall fleet failed, for the first time in regulation history, to meet emission targets—achieving 272 grams per mile, when the standard was 263 grams per mile.[2598] The 2016 model year saw only five major manufacturers perform at or better than their CO_2 footprint standards—Honda, Hyundai, Mazda, Nissan, and Subaru. For the 2017 model year, only three major manufacturers—BMW, Honda, and Subaru—performed better than their CO_2 standards, and the total fleet underperformed compared to the standards—achieving 263 grams per mile, when the fleetwide standard was 258 grams per mile.[2599] The emissions averaging, credit banking and trading system was established to allow manufacturers greater flexibility and lead time to address technical feasibility and cost without sacrificing effectiveness of the standards, but widespread reliance upon credits across the industry may raise concerns about compliance in future years, particularly since the more

[2597] Alliance letter to Administrator Pruitt, Feb. 21, 2017, available at https://autoalliance.org/wp-content/uploads/2017/02/Letter-to-EPA-Admin.-Pruitt-Feb.-21-2016-Signed.pdf.

significant increases in stringency in the 2012 rulemaking have yet to be effective. Taken together, the agencies now believe this information supports the conclusion that the lead time EPA estimated would be sufficient to achieve compliance with the previous standards for MYs 2021-26, was not sufficient.

In this action, EPA is reducing the rate of stringency increases from those adopted in the 2012 rulemaking in part to ensure that the standards remain reasonable and appropriate. As in 2012, EPA is deciding against selecting alternatives that are more stringent or less stringent than appropriate. The final rule analysis projects that the 1.5 percent alternative would result in less significant shortfalls compared to more stringent alternatives, which will ease compliance burdens while nonetheless pushing the market beyond what it would demand in the absence of standards or what would be achieved with less stringent standards. The standards finalized today will result in continuing improvements compared to the 2020 model year, and are best viewed in the context of the larger rulemaking, as shown in the chart below:

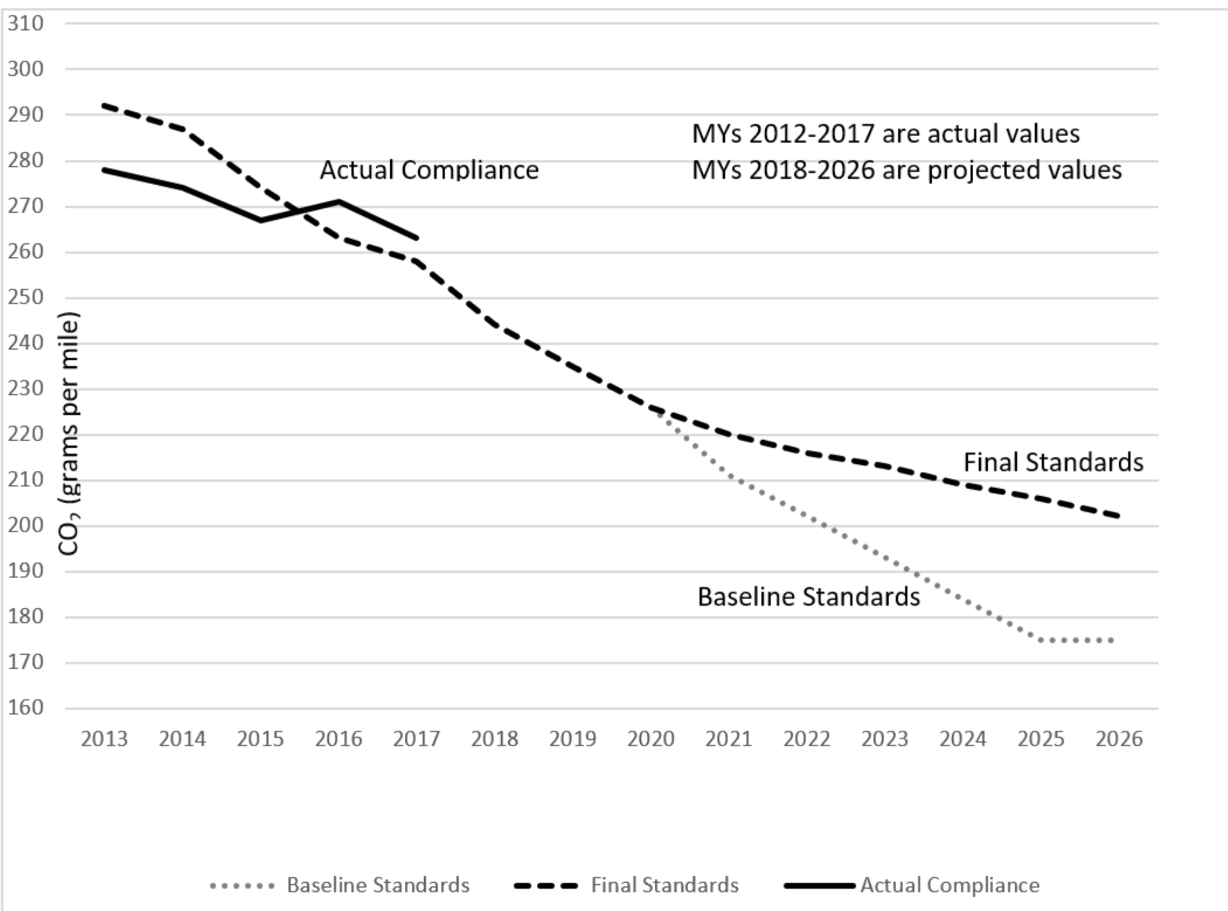

Figure VIII-1 Industry Average CO_2 Standards and Compliance MYs 2012-2026

2. Basis for the CO_2 Standards Under Section 202(a) of the Clean Air Act

Title II of the Clean Air Act (CAA) provides for comprehensive regulation of mobile sources, authorizing EPA to regulate emissions of air pollutants from all mobile source categories. This rule implements a specific provision from Title II, section 202(a).[2600] Section 202(a)(1) states that "[t]he Administrator shall by regulation prescribe (and from time to time revise) … standards applicable to the emission of any air pollutant from any class or classes of new motor vehicles or new motor vehicle engines, which in his judgment cause, or contribute to, air pollution which may reasonably be anticipated to endanger public health or welfare." If EPA makes the appropriate endangerment and cause or contribute findings, then section 202(a) directs EPA to issue standards applicable to emissions of those pollutants.

Any standards under CAA section 202(a)(1) "shall be applicable to such vehicles and engines for their useful life." Emission standards set by the EPA under section 202(a)(1) are technology-based, as the levels chosen must be premised on a finding of technological feasibility. Thus, standards promulgated under section 202(a) are to take effect only after "such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."[2601] EPA must consider costs to those entities which are directly subject to the standards.[2602] Thus, "the [s]ection 202(a)(2) reference to compliance costs encompasses only the cost to the motor-vehicle industry to come into compliance with the new emission standards."[2603] EPA is afforded considerable discretion under section 202(a) when assessing issues of technical feasibility and availability of lead time to implement new technology. Such determinations are "subject to the restraints of reasonableness," which "does not open the door to 'crystal ball' inquiry."[2604] In developing such technology-based standards, EPA has the discretion to consider different standards for appropriate groupings of vehicles ("class or classes of new motor vehicles"), or a single standard for a larger grouping of motor vehicles.[2605]

Although standards under CAA section 202(a)(1) are technology-based, they are not based exclusively on technological capability. EPA has the discretion, and in some instances has been specifically directed by Congress, to consider and weigh various factors along with technological feasibility, such as the cost of compliance[2606] , lead time necessary for

---

[2606] *See* section 202(a)(2).

compliance[2607], safety,[2608] other impacts on consumers,[2609] and energy impacts associated with use of the technology.[2610]

Unlike standards set under provisions such as section 202(a)(3) and section 213(a)(3), EPA is not required to set technology-forcing standards when such standards would not be appropriate. EPA has interpreted a similar statutory provision, CAA section 231[2611], as follows:

> While the statutory language of section 231 is not identical to other provisions in title II of the CAA that direct EPA to establish technology-based standards for various types of engines, EPA interprets its authority under section 231 to be somewhat similar to those provisions that require us to identify a reasonable balance of specified emissions reduction, cost, safety, noise, and other factors. *See, e.g.*, *Husqvarna AB v. EPA*, 254 F.3d 195 (D.C. Cir. 2001) (upholding EPA's promulgation of technology-based standards for small non-road engines under section 213(a)(3) of the CAA). However, EPA is not compelled under section 231 to obtain the ''greatest degree of emission reduction achievable'' as per sections 213 and 202 of the CAA, and so EPA does not interpret the Act as requiring the agency to give subordinate status to factors such as cost, safety, and noise in determining what standards are reasonable for aircraft engines. Rather, EPA has greater flexibility under section 231 in determining what standard is most reasonable for aircraft engines, and is not required to achieve a "technology forcing" result.[2612]

This interpretation was upheld as reasonable in *NACAA v. EPA.*[2613] CAA section 202(a), as with section 231, does not specify the degree of weight to apply to each factor, and EPA accordingly interprets its authority under section 202(a) similarly to its interpretation of section

2609 Since its earliest Title II regulations, EPA has considered the safety of pollution control technologies. *See* 45 FR 14496, 14503 (March 5, 1980). ("EPA would not require a particulate control technology that was known to involve serious safety problems. If during the development of the trap-oxidizer safety problems are discovered, EPA would reconsider the control requirements implemented by this rulemaking.").
2610 *See* George E. Warren Corp. v. EPA, 159 F.3d 616, 623-624 (D.C. Cir. 1998) (ordinarily permissible for EPA to consider factors not specifically enumerated in the CAA).
2611 Section 231(a)(2)(A) of the CAA provides: "The Administrator shall, from time to time, issue proposed emission standards applicable to the emission of any air pollutant from any class or classes of aircraft engines which in his judgment causes, or contributes to, air pollution which may reasonably be anticipated to endanger public health or welfare." Section 231(a)(3) provides in part: "Within 90 days after the issuance of such proposed regulations, he shall issue such regulations with such modifications as he deems appropriate. Such regulations may be revised from time to time." Sectiion 231(b) provides: "Any regulation prescribed under this section (and any revision thereof) shall take effect after such period as the Administrator finds necessary (after consultation with the Secretary of Transportation) to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."
2612 70 FR 69664, 69676 (Nov. 17, 2005).
2613 489 F.3d 1221, 1230 (D.C. Cir. 2007).

231 as set forth above: EPA has discretion in choosing an appropriate balance among the statutory factors.[2614]

As noted above, EPA has found that the elevated concentrations of greenhouse gases in the atmosphere may reasonably be anticipated to endanger public health and welfare.[2615] EPA defined the "air pollution" referred to in CAA section 202(a) to be the combined mix of six long-lived and directly emitted GHGs: carbon dioxide (CO_2), methane (CH_4), nitrous oxide (N_2O), hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), and sulfur hexafluoride (SF_6). The EPA further found under CAA section 202(a) that emissions of the single air pollutant defined as the aggregate group of these same six greenhouse gases from new motor vehicles and new motor vehicle engines contribute to air pollution. As a result of these findings, section 202(a) requires EPA to issue standards applicable to emissions of that air pollutant. New motor vehicles and engines emit CO_2, CH_4, N_2O, and HFC. EPA has established standards and other provisions that control motor vehicle emissions of CO_2, HFCs, N_2O, and CH_4. EPA has not set any standards for PFCs or SF_6 as they are not emitted by motor vehicles.

3. EPA's Conclusion that the Final CO_2 Standards are Appropriate and Reasonable

In this section, EPA discusses the factors, data and analysis the Administrator has considered in the selection of the EPA's revised CO_2 emission standards for MYs 2021 and later and the comments received on EPA's consideration of these factors (see further discussion below on EPA's summary and analysis of comments).

As discussed in Section VIII.A.1 above, the primary purpose of Title II of the Clean Air Act is the protection of public health and welfare, and GHG emissions from light-duty vehicles have been found by EPA to endanger public health and welfare.[2616] The goal of the light-duty vehicle GHG standards is to reduce these emissions which cause or contribute to air pollution which may reasonably be anticipated to endanger public health or welfare, while taking into account other factors as discussed above.

CAA section 202(a)(2) states when setting emission standards for new motor vehicles, the standards "shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to

[2614] *See* Sierra Club v. EPA, 325 F.3d 374, 378 (D.C. Cir. 2003) (even where a provision is technology-forcing, the provision "does not resolve how the Administrator should weigh all [the statutory] factors in the process of finding the 'greatest emission reduction achievable'"); *see also* Husqvarna AB v. EPA, 254 F. 3d 195, 200 (D.C. Cir. 2001) (great discretion to balance statutory factors in considering level of technology-based standard, and statutory requirement "[to give] appropriate consideration to the cost of applying … technology" does not mandate a specific method of cost analysis); Hercules Inc. v. EPA, 598 F. 2d 91, 106-07 (D.C. Cir. 1978) ("In reviewing a numerical standard, we must ask whether the agency's numbers are within a 'zone of reasonableness,' not whether its numbers are precisely right"); Permian Basin Area Rate Cases, 390 U.S. 747, 797 (1968) (same); Federal Power Commission v. Conway Corp., 426 U.S. 271, 278 (1976) (same); Exxon Mobil Gas Marketing Co. v. FERC, 297 F. 3d 1071, 1084 (D.C. Cir. 2002) (same).
[2615] 74 FR 66496 (Dec. 15, 2009).
[2616] *Id.*

the cost of compliance within such period." 42 U.S.C. 7521(a)(2). That is, when establishing emission standards, the Administrator must consider both the lead time necessary for the development of technology that can be used to achieve the emission standards and the resulting costs of compliance on those entities that are directly subject to the standards. In previous rulemakings, including the rulemaking that established the current standards, EPA considered lead time-related elements, including comparative per-vehicle cost increases by manufacturer for both cars and trucks, comparative penetration rates of advanced technologies by manufacturers for both cars and trucks, and lead time concerns about increasing technology penetration rates for these advanced technologies beyond current levels. EPA also considered comparative industry-wide costs and differences between alternatives, framed in terms of total costs and percentage differences between alternatives. These elements are discussed in detail throughout the analysis. As mentioned previously, however, the performance of the fleet in recent years indicates that the lead time deemed as adequate in the 2012 rulemaking was not sufficient.

EPA is not limited to consideration of the factors specified in CAA section 202(a)(2) when establishing standards for light-duty vehicles. In addition to feasibility and cost of compliance, EPA may (and historically has) considered such factors as safety, energy use and security, degree of reduction of both GHG and non-GHG pollutants, technology cost-effectiveness, and costs and other impacts on consumers.

EPA also considers relevant case law. Critical to this series of joint rulemakings with NHTSA, the Court in *Massachusetts v. EPA*[2617], recognized EPA's argument that "it cannot regulate carbon dioxide emissions from motor vehicles" without "tighten[ing] mileage standards . . . ."—a task assigned to DOT. The Court found that "[t]he two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency."[2618] Accordingly, the agencies have worked closely together in setting standards, and many of the factors that NHTSA considers to set maximum feasible standards overlap with factors that EPA considers under the Clean Air Act. Just as EPA considers energy use and security, NHTSA considers these factors when evaluating the need of the nation to conserve energy, as required by EPCA. Just as EPA considers technological feasibility, the cost of compliance, technological cost-effectiveness and cost and other impacts upon consumers, NHTSA considers these factors when weighing the technological feasibility and economic practicability of potential standards. EPA and NHTSA both consider implications of the rulemaking on CO_2 emissions as well as criteria pollutant emissions. And, NHTSA's role as a safety regulator inherently leads to the consideration of safety implications when establishing standards. The balancing of competing factors by both EPA and NHTSA are consistent with each agency's statutory authority and recognize the overlapping obligations the Supreme Court pointed to in directing collaboration.

[2617] 549 U.S. 497, 531 (2007).
[2618] *Id.* at 532.

As discussed in prior rulemakings setting GHG standards,[2619] EPA may establish technology-forcing standards under section 202(a), but it must provide a rationale for concluding that the industry can develop the needed technology in the available time. However, EPA is not *required* to set technology-forcing standards under section 202(a). Rather, because section 202(a), unlike the text of section 202(a)(3) and section 213(a)(3),[2620] does not specify that standards shall obtain "the greatest degree of emission reduction achievable," EPA retains considerable discretion under section 202(a) in deciding how to weigh the various factors, consistent with the language and purpose of the Clean Air Act, to determine what standards are appropriate.

The proposed rule presented an analysis of alternatives, in support of the Administrator's consideration of a range of alternative CO_2 standards as potential revisions of the existing standards for model years 2021 and later, from the previous standards (representing an increase in stringency of approximately 5 percent per year from MY 2021 through MY 2025) to several less stringent alternatives. These alternatives ranged from a zero percent increase in stringency to a stringency increase for passenger cars of 2 percent per year and for light trucks of 3 percent per year, in addition to the baseline alternative consisting of the previous standards.[2621] The analysis supported the range of alternative standards based on factors relevant to the EPA's exercise of its section 202(a) authority, such as emissions reductions of GHGs and other air pollutants, the necessary technology and associated lead-time, the costs of compliance for automakers, the impact on consumers with respect to cost and vehicle choice, and effects on safety. The proposed rule identified the alternative composed of a zero percent increase in stringency as the preferred alternative.

EPA received numerous public comments on the range of stringency alternatives in the proposed rule and the Administrator's consideration of various factors in determining appropriate GHG standards under section 202(a) of the CAA. Below EPA responds to comments on these issues. EPA notes that many comments concerned the technical foundation and analysis upon which EPA was basing its regulatory decisions, such as the modeling of emission control technologies and costs, the safety analysis, and consumer issues. Comments specific to these analyses are discussed elsewhere in this FRIA. The section below addresses comments specifically addressing EPA's considerations in finalizing appropriate CO_2 emissions standards under the CAA.

EPA's conclusion, after consideration of the factors described below, public comments, and other information in the administrative record for this action is that holding CO_2 emissions

---

[2619] *See*, *e.g.*, 77 FR 62624, 62673 (Oct. 15, 2012), EPA and NHTSA final rule for 2017 and later model year light-duty GHG emissions and CAFE standards.

[2620] Section 202(a)(3) provides that regulations applicable to emissions of certain specified pollutants from heavy-duty vehicles or engines "shall contain standards which reflect the greatest degree of emission reduction achievable through the application of technology which the Administrator determines will be available . . . giving appropriate consideration to cost, energy, and safety factors associated with the application of such technology." 42 U.S.C. 7521(a)(3). Section 213(a)(3) contains a similar provision for new nonroad engines and new nonroad vehicles (other than locomotives or engines used in locomotives). 42 U.S.C. 7547(a)(3).

[2621] 83 FR 42990, Table I-4 (August 24, 2018).

standards for MY 2020 flat through MY 2026 is not appropriate or reasonable. EPA concludes steady stringency increases year over year are warranted, but that the MY 2021-2026 standards first established in 2012 are not appropriate taking into account lead time and the various factors described below. Accordingly, the Administrator has concluded that 1.5 percent annual increases in stringency from the MY 2020 standards through MY 2026 (Alternative 3 of this final rule analysis)[2622] are reasonable and appropriate.

a) *Consideration of the Development and Application of Technology to Reduce CO_2 Emissions*

When EPA establishes emission standards under CAA section 202, it considers both what technologies are currently available and what technologies under development may become available. For today's final rule, EPA considered the analysis of the potential penetration into the future vehicle fleet of a wide range of technologies that both reduce CO_2 and improve fuel economy (see FRIA Chapter X). The majority of these technologies have already been developed, have been commercialized, and are in-use on vehicles today. These technologies include, but are not limited to, engine and transmission technologies, vehicle mass reduction technologies, technologies to reduce aerodynamic drag, and a range of electrification technologies. The electrification technologies include 12-volt stop-start systems, 48-volt mild hybrids, strong hybrid systems, plug-in hybrid electric vehicles, and dedicated electric vehicles.

This consideration is especially important given current projections about relatively lower fuel prices than what was projected in 2012. In that rulemaking, EPA expressed concern that some alternatives may require too much advanced technologies (including electrification) in light of uncertain consumer acceptance of added costs, as well as the technologies themselves.[2623] There, EPA concluded that more stringent increases in technology penetration rates raise serious concerns about the ability and likelihood that manufacturers can smoothly implement additional technologies to meet requirements.[2624]

As shown in Section VII in the preamble and in FRIA Section VII, the projected penetration of technologies varies across the Alternatives considered for this final rule. In general, the baseline alternative consisting of the previous EPA standards as finalized in 2012 was projected to result in the highest penetration of advanced technologies into the vehicle fleet, in particular mild hybrids at 7.1 percent penetration and strong hybrids at 9 percent penetration by MY 2030. By contrast, the revised final standards adopted today (1.5 percent per year stringency improvement from MY 2021 through MY 2026) are projected to result in a significantly lower level of mild and strong hybrids used to meet the standards, at 1.6 percent

---

[2622] The numbered Alternatives presented in the SAFE proposed rule (*see* Table I-4 at 83 FR 42990, August 24, 2018) were in some cases defined differently than those presented in this final rule (*see* Section V). Unless otherwise stated, the Alternatives described in this section refer to those presented in this final rule.

[2623] 77 FR 62879.

[2624] *See* 77 FR at 62875, discussion about certain alternatives may require too much electrification and "may well be overly aggressive in the face of uncertain consumer acceptance of both the added costs and the technologies themselves. EPA continues to believe these technology penetration rates are inappropriate given the concerns just voiced." At 62877, "This increase in tech penetration rates raises serious concerns about the ability and likelihood manufacturers can smoothly implement…."

mild hybrids and 2.2 percent strong hybrids by MY 2030. Further, the final rule analysis indicates that the previous CO_2 standards would have led to a projected 5.7 percent penetration of dedicated electric vehicles (EV), with 0.4 percent penetration of plug-in hybrid electric vehicles (PHEV); the revised final standards reduce this projected level to 3.7 percent EV penetration (with 0.2 percent PHEV penetration), which again is more in line with what the EPA believes is a more appropriate projected level of market penetration.

The technology penetration rates in the analysis for the final rule are changed since EPA's prior analysis. These changes in the estimated penetrations in this rulemaking are due to changes in the model that are meant to reflect consumer response to the standards, as well as changes to estimates for technology costs and effectiveness. In the 2017 Final Determination on Model Year 2022-2025 standards, where EPA found there was available and effective technology to meet the MY 2022-2025 standards, the technology was available at reasonable cost to the vehicle manufacturers and consumers, there was adequate lead time, and the standards were feasible and practicable. EPA also found that the previous MY 2022-2025 standards could be met largely through advanced gasoline vehicle technologies, with low levels of electrified vehicles.[2625] The levels of electrified vehicle technologies projected in this final rule to meet the baseline Alternative (the previous GHG standards) differ slightly from those projected in the 2017 Final Determination. In this final rule, EPA projects a combined strong and mild hybrid penetration of 16 percent (compared to 20 percent in the 2017 Final Determination), with the share of mild hybrids somewhat lower (7 percent compared to 18 percent in the 2017 Final Determination) and the share of strong hybrids higher (9 percent compared to 2 percent in in the 2017 Final Determination). EPA projects a total level of plug-in vehicles of 6 percent, similar to the the 5 percent total projected in the 2017 Final Determination, but with a slightly different mix of plug-in hybrid electric vehicles (0.4 percent compared to 2 percent in the 2017 Final Determination) and dedicated electric vehicles (5.7 percent compared to 3 percent in the 2017 Final Determination).

Another aspect of the analysis that EPA considered related to technology development and application is manufacturers' projected level of over-compliance under the alternatives considered for the final rule. Under the least stringent Alternatives (Alternative 1, zero percent stringency improvement, and Alternative 2, 0.5 percent per year stringency improvement), manufacturers overall are projected to over-comply with those levels of stringency. For example, under Alternative 1, manufacturers are projected to achieve a CO_2 level of 206 g/mi in MY 2029, 16 g/mi below (more stringent than) the required target level of 222 g/mi. Similarly, for Alternative 2, manufacturers are projected to achieve a CO_2 level of 205 g/mi in MY 2029, 10 g/mi below the required target level of 215 g/mi. Thus, the industry is projected to considerably over-comply with the Alternative 1 and 2 standards. Under the final standards, the projected level of over-compliance is much narrower, only 4 g/mi (198 g/mi by MY 2029 compared to a 202 g/mi target), and for other alternatives that are more stringent than the final standards, that gap is similar or even more narrow as shown in Preamble Table VII-7. This is an

[2625] "Final Determination on the Appropriateness of the Model Year 2022-2025 Light-Duty Vehicle Greenhouse Gas Emissions Standards under the Midterm Evaluation," EPA-420-R-17-001, January 2017. *See* Table ES-1, page 4-5, and Section II (i), (ii), and (iii), pages 28-24. Hereafter "2017 Final Determination."

indication that the standards in Alternatives 1 and 2 may not represent an appropriate level of stringency when compared to the pace at which manufacturers would be applying technologies. While some level of over-compliance is expected so that manufacturers retain a reasonable compliance margin, Alternatives 1 and 2 would, based on the final rule analysis, result in manufacturers retaining a compliance margin more than 2-3 times that of the other alternatives. The Administrator has rejected those lower stringency Alternatives in part for this reason and believes that the final standards (Alternative 3, 1.5 percent per year stringency improvement) represent an appropriate margin of compliance that can be attained given the projected pace of manufacturers' application of technologies.

EPA received several comments regarding its consideration of the development and application of GHG reducing technologies. The California Air Resources Board (CARB) commented that, despite what they characterize as evidence of widely available technology, EPA has proposed to promulgate emission standards that are less stringent than existing standards and that would lead to increased emissions of GHGs. The New York State Department of Environmental Conservation commented that the proposal did not "appropriately value, or consider, technology advancement and innovation by OEMs and automotive parts suppliers" and noted the role of technology innovation in reducing technology costs. EPA notes that the agencies specifically considered technology cost-savings attributable to experience with technology—in other words, the analysis provides that technology costs reduce over time.

The Center for Biological Diversity (CBD) et al. commented that since technologies exist today that can achieve the current standards, reducing the standards to the level proposed in the NPRM is contrary to the objectives of the Clean Air Act. These parties further commented that EPA failed to make a proposed finding that additional lead-time is necessary, as they argue is required by Section 202(a)(2). The Green Energy Institute at Lewis and Clark Law School and others similarly commented that EPA lacks a reasonable justification for extending the phase-in period for the current standards because compliant technologies currently exist and are already commercially available.

The Attorney General of California and others commented that EPA acknowledges that most or all technology necessary to meet the current standards is available, and does not provide evidence to support how additional lead time is "necessary to permit the development and application of the requisite technology."

In response to the public comments, and as EPA indicated in the proposal and in the 2012 Final Rule establishing the previous standards, the technologies projected to be used to meet the GHG standards, including the alternatives in the proposal as well as the final standards, are currently available and in production. If the appropriateness of the standards were based solely on an assessment of technology availability, and lead time considerations were limited to the development of such technology, EPA might consider more stringent CO_2 standards to be potentially appropriate. But this is not the sole or predominant factor to be weighed. In 2012, EPA had to balance this issue as well. As in 2012, manufacturers today are capable of building vehicles that can meet the standards that any of the regulatory alternatives evaluated in the final rule would require. However, greater uncertainty about consumer acceptance of those technologies (as compared to what EPA believed was likely in 2012) means that providing more lead time is appropriate.[2626]

As in 2012, EPA disagrees with commenters that a finding that necessary technology is available is, by itself, determinative of the appropriate emission standard under CAA section 202(a). As described in the proposed rule and in this section of the final rule, the Administrator weighs technology availability and lead time along with several other factors, including costs, emissions impacts, safety, and consumer impacts in determining the appropriate standards under section 202(a) of the CAA.

Under this analysis, given the factors discussed later in this Section, the previous standards would yield technology penetration rates for advanced technologies beyond what is appropriate and reasonable. By contrast, the final standards are projected to result in more modest penetration rates for advanced technologies that nonetheless will achieve an increased level of technology penetration compared to the standards applicable for MY 2020. For example, the final rule analysis projects that dynamic cylinder deactivation penetration for MY 2030 would be 39.2 percent under the previous standards for, but 34.4 percent under today's final standards. Similarly, turbocharged engine penetration would be a projected 48 percent by MY 2030 under the previous standards, compared to 36.4 percent under the final standards. In addition, mild hybrids are projected to change from 7.1 percent to 1.6 percent, strong hybrids from 9 percent to 2.2 percent, and dedicated electric vehicles from 5.7 percent to 3.7 percent (all for MY 2030) under the final standards instead of the previous standards. The Administrator believes that the level of technology development and application for the final standards is an appropriate balance, in light of the relevant factors considered as a whole, as discussed below.

b) Consideration of the Cost of Compliance

EPA is required to consider costs of compliance when setting standards under section 202(a). The standards finalized today would reduce required technology costs for the industry by an estimated $108 billion for the vehicles produced from MY 2017 through MY 2029 (at 3 percent discount rate, see Section VII) compared to the EPA standards established in 2012. While less-stringent increases would result in additional technology cost savings ($129 billion and $126 billion for Alternatives 1 and 2, respectively), technology cost savings are only one element that EPA considers.

In addition to capital cost savings, the final standards would reduce the per-vehicle costs by $1,250 per vehicle in MY 2030, compared to the standards set in 2012, as shown in Table VII-27. While less-stringent increases would result in greater per-vehicle technology cost-savings, cost-savings alone do not dictate the appropriate standards. For example, Alternatives 1 and 2 would save manufacturers $1,218 and $1,181 in per-vehicle costs in MY 2030 compared to the previously issued standards. Alternatives more stringent than the final standards would be

---

[2626] *See* 77 FR at 62871 ("As stated above, EPA's analysis indicates that there is a technology pathway for all manufacturers to build vehicles that would meet their final standards as well as the alternative standards. The differences between the final standards and these analyzed alternatives lie in the per-vehicle costs and the associated technology penetration rates.").

more burdensome to manufacturers, with Alternatives 4 through 8 ranging from a cost savings to manufacturers of $927 to $351 per-vehicle compared to the previous standards.

The costs to comply projected in this final rule are higher than those previously projected by EPA in the 2017 Final Determination: In 2017 EPA projected that the per-vehicle cost to meet the MY 2025 standards would be $875 on average, with a range of $800 to $1,115 considering a range of sensitivities (in 2015 dollars).[2627] The costs to the auto industry for complying with the previous MY 2022-2025 standards projected in the 2017 Final Determination were $24 billion to $33 billion (in 2015$ at 7 percent and 3 percent discount rates, respectively).[2628] Again, EPA notes that the values in this final rule analysis and the values in the 2017 Final Determination have different points of reference making them not directly comparable, as discussed above.

Several public comments addressed EPA's consideration of costs of compliance in setting the revised standards. The Alliance of Automobile Manufacturers (Alliance) commented that the proposal's cost estimates for the current MY 2021 and later standards differed from what EPA projected in 2012 when setting those standards. The Alliance argued that that those changes in the expected costs of the previously issued standards provide significant reasoned support for EPA's view that the existing standards should be reduced.

The Association of Global Automakers (Global Automakers) commented on the importance of lead time for technology investment. While it agreed that the existing standards are too stringent, it stated that vehicle manufacturers and suppliers have invested $76 billion in manufacturing facilities, and that much of that was for improvement in CO_2 emission reductions and fuel economy improvements. At least some of that investment, according to Global Automakers, was made to meet the standards set in 2012. Global Automakers expressed concern with an abrupt halt to gradual fuel economy improvements, as such an approach could result in stranded capital investments for automakers and suppliers.

CBD and others disagreed with EPA's conclusion that the cost of broader adoption of technologies is unreasonable in light of other factors considered by EPA. CBD and others claimed that the Clean Air Act narrowly allows for consideration of cost only as a question of whether costs of compliance make it infeasible for manufacturers to meet standards within the relevant period. They argue that this consideration relates to lead time, and not to a broader consideration of costs. They assert that broader compliance cost considerations apply only to the motor vehicle industry. They also claim that compliance costs to meet the standards set in 2012 for the 2017-2025 model years are not challenging to the industry.

These commenters also state that the costs to industry to meet the standards are not high enough to require reducing standards, to permit development and application of the required technology. They claim that the only burden that Congress intended to impose as a constraint on

---

[2627] *See* 2017 Final Determination Table ES-1, page 4-5, and II(v), page 24-26.
[2628] *Id.* at Table ES-4, page 7.

emission reduction requirements are costs that are “so severe as to preclude the deployment of required technology during the relevant period.”

The New York State Department of Environmental Conservation commented on the role of technology innovation in considering technology feasibility, while acknowledging that the feasibility analysis allows for consideration of numerous factors argues that since technology exists today to meet the standards for MY 2026, no lead time is necessary. It further states that EPA did not appropriately balance or consider in the proposal future technological advancements and OEM innovation that will further constrain the costs of new technology.

In response to the Alliance’s comment that the projected compliance costs have changed significantly from EPA’s 2012 rule, EPA agrees. Indeed, this is a significant factor in EPA’s conclusion that the previous standards were too stringent. EPA notes that the projected difference between the cost to comply with the previous standards and the costs to comply with the standards established today is lower in this final rule analysis as compared to the projected difference between the proposal’s preferred alternative and the previous standards. EPA concludes that the final standards nevertheless result in significant reductions in required technology costs for auto manufacturers compared to the previous standards.

EPA also considered the Global Automakers’ concern that freezing the standards from MY 2021-2026 as proposed could result in stranded capital for the auto industry and automotive suppliers who have invested significantly in meeting the previous standards. The standards EPA is finalizing today, unlike the proposed preferred alternative, will require the gradual increase in CO_2 improvements across the fleet, at a rate of 1.5 percent per year stringency improvement, thus supporting investments in GHG-reducing technologies, at a pace that EPA believes is more reasonable than that of the previous standards.

EPA disagrees with CBD et al.’s comments that the agency’s consideration of costs is inappropriate or not supported by the record. EPA disagrees that Congress intended section 202(a)(2)’s requirement to give “appropriate consideration to the cost of compliance within such period” to mean that the agency “only consider compliance costs if they are so severe as to preclude deployment of the requisite technology during the period.” EPA does not interpret the Clean Air Act as limiting EPA’s consideration of costs to manufacturers only to the question of whether such costs are so high that a manufacturer could not afford to deploy the technology in question for a given model year—that would be tantamount to suggesting that EPA must always set a standard to achieve “the greatest degree of emission reduction achievable through the application of technology,” which as discussed above is not EPA’s approach to setting standards such as these under section 202(a). And this is particularly important when setting CO_2 standards, which, as described above, have a significant impact on vehicle utility and performance that differs from other standards established under Section 202. As discussed above, Congress specified such technology-forcing standards elsewhere in section 202 and could have done so here (or otherwise specified that standards shall take effect “as soon as practicable” while taking into consideration costs and other factors)—but did not do so. Section 202(a) prevents EPA from implementing standards sooner than feasible, taking into account lead time considerations and the cost of compliance, but does not require standards be implemented as soon as feasible or at the limit of feasibility, taking into account the cost of compliance. EPA notes that it received numerous comments on the analysis underlying the proposed rule, and the analysis for this final rule in fact was changed from the proposal in consideration of these comments, as discussed in Section VI.B. Nevertheless, the projected costs to comply with the previous MY 2021-2026 standards remain significant as discussed above, and EPA has considered these costs along with other factors under the CAA in determining the final standards, as discussed in Section VIII.A.3.h) below.

c) Consideration of Costs to Consumers

In this section EPA considers the cost impacts on consumers. First, the initial up-front costs to consumers are discussed, then the costs associated with fuel expenditures, and finally the total ownership costs to consumers over the life of the vehicles.

In addition to the $1,250 per-vehicle technology costs to the automotive industry described above, which EPA expects could, and likely would, be passed on to consumers, the analysis estimates other per-vehicle costs that could be borne by consumers, specifically costs attributed to changes in financing, insurance, taxes, and other fees, as shown in Section VII. Considering these additional costs, EPA's final standards (Alternative 3) would result in reduced costs to consumers of $1,385 in MY 2029 (at a 3 percent discount rate) compared to EPA's previously issued standards. While alternatives lower in stringency than the final standards would save consumers more (i.e., Alternatives 1 and 2 would save consumers $1,665 and $1,637, respectively, in MY 2029 at 3 percent discount rate), while alternatives more stringent than the final standards would save consumers less (i.e., Alternatives 4 through 7 would save consumers a range of from $1,329 to $620, for MY 2029 at 3 percent discount rate), this is only one of the factors EPA considers in setting standards. On balance, EPA believes that further increases in stringency, compared to the proposal, are appropriate and reasonable.

Compared to the previously issued CO_2 standards, the standards finalized today will result in increased fuel consumption and associated expenditures for consumers. The analysis detailed in the *Federal Register* notice and summarized in Section VII of this FRIA projects the increased fuel consumption for owners of the vehicle over the projected life of the vehicle, up to 39 years, as compared to the previously issued standards as the baseline. For example, as shown in Table VII-84 (at a 3 percent discount rate), consumers will spend $1,461 more in fuel costs over the vehicle lifetime, which the analysis assumes can be up to 39 years, [2629] under today's final standards (Alternative 3) compared to the previously issued standards.

EPA notes that, when comparing lifetime fuel savings for all owners of a vehicle to the upfront additional ownership costs—generally borne by the initial purchaser, a net reduction in benefits of $175 is seen under the final standards. That said, as noted by several commenters, consumers keep vehicles for a much shorter period of time prior to trading the vehicle in for

[2629] For further information of on the modeled distribution of registrations by age see, e.g., Table VI-238 – Registrations, Total VMT, and Proportions of Total VMT by Vehicle Age (in Section VII.D.2.b).2.(d)) which shows the distribution of registrations by vehicle age.

another or selling the vehicle.[2630] CFA, for instance mentioned that consumers retain vehicles for more than five years, and a group of State Comptrollers and Treasurers referred to an IHS Markit report that the average length of time a consumer keeps a new car is approximately 6.6 years. Accordingly, such a simplistic comparative approach would anticipate that a consumer account for fuel savings over a much longer period of time than would be rational. Further, it is important to note that consumers are informed of estimated average annual fuel costs for the vehicle, as well as a comparison of the difference between five years'-worth of fuel costs or savings compared to an average new vehicle on the Monroney label that must be posted on every new vehicle offered for sale.

In the 2017 Final Determination, EPA projected that the previous MY 2022-2025 standards compared to the MY 2021 standards would provide fuel savings of $52 billion to $92 billion and total net benefits of $59 billion to $98 billion (in 2015 dollars and at 7 percent and 3 percent discount rates, respectively, and based on AEO2016 reference case fuel prices). The up-front vehicle costs to consumers were projected to be approximately $926 per vehicle, including the vehicle technology costs, taxes and insurance.[2631] EPA projected that consumers would realize net savings of $1,650 over the lifetime of a new MY 2025 vehicle (net of increased lifetime costs and lifetime fuel savings).[2632] Under the final standards, vehicle sales are expected to increase by 2.2 million vehicles over MY 2017-2029 compared to projected sales under the previous standards. EPA views this projection of vehicle sales increases resulting from the final standards as important in facilitating the turnover of the fleet to newer, safer vehicles, all of which will be subject to increasingly stringent criteria pollutant emission requirements as federal Tier 3 emission standards continue to phase in from MY 2017 through MY 2025.

Below the major comments are summarized regarding EPA's consideration of the impact of the revised standards on consumers. Securing America's Future Energy (SAFE) commented that vehicle prices are influenced by many factors beyond the GHG standards, and that costs to improve fuel economy make up only a portion of the vehicle price. SAFE notes that fuel savings from efficient vehicles offsets increase ownership costs. SAFE further claims, without support, that standards "do not have a major role in creating higher vehicle prices, or in suppressing sales." Accordingly, SAFE argues that pausing fuel economy increases, as proposed in the NPRM, is not justified. SAFE suggests that fuel savings impacts should be discussed along with technology cost increases.

CBD and others commented that EPA's consideration of consumer costs, including finance and insurance costs, cannot outweigh its public health mandate. Such commenters noted that some of the options analyzed in the notice showed that fuel savings of the lifetime of the vehicle outweighed upfront vehicle price increases, and that not choosing such an alternative is

---

[2630] It should be noted, however, that, all else being equal, improved fuel economy can improve resale value of a vehicle. That said, it is not at all clear that consumers generally anticipate potential future incremental trade-in value attributable to improved fuel economy when making a decision as to which new vehicle to purchase.

Again, note the different points of reference for the values presented in this final rule and the 2017 Final Determination in, as discussed above.

not justified. CBD then goes on to argue that the analysis inflates technology costs and undercounts fuel savings.

The California Attorney General and others claim that EPA's consideration of the potential increased costs for consumers related to maintenance, financing, insurance, taxes, and other fees is unjustified, unlawful, and contrary to its prior position that compliance cost considerations include only costs to the motor-vehicle industry.

EPA notes that fuel efficiency and GHG standards affect labor and materials costs, technology add-ons, and sales mix, and expects the estimated cost decrease from these final standards to have a positive effect on the auto market and vehicle buyers. As described in the notice and throughout this FRIA, EPA disagrees that standards have no major impact on increasing prices or suppressing sales. Fuel-saving technology adds costs, and as prices increase, fewer consumers can afford to buy new cars—either because they cannot afford a new car, or because they decide to purchase an older vehicle, or because they decide to keep their existing vehicle. EPA also notes that both the notice and this FRIA discuss fuel savings from the various alternatives analyzed. Some commenters suggest EPA calculate and consider fuel savings, spread over the lifetime of the vehicle up to 39 years and experienced by multiple owners—compared to the upfront vehicle costs, which are generally paid for by the original purchaser either in cash or through additional finance costs over a much shorter period of time. This approach, which would yield a projected $175 in additional costs (additional lifetime outlays for fuel minus avoided upfront vehicle costs) over the multi-owner, lifetime of a vehicle beyond the initial ownership savings, distorts the comparison. Instead, EPA concludes that the upfront vehicle technology costs (and associated financing costs) are a more important factor. In other words, a consumer is more likely to buy a new vehicle at a lower up-front price even if that vehicle will incur a more-than offsetting level of fuel costs over its lifetime that will be borne by the first and all subsequent owners of the vehicle. [2633] By reducing upfront costs, more consumers will be able to afford new vehicles, which will result in a quicker fleet turnover to safer, more efficient vehicles that emit lower amounts of criteria pollutants than the existing fleet. In fact, the agencies project that the revised standards will result in 2.2 million additional new vehicles sold—all of which would meet the latest safety standards and be subject to the phase-in of the Tier 3 criteria pollutant emission standards.

With respect to the comments that consideration of costs to consumers is contrary to CAA section 202(a)(2), EPA disagrees. As discussed above, section 202(a)(2) requires EPA to consider the cost of compliance, which EPA has done, and it allows EPA to consider other costs, including costs to consumers, which EPA also have done, in this rule and past rules setting standards under section 202(a). The statute sets some minimum requirements for EPA's consideration, but permits a wider range of concerns to be considered, including public health and welfare but also safety, costs to consumers, and other factors discussed herein. As discussed above, and below, EPA has considered the effects of a range of potential standards across this

[2633] For further discussion regarding consumers valuation of fuel economy, see preamble section VI.D.1.b).(2) (sales), preamble section VI.D.1.b).(8), and Final Regulatory Impact Analysis section III.C.

entire set of factors. The agency is permitted to take all of these factors into account, and that is what it has done in selecting the final standards.

d) Consideration of GHG Emissions and Other Air Pollutant Emissions

As discussed above, the purpose of GHG standards established under CAA section 202 is to reduce GHG emissions, which EPA has found to endanger public health and welfare, in an appropriate manner that takes into account other factors as directed by Congress and in the reasonable exercise of EPA's discretion under the statute. Today's final standards are projected to increase CO_2 emissions compared to the previously issued standards, by a total of 867 million metric tons (MMT) over the lifetime of MY 1977 through MY 2029 vehicles (see Section VII of this FRIA)—i.e., by 2.9% of the amount projected to be attributable to passenger cars and light trucks under the baseline/augural standards. Of this CO_2 emissions increase, 731 MMT would come from tailpipe emissions, and an additional 136 MMT from upstream sources, both being nearly 3% greater than projected to occur under the baseline/augural standards. The analysis projects that Alternatives more stringent than the final standards would result in smaller increases in CO_2 emissions. Also compared to the baseline/augural standards, and also over the lifetime of MY 1977-2029 vehicles, Alternatives 4 through 7 are projected to increase CO_2 emissions by 826 MMT (2.8%) to 361 MMT (1.2%). Alternatives less stringent than the final standards would increase CO_2 emissions by a greater amount, 1,074 MMT (3.5%) and 1,044 MMT (3.6%), for Alternatives 1 and 2 respectively.[2634]

In addition to GHG emissions, EPA has considered the change in criteria air pollutant emissions impacts due to the revised CO_2 standards. EPA has considered both tailpipe emissions and upstream emissions associated with increased fuel consumption. Unlike with CO_2 emissions, which EPA found to be a long-lived greenhouse gas well-mixed throughout the global atmosphere, criteria pollutant emissions contribute primarily to local and regional air pollution. Generally, tailpipe emissions for volatile organic compounds (VOC), nitrogen oxides (NOx), and particulate matter (PM) decrease under the final standards compared to the previous standards, leading to improvements in human health in areas where air quality improves. Upstream emissions attributable to refining and transportation of the additional fuel needed under less stringent standards increase under the final standards, leading to adverse impacts on public health in locations where air quality worsens. The additional upstream emissions generally exceed the reduced tailpipe emissions, leading to net increases in these pollutants and net increases in adverse health effects. Under the model year analysis (changes in pollutants summed over the

[2634] This FRIA estimates annual GHG emissions from light-duty vehicles under the baseline CO_2 standards, the final standards, and the standards defined by each of the other regulatory alternatives considered. For the final rule issued in 2012, EPA estimated changes in atmospheric CO_2, global temperature, and sea level rise using GCAM and MAGICC with outputs from its OMEGA model. Because the agencies are now using the same model and inputs, outputs from NHTSA's EIS (that used more recent versions of GCAM and MAGICC) were analyzed. Today's analysis estimates that annual GHG emissions from light-duty vehicles under the CO_2 standards and corresponding CAFE standards, which are very similar. Especially considering the uncertainties involved in estimating future climate impacts, the very similar estimates of future GHG emissions under CO_2 standards and corresponding CAFE standards means that climate impacts presented in NHTSA's EIS represent well the climate impacts of the CO_2 standards.

lifetimes of MY 1977-2029 vehicles for calendar year 2017 and later), and relative to total emissions projected to be attributable to passenger car and light trucks under the baseline/augural standards, these increases range from 0.1% (for NOx) to 0.7% (for SO_2 and PM). On the other hand, projected net emissions of carbon monoxide (CO) are 0.4% lower under the final standards than under the baseline/augural standards, and emissions of air toxics (e.g., benzene) are 0.1-0.4% lower under the final standards, varying among different toxic compounds.

In addition to evaluating emissions impacts under the model year analysis described above, EPA has considered the emissions impacts under a calendar year analysis, which provides information over a longer time horizon about the interactions between all vehicle model years on the road in any given calendar year—that is, considering the effects of the revised MY 2021 and later standards on fleet turnover and utilization from calendar year 2017 out to 2050. Both the model year analysis and the calendar year analysis provide relevant information about the impacts of EPA's standards. When viewed from the calendar year analysis perspective that extends through 2050, the emissions impacts of the revised MY 2021 and later standards compared to the baseline/augural standards vary over time, with cumulative differences generally being greater in magnitude than under the model year analysis: EPA's analysis shows cumulative VOC emissions through 2050 under the final standards increasing by a total of nearly 575 thousand tons (1.9%) relative to the cumulative amount projected to accrue through 2050 under the baseline/augural standards. On the same basis, estimated NOx and PM emissions increase by about 173 thousand tons (0.8%) and 16.5 thousand tons (1.7%), respectively. On the other hand, also on the same basis, estimated CO and SO_2 emissions decrease by about 278 thousand tons (0.1%) and 38 thousand tons (0.8%), respectively.

As shown in the NHTSA Final Environmental Impact Statement (FEIS), NHTSA's analysis indicates small air quality improvements in some areas and small decrements in others which could help or hinder individual areas' efforts to attain the NAAQS in the future.

EPA has also considered the health effects of air pollution associated with today's final standards. As discussed above, it is the cumulative contribution of the lower projected vehicle tailpipe emissions with the higher projected upstream emissions (primarily from the production and distribution of gasoline) which impact air quality. As noted above and presented in detail elsewhere in this FRIA, vehicle emissions are generally reduced due to the SAFE final rule.

Due largely to the projected increase in upstream emissions resulting from the increased production and transportation of gasoline resulting from the standards finalized today compared to the previous EPA standards, the Final Rule analysis projects increases in premature deaths, asthma exacerbation, respiratory symptoms, non-fatal heart attacks, and a wide range of other health impacts. While these health impacts are presented in detail elsewhere in this FRIA, two factors suggest that the forgone premature mortality benefits are overstated. First, in the last year, EPA has completed analysis that demonstrated the likelihood that the air quality modeling approach used here (i.e., benefits per ton) overestimates foregone PM premature mortality benefits. Second, the 2012 rulemaking significantly overestimated gasoline price projections in its baseline, predicting lower fuel consumption, thus overestimating the premature mortality benefits in that rule. While gasoline price projections in this rulemaking have been updated to reflect recent data, the potential for this kind of unanticipated fluctuation in gasoline prices remains, thus estimates of fuel consumption and the correlated foregone premature mortality benefits may not capture actual market outcomes.

The valuation of premature mortality effects rely on the results of "benefits per ton" approach (BPT). This approach is a reduced form approach, which is less complex than full-scale air quality modeling, requiring less agency resources and time. Based on EPA's work to examine reduced form approach, the BPT may yield estimates of $PM_{2.5}$- benefits for the mobile sector that are as much as 10 percent greater than those estimated when using full air quality modeling.

The EPA is currently working on a systematic comparison of results from its BPT technique and other reduced-form techniques with results from full-form photochemical modelling. While this analysis employed photochemical modeling simulations, we acknowledge that the Agency has elsewhere applied reduced-form techniques. The summary report from the "Reduced Form Tool Evaluation Project", which has not yet been peer reviewed, is available on EPA's website at *https://www.epa.gov/benmap/reduced-form-evaluation-project-report*. Under the scenarios examined in that report, EPA's BPT approach in the 2012 rule (which was based off a 2005 inventory) may yield estimates of $PM_{2.5}$- benefits for the mobile sector that are as much as 10 percent greater than those estimated when using full air quality modeling. The estimate increases to 30 percent greater for the electricity sector. The EPA continues to work to develop refined reduced-form approaches for estimating $PM_{2.5}$ benefits.

Also, in this regulation, a key projection that influences the estimation about car purchase and driving behavior is the gasoline price projection. From 2008 through 2018, the average monthly gasoline price ranged from less $1/gallon to $4/gallon.[2635] The gasoline price level and the volatility of price changes are major drivers of car purchasing behavior thereby gasoline consumption and the resulting criteria pollutant emissions. If gasoline prices are lower than projected in an analysis, consumers are more likely to purchase less fuel efficient cars, resulting in more emissions and vice versa.

With a lower fuel price projection and an expectation that new vehicle buyers respond to fuel prices, the 2012 rule would have shown much smaller fuel savings attributable to the more stringent standards. Projected fuel prices are considerably lower today than in 2012. The agencies now understand new vehicle buyers to be at least somewhat responsive to fuel prices, and the agencies have therefore updated corresponding model inputs to produce an analysis the agencies consider to be more realistic.

The first of these assumptions, fuel prices, was simply an artifact of the timing of the rule. Following recent periodic spikes in the national average gasoline price and continued volatility after the great recession, the fuel price forecast then produced by EIA (as part of AEO 2011) showed a steady march toward historically high, sustained gasoline prices in the United States. However, the actual series of fuel prices has skewed much lower. As it has turned out, the observed fuel price in the years between the 2012 final rule and this rule has frequently been lower than the "Low Oil Price" sensitivity case in the 2011 AEO, even when adjusted for

[2635] https://www.eia.gov/energyexplained/gasoline/price-fluctuations.php.

inflation. The discrepancy in fuel prices is important to the discussion of differences between the current rule and the 2012 final rule, because that discrepancy leads in turn to differences in analytical outputs and thus to differences in what the agencies consider in assessing what levels of standards are reasonable, appropriate, and/or maximum feasible. Long-term predictions are challenging and the fuel price projections in the 2012 rule were within the range of conventional wisdom *at the time*. However, it does suggest that fuel economy and tailpipe CO_2 regulations set almost two decades into the future are vulnerable to surprises, in some ways, and reinforces the value of being able to adjust course when critical assumptions are proven inaccurate. This value was codified in regulation when EPA bound itself to the mid-term evaluation process as part of the 2012 final rule.[2636]

Because of these uncertainties surrounding air quality modeling of premature mortality effects, the projections of foregone PM premature mortality benefits are uncertain and may be over-stated. Fluctuations in gasoline prices contribute to this uncertainty, making it difficult to accurately project gasoline consumption and its related premature mortality benefits.

The analysis projects that the air pollution emission increases associated with the revised standards will lead to an increase of 440 to 1,000 premature deaths—deaths that occur before the normally expected life span—0.5% more than the number of such deaths projected to occur under the baseline/augural standards and over the lifetime of the MY 1977-MY 2029 vehicles. In addition, a wide range of health impacts are projected to increase by 0.4-0.6% under the final standards compared to occurrences projected to occur the standards established in 2012, as summarized in the Preamble's Table VII-132 *et. seq*.

When quantified using the calendar year (CY) analysis perspective (CYs 2018-2050), under the revised final standards (compared to the previous standards), premature mortality is expected to increase from 460 to 1,010 deaths (i.e., by 0.4%), upper and lower respiratory symptoms are expected to increase by 22,000 cases (0.4%), asthma exacerbations are projected to increase by 16,000 cases (0.4%), acute bronchitis cases are projected by increase by 720 (0.4%), non-fatal heart attacks are projected to increase by 450 (0.4%), hospital admissions for cardiovascular and respiratory issues are projected to increase by 225 (0.4%) cases, and emergency room visits for respiratory issues are projected to increase by 260 (0.4%). In addition, these additional health impacts are expected to result in an additional 61,000 work loss days (0.3% of the number projected under the baseline/augural standards) and 355,000 minor restricted activity days (0.4% more than under that baseline/augural standards) for the public. Compared to the baseline/augural standards, the agencies estimate that the final standards rule will increase by 0.3-0.4% each of the various health impacts accumulated through 2050 (e.g., premature deaths, upper and lower respiratory symptoms, asthma exacerbations, acute bronchitis cases, hospital admissions for cardiovascular and respiratory issues, emergency room visits for respiratory issues).

[2636] *See* 40 CFR 86-1818-12(h).

In the 2017 Final Determination, EPA projected GHG emissions reductions of 540 million metric tons over the lifetimes of MY 2022-2025 vehicles.[2637] EPA also projected criteria pollutant emission reductions for CY2040 of 97,000 tons of VOC, 24,000 tons of NOx, 3,600 tons of $PM_{2.5}$, and 15,000 tons of SO_2.[2638] EPA projected that these emissions reductions would result in positive health benefits through CY2050.[2639] In this final rule, the revised final standards compared to the previous standards are projected to result in an increase in emissions and health incidences, as discussed above, resulting in $5 billion or $3 billion (in 2018 $, and reflecting, respectively, either a 7 percent or 3 percent discount rate) in foregone public health benefits (see Preamble Tables VII-103 and VII-104).

In public comments on these topics, the Attorney General of California and others commented that, in adopting the previous standards, EPA focused on obtaining significant CO_2 emission reductions, but now proposed to increase emissions relative to the previous standards without sufficient justification. They claim that EPA offered no justification of acknowledgement of a change in position, stating that none of the alternatives further the goal of CO_2 emission reductions. They argue that EPA justifies its proposal on the limited impact of the rule on global climate change, and that failing to seek incremental improvements is contrary to the EPA's duties under the Clean Air Act.

The United States Conference of Catholic Bishops commented that considering public safety of any set of standards requires giving significant weight to the effect of air pollution, and that the proposal failed to promote public health and safety.

The Chesapeake Bay Foundation (CBF) claims that the proposal would have significant health consequences that disproportionately impact minority and low-income communities in the Chesapeake Bay. They discuss general impacts of climate change CBF argues that criteria pollutant health impacts of the proposal, should be more heavily weighed against safety impacts of the rule.

The State of Washington commented that the agencies did not analyze public health effects from increased criteria pollutant emissions arising from increased petroleum consumption or environmental justice concerns. They claim that the NPRM's discussion of the negligible impact of the rulemaking on global climate change is "deeply concerning."

As noted above, EPA agrees that the purpose of Title II emission standards is to protect the public health and welfare from air pollution, and in establishing emission standards, the agency is cognizant of the importance of this goal. At the same time, EPA balances multiple factors in determining what standards are reasonable and appropriate. And, contrary to some commenters' views, unlike other provisions in Title II, section 202(a) does not require the Administrator to set standards which result in the greatest degree of emissions control achievable. Thus, in setting these standards, the Administrator has taken into consideration other factors discussed above and below, including not only technological feasibility, lead-time, and

[2637] 2017 Final Determination at Table ES-3, page 6, and Section II (iv), page 24.
[2638] 2016 Proposed Determination at Appendix C, Table C.54, page A-163.
[2639] *Id.* at Table C.87, page A-183.

the cost of compliance, but also potential impacts of vehicle emission standards on safety and other impacts on consumers.

Several commenters claimed that the agencies did not analyze health impacts of the various alternatives, but this is not accurate. First, the notice and PRIA included this information in monetized terms to facilitate the balancing of various factors. Further, NHTSA conducted a comprehensive Draft Environmental Impact Statement, which discussed these effects in detail. For this final rule, these health impacts have been separately itemized, as summarized above. Other commenters claimed that the agencies did not sufficiently consider environmental justice elements in the proposal. This, too, is inaccurate, as discussed elsewhere in this FRIA.

In response to comments of the California Attorney General and others, that the Clean Air Act cannot allow for increases in a regulated emission, EPA notes that the 2012 Final Rule specifically called for a Mid Term Evaluation process that envisioned the potential for an adjustment of the standards in case the stringency increases established in 2012 were no longer reasonable and appropriate. As discussed above, the increases in stringency of the standards for MY 2021-2025 are, on balance, not reasonable and appropriate based on a consideration of the factors described in this FRIA. EPA now recognizes based on updated information and analysis that industry should be provided additional lead time to meet the later model years of standards set in the 2012 rule, and, as discussed in this FRIA, industry is having unanticipated difficulties complying with earlier years of the standards, with fleetwide performance failing to meet CO_2 emission targets in MY 2016 and MY 2017. That is not to say that CO_2 and criteria pollutant emissions are not significant factors in this rulemaking. Indeed, they are weighed heavily along with other important factors considered by EPA, which has led to increasing stringency on a 1.5 percent annual basis for the 2021-2026 model years. Importantly, the agencies project that the revised standards will result in an additional 2 million new vehicles sold before 2030 compared to under the baseline/augural standards. This means that an additional 2 million vehicles will be produced during the phase-in of the Tier 3 emission standards, which implement more stringent tailpipe standards for criteria pollutants, displacing greater numbers of higher-emitting older vehicles and providing significant health benefits. As discussed, when finalizing the Tier 3 standards in 2014, "[t]he final Tier 3 vehicle and fuel standards together will reduce dramatically emissions of NOx, VOC, $PM_{2.5}$, and air toxics."[2640]

Although GHG emissions reductions would be lessened under the standards finalized today compared to the previously issued EPA standards, in light of this assessment indicating higher vehicle costs and associated impacts on consumers, EPA believes that, on balance, the final standards (Alternative 3) are justified and appropriate.

e) Consideration of Consumer Choice

EPA believes that consumer demand is an important consideration in setting CO_2 emission standards, because one of EPA's goals in setting the standards has been and continues to be to allow manufacturers to provide, and consumers to purchase, vehicles with varying attributes and functionality rather than to shift demand to certain vehicle types or sizes. Societal

[2640] 79 FR 23425.

and economic trends play a role in this area as well—if fuel prices are relatively high, demand for fuel-efficient vehicles increase and, as a result, compliance with standards is easier to achieve. If fuel prices are relatively low—as they are now and are projected to be in the mid-term—consumer demand for fuel-efficiency is less strong, making it harder for manufacturers to comply with the standard. While manufacturer difficulty in complying due to lack of consumer demand may not be the deciding factor in determining the appropriate levels of stringency for standards, it is relevant to understanding lead time difficulties, which EPA is required to consider under Section 202(a)(2).

As discussed previously, the EPA CO_2 standards are based on vehicle footprint, and in general smaller footprint vehicles have individual CO_2 targets that are lower (more stringent) than larger footprint vehicles. The passenger car fleet has footprint curves that are distinct from the light-truck fleet. One of EPA's goals in designing the footprint-based standards, in considering the shape, slope, and stringency of the footprint standard curves, and in adopting various compliance flexibilities (e.g., emissions averaging, banking, and trading, air-conditioning credits, off-cycle credits) was to maintain consumer choice. The EPA standards are designed to require reductions of CO_2 emissions over time from the vehicle fleet as a whole, but also to provide sufficient flexibility to the automotive manufacturers so that firms can produce vehicles that serve the needs of their customers. The past several model years in the marketplace show that, while this approach reduces the impact of increased fuel economy on consumer choice, it does not adequately account for changes in consumer preference. As a result, as discussed throughout this FRIA, manufactures are struggling to meet CO_2 emission standards based upon their fleet performance. In fact, the 2017 model year saw that only three major manufacturers had fleets that met the standards. One reason behind these challenges is that, while the footprint-based attribute standards account for vehicle length and width, they do not account for vehicle height or weight. And, since many crossovers sold today are classified as passenger cars and not light trucks, the additional weight of such vehicles to provide for requisite ride height puts pressure on CO_2 emission compliance for automaker passenger car fleets. Similarly, large SUVs are subject to the same footprint-based standards as lighter trucks, putting pressure on CO_2 emission standard compliance. For the 2017 model year, 12 percent of the fleet consisted of car-based SUVs, and 32 percent of the fleet consisted of truck-based SUVs. Taller and heavier vehicles, including crossovers and SUVs, are more popular today than was expected at the time the standards were set[2641]. While automobile manufacturers have continued to offer a broad range of vehicles (e.g., full-size pick-up trucks with high towing capabilities, minivans, cross-over vehicles, SUVs, and passenger cars; vehicles with off-road capabilities; luxury/premium vehicles, supercars, performance vehicles, entry level vehicles, etc.) despite continuing required increases in fuel economy stringency, this has largely been possible because of well-stocked over-compliance credit banks from when standards were less stringent and the ability to acquire credits from other manufacturers. As mentioned earlier, the agencies have concerns whether this is sustainable. Automotive companies have been able to reduce their fleet-wide CO_2 emissions while continuing to produce and sell the many diverse products that serve the needs of

[2641] 2018 EPA Automotive Trends Report: Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975, available at: https://www.epa.gov/automotive-trends/download-automotive-trends-report.

consumers in the market. The agencies recognize that automotive customers are diverse, that automotive companies do not all compete for the same segments of the market, and that increasing stringency in the standards can be expected to have different effects not only on certain vehicle segments but also on certain manufacturers that have developed market strategies around those vehicle segments. Taking into consideration this diversity of the automotive customer base, and of the strategies which have developed to meet specific segments, EPA concludes that the previous standards are not reasonable or appropriate.

In the initial determination, EPA assessed several factors related to consumer choice, including the costs to consumers of new vehicles and fuel savings to consumers, as described in Preamble SectionVII.A.2.c. In 2017, EPA found that the previous standards would increase the upfront costs of vehicles but overall would have positive net benefits because lifetime fuel savings outweighed the lifetime vehicle costs for consumers. As discussed above, the costs of technology to comply with the standards are generally borne by the initial purchaser, with understanding of fuel cost implication given statutorily required disclosures. In contrast, the fuel savings are realized by many subsequent owners over the vehicles' lifetime, which this analysis assumes can be up to 39 years. New vehicle purchasers are not likely to place as much weight on fuel savings that will be realized by subsequent owners. Accordingly, EPA is placing greater weight on the up-front vehicle cost savings to consumers in light of the goal of accelerating the turnover of the motor vehicle fleet to safer cars that emit fewer criteria pollutants.

EPA received many comments regarding the agency's consideration of consumer choice in determining appropriate standards under section 202(a) of the CAA. The Alliance commented that EPA's concerns regarding consumer choice are well founded, stating "in the years since 2012 (and in part due to the unexpected decrease in fuel prices), consumers have demonstrated less interest in high-efficiency/low-emission vehicles than EPA and NHTSA projected in issuing the 2012 Final Rule. As such, compliance with the existing standards would require a substantially greater variance than EPA expected from the vehicle fleet that consumers would otherwise choose."

Global Automakers agreed that consumer acceptance is an important factor, but does not justify holding standards flat through the 2026 model year. Global Automakers further commented that "[f]uel economy remains a factor in vehicle purchase decisions, though perhaps not a dominant one."

CBD and others commented that the Clean Air Act does not allow EPA to reduce stringency based upon consumer choice factors. They point to the diversity of the vehicle fleet and argue that EPA's consideration of projected tech levels and associated costs as "speculative" and not grounded in fact.

U.S. Congressman Mark DeSaulnier claimed that the justification for the proposal appeared to be consumer willingness to buy new vehicles. He claimed that absent any standards whatsoever, automakers could produce more vehicles that consumers would want to purchase. He stated that the standards require all vehicles to become more efficient and that EPA has an overly simplistic understanding of American consumers, who, according to him, are "wary of the price tag" when shopping, but, nonetheless, "overwhelmingly want more efficient vehicles, and they want to reduce the health burden of air pollution."

The Institute for Policy Integrity (IPI) claims, without support, that as fuel efficiency technology is introduced and becomes widespread, consumer attitudes will change and will start focusing on such technology. IPI also claims that manufacturers can change consumer preference through advertising. IPI implies that manufactures play a larger role in shaping consumer options of their needs that consumers do themselves. IPI also comments that academic literature relating to demand- and supply-side obstacles to fuel economy indicates that the proposal's justification runs counter to available evidence.

The University of California Berkeley Environmental Law Clinic (Berkeley) argued against EPA's consideration of consumer choice in setting standards, claiming that low-income households bear exposure to operating costs, fuel price fluctuations, and environmental impacts. Berkeley also claimed that EPA's purported list of features consumers may favor over fuel economy is not supported by evidence, and, in any event, should be categorized into lists of "needs" versus "wants."

Consumer choice is a complex consideration when setting standards. As Congressman DeSaulnier correctly notes, EPA cannot disregard its consideration of public health and welfare based upon the agency-projected whims of consumers. At the same time, the willingness of consumers to pay for fuel economy improvements, which as described above affects vehicle performance and utility in a manner distinguishable from criteria pollutant emissions, has a direct effect upon the ability of manufacturers to sell their product. And as consumers demand vehicles with increased ride height (which, all else being equal, increases CO_2 emissions), establishing standards that account for this—but still require manufacturers to focus on improving emission performance, is reasonable and appropriate.

In response to Global Automakers' comment that consumers do not heavily focus on fuel economy in making purchase decisions, EPA agrees, but notes that this is a consumer's choice, as federal law requires that consumers are made aware of fuel economy impacts, pursuant to 49 U.S.C. 32908. EPA also agrees that the willingness to pay for fuel economy improvements is "not zero."

EPA agrees with the Global Automakers comment that while consumer choice is an important consideration in determining the appropriate level of the revised standards, the final rule analysis does not support holding the standards constant. Although EPA proposed standards at the level of 0 percent increase in stringency from MY 2021 and later, after considering the comments received and based on the updated analysis for this final rule, EPA is finalizing standards with a 1.5 percent per year improvement in stringency from MY 2021 to MY 2026. As indicated in the comments on this topic, there is a range of views and relevant information concerning the extent of consumers' interest in fuel economy and on the role fuel savings plays in consumer purchase decisions.[2642] EPA's understanding is that some consumers value fuel

[2642] Studies of the role of fuel economy in consumer purchase decisions have found a wide range of values (Greene, D., A. Hossain, J. Hofmann, G. Helfand, and R. Beach. "Consumer Willingness to Pay for Vehicle Attributes: What Do We Know?" *Transportation Research Part A* 118 (2018), p. 258-79.). The National Academy of Sciences in 2015 judged that "there is a good deal of evidence that the market appears to undervalue fuel economy relative to its economy more than others, and EPA finds it unnecessary to identify the precise role of fuel economy in consumer purchase decisions because the Administrator believes that the standards should encourage a range of vehicles meeting a range of consumer preferences. Further, as described above, consumers are made aware of the relative fuel price impacts of new vehicles, given the required information label on new vehicles, thus indicating that, in all likelihood, consumers do take fuel expenses into account when making new vehicle purchase decisions.

EPA disagrees with Congressman DeSaulnier's assertion that EPA seeks to set standards that do not affect what manufacturers produce—instead, the agencies examine what consumers are purchasing in the market to determine what standards are appropriate. The agency's assumptions in 2012—that consumers would gravitate toward the purchase of compact sedans and coupes in response to exceedingly high fuel prices—have proved incorrect. Fuel prices have fallen and remained relatively low, and are projected to remain relatively low throughout the period covered by this rulemaking. EPA seeks to achieve improvements in CO_2 emissions, but it is not realistic to expect the high demand for crossover vehicles to abate, or for those vehicles to meet more-stringent standards set for compact sedans. That said, EPA agrees with Congressman DeSaulnier that American consumers are wary of the price of vehicles—popular reporting that consumers may reference explain affordability concerns in crisis terms—even indicating that the average price of a vehicle is now beyond that which is affordable to the median household income of every city outside of Washington, D.C.[2643] This results in significant adverse economic impacts—higher finance charges, taxes, registration fees, and insurance costs, all of which result in challenges qualifying for financing and longer finance terms, which increase the likelihood of negative equity scenarios. EPA also agrees with Congressman DeSaulnier that consumers want increased fuel efficiency and to reduce the impacts of harmful air pollution. These are all true. But direct health impacts of vehicles emissions stem more from criteria pollutant emissions than from CO_2 emissions. And CO_2 emission technology has a significant relationship to the price of vehicles for which consumers are so wary. EPA, with this rulemaking, is attempting to strike the correct balance between a number of factors, including improving efficiency and affordability, which should yield additional sales and an improved rate of fleet turnover to vehicles that have better criteria pollutant emissions—particularly since the vehicles sold subject to this rulemaking will be sold during the phase-in of Tier 3 criteria pollutant emission standards.

In response to Berkeley, low-income consumers are even more sensitive to upfront vehicle purchase prices than they are to the smaller delta between weekly or monthly fuel costs experienced over time between the previous standards and the standards finalized today—they

---

expected present value, but recent work suggests that there could be many reasons underlying this, and that it may not be true for all consumers." National Research Council of the National Academies (2015). *Cost, Effectiveness, and Deployment of Fuel Economy Technologies for Light-Duty Vehicles.* Washington, DC: National Academies Press, p. 9-16.

[2643] *See.*, *e.g.*, Car and Driver, "For Middle-Class Shoppers, New Cars Are Moving out of Reach" November 30, 2019. Available at: https://www.caranddriver.com/news/a30061910/middle-class-car-shoppers-priced-out/; New York Times, "New Cars Are Too Expensive for the Typical Family, Study Finds" July 2, 2016. may well take note of the fact that one cannot pay today's bills with tomorrow's savings. They may also want to take note that the standards finalized today are projected to improve fleet turnover into newer vehicles that emit reduced criteria pollutants.

EPA disagrees with the assertion by CBD and others that the agency has not provided a rationale for its consideration of consumer choice in determining the appropriate standards. EPA notes that despite a variety of vehicles on the market today and over the past several years, the fleet has failed to comply with standards based upon performance beginning with the 2016 model year, and has fallen further behind in the 2017 model year, when only three major automakers complied with CO_2 emission standards based upon performance alone.

In response to IPI's comment that the deployment of more fuel-efficient technologies, combined with manufacturer advertising, will change consumer preference, this runs counter to historical trends. Manufacturers have continuously deployed additional fuel efficiency technology in each model year—which is why EPA continues to see fleetwide improvements in CO2 emissions on new vehicles. And manufacturers have consistently advertised the fuel economy performance of their vehicles. Federal law requires the physical posting fuel economy performance, as well as estimated and comparative fuel cost information, on every new vehicle offered for sale. Notwithstanding this activity, consumer demand, and willingness to pay for technology that reduces CO2 emissions and improves fuel economy, has not matched required standards—which is one of the reasons that EPA is revising the standards today. As discussed in the proposal, EPA recognizes that the diversity in the automotive customer base, combined with the facts and analysis developed by the agency in this rulemaking, raises concerns that the previous standards, if they are not adjusted, may not continue to fulfill the agency's goal of providing sufficient manufacturer flexibility to meet consumer needs and consumer choice preferences in their vehicle purchasing decisions. In the 2012 Final Rule and the Initial Determination, EPA expected that consumers would readily accept fuel-saving technologies in their new vehicles, despite the agency's uncertainty about the role of fuel savings in consumers' purchase decisions. Given low fuel prices and the pronounced market shift to crossovers and SUVs, notwithstanding required disclosers of fuel costs and relative fuel economy performance, EPA now concludes that it is appropriate to account for the shift in consumer preference in concluding that the standards set in 2012 did not provide sufficient lead time for manufacturers to achieve the standards set at that time. EPA remains concerned that the projected level of hybridization and other advanced technologies and the associated vehicle costs necessary to achieve the previous standards are too high from a consumer-choice perspective, and not sufficiently account for consumer acceptance of such technology. While consumers have benefited from improvements over several decades in traditional vehicle technologies, such as advancements in transmissions and internal combustion engines, electrification technologies are a departure from what consumers have traditionally purchased. Strong hybrid and other advanced electrification technologies have been available for many years (20 years for strong hybrids and eight years for plug-in and all electric vehicles), and sales levels have been relatively low, in the 2-3 percent range.[2644] As discussed above, the analysis projects that the 2012 EPA standards would be projected to require a significant increase in hybridization (up to 8 percent for mild hybrids and 10 percent for strong hybrids in MY 2030). This large increase in technology demand over the next decade could lead to automotive companies needing to change the choice of vehicle types they are able to offer to consumers, compared to what the companies would otherwise have offered in the absence of the previously issued standards. As discussed above, manufacturers are, by and large, not meeting existing standards based upon actual fleet performance in CO_2 emissions and are instead relying upon the use of earned or acquired credits. As the previous standards were set to increase significantly through MY 2020 and thereafter, reducing the rate of increase is appropriate and reasonable. Doing so will provide manufacturers with sufficient lead time to meet the standards being set today.

EPA recognizes that one possibility for automotive companies who wish to retain their current vehicle offerings, but face compliance challenges is to purchase GHG emissions credits. In EPA's annual Automotive Trends Report, EPA has reported that credit trading has occurred frequently in the past several years to achieve compliance with the GHG standards.[2645] Credit trading can lower a manufacturer's costs of compliance, both for those selling and those purchasing credits, and this program compliance flexibility is another tool available to auto firms to allow them to continue offering the types of vehicles that customers want. Between MY 2010 and MY 2017, these trades have included 11 firms, with five firms selling CO_2 credits to seven firms.[2646] The number of firms participating in the GHG credits market represents about one-half of the automotive companies selling vehicles in the U.S. market, but since several of these firms are small players, they represent less than half of the vehicle production volume. In total, approximately 48 million Megagrams of CO_2 credits have been traded between firms, which represents 19 percent of the MY 2017 industry-wide bank of credits. That said, more manufacturers have relied upon previously earned credits to achieve compliance. Between MY 2010 and MY 2017, 80% of firms applied previously earned credits. However, long-term planning is an important consideration for automakers, and an automaker who may need to purchase credits as part of a future compliance strategy is not guaranteed to find credits. The automotive industry is highly competitive, and firms may be reluctant to base their future product strategy on an uncertain future credit availability, but face struggles in achieving CO_2 emission reductions in a manner that meets consumer expectations for cost, utility, and performance. Also, pools of available credits continue to decline over time as the standards become more stringent and previously banked credits are either used or expire; indeed, this has happened in recent years.[2647] EPA's views on the availability of the credit market to aid in manufacturers' compliance have changed since the Initial Determination. Based upon the information available to the EPA in early January 2017, the auto industry had outperformed its

---

[2644] For instance, the 2019 calendar year saw only a 1.4% penetration of battery electric vehicles in the light duty fleet, following 1.2% for 2018, 0.6% for 2017, 0.5% for 2016, and 0.4% for 2015. Wards Auto Monthly Sales reports, available at https://wardsintelligence.informa.com/.
[2645] 2018 EPA Automotive Trends Report at Figures 5.15 and 5.17.
[2646] EPA Greenhouse Gas Emission Standards for Light-Duty Vehicles: Manufacturer Performance Report for the 2016 Model Year. EPA-420-R-18-002. January 2019.
[2647] 2018 EPA Automotive Trends Report at Figure 5.17 and Table 5.17.

standards in the four previous compliance years (MYs 2012-2015) and EPA had viewed that as a positive trend.[2648] Since then, however, overall manufacturer performance failed to meet the standard fleetwide, and many manufacturers relied on credits to meet their individual compliance targets. Furthermore, recent experience suggests that availability of the credit bank is becoming a more uncertain means to achieve compliance.[2649] Thus, while credit trading may be a useful flexibility to reduce the overall costs of the program and to smooth the pathway to compliance realizing necessary transitions from vehicle redesign cycles, EPA believes it is important to set standards that preserve consumer choice without relying on credit purchasing availability as a compliance mechanism. As discussed in Section VII, the agencies project that the EPA final standards (Alternative 3, 1.5 percent year over year stringency improvement), will require more realistic penetration of advanced CO_2 emission technologies such as electrification—better ensuring that manufacturers will be able to provide vehicles that meet consumer demand.

f) Consideration of Safety

As discussed above, EPA has long considered the safety implications of its emission standards.[2650] More recently, EPA has considered the potential impacts of emission standards on safety in past rulemakings on GHG standards, including the 2010 rule which established the 2012-2016 light-duty vehicle GHG standards, and the 2012 rule which previously established 2017-2025 light-duty vehicle GHG standards. Indeed, section 202(a)(4)(A) specifically prohibits the use of an emission control device, system or element of design that will cause or contribute to an unreasonable risk to safety.[2651] The relationship between CO_2 emissions and safety is more nuanced. Safety impacts relate to changes in the use of vehicles in the fleet, relative mass changes, and the turnover of fleet to newer and safer vehicles.

The analysis for the final rule projects that there will be a change in vehicle miles traveled (VMT) under the final standards, specifically 607 billion less miles traveled compared to the previous standards case. Based on these projections about reduced VMT in the light-duty fleet, the analysis estimates that fatalities will be reduced by 2584 (out of a total impact of 3269) over the lifetime of MY 1977-2029 vehicles compared to the previous CO_2 standards.[2652] In other words, the reduction in fatalities under the final standards compared to the previous standards is primarily driven by the modeling's projected changes in VMT and associated changes in mobility (i.e., people driving less). The details of the safety assessment are discussed in Section VI in the preamble and in Section VI of the FRIA. Under alternatives with stringency levels lower than the final standards, the analysis projects greater reductions in VMT, and thus projects somewhat greater reductions in fatalities based on these VMT changes. Under

[2648] *See* Initial Determination at page 7-8.
[2649] *Id.* at Figure ES-8.
[2650] *See, e.g.*, 45 FR 14496, 14503 (1980) ("EPA would not require a particulate control technology that was known to involve serious safety problems.").
[2651] 42 U.S.C. 7521(a)(4)(A).
[2652] The number of fatalities projected is a product of two contributing factors: the number of miles driven (VMT) and the risk of driving (i.e., fatalities per mile). Overall in this final rule analysis, the change in fatalities projected is primarily caused by the changes in VMT.

alternatives with stringency levels higher than the final standards, the analysis projects lower reductions in VMT, and thus projects fewer fatalities reduced, See Table VI-289.

EPA notes that the magnitude of the changes in fatalities stemming from changes in mobility projected in this final rule is less than what was presented in the proposed rule. In response to comments, the agencies took a conservative approach to modeling the effects of standard stringency upon safety. The agencies held VMT constant across alternatives. The reasons for the differences in fatality estimates in the final rule compared to the proposed rule, including changes to the modeling inputs and projections based on the agencies' assessment of public comments, are explained elsewhere in this FRIA.

The approach for reporting fatality impacts for this final rule is different than the previous analyses for the Initial Determination and the 2012 rulemaking. First, the analysis quantifies the number of fatalities caused by changes in VMT between each Alternative and the previous standards, whereas previous analyses did not. Second, the safety analysis itself is different from previous analyses that assumed that automakers would not reduce the weight of approximately the lightest half of passenger cars—discounting the safety impacts of mass reduction. Third, while the agencies qualitatively discussed the effect of price increases attributable to increased stringency on vehicle sales, fleet turnover, and the improved safety of newer vehicles, the agencies never attempted to quantify these impacts.

With respect to public comments, the Alliance commented that "EPA has discretion to consider all the relevant factors in setting appropriate emissions standards under §202(a)(1), including vehicle safety. Moreover, given NHTSA's greater expertise in evaluating motor vehicle safety, it is appropriate for EPA to respect the views of its companion agency on those issues." The Alliance commented that "[t]he new safety analysis likewise provides support for EPA's conclusion that the MY 2021–2025 GHG standards are not appropriate and should be reduced in stringency. Indeed, given that the 'primary purpose' of §202(a)(1) is 'the protection of public health and welfare,' EPA would be abdicating its statutory duty if it ignored these concerns."

Global Automakers commented that safety impacts due to the rebound effect should not be attributed to the standards and should not serve as a basis for keeping the standards flat. They further argued that the dynamic scrappage model is flawed and should be removed from the modeling for purposes of the final rule. They also argued, that Congress expressed interest in improving efficiency, emissions, and safety (without no recognition of cost as a factor), and that therefore, improvement in all such areas should provide that improvements in efficiency would not lead to negative safety impacts.

CBD and others commented that safety concerns should not be considered because the record does not indicate that vehicles must be unsafe to meet the previous standards. They further commented that EPA cannot justify reduced stringency upon "rebound" fatalities, and they argue that those fatalities cannot be considered by EPA, since they "stem from voluntary choices by individuals to drive more—not the 'operation or function' of the technologies at issue" (quoting CAA Section 202(a)(4)(A)).

Environmental Defense Fund (EDF) similarly commented that the estimates of fatalities are unsound, as is considering total fatalities resulting from increased stringency, rather than fatality rates. They added that the projected fatalities stem from consumer and manufacture behaviors that are removed from the stringency requirements. They further argue that considering fatalities that are attributable to the standards—particularly rebound fatalities—are inappropriate. EDF, UCS, and Consumers Union argue that fatalities attributable to increased driving are not relevant to agency decisions.

In response to the Alliance comments, EPA has considered safety, as described in this section, and agrees that the potential impacts of emission standards on safety is an important consideration in determining appropriate standards under CAA section 202(a). In response to comments from Global Automakers that the safety analysis in the proposed rule did not support freezing the standards, EPA agrees that safety considerations alone do not justify such an approach, and notes that the safety analysis performed for this final rule has changed from the analysis for the proposed rule based on consideration of public comments. EPA is finalizing standards that are more stringent (1.5 percent per year stringency improvement for MY 2021-2026) than the proposed rule's preferred alternative (0 percent stringency improvement).

Several commenters argued that the proposal's claims of reduced fatalities were based upon projected changes in driving, arguing that that EPA should not decide the level of the standards based on these assumed changes in travel. As discussed above, EPA acknowledged that the reduction in fatalities under the final standards compared to the previous standards are in large part driven by projected changes in driving behavior (i.e., people driving less). While EPA is not seeking to restrict mobility or driving, ignoring impacts associated with this rule would be inappropriate. Moreover, the provisions of Section 202(a)(4) do not preclude EPA from considering such impacts. While EPA has considered the safety assessment for this final rule, as discussed in the following section below, safety was one of several factors considered in deciding on the level of today's final standards.

g) Consideration of Energy Security Impacts

Among other factors EPA considered in selecting the previous standards in the 2012 Final Rule was the effect of the standards on U.S. petroleum imports and energy security.[2653] As discussed in the PRIA, FRIA and in Section Energy Security, the energy security position of the United States has changed dramatically since 2012. The U.S. has become a net *exporter* of petroleum and additional payments by United States consumers resulting from upward pressure on oil price due to additional demand are a transfer that occurs *within* the United States economy.[2654] Additional petroleum use necessarily increases demand and thus subjects the nation to additional risk of price shocks, but this risk is significantly reduced as the United States has dramatically increased domestic petroleum production and has additional capacity to do so.

[2653] *See* 77 FR 62938, *et seq*.

[2654] The U.S. Energy Information Administration EIA estimates that the United States exported more total crude oil and petroleum products in September and October 2019, and expects the United States to continue to be a net exporter. *See Short Term Energy Outlook November 2019*, available at https://www.eia.gov/outlooks/steo/archives/nov19.pdf.

Accordingly, energy security concerns are reduced compared to the assessment in the 2012 rulemaking and do not alter EPA's selection of final revised standards in this rule.

h) Balancing of Factors and EPA's Revised Standards for MY 2021 and Later

As discussed in this section, the Administrator is required to consider a number of factors when establishing emission standards under section 202(a)(2) of the Clean Air Act: the standards "shall take effect after such period as the Administrator finds necessary to permit the development and application of the requisite technology, giving appropriate consideration to the cost of compliance within such period."[2655] For this Final Rule, the Administrator has considered a wide range of potential emission standards (Baseline/No Action Alternative and Alternatives 1 through 7), ranging from the previous EPA standards (Baseline/No Action Alternative), through a number of less stringent alternatives, including the proposed preferred alternative (Alternative 1, 0 percent per year stringency improvement) and what has been chosen as the final standards (Alternative 3, 1.5 percent per year stringency improvement). The Administrator has determined that the revised final standards, which would increase the stringency of the MY 2020 standards by 1.5 percent per year for both passenger cars and light-trucks from MY 2021 through 2026, are appropriate under section 202(a) of the CAA. In addition to technological feasibility, lead-time, and the costs of compliance, the Administrator has also considered the impact of the standards on GHG and non-GHG emissions reductions, the costs to consumers, and vehicle safety.

In addition to comments on each of the factors the Administrator considered discussed above, comments also were received on how the Administrator should balance these factors in determining the appropriate final standards.

The Alliance commented that the CAA provides EPA with significant latitude to exercise its expert judgment in determining the level at which emissions standards should be set. The Alliance commented further that unlike other CAA provisions, §202(a)(1) does not require EPA to set standards that will result in the greatest degree of emission reduction achievable. Instead, the statute leaves EPA flexibility to decide what factors are relevant, and how to weigh those factors, in its decision-making process. The Alliance also commented "EPA also has 'significant latitude' regarding the 'coordination of its regulations with those of other agencies,'" "EPA has discretion to defer to the judgment of other agencies regarding issues within their areas of expertise," and the CAA "gives the agency authority to engage in reasoned decision-making, balancing all of the relevant factors in light of the available facts. EPA has done that here and has provided a reasoned explanation of its determination that the environmental benefits of the existing MY 2021-2025 GHG standards are outweighed by their negative effects on costs and safety."

The American Iron and Steel Institute commented that it favors the general direction taken in the SAFE proposal, including the preferred option for CO_2 standards, and that it believes

[2655] 42 U.S.C. 7521(a)(2).

a final SAFE rule that "balances the priorities of costs to consumers, safety design considerations, employment impacts and total GHG emissions will result in the best outcome."

CBD and others claimed that the justifications EPA offered in the notice are untethered from the statute, and that EPA used a flawed analysis. Further, they claim that EPA did not exercise its own judgment and delegated its responsibilities impermissibly to NHTSA, failing to consider "relevant EPA information."

EPA's analysis is described in detail in this FRIA. EPA decided to use the CAFE model for a number of reasons, described in more detail in Section IV, including that using two models results in an inefficient use of resources, the CAFE model can analyze both EPA's and NHTSA's statutory programs, the CAFE model is capable of modeling incremental improvements of discrete technologies, and EPA believes that the CAFE model provides reasonable results. Merely because EPA has a set of its own analytical tools that model similar effects does not mean that it must use those tools to perform the analysis, and doing so would create unnecessary complication and lead to potential inconsistencies. Since the agencies are establishing standards jointly and seeking to avoid inconsistencies in a manner consistent with Supreme Court direction, using the same model for the analysis is reasonable. Nonetheless, EPA has exercised its own judgment in this final rule.

The California Attorney General and others claim that EPA failed adequately to acknowledge, explain, or justify its departure from the prior determination. They claim that EPA failed to propose or make a finding required by Section 202(a)(2) relating to adequate lead time, inconsistent with EPA's prior explanation that it is provided with limited flexibility in making such a determination.

The California Attorney General and others also claim that EPA's analysis improperly weighs the factors it considers, and that it insufficiently weighed certain factors required under the Clean Air Act, including air pollution. In response, EPA notes that the Clean Air Act does not specify how the Administrator should weigh the factors considered, as discussed elsewhere in this section.

The California Attorney General and others further noted that the purpose of the Clean Air Act is to is to "protect and enhance the quality of the Nation's air resources so as to promote the public health and welfare and the productive capacity of its population."

The Institute for Policy Integrity claimed that the agencies balanced the factors in a way that conflicts with their controlling statutes and weighed the statutory factors without regard for the accuracy of the accompanying cost-benefit analysis.

The National Coalition for Advanced Transportation claimed that the proposal appeared to be based on heightened concerns with cost, consumer acceptance, and safety, and insufficiently on technology availability and emissions reductions. As discussed in this section, EPA is neither relying solely on cost or safety nor ignoring any factors, but rather is balancing a number of factors.

Green Energy Institute at Lewis and Clark Law School et al. commented that the Clean Air Act does not authorize the weakening or freezing of existing standards due to industry costs or consumer preferences. While EPA has broad discretion to revise standards based upon a balancing of factors, the final rule will provide for increasing stringency of 1.5 percent per year from MY 2021 through MY 2026.

Motor & Equipment Manufacturers Association (MEMA) commented that the technology costs from their preferred alternative (Alternative 8 in the notice) were not significant and did not justify holding MY 2020 standards flat in light of other elements, such as preserving investments in fuel saving technology. EPA disagrees, and considers the reductions in costs resulting from the revised final standards, $1,250 per vehicle by MY 2029, to be one important aspect of the justification of these standards.

EPA believes the previously issued standards for MY 2021 and later, considered as a whole, are too stringent. Factors in favor of reduced stringency include manufacturer compliance costs, and the related per-vehicle cost savings. As described above, the agencies project that the final CO_2 standards will reduce manufacturers' MY 2018-2029 compliance costs by $108 billion (when applying a 3% discount rate),and will reduce average MY 2030 vehicle prices $977 (also applying a 3% discount rate). Including other costs, such as financing and insurance, consumers the standards finalized today will result in reduced costs of $1,286 per-vehicle for a MY 2030 vehicle. EPA expects that the final standards will not impede consumers from being able to purchase a new vehicle of their choice or require significant changes in product lines for any manufacturer. In fact, under the final standards, vehicle sales are expected to increase by 2.2 million vehicles over MY 2017-2029 compared to projected sales under the augural standards, a significant increase in vehicles sold over this timeframe see Table VI-190. EPA views this projection of vehicle sales increases resulting from the final standards as important in facilitating the turnover of the fleet to newer, safer vehicles, all of which will be subject to increasingly stringent criteria pollutant emission requirements as federal Tier 3 emission standards continue to phase in from MY 2017 through MY 2025.

Another factor weighing toward reduced stringency is safety. As discussed previously, reduced stringency results in less pressure on manufacturers to reduce mass in vehicles, which, for smaller passenger cars has negative safety implications when involved in accidents with heavier vehicles. Further, as vehicle prices decrease compared to the previous standards, more consumers will be able to afford newer vehicles, which are significantly safer. Lastly, as vehicles will not be required to be as fuel efficient as under the previous standards, "rebound" driving will be reduced. The agencies project a reduction in 605 billion miles traveled by light-duty vehicles produced through MY 2029, and project that this reduced VMT will lead to 2,584 fewer highway fatalities under the final standards compared to the previous CO_2 standards (i.e., people are projected to drive less under the final standards with an associated reduction in driving-related fatalities). While, notwithstanding EPA's involvement with State and local Transportation Control Measures (TCMs), the Administrator does not seek to change the way people drive—EPA's intention is not to restrict mobility, or to discourage driving, based on the level of the standards—EPA nonetheless believes it is appropriate to consider this projection.[2656]

[2656] Information regarding TCMs is available at https://www.epa.gov/statelocalenergy/transportation-control-measures.

The agencies also project that accelerated fleet turnover attributable to the change in standards will lead to the avoidance of a further 447 fatalities, and that the reduced need for reductions of vehicle mass will lead to the avoidance of a further 238 fatalities. In other words, the agencies project that the change in CO_2 standards will lead to 3,269 fewer fatalities over the useful lives of vehicles produced through MY 2029.

Factors that weigh in favor of increased stringency options are increased upstream criteria pollutant emissions attributable to additional refining and other fuel-related activities, as well as increased CO_2 emissions and consumer fuel expenditures.

As described above, the agencies project that the revised final standards will have a negative impact on air quality health outcomes, including a projected increase of 444 to 1000 premature deaths from increased air pollution over the lifetime of the MY 1977-2029 vehicles on the road after calendar year 2017 cumulative through CY 2068, under EPA's CO_2 program[2657]. EPA recognizes that the final standards are projected to increase CO_2 emissions compared to the previous EPA standards. However, EPA notes that, unlike other provisions in Title II referenced above, section 202(a) does not require EPA to set standards for light-duty vehicles which result in the "greatest degree of emission reduction achievable." EPA has not chosen the standard that hasthe highest estimated net soial benefits. However, as discussed elsewhere in this FRIA, from a cost-benefit perspective, the differences among the various alternatives are relatively narrow. EPA believes consideration of costs and benefits is certainly relevant to its exercise of discretion in selecting appropriate standards, but also recognizes that some costs and benefits are difficult to quantify, and additional factors can pove material under the Clean Air Act as well in those policy decisions. For example, EPA notes that the agency decided against pursuing more stringent alternatives analyzed in both the rulemaking establishing 2012-2016 standards and the rulemaking establishing 2017-2025 standards.

EPA has also given weight to the policy goal of establishing CO_2 standards which are coordinated with NHTSA's CAFE standards. While not a statutory requirement, EPA has considered the importance of having coordinated and harmonized EPA CO_2 and CAFE programs, while recognizing the different statutory authorities for those programs, since the establishment of the EPA CO_2 program. The agencies discussed the importance of having one national program in the SAFE Vehicles Part 1 joint action.[2658] In today's joint final rule, DOT is establishing CAFE standards for MY 2021-2026 which increase in stringency at a level of 1.5 percent per year. The revised EPA standards will also increase in stringency at a rate of 1.5 percent per year. Coordinating revisions to the GHG and CAFE standards in order to maintain one national program is a factor the Administrator has consideration in determining the revised GHG standards.

In light of available statutory discretion and the range of factors that the statute authorizes and permits the Administrator to consider, and his consideration of the factors discussed above,

[2657] The agencies believe that these premature mortality estimates may be over-estimated. Please see more detailed discussions in Sections VI.D.3.d) and VIII.A.3.d) in the preamble, and in similar discussions in this final regulatory impact analysis.
[2658] 84 FR 51,310 (Sept. 27, 2019).

the EPA concludes that reducing the stringency of the MY 2021-2026 standards is an appropriate approach under section 202(a). Therefore, based on the data and analysis detailed in this final rule, the Administrator concludes that the previous MY 2021 and later CO_2 standards are too stringent, and is establishing revised standards for MY 2021 through MY 2026 at a level of 1.5 percent per year improvement in stringency.

In response to comments concerned about EPA's proposal to freeze the MY 2021-2026 standards at MY 2020 levels, EPA notes that it is finalizing the 1.5 percent per year improvement in stringency level and not the 0 percent improvement level proposed, after considering the somewhat higher costs to industry and up-front vehicle costs to the consumer and slightly lower GHG emissions and health-related impacts compared to the proposed preferred alternative. The Administrator has taken these tradeoffs into account in his balancing of factors under section 202(a) of the CAA.

While the set of factors considered by EPA under section 202(a) of the CAA in today's final rule and under the midterm evaluation regulations[2659] in the Initial Determination are similar and overlapping, the Administrator recognizes that he is balancing these factors differently in this final rule than in the Initial Determination. In the Initial Determination, EPA's decision that the previous MY 2022-2025 standards were appropriate was based on conclusions that the standards were feasible within the lead time provided at reasonable costs, the standards would result in significant reductions in GHG emissions and oil consumption and associated fuel savings for consumers, and the standards would yield significant benefits to public health and welfare and positive net benefits overall, without adverse impacts on industry, safety, or consumers.[2660]

Since the Initial Determination, EPA has completed its compliance review of the first two model years covered by the 2012 final rule. Notwithstanding widespread availability of vehicles that meet or exceed their CO_2 emission targets, consumers are not expressing sufficient interest in fuel economy in their purchasing decisions to enable manufacturers to meet the standards based upon fleet performance. Although manufacturers earned significant credits in the early years of the agency's CO_2 regulation history, these credits are being applied broadly across the industry and well in advance of the more aggressive model year stringency increases. While some manufacturers, including alternative fuel automakers are earning significant tradable credits, they do not have to trade them. And building a program around the potential for acquiring credits from competing manufacturers is not the intention of this action. While EPA is analyzing the differences between these standards and the previous standards for this rulemaking, EPA cannot ignore that this rulemaking was foreseen in the 2012 rulemaking. The prospect of revising the standards was expressly envisioned in that rulemaking based upon the uncertainty in the assumptions and future projections at that time. When viewed from the perspective of the larger set of MY 2017 through MY 2026 standards rulemakings, the standards finalized today fit the pattern of gradual, tough, but feasible stringency increases that take into account real world performance, shifts in fuel prices, and changes in consumer behavior toward

[2659] 40 CFR 86.1818-12(h).
[2660] Initial Determination, Section III, page 29-30.

crossovers and SUVs and away from more efficient sedans. This approach ensures that manufacturers are provided with sufficient lead time to achieve standards, considering the cost of compliance.

In this final rule, the EPA is placing greater weight on the costs to industry and the up-front vehicle costs to consumers. EPA believes that the costs to both industry and automotive consumers would have been too high under the previous standards, and that the standards should be revised to be less stringent to lower these costs. EPA believes that by lowering the auto industry's costs to comply with the program, with a commensurate reduction in per-vehicle costs to consumers, the final rule is enhancing the ability of the fleet to turn over to newer, cleaner and safer vehicles.

EPA believes that the characteristics and impacts of these and other alternative standards generally reflect a continuum in terms of technical feasibility, cost, lead time, consumer impacts, emissions reductions, and oil savings, and other factors evaluated under section 202(a). In determining the appropriate standard to adopt in this context, EPA judges that the final standards are appropriate and preferable to more stringent alternatives based largely on consideration of cost—both to manufacturers and to consumers—and the potential for overly aggressive penetration rates for advanced technologies relative to the penetration rates seen in the final standards, especially in the face of an unknown degree of consumer acceptance of both the increased costs and of the technologies themselves—particularly given current projections of fuel prices during that timeframe. At the same time, the final rule helps to address these issues by maintaining incentives to promote broader deployment of advanced technologies, and so provides a means of encouraging their further penetration while leaving manufacturers alternative technology choices. EPA thus judges that more stringent alternatives, which would necessitate even more technology and more cost, would not be appropriate. Instead, EPA is adopting a more gradual increase in stringency to ensure that the benefits of reduced GHG emissions are achieved without the potential for disruption to automakers or consumers.

B. NHTSA's Statutory Obligations and Why the Selected Standards are Maximum Feasible as Determined by the Secretary

In this section, NHTSA discusses the factors, data and analysis that the agency has considered in the selection of the CAFE standards for MYs 2021 and later and the comments received on NHTSA's consideration of these factors (see further discussion below on NHTSA's summary and analysis of comments).

As discussed in more detail below, the primary purpose of EPCA, as amended by EISA, and codified at 49 U.S.C. chapter 329, is energy conservation, and fuel economy standards help to conserve energy by requiring automakers to make new vehicles travel a certain distance on a gallon of fuel.[2661] The goal of the CAFE standards is to conserve energy, while taking into account the statutory factors set forth at 49 U.S.C. 32902(f), as discussed below.

49 U.S.C. 32902(f) states when setting maximum feasible CAFE standards for new vehicles, the Secretary of Transportation[2662] "shall consider technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy." In previous rulemakings, including the 2012 final rule that established CAFE standards for MY 2021 and set forth augural standards for MYs 2022-2025, NHTSA considered technological feasibility, including the availability of various fuel-economy-improving technologies to be applied to new vehicles in the timeframe of the standards depending on the ultimate stringency levels, and also considered economic practicability, including the differences between a range of regulatory alternatives in terms of effects on per-vehicle costs, industry-wide costs, the ability of both the industry and individual manufacturers to comply with standards at various levels, as well as effects on vehicle sales, industry employment, and consumer demand. NHTSA also considered how compliance with other motor vehicle standards of the Government might affect manufacturers' ability to meet CAFE standards represented by a range of regulatory alternatives, and how the need of the U.S. to conserve energy could be more or less met under a range of regulatory alternatives, in terms of considerations like costs to consumers, the national balance of payments, environmental implications like climate and smog effects, and foreign policy effects like the likelihood that U.S. military and other expenditures could change as a result of more or less oil consumed by the U.S. vehicle fleet. These elements are discussed in detail throughout this analysis. As will be discussed in greater detail below, while NHTSA is considering all of the same factors in setting today's CAFE standards that it considered in previous rulemakings, and in many instances in a similar way as it considered those factors in previous rulemakings, the facts on the ground have changed and NHTSA is therefore choosing to set CAFE standards at a different level from what the 2012 final rule set forth.

NHTSA is not limited to consideration of the factors specified in 49 U.S.C. 32902(f) when establishing CAFE standards for passenger cars and light trucks. In addition to the factors enumerated above, NHTSA may (and historically has) considered such factors as safety and the environment.

NHTSA also considers relevant case law. Critical to this series of joint rulemakings with EPA, the Court in *Massachusetts v. EPA*[2663], recognized EPA's argument that "it cannot regulate carbon dioxide emissions from motor vehicles" without "tighten[ing] mileage standards . . . ."—a task assigned to DOT. The Court found that "[t]he two obligations may overlap, but there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency."[2664] Accordingly, the agencies have worked closely together in setting standards,

---

[2661] While individual vehicles need not meet any particular mpg level, as discussed extensively elsewhere in this FRIA, it is broadly true that fuel economy standards require vehicle manufacturers' fleets to meet certain fuel economy levels as set forth by NHTSA in regulation.
[2662] By delegation, NHTSA.
[2663] 549 U.S. 497, 531 (2007).
[2664] *Id.* at 532.

and many of the factors that NHTSA considers to set maximum feasible standards overlap with factors that EPA considers under the Clean Air Act. Just as EPA considers energy use and security, NHTSA considers these factors when evaluating the need of the nation to conserve energy, as required by EPCA. Just as EPA considers technological feasibility, the cost of compliance, technological cost-effectiveness and cost and other impacts upon consumers, NHTSA considers these factors when weighing the technological feasibility and economic practicability of potential standards. EPA and NHTSA both consider implications of the rulemaking on CO_2 emissions as well as criteria pollutant emissions. And, NHTSA's role as a safety regulator inherently leads to the consideration of safety implications when establishing standards. The balancing of competing factors by both EPA and NHTSA are consistent with each agency's statutory authority and recognize the overlapping obligations the Supreme Court pointed to in directing collaboration. NHTSA also considers the Ninth Circuit's decision in *Center for Biological Diversity v. NHTSA*[2665] which remanded NHTSA's 2006 final rule establishing standards for MYs 2008-2011 light trucks and underscored that "the overarching purpose of EPCA is energy conservation."

The proposed rule presented an analysis of a wide range alternatives as potential revisions of the existing standards for model year 2021 and new standards for model years 2022-2026. These alternatives ranged from a zero percent increase in stringency to a stringency increase for passenger cars of 2 percent per year and for light trucks of 3 percent per year, in addition to the baseline alternative consisting of the augural standards.[2666] The analysis supported the range of alternative standards based on factors relevant to NHTSA's exercise of its 49 U.S.C. 32902(f) authority, such as fuel saved and emissions reduced, the technologies available to meet the standards, the costs of compliance for automakers and their abilities to comply by applying technologies, the impact on consumers with respect to cost and vehicle choice, and effects on safety. The proposed rule identified the alternative composed of a zero percent increase in stringency as the preferred alternative.

NHTSA received numerous public comments on the range of stringency alternatives in the proposed rule and NHTSA's consideration of various factors in determining maximum feasible CAFE standards under 49 U.S.C. chapter 329. Below NHTSA responds to comments on these issues. NHTSA notes that many comments concerned the technical foundation and analysis upon which NHTSA was basing its regulatory decisions, such as the modeling of fuel economy-improving technologies and costs, the safety analysis, and consumer issues. Comments specific to these analyses are discussed elsewhere in this FRIA. The section below addresses comments specifically addressing NHTSA's considerations in finalizing maximum feasible CAFE standards under 49 U.S.C. chapter 329.

NHTSA's conclusion, after consideration of the factors described below, public comments, and other information in the administrative record for this action is that 1.5 percent annual increases in stringency from the MY 2020 standards through MY 2026 (Alternative 3 of

---

[2665] 538 F.3d 1172 (9th Cir. 2008).
[2666] 83 FR 42990, Table I-4 (Aug. 24, 2018).

this final rule analysis)[2667] are maximum feasible. Holding CAFE standards for MY 2020 flat through MY 2026, as proposed, would unduly weigh economic practicability concerns more heavily than the need of the United States to conserve energy, while finalizing the MY 2021 and augural standards first established and set forth in 2012 would place undue weight on the need of the U.S. to conserve energy while being beyond economically practicable, as described in more detail below.

The following sections discuss in more detail the statutory requirements and considerations involved in NHTSA's determination of maximum feasible CAFE standards, comments received on those issues, and NHTSA's explanation of its balancing of factors for this final rule.

1. EPCA, as Amended by EISA

EPCA, as amended by EISA, contains a number of provisions regarding how to set CAFE standards. DOT (by delegation, NHTSA)[2668] must establish separate CAFE standards for passenger cars and light trucks[2669] for each model year,[2670] and each standard must be the maximum feasible that the Secretary (again, by delegation, NHTSA) believes the manufacturers can achieve in that model year.[2671] In determining the maximum feasible level achievable by the manufacturers, EPCA requires that NHTSA consider four statutory factors of technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy.[2672] In addition, NHTSA has the authority to consider (and traditionally does) other relevant factors, such as the effect of the CAFE standards on motor vehicle safety and consumer preferences.[2673] The ultimate determination of what standards can be considered maximum feasible involves a weighing and balancing of factors, and the balance may shift depending on the information before NHTSA about the expected circumstances in the model years covered by the rulemaking. The agency's decision must also support the overarching purpose of EPCA, energy conservation, while balancing these factors.[2674]

[2667] The numbered Alternatives presented in the SAFE proposed rule (*see* Table I-4 at 83 FR 42990, August 24, 2018) were in some cases defined differently than those presented in this final rule (*see* Section V). Unless otherwise stated, the Alternatives described in this section refer to those presented in this final rule.
[2668] EPCA and EISA direct the Secretary of Transportation to develop, implement, and enforce fuel economy standards (*see* 49 U.S.C. 32901 *et. seq*.), which authority the Secretary has delegated to NHTSA at 49 CFR 1.95(a).
[2669] 49 U.S.C. 32902(b)(1) (2007).
[2670] 49 U.S.C. 32902(a) (2007).
[2671] *Id*.
[2672] 49 U.S.C. 32902(f) (2007).
[2673] Both of these additional considerations also can be considered part of economic practicability, but NHTSA also has the authority to consider them independently of that statutory factor.
[2674] Center for Biological Diversity v. NHTSA, 538 F. 3d 1172, 1197 (9th Cir. 2008) ("Whatever method it uses, NHTSA cannot set fuel economy standards that are contrary to Congress's purpose in enacting the EPCA – energy conservation.").

Besides the requirement that the standards be maximum feasible for the fleet in question and the model year in question, EPCA/EISA also contain several other requirements, as explained below.

a) Lead Time

EPCA requires that NHTSA prescribe new CAFE standards at least 18 months before the beginning of each model year.[2675] Thus, if the first year for which NHTSA is proposing to set new standards in this NPRM is MY 2022, NHTSA interprets this provision as requiring the agency to issue a final rule covering MY 2022 standards no later than April 1, 2020.

For amendments to existing standards, EPCA requires that if the amendments make an average fuel economy standard more stringent, at least 18 months of lead time must be provided.[2676] EPCA contains no lead time requirement to amend standards if the amendments make an average fuel economy standard less stringent. NHTSA therefore interprets EPCA as allowing amendments to reduce a standard's stringency up until the beginning of the model year in question. In the NPRM, NHTSA proposed to amend the standards for model year 2021. NHTSA explained that since the agency was proposing to reduce these standards, the action was not subject to a lead time requirement.

The States and Cities commenters argued that NHTSA had counted 18 months incorrectly, and that "18 months prior to September 1, 2021 is in fact March 1, 2020."[2677] NHTSA agrees that 18 months prior to September 1 would be March 1 of the year prior; the statement in the NPRM that "NHTSA has consistently interpreted the "beginning of the model year" as September 1 of the CY prior" was a typographical error. As prior Federal Register notices indicate, NHTSA has in fact long interpreted the beginning of the model year for CAFE compliance purposes as *October* 1 of the CY prior.[2678] Thus, counting backwards, 18 months prior to October 1 is properly identified as April 1, meaning that new standards for MY 2022 must be established by April 1, 2020.

With regard to the amendments to the MY 2021 standards, a coalition of environmental groups commented that NHTSA's legal construction of EPCA's lead time requirement as not applying to MY 2021 was "not…permissible," arguing that section 32902(g)(1) only permits amendments to existing CAFE standards that "meet[ ] the requirement of subsection (a) or (d) as appropriate," and that section 32902(a) requires fuel economy standards to be prescribed 18 months before the beginning of the model year.[2679] The environmental group coalition therefore argued that the two identified provisions must be read together to compel all amendments to standards to be prescribed at least 18 months before a model year, and concluded that because it

was impossible to finish a final rule 18 months before the start of MY 2021, that MY 2021 standards could not be amended.[2680] The States and Cities group provided similar comments, arguing that NHTSA's interpretation of (g)(2) rendered the reference in (g)(1) to (a) "a nullity," and that the "as appropriate" language in (g)(1) referred to the determination of whether providing 18 months of lead time was appropriate, rather than to whether (a) or (d) was the relevant provision governing the standards in question.[2681] NCAT commented that "Congress in § 32902 has indicated that at least 18 months of lead time are appropriate when setting standards," and stated that "Manufacturers' need for adequate lead time when designing products and developing compliance strategies is the same regardless of whether the agency is making standards more stringent, less stringent, or simply changing the structure or compliance options provided under the standards."[2682] NADA, in contrast, argued that NHTSA does "have the authority and discretion to reopen the MY 2021 standards," and that the "mandate for at least 18 months of lead time before new standards may take effect does not apply to instances, such as for MY 2021, where standards are being relaxed."[2683] CEI also agreed with NHTSA's interpretation of lead time set forth in the NPRM.[2684]

NHTSA agrees that section 32902(g)(1) states that amendments must meet the requirements of subsection (a) or (d) as appropriate, and that 32902(a) states that standards must be prescribed 18 months in advance of the model year. However, NHTSA cannot agree that the 18-month lead time requirement applies to amendments to existing standards that reduce stringency. Section 32902(g)(2) clearly states that "[w]hen the Secretary of Transportation prescribes an amendment under this section that makes an average fuel economy standard *more stringent* (emphasis added), the Secretary shall prescribe the amendment … at least 18 months before the beginning of the model year to which the amendment applies." Commenters' construction of the statute would render superfluous the words "more stringent" in 32902(g)(2), and there is a presumption against superfluity.[2685] Congress purposely included the words "more stringent" in order to exclude the contrary situation—"less stringent"—from the 18-month lead time requirement. A plain reading of (g)(1) simply provides that the Secretary (by delegation, NHTSA) should refer to the correct provision depending on whether the standard being amended is generally applicable (pointing to section (a)) or a standard applicable to low-volume manufacturer pursuant to an exemption (pointing to section (d)). Reading (g)(1) and (g)(2) together is the appropriate way to give effect to both provisions. This reading provides that NHTSA may amend the MY 2021 standard by following the requirements for generally-applicable standards; this reading also provides that 18 months' lead time is only required for amendments that *increase* stringency. NHTSA also does not agree that (g)(1) can be read to imply that the agency must provide 18 months of lead time "if appropriate," as the States and Cities suggest, nor that there is any statutory basis to extend the lead time requirement to changes to the "structure or compliance options provided under the standards" as NCAT suggests. If new off-cycle technologies could not be recognized toward compliance without providing 18 months'

lead time, manufacturer efforts to rely on that compliance flexibility to redress past shortfalls would be frustrated.

Moreover, automakers need more time to respond when NHTSA amends standards to be more stringent—doing so would likely require automakers to change their product and/or sales plans to ensure that they will meet more-stringent standards than those standards for which they may have already prepared. But such product or sales plans would not necessarily *need* to be changed if standards were amended to be less stringent—in fact an automaker would be rewarded by keeping existing plans to comply in place with additional bankable and tradable overcompliance credits. However, the environmental group coalition argued that "[c]hanging the MY 2021 standard at this late date would penalize technologically advanced automakers and parts suppliers, who have already made significant investments in updating their technology."[2686] The States and Cities group made similar comments,[2687] as did NCAT.[2688] The environmental group coalition further suggested that amending the MY 2021 standard would reduce the need for (and thus the value) of overcompliance credits, "which would be disruptive to the manufacturers that have done the most to further EPCA's conservation goals."[2689] NCAT made similar comments, arguing that "The practical and financial impact of the change accordingly is not materially different from increasing the stringency of a standard this late in the product cycle."[2690]

NHTSA believes that to the extent that some manufacturers have already invested in future fuel economy improvements, those manufacturers will continue to be well-positioned both to respond to increasing standards in the future, and to take advantage of any market demand for higher fuel economy/reduced tailpipe CO_2 emissions from consumers who put a premium on those aspects. NHTSA is also aware that several companies have self-imposed emissions-reduction goals which may drive their decisions on technology application regardless of regulatory obligations. NHTSA does not believe that companies which have already invested in higher levels of technology consider those investments to be bad ones. The agencies note that manufacturer commenters, despite the concerns expressed by others, did *not* comment about a lack of lead time associated with changing the MY 2021 standards; rather, many manufacturer commenters expressly cited the need to revise MY 2021 standards, arguing that the previously-established values are beyond maximum feasible. Regarding the value of overcompliance credits under more or less stringent standards, NHTSA agrees that the need for credits may be less under less stringent standards, but this is true regardless of the lead time question. Further, NHTSA does not believe that this suggests only standards that compel reliance on overcompliance credits (especially those earned by competitors) can be maximum feasible; this topic will be addressed in further detail below, and regardless, NHTSA is prohibited from considering credit availability in determining maximum feasible CAFE standards.

b) Separate Standards for Cars and Trucks, and Minimum Standards for Domestic Passenger Cars

As discussed above, EPCA requires NHTSA to set separate CAFE standards for passenger cars and light trucks for each model year.[2691] NHTSA interprets this requirement as preventing the agency from setting a single combined CAFE standard for cars and trucks together, based on the plain language of the statute. Congress originally required separate CAFE standards for cars and trucks to reflect the different fuel economy capabilities of those different types of vehicles,[2692] and over the history of the CAFE program, has never revised this requirement. Even as many cars and trucks have come to resemble each other more closely over time—many crossover and sport-utility models, for example, come in versions today that may be subject to either the car standards or the truck standards depending on their characteristics—it is still accurate to say that vehicles with truck-like characteristics such as 4 wheel drive, cargo-carrying capability, etc., consume more fuel per mile than vehicles without these characteristics. Thus, NHTSA believes that the different fuel economy capabilities of cars and trucks would generally make separate standards appropriate for these different types of vehicles, regardless of the plain language of the statute which requires such treatment.

EPCA, as amended by EISA, also requires another separate standard to be set for domestically-manufactured[2693] passenger cars. Unlike standards for passenger cars and light trucks described above, the compliance burden of the minimum domestic passenger car standard is the same for all manufacturers: the statute clearly states that any manufacturer's domestically-manufactured passenger car fleet must meet the greater of either 27.5 mpg on average, or

> 92 percent of the average fuel economy projected by the Secretary for the combined domestic and non-domestic passenger automobile fleets manufactured for sale in the United States by all manufacturers in the model year, which projection shall be published in the Federal Register when the standard for that model year is promulgated in accordance with [49 U.S.C. 32902(b)].[2694]

Since that requirement was promulgated, the "92 percent" has always been greater than 27.5 mpg. NHTSA published the 92-percent minimum domestic passenger car standards for model years 2017-2025 at 49 CFR 531.5(d) as part of the 2012 final rule. For MYs 2022-2025, 531.5(e) states that these were to be applied if, when actually proposing MY 2022 and subsequent standards, the previously identified standards for those years are deemed maximum feasible, but if NHTSA determines that the previously identified standards are not maximum

[2691] 49 U.S.C. 32902(b)(1) (2007).
[2692] Indeed, EPCA initially only required NHTSA to establish CAFE standards for passenger cars; establishment of light truck standards was permissible.
[2693] In the CAFE program, "domestically-manufactured" is defined by Congress in 49 U.S.C. 32904(b). The definition roughly provides that a passenger car is "domestically manufactured" as long as at least 75% of the cost to the manufacturer is attributable to value added in the United States, Canada, or Mexico, unless the assembly of the vehicle is completed in Canada or Mexico *and* the vehicle is imported into the United States more than 30 days after the end of the model year.
[2694] 49 U.S.C. 32902(b)(4) (2007).

feasible, the 92-percent minimum domestic passenger car standards would also change. This is consistent with the statutory language that the 92-percent standards must be determined at the time an overall passenger car standard is promulgated and published in the Federal Register. Thus, any time NHTSA establishes or changes a passenger car standard for a model year, the minimum domestic passenger car standard for that model year will also be evaluated or reevaluated and established accordingly. NHTSA explained this in the rulemaking to establish standards for MYs 2017 and beyond and received no comments.[2695]

The 2016 Alliance/Global petition for rulemaking asked NHTSA to revise the 92-percent minimum domestic passenger car standards retroactively for MYs 2012-2016 "to reflect 92 percent of the required average passenger car standard taking into account the fleet mix as it actually occurred, rather than what was forecast." The petitioners stated that doing so would be "fully consistent with the statute."[2696]

NHTSA explained in the NPRM that NHTSA understood that determining the 92 percent value ahead of the model year to which it applies, based on the information then available to the agency, would result in a different mpg number than if NHTSA determined the 92 percent value based on the information available at the end of the model year in question. NHTSA further explained that it understood that determining the 92 percent value ahead of time could make the minimum domestic passenger car standard more stringent than it could be if it were determined at the end of the model year, *if* manufacturers end up producing more larger-footprint passenger cars than what NHTSA had originally anticipated.

Accordingly, NHTSA sought comment on the request by Alliance/Global. Additionally, recognizing the uncertainty inherent in projecting specific values far into the future, NHTSA also sought comment on whether it is possible to define the 92 percent valueas a range, if NHTSA defined the values associated with a CAFE standard (i.e., the footprint curve) as a range rather than as a single number. NHTSA referred to the sensitivity analysis included in the proposal and in the accompanying PRIA as a basis for such an mpg range "defining" the passenger car standard in any given model year. If NHTSA took that approach, 92 percent of that "standard" would also, necessarily, be a range. NHTSA broadly sought comment on that approach or other similar approaches.

The Alliance and FCA commented that they "supported the NHTSA proposal" to calculate 92 percent as a range rather than as a single value, with the ultimate minimum domestic passenger car standard to be determined at the end of the MY to which it applies.[2697] Both organizations cited compliance difficulties when the 92 percent calculated at the time of the rulemaking turns out to be more stringent than 92 percent of the final MY compliance

[2696] Automobile Alliance and Global Automakers Petition for Direct Final Rule with Regard to Various Aspects of the Corporate Average Fuel Economy Program and the Greenhouse Gas Program (June 20, 2016) at 5, 17-18, available at https://www.epa.gov/sites/production/files/201609/documents/petition_to_epa_from_auto_alliance_and_global_automakers.pdf (hereinafter Alliance/Global Petition).
[2697] Alliance, NHTSA-2018-0067-12073, Full Comment Set, at 41; FCA, NHTSA-2018-0067-11943, at 64.

obligations for passenger cars, and argued that minimum domestic passenger car standards should be recalculated as part of this rulemaking for all model years, rather than only MYs 2021-2026, in order to ameliorate that compliance difficulty retroactively. The Alliance argued that the 18 month lead time requirement should not be interpreted to apply to the minimum domestic passenger car standards, because if the 92 percent value is a range like the overall passenger car curve, then that value cannot be determined until after the model year is completed.[2698] Because manufacturers' individual compliance obligations are not subject to the 18 month lead time requirement, the Alliance requested that the 92 percent should similarly not be.[2699] Separately, Kreucher commented that NHTSA should expand the credit transfer provision to allow transferred credits to be used to meet the minimum domestic passenger car standard.[2700]

In contrast, the States and Cities and ACEEE opposed changes to the minimum domestic passenger car standard, with the States and Cities commenting that NHTSA "is proposing to retroactively revise the 92 percent based on actual fleet mix"[2701] and ACEEE simply noting that the Alliance/Global had requested that NHTSA do this.[2702] ACEEE stated that NHTSA did not have discretion to alter the statutory requirement, and argued that calculating 92 percent at the end of the model year was "entirely counter to the intent of the law—the so-called backstop is designed explicitly to protect against the market shifts for which the [industry is] asking the standard to be adjusted."[2703] The States and Cities similarly argued that "the 92 percent requirement is expressly intended to be a projection, not a retrospective recalculation," and "the statute does not contemplate a 'range,' but rather a 'minimum' with a set value—92 percent. If Congress had intended the value to be a range, it would have included that language in the statute, and would not have determined the value with such specificity."[2704]

NHTSA considered comments about setting the MDPCS as a range. NHTSA recognizes that the approach discussed in the NPRM may not be within our statutory authority and therefore is setting the standards as specific values.

NHTSA agrees that setting the MDPCS after the model year is completed and the total passenger car fleet standard is known would provide standards that adapt with changes in consumer demand. However, such an approach would not establish the final numerical value until significantly after the model year completed, only after final compliance data has been submitted by all manufacturers and EPA and NHTSA have completed compliance work for the total passenger car fleet. In addition, the standard would be based on the production of all manufacturers of passenger cars, providing no means for an individual manufacturer to have

[2700] Kreucher, NHTSA-2018-0067-0444, at 11.
[2701] States and Cities, NHTSA-2018-0067-11735, at 79.
[2702] ACEEE, NHTSA-2018-0067-12122, Attachment (joint NGO comment to manufacturer petition for flexibilities), at 15.
[2703] *Id*. ACEEE cited a NHTSA statement in the 2010 final rule establishing standards for MYs 2012-2016 in support of this argument, noting that NHTSA had said "this minimum standard was intended to act as a 'backstop,' ensurng that domestically-manufactured passenger cars reached a given mpg level *even if the market shifted in ways likely to reduce overall fleet mpg*." *Id.* (emphasis added).
[2704] States and Cities, NHTSA-2018-0067-11735, at 79.

certainty over its final standard. Individual manufacturers likewise would have no control over the value by controlling their production mix. For these reasons, NHTSA is denying the Alliance/Global petition that the 92 percent value for the MDPCS be determined based on the information available at the end of the model year in question.

That said, NHTSA agrees that the actual total passenger car fleet standards have differed significantly the 2012 projection, and examined the projections from past rulemakings in greater detail. NHTSA reviewed the total passenger car fleet (all domestic and import passenger cars) standard that was projected at the time of rulemakings for MYs 2011 to 2018 and compared those projections to the actual total fleet passenger car standard for each of those model years from compliance data, based on the actual footprints and production volume of the models produced in those model years. Table VIII-1 shows the projected standards and the actual standards on a fuel economy basis, and Table VIII-2 shows the fuel economy values converted to fuel consumption values which was used as the basis for and analyzing the differences between the projected standards and actual standards.[2705] Table VIII-2 also shows the percentage difference between the total passenger car fleet standard at the time of the rulemaking and the actual fleet standard based on compliance data.

Table VIII-1 Projected Total Passenger Car Fleet Standard at the Time or Rulemaking Compared to the Actual Total Passenger Car Fleet Standard for the Model Year Based on Compliance Data

	Fuel Economy (mpg)							
	2011	2012	2013	2014	2015	2016	2017	2018
Projected Total Passenger Car Fleet Standard – From Rulemaking Analyses								
Final Standard	30.2	33.4	34.1	34.9	36.2	37.7	39.9	41.3
2011-2015 NPRM	31.2	32.8	34.0	34.8	35.8			
2012-2016 NPRM		33.6	34.3	35.2	36.4	37.9		
2017-2025 NPRM							40.0	41.4
Actual Required Total Passenger Car Fleet CAFE Standard – From Compliance Data								
Total Passenger Car Fleet Standard	30.2	33.0	33.5	34.2	35.5	36.9	39.0	40.6

[2705] Consistent with EPCA/EISA and corresponding regulations, CAFE compliance calculations have been conducted on a mile per gallon basis. However, engineering computations have almost exclusively been conducted on a fuel consumption basis (i.e., in gallons per mile), because the underlying engineering relationships are more meaningfully defined on a fuel consumption basis.

Table VIII-2 Projected and Actual Total Passenger Car Fleet Standards and Differences on a Fuel Consumption Basis

	Fuel Consumption (gallons per mile)							
	2011	2012	2013	2014	2015	2016	2017	2018
Projected Fuel Consumption From Rulemaking Analyses = 1/ (Projected Total Passenger Car Fleet Standard)								
Final Standard	0.0331	0.0300	0.0293	0.0287	0.0276	0.0265	0.0251	0.0242
2011-2015 NPRM	0.0321	0.0305	0.0294	0.0288	0.0280			
2012-2016 NPRM		0.0298	0.0291	0.0284	0.0275	0.0264		
2017-2025 NPRM							0.0250	0.0241
Actual Required Fuel Consumption From Compliance Data = 1/(Actual Required Total Passenger Car Fleet CAFE)								
Total Passenger Car Fleet (domestic + import)	0.0331	0.0303	0.0299	0.0292	0.0282	0.0271	0.0256	0.0246
Percentage Difference (Projected Standard vs. Actual Standard)								
Final Standard	0.1%	1.1%	1.9%	2.0%	2.0%	2.2%	2.3%	1.7%
2011-2015 NPRM	3.3%	-0.5%	1.6%	1.7%	0.7%			
2012-2016 NPRM		1.8%	2.5%	3.0%	2.6%	2.8%		
2017-2025 NPRM							2.6%	2.0%
Average	1.7%	0.8%	2.0%	2.2%	1.8%	2.5%	2.4%	1.9%
Average MYs 2011 - 2018	1.9%							

The data show that the standards projected in 2012 were consistently more stringent than the actual standards, by an average of 1.9 percent. This difference indicates that in rulemakings conducted in 2009 through 2012, the agencies' projections of passenger car vehicle footprints and production volumes consistently underestimated the consumer demand for larger passenger cars over the MYs 2011 to 2018 period.

To establish minimum standards for domestic passenger cars in these past rulemakings, NHTSA computed the average of manufacturers' requirements given the attribute-based standards being issued, and given the projected distribution of passenger car footprints as indicated in the analysis fleet (aka market forecast) used to analyze impacts of the standards. The joint NHTSA-EPA rulemaking establishing standards for MYs 2012-2016 presented analysis that, in turn, used a "2008-based" market forecast that combined detailed information regarding the MY 2008 fleet with a commercial market forecast (by brand and segment) and a range of agency assumptions. Importantly, the commercial market forecast showed Chrysler's production falling dramatically, and never recovering; as well as Chrysler passenger cars being distributed more than most OEMs (other than Jaguar and Mercedes) toward larger footprints, and this forecast impacted the NHTSA's projection of overall average requirements for passenger cars under the footprint-based standards. For example, the 2008-based forecast showed production of Chrysler brands (Chrysler, Dodge, Jeep, and Ram) for the U.S. market totaling 0.8 million units by MY 2017, and today's analysis fleet uses a MY 2017 fleet showing 1.9 million Chrysler-branded units. Also, among the agencies' assumptions, was that some manufacturers (Chrysler, Ford, Subaru, Mazda, and Mitsubishi) would rapidly increase production of small footprint vehicles not observed in the MY 2008 fleet.

The joint rulemaking establishing standards for MYs 2017-2025 also used this 2008-based fleet for the NPRM, showing more than 1.3 million units smaller than 41 square feet in MY 2017, far more than the 0.3m units shown in the model inputs for today's analysis. For the 2012 final rule, the agencies conducted side-by-side analysis, one using the 2008-based fleet, and one using a 2010-based fleet. The 2010-based fleet used a newer commercial forecast that was considerably more sanguine regarding, for example, FCA's prospects. Minimum standards for domestic passenger cars were based on an average of results for the 2008-based and 2010-based total passenger car fleets.

The analysis fleet underlying today's reference case analysis is discussed above in Section VI.A.2 and available in full detail with the model inputs and outputs accompanying today's notice.[2706] For the current rulemaking, NHTSA also considered that, unlike the passenger car standards and light truck standards which are vehicle attribute-based and automatically adjust with changes in consumer demand, that MDPCSs are not attribute-based, and therefore do not adjust with changes in consumer demand. They are fixed standards that are established at the time of the rulemaking. The MYs 2011-2018 MDPCS were more stringent and placed more burden on manufacturers of domestic passenger cars than was projected and expected at the time of the rulemakings. NHTSA agrees with the Alliance's concerns over the impact of changes in consumer demand on manufacturers' ability to comply with the MDPCS and in particular, manufacturers that produce larger passenger cars domestically.

Additionally, as discussed in more detail in Section VIII.B.4 below, consumer demand may shift even more in the direction of larger passenger cars if fuel prices continue to remain low. The fuel prices used in the analysis for this final rule rely on EIA's future forecasts of fuel prices, which were made prior to the recent collapse of oil prices. If the former OPEC+ members continue to pursue market share, fuel prices will likely continue to drop. If, instead of pursuing market share, they try to control prices restricting supply, U.S. shale production could begin to ramp back up and exert downward pressure on price. If fuel prices end up even lower than our analysis assumes, benefits from saving additional fuel will be worth even less to consumers. Our analysis captures none of these effects. Sustained low oil prices can be expected to have real effects on consumer demand for additional fuel economy, and consumers may foreseeably be even less interested in smaller passenger cars than they are at present.

To help avoid similar outcomes in the rulemaking timeframe to what has happened with the MDPCS over the last several model years, NHTSA determined it is reasonable and appropriate to consider the recent projection errors as part of estimating the projected total passenger car fleet fuel economy for MYs 2021-2026. As stated above the average difference over MYs 2011-2018 was 1.9 percent. As explained above, those differences are largely attributable to aspects of the forecasts that turned out to be far different from reality. NHTSA is projecting the total passenger car fleet fuel economy using the central analysis value in each model year and applying an offset based on the historical 1.9 percent difference identified for

[2706] https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system.

MYs 2011-2018. Table VIII-3 hows the calculation values used to determine the total passenger car fleet fuel economy value for each model year.

NHTSA will continue its practice of determining the MDPCS as specific values at the same time that it sets passenger car standards, at 92 percent of the projected passenger cars standard in each model year. Table VIII-3 also shows the computations for the MDPCS for each model year. The new MDPCS are prescribed in the regulatory text below.

Table VIII-3 Calculation of the Projected Total Passenger Car Fleet Standard and the Minimum Domestic Passenger Car Standard (92 Percent of the Total Passenger Car Standard)

	2021	**2022**	**2023**	**2024**	**2025**	**2026**
Projected Total PC Fleet Standard - Central Analysis (mpg)	44.2	44.9	45.6	46.3	47.0	47.7
Offset: Average Historical Difference Between Regulatory Analyses and Actual Total PC Fleet Standard (percent)	-1.9	-1.9	-1.9	-1.9	-1.9	-1.9
Offset: Average Historical Difference Between Regulatory Analyses and Actual Total PC Fleet Standard (mpg)	-0.82	-0.81	-0.88	-0.88	-0.89	-0.89
Projected Total PC Standard Accounting for Historical Offset (mpg)	43.4	44.1	44.7	45.4	46.1	46.8
Minimum Domestic Passenger Car Standard = 92% of Projected Total PC Standard Accounting for Historical Offset (mpg)	39.9	40.6	41.1	41.8	42.4	43.1

Table VIII-4 lists the minimum domestic passenger car standards reflecting the updated analysis discussed above, and comparing these to standards that would correspond to each of the other regulatory alternatives considered. NHTSA has updated these to reflect its overall analysis and resultant projection for the CAFE standards finalized today, highlighted below as "Preferred (Alternative 3)," and has calculated what those standards would be under the no action alternative (as issued in 2012, as updated for the NPRM, and as further updated by today's analysis) and under the other alternatives described and discussed further in Section V, above. As explained in a separate memorandum to the document, while the CAFE Model analysis underlying the FEIS, FRIA, and final rule does not reflect this change, separate analysis that does reflect the change demonstrates that doing so does not change estimated impacts of any of the regulatory alternatives under consideration.

Table VIII-4 Minimum Standards for Domestic Passenger Car Fleets

Alternative	**2021**	**2022**	**2023**	**2024**	**2025**	**2026**
No Action (2012)	42.7	44.7	46.8	49.0	51.3	
No Action (NPRM)	41.9	43.8	45.9	48.0	50.3	50.3
No Action (updated)	41.0	42.9	44.9	47.1	49.3	49.3
Alternative 1	39.4	39.4	39.4	39.4	39.4	39.4
Alternative 2	39.6	39.7	39.9	40.1	40.4	40.6
Preferred (Alternative 3)	**39.9**	**40.6**	**41.1**	**41.8**	**42.4**	**43.1**
Alternative 4	39.7	40.1	40.6	41	41.4	41.8
Alternative 5	41	41.4	41.9	42.3	42.7	43.1
Alternative 6	40.1	41	41.8	42.7	43.5	44.4
Alternative 7	41	41.9	42.7	43.6	44.5	45.4

c) Attribute-based and Defined by Mathematical Function

EISA requires NHTSA to set CAFE standards that are "based on 1 or more attributes related to fuel economy and express[ed]…in the form of a mathematical function."[2707] Historically, NHTSA has based standards on vehicle footprint and proposes to continue to do so for all the reasons described in previous rulemakings. As in previous rulemakings, NHTSA proposed to define the standards in the form of a constrained linear function that generally sets higher (more stringent) targets for smaller-footprint vehicles and lower (less stringent) targets for larger-footprint vehicles. These footprint curves are discussed in much greater detail in Section V above. NHTSA sought comment both on the choice of footprint as the relevant attribute and on the rationale for the constrained linear functions chosen to represent the standards; those comments and NHTSA's responses are discussed above in Section V.

d) Number of Model Years for Which Standards May be Set at a Time

EISA also states that NHTSA shall "issue regulations under this title prescribing average fuel economy standards for at least 1, but not more than 5, model years."[2708] In the 2012 final rule, NHTSA interpreted this provision as preventing the agency from setting final standards for all of MYs 2017-2025 in a single rulemaking action, so the MYs 2022-2025 standards were termed "augural," meaning "that they represent[ed] the agency's current judgment, based on the information available to the agency [then], of what levels of stringency would be maximum feasible in those model years."[2709] That said, NHTSA also repeatedly clarified that the augural standards were in no way final standards and that a future *de novo* rulemaking would be necessary in order both to propose and to promulgate final standards for MYs 2022-2025.

[2707] 49 U.S.C. 32902(b)(3)(A).
[2708] 49 U.S.C. 32902(b)(3)(B).
[2709] 77 FR 62623, 62630 (Oct. 15, 2012).

In the NPRM, NHTSA proposed to establish new standards for MYs 2022-2026 and to revise the previously-established final standards for MY 2021. NHTSA explained that legislative history suggests that Congress included the five year maximum limitation so NHTSA would issue standards for a period of time where it would have reasonably realistic estimates of market conditions, technologies, and economic practicability (i.e., not set standards too far into the future).[2710] However, NHTSA suggested that the concerns Congress sought to address by imposing those limitations are not present for nearer model years where NHTSA already has existing standards, and noted that revisiting existing standards is contemplated by both 49 U.S.C. § 32902(c) and 32902(g). NHTSA stated that the agency therefore believed that it is reasonable to interpret section 32902(b)(3)(B) as applying only to the establishment of *new* standards rather than to the combined action of establishing new standards and amending existing standards.

Moreover, NHTSA argued, it would be an absurd result if the five year maximum limitation were interpreted to prevent NHTSA from revising a previously-established standard that the agency had determined to be beyond maximum feasible, while concurrently setting five years of standards not so distant from today. The concerns Congress sought to address are much starker when NHTSA is trying to determine what standards would be maximum feasible 10 years from now as compared to three years from now.

NADA commented that NHTSA has discretion and authority to set standards for MY 2026 and that the "statutory five-year rule is not a barrier to doing so,"[2711] while the environmental group coalition argued that NHTSA "is limited to prescribing fuel economy standards for only five model years at a time," but "[h]ere, NHTSA is setting standards for six model years, 2021 through 2026. This exceeds NHTSA's statutory authority."[2712] Consumers Union argued that "[i]f Congress had intended the statute to only apply to the establishment of new standards, as the agencies contend, it certainly could have stated as such. But Congress did not include any language even hinting at this interpretation."[2713]

NHTSA continues to believe, consistent with the legislative history, that the five year limitation was intended to prevent NHTSA from setting standards too far into the future, recognizing that predicting the future is difficult. Consumers Union is correct that nothing in the statute compels the interpretation that the five year limitation applies only to the setting of new standards rather than to the combined action of establishing new standards and amending existing standards, but NHTSA does not believe that the statute precludes this interpretation, either. The statute allows NHTSA to revisit existing standards; the statute separately allows NHTSA to prescribe new standards for at least 1, but not more than 5, model years when it "issues regulations." It is not clear whether the statute precludes multiple concurrent or quickly-sequential rulemakings "issuing regulations" for different periods of time. If this approach were used, for example, to try to set ten years' worth of CAFE standards essentially at once, this would appear directly contrary to the statute. If this approach were used to revisit an existing standard and then (in a separate rulemaking) set five years' worth of standards for the

immediately ensuing model years, this would seem consistent with Congressional intent, but an unnecessary use of tax dollars that could be saved by consolidating agency (and commenter) work into a single rulemaking action. NHTSA does not believe that Congress intended to force the agency to waste resources, and continues to believe that the current interpretation is reasonable and appropriate.

e) Maximum Feasible Standards

As discussed above, EPCA requires NHTSA to consider four factors in determining what levels of CAFE standards would be maximum feasible, and NHTSA presents in the sections below its understanding of the meaning of those four factors. All factors should be considered, in the manner appropriate, and then the maximum feasible standards should be determined.

(1) Technological Feasibility

"Technological feasibility" refers to whether a particular method of improving fuel economy is available for deployment in commercial application in the model year for which a standard is being established. Thus, NHTSA is not limited in determining the level of new standards to technology that is already being commercially applied at the time of the rulemaking. For the proposal, NHTSA explained that it had considered a wide range of technologies that improve fuel economy, subject to the constraints of EPCA regarding how to treat alternative fueled vehicles, such as battery-electric vehicles, in determining maximum feasible standards, and considering the need to account for which technologies have already been applied to which vehicle model/configuration, and the need to realistically estimate the cost and fuel economy impacts of each technology. NHTSA explained that it had not attempted to account for every technology that might conceivably be applied to improve fuel economy and considered it unnecessary to do so given that many technologies address fuel economy in similar ways.[2714] NHTSA noted that technological feasibility and economic practicability are often conflated, trying to explain that the question of whether a fuel-economy-improving technology does or will exist (technological feasibility) is a different question from what economic consequences could ensue if NHTSA effectively requires that technology to become widespread in the fleet and the economic consequences of the absence of consumer demand for technology that are projected to be required (economic practicability). NHTSA explained that it is therefore possible for standards to be technologically feasible but still beyond the level that NHTSA determines to be maximum feasible due to consideration of the other relevant factors.

The States and Cities commenters argued that NHTSA's interpretation of the technological feasibility factor was unreasonable, stating that "…fuel economy standards under EPCA are 'intended to be technology forcing' because Congress recognized 'that 'market forces . . . may not be strong enough to bring about the necessary fuel conservation which a national

[2714] For example, NHTSA has not considered high-speed flywheels as potential energy storage devices for hybrid vehicles; while such flywheels have been demonstrated in the laboratory and even tested in concept vehicles, commercially available hybrid vehicles currently known to NHTSA use chemical batteries as energy storage devices, and the agency has considered a range of hybrid vehicle technologies that do so.

energy policy demands.'"[2715] The States and Cities commenters thus argued that all alternatives less stringent than the baseline/augural standards alternative were unacceptable because they would not force technologies to be developed and applied, and NHTSA had "conce[ded] that the technology already exists that could meet the more stringent augural standards."[2716] These commenters stated that "NHTSA is therefore impermissibly and unreasonably (and even implicitly) re-interpreting this factor in a manner contrary to the plain meaning of 'feasibility' and ignoring EPCA's technology-forcing purpose. *See Chevron*, 467 U.S. at 843; *Fox Television*, 556 U.S. at 515 ('An agency may not … depart from a prior policy *sub silentio*.')." CARB[2717] and CBD *et al.*[2718] also argued that EPCA was intended to be technology forcing.

The States and Cities commenters also argued that NHTSA had previously stated in rulemakings that it considered "*all* types of technologies that improve real-world fuel economy," but in the NPRM NHTSA stated instead that it had "not attempted to account for every technology that might conceivably be applied to improve fuel economy and consider[ed] it unnecessary to do so given that many technologies address fuel economy in similar ways."[2719] The States and Cities commenters stated that "[t]his is an unexplained departure from the agency's past practice and prior interpretation of 'technological feasibility,' citing *Fox Television*, and argued that NHTSA had not explained "1) what 'similar ways' means, or 2) why the fact that a technology that might improve fuel economy 'in similar ways' to another technology obviates NHTSA's obligation to consider its availability, particularly given the differences in costs between different technologies."[2720] The States and Cities commenters pointed to the examples of HCR1 and HCR2 as technologies "already widely available in the market" that should have been considered, and claimed that NHTSA had "failed to even consult with EPA regarding which technologies the agency considered," "result[ing] in fundamentally flawed predictions of what technology can be applied in model years 2021-2026."[2721]

Mazda, in contrast, stated that it agreed that "mere development and introduction of advanced fuel efficient technologies is not sufficient for manufacturers to comply with established GHG and fuel efficiency standards. The technologies must be widely adopted by consumers for them to provide the expected environmental benefit."[2722] Mr. Kreucher stated that manufacturers have been applying "unprecedented levels of technology" but are still falling short of their compliance obligations, pointing in particular to light truck compliance in MY 2016.

Kreucher argued that "[t]his indicates a serious overestimation of technological feasibility in the prior [2012] analysis that must be corrected."[2723]

UCS stated that the NPRM analysis "undermined" an assessment of "technical feasibility," by "paint[ing] fuel-saving technologies as less effective and more costly than real-world data indicate," through several mechanisms.[2724] First, UCS argued that the analysis had underestimated ICE efficiency possibilities, "frequently ignoring technology that is already commercialized or is widely anticipated to be readily available within the timeframe of the standards."[2725] Second, UCS suggested that the NPRM analysis had "overstate[d] the degree to which manufacturers have deployed some of the most cost-effective technologies, while errors in full vehicle simulation and rampant disregard for the current state of technology underestimates the potential for future improvement."[2726] UCS claimed that "[f]requently the agencies have departed from past precedence in specific ways *in order to* increase technology costs associated with technology deployment, sometimes failing to provide even a glimmer of reasonable justification for such decisions."[2727] (emphasis added) Third, UCS argued that the model had been deliberately constructed to avoid choosing the most cost-effective technology pathways, showing higher costs and more future overcompliance than UCS analysis showed.[2728] Finally, UCS argued that better modeling of credit trading and use would further reduce technology costs. UCS concluded that "The mischaracterization of technology and unrealistic model construction lead to an inaccurate assessment of technological feasibility, effectively undermining this factor's weight in considering maximum feasible standards."[2729]

Contrary to the assertion by several commenters that NHTSA has historically claimed that it *must* set technology-forcing standards, NHTSA has previously described the technological feasibility factor as *allowing* the agency to set standards that force the development and application of new fuel-efficient technologies.[2730] In the same preamble section in which that description was set forth, NHTSA stated that "[i]t is important to remember that technological feasibility must also be balanced with the other of the four statutory factors. Thus, while 'technological feasibility' can drive standards higher by assuming the use of technologies that are not yet commercial, 'maximum feasible' is also defined in terms of economic practicability, for example, which might caution the agency against basing standards (even fairly distant standards) *entirely* on such technologies."[2731] NHTSA further stated that "…as the 'maximum feasible' balancing may vary depending on the circumstances at hand for the model year in

[2731] *Id*.

which the standards are set, the extent to which technological feasibility is simply met or plays a more dynamic role may also shift."[2732]

NHTSA continues to believe that, for purposes of this rulemaking covering standards for MYs 2021-2026, the crucial question is not whether technologies exist to meet the standards—they do. The question is rather, given that the technology exists, how much of it should be required to be added to new cars and trucks in order to conserve more energy, and how to appropriately balance additional energy conserved and additional cost for new vehicles. Regardless of whether technological feasibility *allows* the agency to set technology-forcing standards, technological feasibility does not *require*, by itself, NHTSA to set technology-forcing standards if other statutory factors would point the agency in a different direction. NHTSA has expressed this interpretation of technological feasibility over the course of multiple rulemakings.[2733] The States and Cities commenters appear, at the root, to be contesting the agency's determination of maximum feasible standards, by way of arguing that NHTSA must interpret the technological feasibility factor as necessarily driving greater energy conservation. The balancing of factors to determine maximum feasible standards is a separate issue, for which EPCA/EISA gives NHTSA considerable discretion.

The States and Cities commenters focus on previous rulemaking language when they suggest that the agency was arbitrary and capricious for not explaining more fully why it need not expressly evaluate every single technology that does or could exist in MYs 2021-2026. While NHTSA stated in 2012 that it had "considered all types of technologies that improve real-world fuel economy, including air-conditioner efficiency and other off-cycle technology, PHEVs, EVs, and highly-advanced internal combustion engines not yet in production,"[2734] that statement was only one in a larger discussion. The 2012 final rule also stated expressly that "[t]here are a number of other potential technologies available to manufacturers in meeting the 2017-2025 standards *that the agencies have evaluated but have not considered* in our final analyses. These include HCCI, 'multi-air', and camless valve actuation, and other advanced engines currently under development."[2735] (emphasis added) Thus, even under the prior analysis that some commenters appear to prefer, it is not entirely correct to say that NHTSA had considered *all* technologies in existence or that could exist, because some technologies were clearly and purposely left out of the prior rule's analysis. In response to commenters' apparent confusion regarding NHTSA's statement that it did not consider technologies that improved fuel economy in "similar ways" as other technologies discussed in the NPRM, the meaning behind that statement was discussed at greater length in the section of the NPRM that substantively covered those technologies. For example, in discussing the "HCR2" technology, the agencies explained that while the agencies were not modeling HCR2 expressly due to concerns that it remained "entirely speculative," "[t]he CAFE model allows for incremental improvement over existing HCR1 technologies with the addition of improved accessory devices (IACC), a technology that is available to be applied on many baseline MY 2016 vehicles with HCR1

[2735] 77 FR at 62706 (Oct. 15, 2012).

engines and may be applied as part of a pathway of compliance to further improve the effectiveness of existing HCR1 engines."[2736] In this and in other instances, technologies included in the analysis improved fuel economy in similar ways to other technologies not included. Here, HCR1, when combined with IACC, results in "a step past" HCR1, which is similar to the unproven HCR2. As in the 2012 rule, the agencies explained in the NPRM why certain technologies were not considered, and sought comment. In response to comments received, some technologies have been added to the analysis for the final rule. See Section VI for more information.

While the agencies respond to many of UCS's analytical concerns in Sections IV and VI (which include extensive discussion of changes made in response to comments), NHTSA recognizes that some commenters believe that more technologies are "available for deployment" more widely, and sooner, than the final rule's analysis reflects. This question has long been a topic of debate in CAFE and CO_2 rulemakings—the agencies consider which technologies can be applied to which vehicles in which model years in order to assess the costs and benefits of pushing the industry to reach different levels of standards, which in turn helps to inform stringency determinations. In response to comments, the agencies have expanded the number of technologies and the vehicles to which they may be applied for this final rule, but continue to disagree that certain technologies can be applied widely in the rulemaking timeframe. NHTSA does not believe, for example, that HCCI will be unavailable for widespread application in the rulemaking timeframe because it *wishes* to believe this prediction—NHTSA believes it based on the fact that HCCI has been in the research phase for several decades, and the only production applications to date use a highly-limited version that restricts HCCI combustion to a very narrow range of engine operating conditions. Section VI contains further discussion of these issues.

(2) Economic Practicability

"Economic practicability" has traditionally referred to whether a standard is one "within the financial capability of the industry, but not so stringent as to" lead to "adverse economic consequences, such as a significant loss of jobs or unreasonable elimination of consumer choice."[2737] In evaluating economic practicability, NHTSA considers the uncertainty surrounding future market conditions and consumer demand for fuel economy alongside consumer demand for other vehicle attributes. NHTSA has explained in the past that this factor can be especially important during rulemakings in which the auto industry is facing significantly adverse economic conditions (with corresponding risks to jobs). Consumer acceptability is also a major component of economic practicability,[2738] which can involve consideration of anticipated consumer responses not just to increased vehicle cost, but also to the way manufacturers may change vehicle models and vehicle sales mix in response to CAFE standards. In attempting to

[2738] *See*, *e.g.*, Center for Auto Safety v. NHTSA (CAS), 793 F.2d 1322 (D.C. Cir. 1986) (Administrator's consideration of market demand as component of economic practicability found to be reasonable); *see also* Public Citizen v. NHTSA, 848 F.2d 256 (Congress established broad guidelines in the fuel economy statute; agency's decision to set lower standards was a reasonable accommodation of conflicting policies).

determine the economic practicability of attribute-based standards, NHTSA considers a wide variety of elements, including the annual rate at which manufacturers can increase the percentage of their fleet that employs a particular type of fuel-saving technology,[2739] and manufacturer fleet mixes. NHTSA also considers the effects on consumer affordability resulting from costs to comply with the standards, and consumers' valuation of fuel economy, among other things.

Prior to the MYs 2005-2007 rulemaking under the non-attribute-based (fixed value) CAFE standards, NHTSA generally sought to ensure the economic practicability of standards in part by setting them at or near the capability of the "least capable manufacturer" with a significant share of the market, i.e., typically the manufacturer whose fleet mix was, on average, the largest and heaviest, generally having the highest capacity and capability so as not to limit the availability of those types of vehicles to consumers. In the first several rulemakings establishing attribute-based standards, NHTSA applied marginal cost-benefit analysis, considering both overall societal impacts and overall consumer impacts. Whether the standards maximize net benefits has thus been a significant, but not dispositive, factor in the past for NHTSA's consideration of economic practicability. Executive Order 12866, as amended by Executive Order 13563, states that agencies should "select, in choosing among alternative regulatory approaches, those approaches that maximize net benefits. . ." In practice, however, agencies, including NHTSA, must consider that the modeling of net benefits does not capture all considerations relevant to economic practicability. Therefore, as in past rulemakings, NHTSA explained in the NPRM that it was considering net societal impacts, net consumer impacts, and other related elements in the consideration of economic practicability.

NHTSA's consideration of economic practicability depends on a number of elements. Expected availability of capital to make investments in new technologies matters; manufacturers' expected ability to sell vehicles with certain technologies matters; likely consumer choices matter; and so forth. NHTSA explained in the NPRM that NHTSA's analysis of the impacts of the proposal incorporated assumptions to capture aspects of consumer preferences, vehicle attributes, safety, and other elements relevant to an impacts estimate; but stated that it is difficult to capture every such constraint. Therefore, NHTSA explained, it is well within the agency's discretion to deviate from the level at which modeled net benefits are maximized if the agency concludes that that level would not represent the maximum feasible level for future CAFE standards. Economic practicability is complex, and like the other factors must also be considered in the context of the overall balancing and EPCA's overarching purpose of energy conservation. Depending on the conditions of the industry and the assumptions used in the agency's analysis of alternative standards, NHTSA stated that it could well find that standards that maximize net benefits, or that are higher or lower, could be at the limits of economic practicability, and thus potentially the maximum feasible level, depending on how the other factors are balanced.

NHTSA also stated in the NPRM that while the agency would discuss safety as a separate consideration, NHTSA also considered safety as closely related to, and in some circumstances a subcomponent of, economic practicability. On a broad level, manufacturers have finite resources

[2739] For example, if standards effectively require manufacturers to make technologies widely available that consumers do not want, or to make technologies widely available before they are ready to be widespread, NHTSA believes that these standards could potentially be beyond economically practicable.

to invest in research and development. Investment into the development and implementation of fuel saving technology necessarily comes at the expense of investing in other areas such as safety technology. On a more direct level, when making decisions on how to equip vehicles, manufacturers must balance cost considerations to avoid pricing further consumers out of the market. As manufacturers add technology to increase fuel efficiency, they may decide against installing additional safety equipment to reduce cost increases. And as the price of vehicles increase beyond the reach of more consumers, such consumers continue to drive or purchase older, less safe vehicles. In assessing practicability, NHTSA also considers the harm to the Nation's economy caused by highway fatalities and injuries.

CARB, the States and Cities commenters, and UCS all commented that the NPRM analysis, as the States and Cities put it, had "inexplicably inflat[ed] technology costs and rel[ied] on flawed models to predict impacts on vehicle sales."[2740] Both CBD *et al.* and UCS suggested that it was incorrect to assume that manufacturers would pass on 100 percent of cost increases as price increases to consumers.[2741] UCS further stated that "The agencies have then strategically excluded well-established academic literature to limit the assumptions used to define a consumer's willingness to pay in ways that further increase costs to consumers and/or decrease the consumer benefits of fuel economy and greenhouse gas emissions."[2742] UCS argued that assuming full pass-through of cost increases as price increases and assuming that consumers may not fully value improvements in fuel economy "arbitrar[ily] … depress the sales of highly fuel-efficient vehicles in the model by systematically negating consumer benefits of these vehicles."[2743] The States and Cities further argued that NHTSA had not "substantiated its concern that an increase in new vehicle prices would place a particular burden on 'low-income purchasers,'" and stated that NHTSA had "assume[d], without explanation, that" less-stringent fuel economy standards resulted in greater net savings for consumers, which NHTSA "acknowledge[d], without justification, 'is a significantly different analytical result from the 2012 final rule.'"[2744] The States and Cities commenters implied that this different result and NHTSA's "failure to acknowledge it" was impermissible under the standard set forth in *Fox Television*.[2745]

A number of commenters stated that the NPRM's estimates of job losses associated with the proposal conflicted with NHTSA's concerns about job losses if more stringent standards were promulgated. CBD *et al*. argued that NHTSA could not reasonably conclude that job losses make less-stringent standards more economically practicable than more-stringent standards.[2746] The States and Cities commenters stated that "[b]y declining to address its own findings of significant job losses in the auto sector, NHTSA has ignored an important aspect of the problem

and failed to propose a 'rational connection between the facts found and the choice made.'"[2747] The States and Cities commenters also argued that "the agency failed to acknowledge or explain its break with its own interpretation and practice of considering whether standards would cause a 'significant loss of jobs.'"[2748] Some commenters argued that more-stringent standards would create more jobs (and conversely, that less-stringent standards would result in job losses), primarily for supplier companies,[2749] and some noted that other studies had concluded that more-stringent standards would increase employment, citing, for example, the report by Synapse Energy Economics, Inc. on "Cleaner Cars and Job Creation."[2750] Some commenters further argued that less-stringent standards would hurt U.S. GDP,[2751] and some argued that they would hurt U.S. industry's international competitiveness because other countries/regions have more stringent standards, and investment may shift to those countries if U.S. standards do not continue to compel it.[2752] The States and Cities commenters stated that failing to address fully "the negative employment and GDP impacts of the Proposed Rollback is an abdication of NHTSA's clear statutory duty to consider the economic practicability of its proposed standards, and an impermissible interpretation of the statutory text."[2753]

Commenters disagreed on whether and how NHTSA should consider consumer demand. Mr. Kreucher, the Texas Congressional Delegation,[2754] and Senator Inhofe,[2755] among others, all argued that considering consumer demand for fuel economy was important, while other commenters argued that while it may be permissible for NHTSA to consider consumer demand, NHTSA could not elevate that consideration above others. CARB and the States and Cities commenters both cited language from *CAS v. NHTSA* for the premise that "Congress intended energy conservation to be a long-term effort that would continue through temporary improvements in energy availability. Thus, it would clearly be impermissible for NHTSA to rely on consumer demand to such an extent that it ignored the overarching goal of fuel conservation."[2756] The Minnesota agencies stated that "making sweeping assumptions about consumer preferences should not trump the clear public benefit to reducing GHG emissions through these standards."[2757] Mr. Kreucher commented, in contrast, that consumer preferences are driven entirely by "[l]ong term fuel price expectations and fuel price alone," and disagreed with the historical "implicit assumption that if you build it customers will come."[2758]

The Minnesota agencies argued that focusing on consumer preferences represented an "unreasonable and unprecedented shift in interpretation."[2759] The States and Cities commenters stated similarly that NHTSA had "redefined 'economically practicable' to categorically exclude standards that, based on some unspecified metric, 'widely apply technologies that consumers do not want,'" and argued that "NHTSA has offered no explanation for how it would define 'wide application,' much less how it would supposedly determine what consumers do or do not want."[2760] The States and Cities commenters argued that it was internally inconsistent (and therefore arbitrary and capricious) for NHTSA to rely in its justification on concerns about consumer acceptance of technologies, while concurrently "acknowledging the 'extensive debate over how much consumers do (and/or should) value fuel savings and fuel economy as an attribute in new vehicles'"[2761] The States and Cities commenters stated that the NPRM's modeling "assume[ed] that consumers assign no value to fuel savings whatsoever," and that "This assumption is not only implausible but also flies in the face of the Agency's own statements that consumers likely value between half of and all future fuel savings."[2762]

With regard to whether consumers *do* want more fuel economy, NESCAUM stated that "the most recent surveys indicate that consumers continue to place a high value on fuel efficient vehicles of all types,"[2763] while Alliance for Vehicle Efficiency stated that "Consumers have adopted incremental changes to new vehicles that increase fuel economy that don't compromise on power, size or safety."[2764] The States and Cities commenters argued that "consumer choice is, in fact, enhanced by providing consumers with the option of purchasing higher-efficiency vehicles."[2765] CBD *et al*. and the States and Cities commenters stated that NHTSA had simply made assertions about consumer demands without supporting evidence,[2766] with the States and Cities commenters also arguing that the fuel price assumptions in the NPRM were "unsupported" and "contradicted by recent evidence," despite NHTSA's arguments that low fuel prices made "fuel efficiency less attractive to consumers."[2767] Somewhat in contrast, NESCAUM stated that "[g]iven recent consumer preferences for larger vehicles, maximizing fuel efficiency and GHG emission reductions in larger footprint vehicles is even more important," noting that footprint based standards "are intentionally flexible to accommodate industry and consumer preferences."[2768] NESCAUM also stated that many HEV/PHEV/EV models are now available and that their sales "reflect[ ] growing consumer acceptance of the technology, …despite the low availability of electric vehicle models in the Northeast Section 177 States and the auto industry's continuing failure to actively market [them]."[2769]

[2769] *Id*. at 3.

Regarding the NPRM's statement that safety could be a subcomponent of economic practicability, the States and Cities commenters stated that this was "an unreasonable interpretation of this factor, given that safety concerns are not discussed in EPCA and have no direct correlation to whether a standard is economically practicable."[2770] The States and Cities commenters further stated that "NHTSA has never before analyzed safety considerations as falling under this factor, and fails to explain its reason for doing so now,"[2771] and said that it was "unmoored from reality" for NHTSA to state without support that "[i]nvestment into the development and implementation of fuel saving technology necessarily comes at the expense of investing in other areas such as safety technology."[2772] The States and Cities commenters argued that investment in fuel economy rather than safety "does not explain why safety should be folded into a consideration of whether standards are economically practicable."[2773] IPI argued that "[i]t is arbitrary for NHTSA to count alleged safety costs as support for its propose [*sic*] rollback both under the economic practicability factor and as its own separate 'bolster[ing] factor,' and yet never fully monetize climate- and pollution-related deaths and other welfare impacts under either the need to conserve energy factor nor under the economic practicability factor."[2774]

In response to these comments, NHTSA continues to believe that it is reasonable to interpret "economic practicability" as the agency has long interpreted it: as a question of whether a standard is one "within the financial capability of the industry, but not so stringent as to" lead to "adverse economic consequences, such as a significant loss of jobs or the unreasonable elimination of consumer choice."[2775] NHTSA disagrees that this interpretation is new or divergent from past interpretations of economic practicability—this is, to the word, the same interpretation set forth in the 2010 and 2012 final rules, and in multiple earlier rules. Commenters disagreeing with the NPRM's assessment of economic practicability seem, fundamentally, to be disagreeing with how NHTSA *applied* this interpreted definition of economic practicability to the information then before the agency, and also with the agency's conclusion of how economic practicability weighed against the other statutory factors.

The following text explains why NHTSA continues to believe that the pieces of the analysis it categorizes as relevant to economic practicability fit within the long-standing definition of that factor. Section VIII.B.4 below will explain how the agency has considered those pieces of the analysis in balancing economic practicability with the other statutory factors.

NHTSA has consistently described the manner in which it applies the "economic practicability" factor, and has given considerable weight to the phrasing of this description. Parsing the words of this description can be useful:

[2770] States and Cities, NHTSA-2018-0067-11735, at 70 ("arbitrary and capricious for agency to rely on factors 'which Congress has not intended it to consider'") (citing Chevron, 467 U.S. at 843; State Farm, 463 U.S. at 43).
[2771] *Id*. (citing Fox Television, 556 U.S. at 515).
[2772] *Id*.
[2773] *Id*.
[2774] NYU IPI, NHTSA-2018-0067-12213, Appendix, at 6-7.
[2775] 67 FR 77015, 77021 (Dec. 16, 2002).

The core of the description is the phrase "within the financial capability of the industry," but not so stringent as to lead to "adverse economic consequences." The following clause "such as a significant loss of jobs or the unreasonable elimination of consumer choice" is set off by a comma from "consequences," and use of the phrase "such as" indicates that it is a nonrestrictive clause.[2776] A nonrestrictive clause means that "significant loss of jobs" and "unreasonable elimination of consumer choice" are *examples* of "adverse economic consequences," but are not an exclusive list of the possible adverse economic consequences that NHTSA may consider. Further evidence that this clause was intended simply to offer examples comes from the 1977 final rule establishing passenger car standards for MYs 1981-1984, in which NHTSA examined the potential meaning of "economic practicability" at length and concluded that it should be interpreted as "requiring the standards to be within the financial capability of the industry, but not so stringent as to threaten substantial economic hardship for the industry," i.e., lacking the final clause.[2777]

A number of commenters took issue with NHTSA's consideration of consumer demand, citing the 1986 D.C. Circuit decision *CAS v. NHTSA* for the proposition that consumer demand cannot drive the balancing of factors in determining maximum feasible standards. In that case, the D.C. Circuit stated that "[i]t is axiomatic that Congress intended energy conservation to be a long term effort that would continue through temporary improvements in energy availability. Thus, it would clearly be impermissible for NHTSA to rely on consumer demand to such an extent that it ignored the overarching goal of fuel conservation."[2778] NHTSA agrees that the *CAS* decision makes this point, and that the 9th Circuit decision in *CBD v. NHTSA* also underscored that the overarching purpose of EPCA is energy conservation. That said, the *CAS* decision also contains a number of other points that are relevant both to the facts at hand in *this* rulemaking and NHTSA's current use of consumer demand as an aspect of economic practicability and as a consideration in determining maximum feasible standards. NHTSA will discuss *CAS* more extensively below in Section VIII.B.4, but this section will cover it briefly, specifically with respect to NHTSA's interpretation of economic practicability.

As noted in the NPRM and in the 2012 final rule, the *CAS* decision found NHTSA's consideration of market demand as a component of economic practicability reasonable.[2779] In *CAS*, petitioners the Center for Auto Safety, Public Citizen, Union of Concerned Scientists, and Environmental Policy Institute sued NHTSA over CAFE standards for MY 1986, arguing that NHTSA could not determine stringency on the basis of low expected consumer demand for fuel economy, and "that technology permitted greater fuel savings and that the statutorily required 'maximum feasible' level of fuel economy is higher than the standard" determined by

---

[2776] *See* Strunk, William and E.B. White, *The Elements of Style,* Fourth Edition (2000), Rule 3, at 2-7.
[2777] 42 FR 33534, 33537 (Jun. 30, 1977). It is worth noting that the agency considered and rejected an interpretation of economic practicability at that time based solely on cost-benefit analysis, stating "A cost-benefit analysis would be useful in considering these factors [of economic practicability], but sole reliance on such an analysis would be contrary to the mandate of the act." *Id*.
[2778] CAS, 793 F.2d 1322, 1340 (D.C. Cir. 1986).
[2779] 83 FR at 43208, fn. 402; 77 FR at 62668, fn. 111 (both citing CAS, 793 F.2d 1322, 1338 (D.C. Cir. 1986)).

NHTSA.[2780] The court followed *Chevron* in evaluating whether NHTSA could consider consumer demand, and found that Congress had not directly spoken to the consideration of consumer demand. The court then assessed whether NHTSA's interpretation of the statute "represents a reasonable accommodation of conflicting policies that were committed to the agency's care by statute," stating that "The agency's interpretation of the statutory requirements is due considerable deference and must be found adequate if it falls within the range of permissible constructions."[2781]

In assessing NHTSA's interpretation, the court stated that "Consumer demand is not specifically designated as a factor, but neither is it excluded from consideration; the factors of 'technological feasibility' and 'economic practicability' are each broad enough to encompass the concept. Thus, the unadorned language of the statute does not indicate a congressional intent concerning the precise objections raised by the petitioners." The court then examined EPCA's legislative history and concluded that "this language neither precludes nor requires lower standards when consumer demand for heavy vehicles is strong. The agency is directed to weigh the 'difficulties of individual automobile manufacturers;' there is no reason to conclude that difficulties due to consumer demand for a certain mix of vehicles should be excluded."[2782] The court even noted that "the petitioners [did] not challenge the consideration of consumer demand *per se*, but rather the weight the agency has given the factor in downgrading standards…."[2783]

NHTSA continues to believe that it is reasonable to consider consumer demand as an element of economic practicability, as the *CAS* court recognized. Comments objecting to the consideration of consumer demand appear to focus more, like the petitioners in *CAS*, on the agency's focus on consumer demand in the overall balancing of factors to determine what CAFE standards would be maximum feasible, insofar as they are expressing concern about consumer demand undermining energy conservation. Again, this question will be addressed further in Section VIII.B.4 below. To the extent that commenters dispute *any* consideration of consumer demand, the D.C. Circuit put that question to rest decades ago.

Related to the agency's consideration of consumer demand, a number of commenters took issue with the agencies' estimates of the cost of meeting higher fuel economy standards, arguing essentially that the analysis was deliberately constructed to inflate costs and minimize consumer willingness to pay for fuel economy improvements in order to arrive at a policy conclusion that higher fuel economy standards would not be economically practicable. NHTSA does not believe that commenters mean to argue with the agency's legal interpretation (i.e., the *consideration* of cost as an aspect of economic practicability), but rather with the agencies' analytical findings which inform that consideration. Comments on those analytical findings, and the agencies' responses and changes to the analysis in response to those comments, are discussed in Sections VI and VII above. Consumer willingness to pay for additional fuel economy in their new vehicles, in particular, is represented throughout the final rule analysis as 2.5 years—that is,

---

[2780] *CAS*, at 1328.
[2781] *CAS*, at 1338.
[2782] *CAS*, at 1338-1339.
[2783] *CAS*, at 1340.

that consumers value, and manufacturers will voluntarily add, fuel economy-improving technology that pays for itself in fuel savings within 2.5 years.

More generally, NHTSA believes that the cost of meeting CAFE standards is inherently relevant to assessing whether those standards are "within the financial capability of the industry but not so stringent as to lead to adverse economic consequences," for two primary reasons. First, vehicle manufacturers tend to have relatively fixed budgets for R&D and production, which are tied to overall revenues. If more of those budgets are spent on improving fuel economy, less of those budgets are available to spend on other vehicle characteristics (such as advanced safety features, or better performance or utility) that might improve sales. Offering less of those other vehicle characteristics in a market where many consumers are not particularly focused on fuel economy could lead to adverse economic consequences for those manufacturers. Manufacturers cannot simply increase budgets or turn limited resources toward supplying more of vehicle characteristics that do not motivate most sales. To the extent that more stringent standards drive manufacturing costs higher and those costs are passed forward to consumers in the form of price increases, those price increases can affect vehicle sales to some extent. NHTSA understands that some commenters disagree that higher manufacturing costs are necessarily passed forward to consumers in the way that the agencies have modeled them being passed forward, but the agencies do not have adequate information on which to base a different approach. Commenters disagreeing with this approach generally object on two fronts: first, because they believe that automakers cross-subsidize cost increases by raising the prices of certain models rather than all models, and second, because they believe that automakers could absorb regulatory costs and reduce profits. The agencies do not have enough information to model either of those issues in a meaningful way. Some amount of cross-subsidization no doubt occurs, but automakers closely hold pricing strategy information. The agencies do not attempt to model automakers voluntarily reducing profits in response to standards, again in part because the agencies do not have sufficient information, but also because these companies are publicly-traded and taking losses is not a long-term solution for companies whose success is measured by profitability. NHTSA believes that the analytical approach used today is reasonable given the information available to the agencies. While today's analysis does not show large sales effects due to price increases, and even accounting for fuel economy differences in this final rule *still* does not show large sales effects, it seems reasonable to call negative sales effects "adverse economic consequences."

Also related to consumer demand, NHTSA has previously considered manufacturer "shortfalls" as an aspect of economic practicability.[2784] The CAFE standards are corporate average standards, by definition, giving manufacturers the flexibility to decide how to distribute fuel economy-improving technologies throughout their fleet. In other words, no given vehicle need, itself, meet a standard or even its "target" on the target curve, as long as the fleet as a whole meets the standard. However, CAFE compliance is measured on a sales-weighted basis, so if a manufacturer ultimately sells more vehicles that perform poorly relative to their targets than it sells vehicles that beat their targets, the manufacturer may fall short of its compliance obligation despite having applied fuel economy-improving technologies in amounts that the

---

[2784] *See* 77 FR at 63040-43 (Oct. 15, 2012).

manufacturer originally anticipated would result in compliance. Recent compliance trends have illustrated this phenomenon, as discussed in Section IV above. When fuel is relatively inexpensive, Americans tend to be less interested in saving money on fuel, and thus less interested in fuel economy as compared to other vehicle attributes. Compliance shortfalls represent this consumer decision-making playing out in the market, and can thus be evidence of economic impracticability if sufficiently widespread.[2785]

As with the above-discussed aspects of economic practicability, commenters who objected to NHTSA's consideration of employment impacts disagreed less with the principle of considering employment impacts, and more with how NHTSA discussed employment impacts in the proposal's justification given the NPRM's findings on employment. Namely, the NPRM included a simplistic analysis that converted reduced technology costs under the preferred alternative relative to the augural standards into "job years" metric and estimated U.S. auto sector labor would be slightly reduced under the proposal as compared to under the augural standards (reflecting those reduced technology costs). Although new vehicle sales increased slightly under the NPRM's preferred alternative, this was offset because "manufacturing, integrating, and selling less technology means using less labor to do so."[2786] However, NHTSA expressed concern in the proposal justification section that "there could be potential for…loss of U.S. jobs…under nearly all if not all of the regulatory alternatives considered…."[2787] A number of commenters argued that if more stringent standards led to higher employment, as the NPRM (and also outside analyses) appeared to show, there was no way that less stringent standards could be *more* economically practicable.

As in the NPRM, NHTSA recognizes that the employment analysis for this final rule does not capture certain potential effects that may be important. NHTSA explained in the NPRM that the NPRM's employment analysis did not account for the risks that vehicle sales may be facing a bubble situation, or that manufacturers facing higher production costs might choose to move production overseas.[2788] This topic is discussed at greater length in Section VIII.B.4 below.

Commenters addressing NHTSA's consideration of safety as an aspect of economic practicability argued generally that EPCA did not call for discussion of safety concerns, and that it was unreasonable to assume that requiring higher levels of fuel economy might preclude investment in further vehicle safety improvements. NHTSA has already explained above that the long-standing definition of "economic practicability" lists example "adverse economic consequences" in a nonrestrictive clause format, meaning that other things besides employment and consumer choice impacts could cause economic consequences and be relevant to economic practicability. NHTSA believes that it is reasonable and appropriate to consider some aspects of safety as part of its consideration of economic practicability, because NHTSA continues to

---

[2785] *See*, *e.g.*, Alliance comments (Full Comment Set) at 25-29, describing automaker shortfalls in terms of fleet fuel economy increases required by augural and prior standards.
[2786] 83 FR at 43436 (Aug. 24, 2018).
[2787] *Id*. at 43216.
[2788] *Id*. at 43224-25.

believe that vehicle manufacturers have finite budgets for R&D and production that may be spent on fuel economy improvements when they may otherwise be spent on safety improvements, among other things that consumer value. Some commenters said that that was not a reasonable assumption, but it is supported by statements from vehicle manufacturers,[2789] and NHTSA does not have a reason to disbelieve that companies have limited budgets. Moreover, case law does not object to consideration of safety as an aspect of economic practicability.[2790] With regard to IPI's comment about monetization of climate and pollution-related deaths and other welfare impacts, the social cost of carbon and criteria pollutant damages estimates are intended to account for these impacts, and are considered both as part of the cost-benefit analysis and under the environmental implications aspect of the need of the U.S. to conserve energy. Given that the decision about what standards are "maximum feasible" is made by considering all of the factors, it is therefore less relevant under which factor a given issue is considered, so long as it is appropriately considered. To the extent that IPI disagrees with those estimated valuations, Section VI discusses comments on those topics and the agencies' responses.

Based on the above, NHTSA continues to believe that its interpretation of economic practicability is reasonable. Section VIII.B.4 will discuss how NHTSA has considered and balanced economic practicability for this final rule, and also respond to comments that addressed the NPRM's application of economic practicability to the information before the agency at that time.

(3) The Effect of Other Motor Vehicle Standards of the Government on Fuel Economy

"The effect of other motor vehicle standards of the Government on fuel economy" involves analysis of the effects of compliance with emission, safety, noise, or damageability standards on fuel economy capability and thus on average fuel economy. In many past CAFE rulemakings, NHTSA has said that it considers the adverse effects of other motor vehicle standards on fuel economy. It said so because, from the CAFE program's earliest years[2791] until recently, the effects of such compliance on fuel economy capability over the history of the CAFE program have been negative ones. For example, safety standards that have the effect of increasing vehicle weight thereby lower fuel economy capability, thus decreasing the level of

---

[2789] *See, e.g.*, Toyota comments at 6, NHTSA-2018-0067-12098 ("There are now more realistic limits placed on the number of engines and transmissions in a powertrain portfolio which better recognizes manufacturers must manage limited engineering resources and control supplier, production, and service costs.").

[2790] Competitive Enterprise Institute v. NHTSA, 901 F.2d 107, 120, n. 11 ("Petitioners have never clearly identified the precise statutory basis on which safety concerns should be factored into the CAFE scheme, although they alluded to occupant safety as part of the 'economic practicability' criterion in their MY 1989 petition to NHTSA and at oral argument. We do not find this failure fatal, however, because NHTSA has always examined the safety consequences of the CAFE standards in its overall consideration of relevant factors since its earliest rulemaking under the CAFE program, (citations omitted). Moreover, NHTSA itself believes Congress was cognizant of safety issues when it enacted the CAFE program. As evidence, NHTSA discusses a congressional report that dealt with the safety consequences of a downsized fleet of cars which had been considered by Congress during its enactment of the CAFE program.").

[2791] 42 FR 63184, 63188 (Dec. 15, 1977). *See also* 42 FR 33534, 33537 (Jun. 30, 1977).

average fuel economy that NHTSA can determine to be feasible. In the analyses for both the NPRM and this final rule, NHTSA has considered the additional weight that it estimates would be added in response to new safety standards during the rulemaking timeframe.[2792] NHTSA has also accounted for EPA's "Tier 3" standards for criteria pollutants in its estimates of technology effectiveness in both the NPRM and final rule analyses.[2793]

NHTSA discussed in the NPRM whether to consider EPA's CO_2 standards as an "other motor vehicle standard of the Government" among the other regulations typically considered, and if so, how. NHTSA explained that in the 2012 final rule establishing CAFE standards for MYs 2017-2021, NHTSA recognized that "To the extent the GHG standards result in increases in fuel economy, they would do so almost exclusively as a result of inducing manufacturers to install the same types of technologies used by manufacturers in complying with the CAFE standards."[2794] NHTSA concluded in 2012 that "no further action was needed" because "the agency had already considered EPA's [action] and the harmonization benefits of the National Program in developing its own [action]."[2795]

In the NPRM, NHTSA considered the issue afresh, and determined that it was clear based on a purely textual analysis of the statutory language that EPA's CO_2 standards applicable to light-duty vehicles are literally "other motor vehicle standards of the Government," in that they are standards set by a Federal agency that apply to motor vehicles. Basic chemistry makes fuel economy and tailpipe CO_2 emissions two sides of the same coin, as discussed at length above, and when two agencies functionally regulate both (because when regulating fuel economy, CO_2 emissions are necessarily also regulated, and vice versa), it would be absurd not to link the standards.[2796] The global warming potential of N_2O, CH_4, and HFC emissions are not closely linked with fuel economy, but neither do they affect fuel economy capabilities. Simply concluding that EPA's CO_2 standards *were* "other motor vehicle standards of the Government," however, did not answer *how* should NHTSA should consider them.

NHTSA acknowledged in the NPRM that some stakeholders had previously suggested that NHTSA should implement this statutory factor by letting EPA decide what CO_2 standards are appropriate and reasonable under the CAA and then simply setting CAFE standards with reference to CO_2 stringency. NHTSA disagreed that such an approach would be a reasonable interpretation of EPCA, explaining that while EPA and NHTSA consider some similar factors under the CAA and EPCA/EISA, respectively, they are not identical, and standards that are appropriate under the CAA may not be "maximum feasible" under EPCA/EISA, and vice versa. Moreover, NHTSA explained, considering EPCA's language in the context in which it was written, it seemed unreasonable to conclude that Congress intended EPA to dictate CAFE

[2792] PRIA, Chapter 5; FRIA, Section 5.
[2793] PRIA, Chapter 6; FRIA, Section 6.
[2794] 77 FR 62624, 62669 (Oct. 15, 2012).
[2795] *Id*.
[2796] In fact, EPA includes tailpipe CH_4, CO, and CO_2 in the measurement of tailpipe CO_2 for CO_2 compliance using a carbon balance equation so that the measurement of tailpipe CO_2 exactly aligns with the measurement of fuel economy for the CAFE compliance.

stringency. In fact, Congress clearly separated NHTSA's and EPA's responsibilities for CAFE under EPCA by giving NHTSA authority to set standards and EPA authority to measure and calculate fuel economy. If Congress had wanted EPA to set CAFE standards, it could have given that authority to EPA in EPCA or at any point since Congress amended EPCA.[2797]

NHTSA explained that NHTSA and EPA are obligated by Congress to exercise their own independent judgment in fulfilling their statutory missions, even though both agencies' regulations affect both fuel economy and CO_2 emissions. Because of this relationship, it is incumbent on both agencies to coordinate and look to one another's actions to avoid unreasonably burdening industry through inconsistent regulations,[2798] but both agencies' programs must stand on their own merits. As with other recent CAFE and CO_2 rulemakings, NHTSA explained that the agencies were continuing do all of these things in the proposal.

With regard to standards issued by the State of California, the NPRM explained that State tailpipe standards (whether for CO_2 or for other pollutants) do not qualify as "other motor vehicle standards of the Government" under 49 U.S.C. 32902(f), and that therefore, NHTSA would not consider them as such in proposing maximum feasible average fuel economy standards. NHTSA explained that States may not adopt or enforce standards related to fuel economy standards, which are preempted under EPCA, regardless of whether EPA granted any waivers under the Clean Air Act (CAA).

NHTSA and EPA agreed in the NPRM that State tailpipe CO_2 emissions standards do not become Federal standards and qualify as "other motor vehicle standards of the Government," when subject to a CAA preemption waiver. NHTSA stated that EPCA's legislative history supports that position, as follows:

EPCA, as initially passed in 1975, mandated average fuel economy standards for passenger cars beginning with model year 1978. The law required the Secretary of Transportation to establish, through regulation, maximum feasible fuel economy standards[2799] for model years 1981 through 1984 with the intent to provide steady increases to achieve the standard established for 1985 and thereafter authorized the Secretary to adjust that standard.

For the statutorily-established standards for model years 1978-1980, EPCA provided each manufacturer with the right to petition for changes in the standards applicable to that manufacturer. A petitioning manufacturer had the burden of demonstrating a "Federal fuel economy standards reduction" was likely to exist for that manufacturer in one or more of those model years and that it had made reasonable technology choices. "Federal standards," for that

[2797] The NPRM noted, for instance, that EISA was passed after the Massachusetts v. EPA decision by the Supreme Court. If Congress had wanted to amend EPCA in light of that decision, it would have done so at that time, but did not.
[2798] Massachusetts v. EPA, 549 U.S. 497, 532 (2007) ("[T]here is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.").
[2799] As is the case today, EPCA required the Secretary to determine "maximum feasible average fuel economy" after considering technological feasibility, economic practicability, the effect of other Federal motor vehicle standards on fuel economy, and the need of the Nation to conserve energy. 15 U.S.C. 2002(e) (recodified July 5, 1994).

limited purpose, included not only safety standards, noise emission standards, property loss reduction standards, and emission standards issued under various Federal statutes, but also "*emissions standards applicable by reason of section 209(b) of [the CAA]*."[2800] (Emphasis added). Critically, all definitions, processes, and required findings regarding a Federal fuel economy standards reduction were located within a single self-contained subsection of 15 U.S.C. 2002 that applied only to model years 1978-1980.[2801]

In 1994, Congress recodified EPCA. As part of this recodification, the CAFE provisions were moved to Title 49 of the United States Code. In doing so, unnecessary provisions were deleted. Specifically, the recodification eliminated subsection (d). The House report on the recodification declared that the subdivision was "executed," and described its purpose as "[p]rovid[ing] for modification of average fuel economy standards for model years 1978, 1979, and 1980."[2802] It is generally presumed, when Congress includes text in one section and not in another, that Congress knew what it was doing and made the decision deliberately.

NHTSA stated in the NPRM that it had previously considered the impact of California's Low Emission Vehicle standards in establishing fuel economy standards and occasionally has done so under the "other standards" sections.[2803] During the 2012 rulemaking, NHTSA sought comment on the appropriateness of considering California's tailpipe CO_2 emission standards in this section and concluded that doing so was unnecessary.[2804] In light of the legislative history discussed above, however, NHTSA stated in the NPRM that such consideration would be inappropriate, and confirms that consideration of California's LEV standards as among the "other standards of the Government" was inappropriate.

Commenters addressing criteria pollutant standards generally supported NHTSA's approach in the NPRM. AFPM commented that NHTSA "must consider the effect on fuel economy of EPA's Title II standards, including the use of catalytic converters, PM traps and other technologies that address emissions and have a fuel economy impact."[2805] Ford also stated that previous analyses "did not assess the impact of the criteria pollutant emission standards that were adopted subsequent to the [2012 final rule]," which Ford said "increased the challenge of meeting the fuel economy and GHG targets and should be taken into consideration."[2806] Ford stated that the NPRM appropriately included "updat[ed] core engine maps using correct, regular-grade octane test fuel," and that it accounts for "ultra-low 2025 MY Tier 3 and LEVIII emissions standards [which] will require aggressive cold start strategies [that] consume additional fuel at start-up in order to rapidly heat the catalyst to an effective operating temperature, which

---

[2800] Section 202 of the CAA (42 U.S.C. 7521) requires EPA to prescribe air pollutant emission standards for new vehicles; Section 209 of the CAA (42 U.S.C. 7543) preempts state emissions standards but allows California to apply for a waiver of such preemption.
[2801] As originally enacted as part of Public Law 94-163, that subsection was designated as section 502(d) of the Motor Vehicle Information and Cost Savings Act.
[2802] H.R. Rep. No. 103-180, at 583-584, tbl. 2A.
[2803] *See, e.g.*, 68 FR 16896, 71 FR 17643.

[2805] AFPM, NHTSA-2018-0067-12078, at 52.
[2806] Ford, NHTSA-2018-0067-11928, at 7.

degrades CO_2 and fuel economy performance on the FTP test [and] was not considered previously…."[2807]

Regarding how NHTSA should consider EPA's CO_2 standards as "other motor vehicle standards of the Government," ACEEE suggested amongst its comments that, in considering EPA's CO_2 standards, "NHTSA should not weaken its program … to compensate for … inevitable, modest differences" between EPA's and NHTSA's programs.[2808] "Indeed, to the extent that differences in the requirements of the two programs remain, it is clear that the more stringent requirement in any given respect should govern the obligations of the manufacturer."[2809] AFPM commented similarly that "Although NHTSA must consider the effect of other governmental regulations, Congress intended that NHTSA would have exclusive authority over a single set of national fuel economy standards."[2810] Mr. Dotson expressed his belief that "Congress was cognizant of the relationship between EPCA and the Clean Air Act when crafting EISA" and cited and discussed various types of legislative history for the proposition that EISA had not limited EPA's CAA authority, and that various legislative efforts to do so had been put forth in some fashion and had failed.[2811]

NHTSA agrees that while it is appropriate for NHTSA to coordinate with and look to EPA's actions to avoid unreasonably burdening industry through inconsistent regulations, it would not be appropriate for NHTSA to reduce stringency below levels it believes to be maximum feasible solely for purposes of accommodating differences between programmatic flexibilities. The 2012 final rule clearly stated that while the agencies had made efforts to align their standards, programmatic differences existed, and how manufacturers chose to rely on compliance flexibilities could affect the relative stringency of NHTSA's and EPA's standards:

> We note, however, that the alignment is based on the assumption that manufacturers implement the same level of direct A/C system improvements as EPA currently forecasts for those model years, and on the assumption of PHEV, EV, and FCV penetration at specific levels. If a manufacturer implements a higher level of direct A/C improvement technology (although EPA predicts 100% of manufacturers will use substitute refrigerants by MY 2021, and the GHG standards assume this rate of substitution) and/or a higher penetration of PHEVs, EVs and FCVs, then NHTSA's standards would effectively be more stringent than EPA's. Conversely, if a manufacturer implements a lower level of direct A/C improvement technology and/or a lower penetration of PHEVs, EVs and FCVs, then EPA's standards would effectively be more stringent than NHTSA's. Several manufacturers commented on this point and suggested that this meant

2808 ACEEE, NHTSA-2018-0067-12122, joint NGO comment to Alliance/Global petition for flexibilities, at 3.
2809 *Id*.
2810 AFPM, NHTSA-2018-0067-12078, at 52.
2811 Dotson, EPA-HQ-OAR-2018-0283-4132, Appendix A, at A2-A23. NHTSA disagrees with the persuasiveness of the legislative history cited by Mr. Dotson, which includes floor debates, colloquies, and other similar information that does not reflect the agreement of the Congress as a whole. NHTSA looks to the language Congress actually passed and the President signed into law.

> the standards were not aligned, because NHTSA's standards might be more stringent in some years than EPA's. This reflects a misunderstanding of the agencies' purpose. The agencies have sought to craft harmonized standards such that manufacturers may build a single fleet of vehicles to meet both agencies' requirements. That is the case for these final standards. *Manufacturers will have to plan their compliance strategies considering both the NHTSA standards and the EPA standards and assure that they are in compliance with both, but they can still build a single fleet of vehicles to accomplish that goal*.[2812]

Thus, NHTSA has been consistent in its position that CO_2 stringency does not and should not, by itself, dictate CAFE stringency. That said, consideration of EPA's standards was inherent in development of this final rule, given that the same technologies improve fuel economy and reduce CO_2 emissions, and given that CO_2 emissions represent the majority of GHGs produced by light-duty vehicles, and given that the agencies have conducted the analysis for this rulemaking jointly. NHTSA believes that EPA's standards have been fully and appropriately considered as part of its decision on these final standards. To be clear, NHTSA did not assert in the NPRM that EISA constrained EPA's authorities under the CAA and do not disagree with that aspect of Mr. Dotson's comment.

Chemours argued that, contrary to the NPRM's statements about having considered EPA's GHG standards in developing the proposal, NHTSA had *not* adequately considered EPA's GHG standards because only the no-action alternative reflected EPA regulation of the non-CO_2 GHGs, and the analysis did not otherwise account for the non-CO_2 GHG standards.[2813] Chemours stated that those standards were "required, pursuant to CAA section 202(a), to address 'air pollution' from mobile sources," and that "No assessment was done as to whether such standards could be made less stringent in order to avoid the various issues identified (*e.g.*, changes in technology since the 2012 final rule, costs to consumers, the effect of 'diminishing returns,' a changed petroleum market and other factors."[2814]

NHTSA disagrees that it was necessary for NHTSA to consider EPA's standards for non-CO_2 GHG emissions any further than as discussed above. Regulation of CH_4, N_2O, and HFCs affects fuel economy only indirectly, if at all. As explained above and in the 2012 final rule, while NHTSA recognizes that some manufacturers may choose paths to compliance with EPA's GHG standards that make their compliance with CAFE standards more challenging, the agencies previewed this possibility and stated their expectation that manufacturers could make these decisions for themselves. To the extent that Chemours is asking NHTSA to examine regulatory alternatives reflecting less stringent CAFE standards in light of changed conditions since the 2012 final rule, that is exactly what the NPRM and final rule analyses have done.

A number of commenters disagreed with NHTSA's explanation of how State standards need not be considered under this factor. The States and Cities commenters stated that NHTSA

[2812] 77 FR at 63054-55 (Oct. 15, 2012) (emphasis added).
[2813] Chemours, NHTSA-2018-0067-12018, at 25.
[2814] *Id*. at 25-26.

was required to consider State tailpipe standards because 49 U.S.C. 32902(f) does not specify that "Government" refers only to "Federal" government; because NHTSA had not offered compelling evidence or arguments that Congress did *not* intend NHTSA to consider State tailpipe standards; and because "case law … states unequivocally that California's standards must be considered by NHTSA under this factor [citing *Green Mountain Chrysler*'s "federalizing" language]."[2815] The States and Cities commenters further argued that NHTSA was trying to argue simultaneously that it could not consider State standards under the "other standards" factor but *could* consider State standards "under other EPCA factors, if and when it sees fit" (citing NPRM language that technological feasibility and economic practicability are broad factors allowing NHTSA to consider elements not specifically designated by Congress).[2816] The States and Cities commenters further argued, citing *Fox Television*, that NHTSA was deviating from past practice without a reasoned explanation by not specifically requesting comment in the NPRM on the fact that it was not considering California's standards as "other motor vehicle standards of the Government."[2817]

With regard to NHTSA's analysis of EPCA's original language for MYs 1978-80 and the 1994 positive law recodification, the States and Cities commenters stated that "NHTSA's statutory and legislative history arguments related to standards for model years 1978-1980 lack merit, as NHTSA has provided no reasonable argument that Congress meant NHTSA to consider a wider range of standards for those years than for others," and stated that the section in question "was removed from the statute because it expired, not because Congress took issue with NHTSA's consideration of California's waiver standards."[2818] Mr. Dotson commented similarly that NHTSA could not rely on the 1994 positive law codification as basis to conclude that State tailpipe standards (whether for GHGs or other emissions) do not qualify as "other motor vehicle standards of the Government," because it said "without substantive change…."[2819]

Additionally, the States and Cities commenters stated that NHTSA could not argue that California's emissions standards are not "other motor vehicle standards of the Government" because they are preempted, because NHTSA "has no authority to decide whether or not California's standards are preempted," and "one of the reasons California's Advanced Clean Cars program is not preempted by EPCA is *because* those standards are 'other motor vehicle standards of the Government' within the meaning of EPCA."[2820] Besides this comment, a number of comments were submitted regarding NHTSA's statements in the NPRM about EPCA's preemption provision and how it applied to California's standards. Those comments

have been addressed[2821] as part of the separate final rule published on September 27, 2019,[2822] and will not be discussed further as part of this action.

NHTSA affirms that its interpretation set forth in the NPRM that "other motor vehicle standards of the Government" does not apply to State emissions standards that relate to fuel economy. NHTSA does not understand how 49 U.S.C. 32919 could be given effect if the purpose of the "other motor vehicle standards of the Government" provision is to compel their inclusion in NHTSA's decision-making. NHTSA continues to disagree with the two district court cases suggesting that the "other motor vehicle standards of the Government" provision obviates 49 U.S.C. 32919, as explained at some length in the "One National Program" final rule preceding this regulatory action.[2823] NHTSA refers readers to that document for more detail on this topic.

With regard to State tailpipe standards that do not directly relate to fuel economy, NHTSA continues to believe that Congress's original direction to consider "emissions standards applicable by reason of section 209(b) of [the CAA]" applied only to CAFE standards for MYs 1978-1980, as discussed in the NPRM. NHTSA agrees that the 1994 positive law recodification was not intended to make substantive changes to EPCA; the NPRM explained that, in dropping Section 502(d), Congress made clear that that provision was executed, *and that provision expressly directed NHTSA to consider State standards that had been granted preemption waivers under CAA 209(b)*. In order for States even to have their own emissions standards for motor vehicles, California must be granted a waiver of preemption under CAA section 209(b). If Congress had intended for NHTSA to continue to consider State tailpipe standards post-MY 1980, the direction to consider emissions standards that had been granted Section 209 waivers could have been placed elsewhere in the statute. Congress did not do so.[2824] While NHTSA may have considered State tailpipe standards in the past, it is not bound to do so, and NHTSA does not believe that it is unreasonable to consider those standards under technological feasibility or economic practicability *if* they are to be considered.

State tailpipe standards primarily affect fuel economy by requiring gasoline ICE vehicles to burn additional fuel when the engine first starts. For most gasoline engines on the road today, the majority of tailpipe NO_X, NMOG, and CO emissions occur during "cold start," before the three-way catalyst has reached the very high temperature (*e.g.*, 900-1000°F), at which point it is able to convert (through oxidation and reduction reactions) those emissions into less harmful derivatives. By strictly limiting the amount of those emissions, tailpipe smog standards require the catalyst to be brought to temperature extremely quickly, so modern vehicles employ cold

[2821] To the extent that any individual comment was not specifically addressed, NHTSA believes that the substance and themes of all substantive comments on EPCA preemption were addressed as part of that final rule.
[2822] 84 FR 51310.
[2823] *See*, *e.g.*, 84 FR at 51323 (Sep. 27, 2019).
[2824] The negative inference canon is logically and reasonably employed here, particularly given that, as a factual matter and as discussed further below, considering EPA's Tier 3 standards (which are clearly "other motor vehicle standards of the Government") effectively accounts for the technological implications of California's LEVIII standards.

start strategies that intentionally release fuel energy into the engine exhaust to heat the catalyst to the relevant temperature as quickly as possible. The additional fuel that must be used to heat the catalyst is typically referred to as a "cold-start penalty," meaning that vehicle's fuel economy (over a test cycle) is reduced because the fuel consumed to heat the catalyst did not go toward the goal of moving the vehicle forward.[2825] The Autonomie work employed to develop technology effectiveness estimates for this final rule does, in fact, account for cold-start penalties.[2826] The Autonomie model documentation discusses the fact that cold-start penalties were derived from an EPA database of MY 2016 vehicles, which would have met both EPA and California smog standards. Moreover, EPA regulations allow manufacturers to employ LEVIII data for Tier 3 compliance. Based on all of these factors, NHTSA believes that the negative fuel economy effects of California's tailpipe standards for smog-related emissions are reasonably represented in the analysis for the final rule, regardless of whether NHTSA was obligated by law to consider them expressly.

Ultimately, it would be illogical for NHTSA to consider legally unenforceable standards to be "other motor vehicle standards of the Government." That is the case for State standards preempted by EPCA. While NHTSA understands that certain commenters disagree with a separate final rule that NHTSA issued concerning EPCA preemption, and the particular State standards that NHTSA considers preempted by EPCA, those issues are outside the scope of this final rule.

(4) The Need of the United States to Conserve Energy

NHTSA has historically interpreted "the need of the United States to conserve energy" to mean "the consumer cost, national balance of payments, environmental, and foreign policy implications of our need for large quantities of petroleum, especially imported petroleum."[2827]

(a) Consumer Costs and Fuel Prices:

NHTSA explained in the NPRM that fuel for vehicles costs money for vehicle owners and operators. All else equal—a critical caveat—consumers benefit from vehicles that need less fuel to perform the same amount of work. Future fuel prices are a critical input into the economic analysis of potential CAFE standards because they determine the value of fuel savings both to new vehicle buyers and to society, the amount of fuel economy that the new vehicle market is likely to demand in the absence of new standards, and they inform NHTSA about the "consumer cost…of our need for large quantities of petroleum." In the proposal, NHTSA's analysis relied on fuel price projections from the U.S. Energy Information Administration's (EIA) Annual Energy Outlook (AEO) for 2017; in the final rule, on fuel price projections derived

[2825] For more information on this, *see*, *e.g.*, Pihl, Josh A., *et al*., "Development of a Cold Start Fuel Penalty Metric for Evaluating the Impact of Fuel Composition Changes on SI Engine Emissions Control," Oak Ridge National Laboratory, 2018. [2827] 42 FR 63184, 63188 (Dec. 15, 1977).

from the version of NEMS used to produce AEO 2019. Federal government agencies generally use EIA's price projections in their assessment of future energy-related policies.

Several commenters stated that consumer costs for fuel were an important consideration. ACEEE stated that "The average U.S. household still spent nearly $2,000 on gasoline and motor oil (directly) in 2017, making oil savings very relevant for consumers," and argued that "Oil price volatility remains a threat to U.S. consumers and businesses—the price of crude oil has more than doubled since 2016, belying the theoretical suggestion in the notice that conditions for oil price shocks no longer exist," suggesting that further fuel efficiency improvements were necessary to protect consumers.[2828] NESCAUM commented that prior analyses had suggested that consumers would save $6,000 on net, after paying more for their vehicles upfront, and that the proposal would cost consumers more in fuel.[2829] Both NESCAUM and the States and Cities commenters stated that higher fuel costs would disproportionately affect low-income consumers, who spend a higher share of their income on fuel costs.[2830] The Congressional Tri-Caucus commented that "As we see oil prices rising again, it makes no sense for DOT to roll back these standards."[2831] The States and Cities commenters argued that increased gas expenditures would result "in negative economy-wide effects" for many years "given that cars sold in the model years for which NHTSA proposes to freeze standards will, according to the Agencies, be on the road for decades," and stated that "NHTSA's analysis is arbitrary and capricious because it entirely fails to consider how the Proposed Rollback would impact consumers and the economy as a whole due to increased gasoline expenditures."[2832] The States and Cities commenters further argued that NHTSA was incorrect in the NPRM when it interpreted "the relevant question for the need of the U.S. to conserve energy is not whether there will be *any* movement in prices but whether that movement will be sudden and large,"[2833] and cited *State Farm* to say that NHTSA had "failed to consider an important aspect of the problem" by "failing to analyze the likely impact of even moderate future increases and volatility in fuel prices."[2834]

A number of commenters addressed consumer willingness to pay more money upfront in order to save money on fuel costs. Many of these comments are addressed in Section VI.C as part of the discussion of how sales are modeled. More specifically in the context of how NHTSA interprets the need of the U.S. to conserve energy, IPI commented that NHTSA was incorrect that "consumers' need to save money is now 'less urgent' and no longer supports a strong overall need to conserve energy. The agencies assert that past rulemakings were overly and paternalistically focused on 'myopia.' This statement ignores all the other pathways through which the 2012 standards benefit consumers' need to save money, including by correcting informational asymmetries, attention costs, and other informational failures; positional

externalities; and various other supply-side and demand-side explanations for consumers' inability to achieve in an unregulated market the level of fuel economy that they desire. These components of the national need to conserve energy are discussed at length throughout these comments, and were specifically considered by the agencies in the 2012 rule."[2835]

Several commenters disagreed with NHTSA's suggestion in the NPRM that increasing U.S. production and exports reduced volatility in the oil market. Securing America's Energy Future stated that "…recent events are an important validation of public policies that support long-term goals like efficiency and fuel diversity. Indeed, in the absence of fuel-efficiency standards, global oil price volatility would likely render the country even more exposed to oil price shocks than it is currently."[2836] Mr. Bordoff, IPI, the States and Cities commenters, and UCS all commented that the oil market is global, so increasing U.S. production does not prevent price shocks that occur due to non-U.S. events or circumstances. Mr. Bordoff stated that "In a globalized oil market, the consequence of a supply disruption anywhere is a price increase everywhere—regardless of how much oil the U.S. imports."[2837] UCS made similar comments.[2838] Mr. Bordoff further commented that U.S. gasoline prices still follow the fluctuations in global crude oil prices regardless of the U.S. oil import/export balance,[2839] and stated that "Gasoline prices at the pump are especially sensitive to changes in the global crude oil price due to the relatively low level of fuel taxation [in the U.S.] compared to other OECD countries."[2840] Mr. Bordoff stated that gas price spikes are still possible due to ongoing geopolitical challenges in major oil producing areas, and concluded that "Continuing with planned fuel economy increases through CAFE standards is one effective way to reduce the oil intensity of the economy and mitigate the adverse impact of future oil price increases on American drivers."[2841] The States and Cities commenters cited to and echoed Mr. Bordoff's comments on this point.[2842] CARB commented that the proposal had relied on AEO 2017, which reflected fuel prices that still assumed the augural standards remained in place, but that AEO 2018 assumes "no new fuel efficiency standard" and held fuel economy flat after 2021, and showed fuel prices would be higher.[2843]

Mr. Bordoff also commented that the future of shale oil in the U.S. was uncertain, and therefore increased U.S. oil production was not a basis on which to assume future global price stability.[2844] Mr. Bordoff argued that "Although shale oil is more responsive to price changes than conventional supply, it cannot serve as a swing supplier to stabilize oil markets in the way true spare capacity (held by Saudi Arabia) can. It takes at least 6-12 months for U.S. shale to

respond to price changes."[2845] Bordoff continued, stating that "For example, although shale oil is more responsive to oil prices, oil prices still plunged below $30 per barrel at the start of 2016 and soared to $80 per barrel earlier this year. Shale oil could not swing quickly enough to stabilize markets. This role fell to OPEC instead in both cases, first to put a floor under prices by cutting supply and, more recently, to provide relief by ramping up production."[2846] Bordoff further commented that political or popular pressures due to environmental concerns may significantly increase the cost and/or difficulty of expanding shale infrastructure,[2847] and that even disregarding uncertainty in supply, ongoing uncertainty in demand (both U.S. and abroad) also contributed to global price uncertainty.[2848]

NHTSA agrees with commenters that consumer costs for fuel are relevant to the need of the U.S. to conserve energy. NHTSA also agrees that future fuel prices are uncertain, and that shale oil development in the U.S. is (1) still proceeding and subject to uncertainty, (2) very different from traditional sources like Saudi Arabia, and (3) not enough, by itself, to preclude any possibility of major swings in future global oil prices. That said, NHTSA continues to believe that U.S. shale development may reduce the negative price effects of global price swings due to events and situations outside of our borders. Shale represents a large, new, relatively-geopolitically-stable oil supply source, and traditional oil producers appear to understand that stabilizing prices below the price at which shale production starts to ramp up faster helps those traditional producers take market advantage of their lower cost of production.[2849] The net effect of this, for American drivers, should be greater fuel price stability, at least at the upper end of fuel prices. NHTSA also continues to believe that, for purposes of considering consumer cost of fuel as part of the need of the U.S. to conserve energy, the fact that Americans' gasoline costs might be minutely lower under more stringent CAFE standards and minutely higher under comparatively less stringent CAFE standards is not dispositive by itself. There is some tolerance in the market for some amount of fluctuation in fuel prices, as evidenced by the discussion in Section VI. Slow increases in fuel prices are relatively easy for households to absorb; sharp increases are more difficult.

Increases in CAFE stringency reduce the effects of all types of increases in fuel prices, at least to the extent that people can buy new cars and trucks, but as discussed below in Section VIII.B.4, fuel costs and per-vehicle costs balance against one another for many buyers. With

respect to relatively low U.S. gasoline taxes creating more pass-through effects of global oil price fluctuations, that would be true regardless of stringency. Broadly speaking, while consumer fuel costs are an important consideration of the need of the U.S. to conserve energy, at this time NHTSA believes, as discussed in Section VI, that American consumers generally understand fuel costs and their tolerance for fluctuations, and tend to purchase vehicles accordingly. Requiring consumers to save more fuel over the longer term by spending more money upfront on new vehicle purchases may involve more tradeoffs than suggested in prior rulemakings, and this rulemaking seeks to keep these possible tradeoffs in mind.

(b) National Balance of Payments:

As the NPRM explained, the need of the United States to conserve energy has historically included consideration of the "national balance of payments" because of concerns that importing large amounts of oil created a significant wealth transfer to oil-exporting countries and left the U.S. economically vulnerable.[2850] As recently as 2009, nearly half the U.S. trade deficit was driven by petroleum,[2851] yet this concern has largely laid fallow in more recent CAFE actions, arguably in part because other factors besides petroleum consumption have since played a bigger role in the U.S. trade deficit. Given recent significant increases in U.S. oil production and corresponding decreases in oil imports, this concern seems likely to remain fallow for the foreseeable future.[2852] Increasingly, changes in the price of fuel have come to represent transfers between domestic consumers of fuel and domestic producers of petroleum rather than gains or losses to foreign entities. NHTSA explained in the NPRM that some commenters have lately raised concerns about potential economic consequences for automaker and supplier operations in the U.S. due to disparities between CAFE standards at home and their counterpart fuel economy/efficiency and CO_2 standards abroad. NHTSA finds these concerns more relevant to technological feasibility and economic practicability than to the national balance of payments. Moreover, to the extent that an automaker decides to globalize a vehicle platform to meet more stringent standards in other countries, that automaker would comply with United States' standards and additionally generate overcompliance credits that it can save for future years if facing compliance concerns, or sell to other automakers. While CAFE standards are set at maximum feasible rates, efforts of manufacturers to exceed those standards are rewarded not

---

[2850] *See* 42 FR 63184, 63192 (Dec. 15, 1977) ("A major reason for this need [to reduce petroleum consumption] is that the importation of large quantities of petroleum creates serious balance of payments and foreign policy problems. The United States currently spends approximately $45 billion annually for imported petroleum. But for this large expenditure, the current large U.S. trade deficit would be a surplus.").

[2851] *See Today in Energy: Recent improvements in petroleum trade balance mitigate U.S. trade deficit*, U.S. Energy Information Administration (July 21, 2014), https://www.eia.gov/todayinenergy/detail.php?id=17191.

[2852] For an illustration of recent increases in U.S. production, *see, e.g., U.S. crude oil and liquid fuels production, Short-Term Energy Outlook,* U.S. Energy Information Administration (June 2018), https://www.eia.gov/outlooks/steo/images/fig13.png. While it could be argued that reducing oil consumption frees up more domestically-produced oil for exports, and thereby raises U.S. GDP, that is neither the focus of the CAFE program nor consistent with Congress' original intent in EPCA. EIA's Annual Energy Outlook (AEO) series provides midterm forecasts of production, exports, and imports of petroleum products, and is available at https://www.eia.gov/outlooks/aeo/.

only with additional credits but a market advantage in that those consumers who place a large weight on fuel savings will find such vehicles that much more attractive.

Several commenters addressed how much oil the U.S. imports, and the assumptions about imports in the NPRM analysis. Securing America's Energy Future commented that "Because there are no readily available substitutes to oil in the U.S. transportation sector, volatile crude oil and petroleum product prices represent an enduring threat to the U.S. economy."[2853] ACEEE commented that overall U.S. oil imports are higher now than they were in 1975, and nearly as high as they were in 2012, and also stated that compared to a small overall trade surplus in 1975, "the U.S. now runs a large overall trade deficit."[2854] The States and Cities commenters made a similar point, arguing that the U.S. still imports large amounts of petroleum; that imports made up about 25 percent of total U.S. oil consumption in 2017; and that EIA indicates that "imports as a share of oil consumption in the United States are only about 10% lower today as compared to 1975, and we are producing the same amount of crude oil domestically today as we were in 1970."[2855] IPI stated that EIA analysis shows that the "U.S. will continue to import crude oil through 2050 and 'remains a net importer of petroleum and other liquids on an energy basis.'"[2856] CARB disagreed that the U.S. was projected to become a net petroleum exporter, and stated that even if it were, the rollback would have negative effects on the U.S., because (1) it ignores short-run damages caused by increased oil consumption and imports; (2) relies on projections of net imports of oil which also do not take account of the effects of the proposed rule; and (3) is not supported by the evidence.[2857]

Regarding assumptions about oil imports in the NPRM analysis, the States and Cities commented that in 2016 the agencies had assumed that "90% of fuel savings from existing standards would lead directly to a reduction in imported oil," and argued that the NPRM analysis had ignored that previous assumption and "la[id] great emphasis on the fact that 'oil imports have declined while exports have increased' since 2005."[2858] IPI argued that the NPRM analysis was internally inconsistent, assuming in NHTSA's need of the nation discussion that "additional gasoline consumption will be entirely domestic," while "upstream emissions calculations assume that 95% of increased consumption will either be from foreign refining or from foreign crude imports," and suggested that this inconsistency was purposeful to make the NPRM analysis look more favorable to the proposal.[2859] ACEEE commented that "The EIA AEO side cases suggest that reduced oil demand will primarily reduce oil imports, thus improving the overall balance of trade regardless of the narrow balance of trade in petroleum."[2860]

[2860] ACEEE, NHTSA-2018-0067-12122, at 2.

Regarding the effects on the U.S. economy of increasing U.S. oil production, Mr. Morris agreed with the NPRM's suggestion that U.S. self-sufficiency in petroleum supply meant that higher consumer payments for fuel under less-stringent CAFE standards would be transfers within the U.S. economy, and stated that "[a]t that point, the initial purpose of EPCA is entirely obviated."[2861] The States and Cities commenters, in contrast, argued that focusing on this effect meant that NHTSA essentially claims that increasing revenues of oil companies—which report annual profits in the billions—is an even trade-off for adding cost pressures and oil-price shock exposure to American households."[2862] The States and Cities commenters stated that "…this assertion ignores the negative economic impacts that would result from increasing the cost burden on oil consumers," and was "…so implausible that it could not be ascribed to a difference of view or the product of agency expertise,' citing *State Farm*, 463 U.S. at 43.[2863]

As discussed above, NHTSA agrees that oil is a global commodity. Living in a globalized economy necessarily means that supply disruptions (and thus, price effects) can come from a great variety of sources—this was why the CAFE program was created, in recognition of this risk. Increasing U.S. energy independence reduces this risk. There are two ways to increase petroleum independence: to use less petroleum, and to produce more of our own petroleum and use less petroleum purchased from abroad. Both approaches work, and both are being followed today.

NHTSA also agrees that the Draft TAR text describes the analytical assumption that for every gallon of fuel not consumed as a result of more stringent standards, imported crude would be reduced by 0.9 gallons. The Draft TAR stated that this assumption was based on "changes in U.S. crude oil imports and net petroleum products in the AEO 2015 Reference Case in comparison [*sic*] the Low (i.e., Economic Growth) Demand Case," and also on a 2013 paper by Paul Leiby which "suggests that 'Given a particular reduction in oil demand stemming from a policy or significant technology change, the fraction of oil use savings that shows up as reduced U.S. imports, rather than reduced U.S., supply, is actually quite close to 90 percent, and probably close to 95 percent.'"[2864]

EIA data clearly states that while the U.S. still relies on oil imports, it is producing an increasingly large share of the petroleum it consumes.[2865] In 2018, domestic petroleum production made up 86 percent of domestic consumption, while imports made up 11 percent. EIA data also clearly states that U.S. reliance on petroleum imports peaked in 2005 and has declined since then, and that the import-percentage-of-consumption in 2018 was the lowest it has been since 1957—this despite the fact that overall U.S. petroleum consumption has increased significantly over that time period as the on-road fleet has grown and VMT (both individual and collective) has increased. Of the 11 percent of oil consumed that was imported, 43 percent came

[2863] *Id*.
[2864] Draft TAR, 2016, Chapter 10, Endnote 39, p. 10-59.
[2865] EIA, "Oil: Crude and Petroleum Products Explained, Oil Imports and Exports," updated May 29, 2019, available at https://www.eia.gov/energyexplained/oil-and-petroleum-products/imports-and-exports.php.

from Canada, and 16 percent came from Persian Gulf countries. AEO 2019 states that under its Reference case assumptions, which it describes as a "best assessment" and "a reasonable baseline case,"[2866] the U.S. remains projected to become a net exporter of petroleum liquids by 2020.[2867] During several weeks in 2019, the U.S. also exported more oil than it imported.[2868]

U.S. Census data indicate that the U.S. balance of trade has generally grown over time, although it has fluctuated since peaking in 2006.[2869] U.S. Census data further indicate that the U.S. petroleum balance of trade, in particular, has fluctuated over time, peaking in 2008 at roughly -$386 million and decreasing to -$50 million in 2018. 2019 trends demonstrate further decreases. In percentage terms, petroleum trade as a percentage of total trade went from roughly 52 percent in 1992 (the earliest year for which Census appears to have data online), to 47 percent in 2008, to less than 6 percent in 2018. In terms of national balance of payments, this is fairly clear evidence that petroleum has decreased rapidly as part of the problem. Part of this is due to improvements in fleet fuel economy over time, and part is due to increases in U.S. production, particularly in the last several years.

NHTSA notes also that the Draft TAR previewed the possibility of this outcome, discussing the "Shale Oil Revolution" and the fact that "[t]he recent economics literature on whether oil shocks are the threat to economic stability that they once were is mixed."[2870] The Draft TAR stated that because of increased U.S. shale oil production, "The resulting decrease in foreign imports…effectively permits U.S. supply to act as a buffer against artificial or other supply restrictions (the latter due to conflict or a natural disaster, for example)."[2871]

Since the Draft TAR was issued, U.S. shale production has developed even further, and U.S. petroleum imports have continued to fall. If more oil is being produced in the U.S., and more of domestic consumption comes from domestic production, then even though oil is a global commodity and thus subject to price changes resulting from non-U.S. events, the U.S. economy is inherently better off. When money moves around within the U.S. instead of having to leave the U.S., and everyone's needs are being met, U.S. citizens are better off when things outside the U.S. go wrong—this is what NHTSA means when it refers to within-U.S. transfers not being a bad thing as compared to greater reliance on imports for consumption needs. To the extent that some commenters find within-U.S. transfers problematic because they increase U.S. oil company revenues without reducing fuel cost burdens on consumers, NHTSA notes that, as discussed above, consumers seem willing and able to tolerate some amount of fuel price increases and fluctuation risk, as evidenced by their purchasing decisions. Prices may still fluctuate, but shortages may foreseeably be reduced.

[2870] *See* Draft TAR at 10-30 – 10-33.
[2871] Draft TAR at 10-31.

The Draft TAR stated that "despite continuing uncertainty about oil market behavior and outcomes and the sensitivity of the U.S. economy to oil shocks, it is generally agreed that it is beneficial to reduce petroleum fuel consumption from an energy security standpoint. It is not just imports alone, but both imports and consumption of petroleum from all sources and their role in economic activity, that may expose the U.S. to risk from price shocks in the world oil price. Reducing fuel consumption reduces the amount of domestic economic activity associated with a commodity whose price depends on volatile international markets." NHTSA continues to agree with these statements, but cannot ignore the fact that increased U.S. petroleum production represents the other side of the coin. Again, both national balance of payments and energy security can be improved on both the supply side and the demand side. While today's final rule continues to improve on the demand side by setting standards that continue to push CAFE levels upward, it also recognizes that supply side improvements are playing a role.

(c) Environmental Implications

The NPRM explained that higher fleet fuel economy can reduce U.S. emissions of CO_2 as well as various other pollutants by reducing the amount of oil that is produced and refined for the U.S. vehicle fleet, but can also increase emissions by reducing the cost of driving, which can result in increased vehicle miles traveled (i.e., the rebound effect). Thus, the net effect of more stringent CAFE standards on emissions of each pollutant depends on the relative magnitudes of its reduced emissions in fuel refining and distribution and increases in its emissions from vehicle use. Fuel savings from CAFE standards also necessarily result in lower emissions of CO_2, the main gas emitted as a result of refining, distribution, and use of transportation fuels. Reducing fuel consumption directly reduces CO_2 emissions because the primary source of transportation-related CO_2 emissions is fuel combustion in internal combustion engines.

NHTSA has considered environmental issues, both within the context of EPCA and the context of the National Environmental Policy Act (NEPA), in making decisions about the setting of standards since the earliest days of the CAFE program. As courts of appeal have noted in three decisions stretching over the last 20 years,[2872] NHTSA defined "the need of the United States to conserve energy" in the late 1970s as including, among other things, environmental implications. In 1988, NHTSA included climate change concepts in its CAFE notices and prepared its first environmental assessment addressing that subject.[2873] It cited concerns about climate change as one of its reasons for limiting the extent of its reduction of the CAFE standard for MY 1989 passenger cars.[2874] Since then, NHTSA has considered the effects of reducing tailpipe emissions of CO_2 in its fuel economy rulemakings pursuant to the need of the United States to conserve energy by reducing petroleum consumption.

[2872] CAS, 793 F.2d 1322, 1325 n. 12 (D.C. Cir. 1986); Public Citizen, 848 F.2d 256, 262-63 n. 27 (D.C. Cir. 1988) (noting that "NHTSA itself has interpreted the factors it must consider in setting CAFE standards as including environmental effects"); CBD, 538 F.3d 1172 (9th Cir. 2007).
[2873] 53 FR 33080, 33096 (Aug. 29, 1988).
[2874] 53 FR 39275, 39302 (Oct. 6, 1988).

Many commenters addressed the environmental implications of CAFE standards and the proposal. ACEEE stated that "The environmental need to save energy is much greater than we realized in 1975," and that "The notice argues that since improved standards will not by themselves solve global warming, they are not necessary. That logic would equally suggest that since no one soldier would win a war, we should never deploy any troops. No one measure will solve global warming….vehicle standards have been the most important."[2875] The Harvard environmental law clinic commenters similarly stated that "It is illogical to argue against taking a single step on the basis that a single step is insufficient to reach one's goal," and commented that it was unreasonable for the DEIS to state that "[t]he emission reductions necessary to keep global emissions within this carbon budget could not be achieved solely with drastic reductions in emissions from the U.S. passenger car and light truck fleet."[2876] UCS also argued that with respect to the environmental implications of the standards, NHTSA's "argument that the augural standards would only limit global warming by 0.02 degrees C in 2100 actually *supports* the need to maintain the standards. That a single U.S. policy could make that much difference in limiting global warming is, in fact, quite significant."[2877]

The States and Cities commenters objected to NHTSA's consideration in the NPRM of "whether rapid ongoing increases in CAFE stringency . . . can sufficiently address climate change to merit their costs," arguing that NHTSA had "completely disregard[ed] environmental costs" contrary to NHTSA's own long-standing approach to CAFE standards.[2878] The States and Cities commenters then framed the CO_2 impacts of the proposal in tons (specifically, 7,400 million metric tons additional CO_2 emitted by 2100 as compared to the augural standards) and argued that "the agency effectively ignores its own findings, in a sharp and unexplained break with the agency's past practice of considering climate impacts," citing *Fox Television*, 556 U.S. at 515 and the 2010 and 2012 final CAFE rules which discussed reduced economic damages from lower climate impacts for those standards compared to their baselines.[2879] IPI also argued that if NHTSA had focused on economic damages rather than fractions of degrees Celsius, "Once climate damages are fully monetized (as the agencies are required to do), it will become apparent that the proposed rollback will cause billions of dollars in climate damages. Billions of dollars lost to avoidable climate damages is not a small effect, and it very clearly is a 'destructive and wasteful' effect."[2880] CARB also argued that the NPRM had "wholly fail[ed] to analyze the economic effects of the climate change and public health implications of the rollback," stating that [t]he Agencies assert these are insignificant, but that is only because the Agencies' projections of climate change are so extreme. An appropriate analysis of a proposal that speeds progress toward such a calamitous condition must acknowledge and analyze the expected effects."[2881]

The States and Cities commenters also argued that NHTSA had not explained what the NPRM's definition of "conservation" as meaning "avoid[ing] wasteful or destructive use" "actually means and how it changes the agency's past practice of considering environmental impacts," citing *State Farm*, 463 U.S. at 43, and *Fox Television*, 556 U.S. at 515.[2882]

Regarding non-climate impacts, IPI commented that the NPRM "only briefly mention[ed] the possible effects on other emissions without detailing any of the myriad non-climate public health and welfare consequences from pollution associated with petroleum production and combustion for motor vehicles."[2883] The States and Cities commenters similarly stated that "NHTSA's evaluation of this factor fails to include any analysis of environmental costs related to air quality," and that the NPRM/DEIS analysis substantially understates the actual impacts of the Proposed Rollback on criteria air pollutants (such as NOx and PM) and air toxics (such as benzene), making it inappropriate to rely upon."[2884]

NHTSA agrees that the NPRM considered environmental implications of the standards somewhat differently from past rulemaking discussions. The 2012 final rule, for example, stated that "[t]he need of the nation to conserve energy has long operated to push the balancing toward more stringent standards," and asked "[i]n this final rule, then, the question raised by this factor, combined with technological feasibility, becomes 'how stringent can NHTSA set standards before economic practicability considerations intercede?'"[2885] The NPRM discussed the dictionary definition of "to conserve," tentatively concluded that thousandths of a degree centigrade in 2100 did not rise to the level of being "wasteful," and suggested that ultimately "we no longer view the need of the U.S. to conserve energy as nearly infinite."[2886] This is an evolution in interpretation that was expressly acknowledged in the NPRM—the words "we no longer view" clearly indicate acknowledgement of a change in view, i.e., interpretation. The NPRM's climate findings were not ignored, they were directly examined and discussed at 83 FR 43215-16 in the context of NHTSA's interpretation of their significance. The NPRM also discussed overall costs and benefits and net benefits in the context of the proposed maximum feasible determination, and the cost of carbon emissions was included in those values. This final rule similarly directly examines and discusses the analytical findings below.

Moreover, contrary to commenters' statements that NHTSA did not acknowledge that its interpretation of the effect of the "need of the U.S. to conserve energy" factor was changing, or that the balancing of factors was different, the NPRM directly stated that:

> NHTSA well recognizes that the decision it proposes to make in today's NPRM is different from the one made in the 2012 final rule that established standards for MY 2021 and identified 'augural' standard levels for MYs 2022-2025. Not only do we believe that the facts before us have changed, but we believe that those facts have changed

---

sufficiently that the balancing of the EPCA factors and the other considerations must also change. The standards that we are proposing today reflect that balancing.[2887]

NHTSA believes that this is clear acknowledgement of the differences in interpretation and the effect of those differences on policy decisions.

That said, NHTSA agrees (indeed, has always agreed) with commenters that environmental implications exist as a result of changes in CAFE stringency. While CO_2 emissions will be higher under this final rule than if NHTSA had determined that the augural standards were maximum feasible, they will be lower than they would have been under the proposal—for the "standard setting" runs, which are what NHTSA looks at for assistance in determining maximum feasible standards, NHTSA estimates that, accounting for both tailpile and upstream emissions, CO_2 emissions in 2050 under the final standards will total 1,134 mmt, as compared to 1,149 mmt under the proposed standards, or 1,020 mmt under the augural standards. According to the Final EIS, which uses a "real-world" analysis that incorporates models and modeling approaches that permit the agency to take a hard look at the potential environmental impacts of the rule,[2888] NHTSA estimates that these amounts of CO_2 emissions would lead to the following global temperature, sea level, and ocean acidification effects[2889]:

[2887] 83 FR at 43213. *See also* 83 FR at 43226 ("In the 2012 final rule…, NHTSA stated that 'maximum feasible standards would be represented by the mpg levels that we could require of the industry before we reach a tipping point that presents risk of seriously adverse economic consequences.' [citation omitted] However, the context of that rulemaking was meaningfully different from the current context. At that time, NHTSA understood the need of the U.S. to conserve energy as necessarily pushing the agency toward setting stricter and stricter standards. Combining a then-paramount need of the U.S. to conserve energy with the perception that technological feasibility should no longer be seen as a limiting factor, NHTSA then concluded that only significant economic harm would be the basis for controlling the pace at which CAFE stringency increased over time. Today, the relative importance of the need of the U.S. to conserve energy has changed … a great deal even since the 2012 rulemaking. [T]he need of the U.S. to conserve energy may no longer disproportionately outweigh other statutorily-mandated considerations such as economic practicability—even when considering fuel savings from potentially more-stringent standards.").

[2888] *See* Kleppe v. Sierra Club, 427 U.S. 390, 410, n. 21 (1976).

[2889] As discussed in Section 5.3.1 of the FEIS, NHTSA used the Global Change Assessment Model (GCAM) Reference scenario to represent the No Action Alterantive (Alternative 0) in the modeling runs used to create **Error! Reference source not found.**. The GCAM Reference Scenario is based on a set of assumptions about drivers such as population, technology, and socioeconomic changes, in the absence of global action to mitigate climate change. It can be described as a "business-as-usual" scenario. NHTSA also conducted an analysis in Chapter 8 of the FEIS using the GCAM6.0 scenario, which assumes a moderate level of global GHG reductions and corresponds to stabilization, by 2100, of total radiative forcing and associated CO_2 concentrations at roughly 678 ppm. Several commenters argued that NHTSA presented climate results in the NPRM/DEIS in the context of a "doomsday scenario," in which no actions at all are taken to mitigate carbon emissions, but NHTSA emphasizes that this is simply the GCAM Reference Scenario, which is a reasonable scenario to run given that GCAM is a widely accepted climate model. Running the analysis using the GCAM Reference Scenario and GCAM6.0 Scenario results in different absolute values for the climate variables presented in this table and Table 8.6.4-1 of the FEIS, but again, this is because of the underlying scenarios, which reflect very different levels of global action. When the differences in levels of global action are accounted for, the relative impact of each action alternative as compared to the No Action Alternative is very similar. Thus, regardless of what GCAM scenario the agencies consider regarding global action to mitigate climate change, it is still meaningful to draw conclusions about the relative impacts of the alternatives, because the alternatives are what is within the agencies' authority to affect.

Table VIII-5 – Environmental Effects (Climate) of Alternatives Considered Under CAFE Program[a]

Notes:
[a] The numbers in this table have been rounded for presentation purposes. As a result, the increases might not reflect the exact difference of the values in all cases.
[b] The values for global mean surface temperature and sea-level rise are relative to the average of the years 1986 to 2005.
[c] Temperature changes reported as 0.000 are more than zero but less than 0.001.
[d] Sea-level rise changes reported as 0.00 are more than zero but less than 0.01.
[e] Ocean pH changes reported as 0.0000 are less than zero but more than -0.0001.
CO_2 = carbon dioxide; °C = degrees Celsius; ppm = parts per million; cm = centimeters

NHTSA understands that some commenters view climate change as an imminent existential threat. NHTSA does not agree, however, that Congress intended for NHTSA to set aside other statutory factors in determining what CAFE standards would be maximum feasible. Even the maximum feasible discussion for the 2012 final rule stated that

> We recognize that higher standards would help the need of the nation to conserve more energy…, but based on our analysis and the evidence presented by the industry, we conclude that higher standards would not represent the proper balancing for MYs 2017-2025 cars and trucks. [footnote omitted] We conclude that the correct balancing recognizes economic practicability concerns as discussed above, and sets standards at the levels that the agency is promulgating in this final rule for MYs 2017-2021 and presenting for MYs 2022-2025.[2890]

The footnote following the last sentence quoted above further stated that "We underscore that the agency's decision regarding what standards would be maximum feasible for MYs 2017-2025 is made with reference to the rulemaking time frame and the circumstances of this final rule. Each CAFE rulemaking (indeed, each stage of any given CAFE rulemaking) presents the agency with new information that may affect how the agencies we balance the relevant factors."[2891] NHTSA has been consistent over time, despite commenters' suggestions to the contrary, that maximum feasible is a balancing of factors; that all factors must be considered; and that information before the agency may change how the agency both understands and balances the statutory factors.

With regard to criteria and toxic air pollutant emissions, NHTSA agrees with commenters that the NPRM discussion of environmental implications did not specifically identify these emissions, but notes that air quality issues were discussed in a variety of places in the NPRM, DEIS, and PRIA, and that the monetized effects of air quality impacts were included in the overall cost-benefit analysis which informed NHTSA's balancing of factors, as discussed above. To the extent that commenters disagreed with the values or the agency's air quality analyses, those topics will be addressed in Section VII and VIII and in the FEIS. NHTSA has considered all of these findings along with other factors, as discussed below.

(d) Foreign Policy Implications

In the NPRM, NHTSA explained that U.S. consumption and imports of petroleum products impose costs on the domestic economy that are not reflected in the market price for crude petroleum or in the prices paid by consumers for petroleum products such as gasoline. These costs include (1) higher prices for petroleum products resulting from the effect of U.S. oil demand on world oil prices, (2) the risk of disruptions to the U.S. economy caused by sudden increases in the global price of oil and its resulting impact of fuel prices faced by U.S. consumers, and (3) expenses for maintaining the strategic petroleum reserve (SPR) to provide a response option should a disruption in commercial oil supplies threaten the U.S. economy, to allow the U.S. to meet part of its International Energy Agency obligation to maintain emergency

[2890] 77 FR at 63055.
[2891] *Id* at fn. 1275.

oil stocks, and to provide a national defense fuel reserve.[2892] Higher U.S. consumption of crude oil or refined petroleum products increases the magnitude of these external economic costs, thus increasing the true economic cost of supplying transportation fuels above the resource costs of producing them. Conversely, *reducing* U.S. consumption of crude oil or refined petroleum products (by reducing motor fuel use) can reduce these external costs.

The NPRM stated that while these costs are considerations, the United States has significantly increased oil production capabilities in recent years to the extent that the U.S. is currently producing enough oil to satisfy nearly all of its energy needs and is projected to continue to do so or become a net energy exporter. This has added new stable supply to the global oil market and reduced the urgency of the U.S. to conserve energy. The NPRM referred readers to the balancing discussion for more detail on this issue.

Securing America's Energy Future commented that continuing to raise stringency would be good for energy security, spur innovation, and "advance the administration's energy dominance agenda."[2893] CARB argued that the proposal would "significantly diminish U.S. energy security," "…contrary to the President's recent executive order to promote national security, and contrary to the intent of Congress in EPCA."[2894]

Several commenters disagreed with the NPRM's suggestion that increases in U.S. oil production reduced the foreign policy implications relevant to the need of the U.S. to conserve energy. ACEEE commented that because the market for oil is global, "…regardless of actual imports, the nation is still affected by what happens to oil worldwide, and oil remains a foreign policy concern…."[2895] Securing America's Energy Future commented that increased U.S. production "…has reduced some of the negative consequences of oil dependence, energy security is primarily a function of consumption, not production."[2896] IPI argued that "…the agencies falsely and inconsistently argue that the need to conserve energy has diminished because U.S. reliance on foreign oil has decreased," disagreeing with the NPRM's assumption that monopsony and military security costs resulting from the proposal would be zero.[2897] The States and Cities commenters raised similar points, stating that "U.S. military and foreign policy institutes" place emphasis on "global oil market stability and the stability of major oil-exporting nations," which the States and Cities argued had not changed as U.S. exports have risen.[2898] The States and Cities commenters further argued that if a quarter of U.S. oil consumed is still

---

[2892] While the U.S. maintains a military presence in certain parts of the world to help secure global access to petroleum supplies, that is neither the primary nor the sole mission of U.S. forces overseas. Moreover, the scale of oil consumption reductions associated with CAFE standards would be insufficient to alter any existing military missions focused on ensuring the safe and expedient production and transportation of oil around the globe. Chapter 7 of the PRIA discussed this topic in more detail.
[2893] Securing America's Energy Future, NHTSA-2018-0067-12172, at 6.
[2894] CARB, NHTSA-2018-0067-11783, at 316.
[2895] ACEEE, NHTSA-2018-0067-12122, main comments, at 2.
[2896] Securing America's Energy Future, NHTSA-2018-0067-12172, at 6.
[2897] IPI, NHTSA-2018-0067-12213, Appendix, at 2-3.
[2898] States and Cities, NHTSA-2018-0067-11735, at 76-77.

imported, then increases in consumption would necessarily raise imports, and thus also monopsony and military security costs associated with those imports.[2899]

CARB questioned whether it was accurate to assume that the U.S. would ever reach net exporter status, and commented that even if becoming a net exporter helped to insulate the Nation from the effects of reducing CAFE stringency, it would not lead to greater energy security until at least 2029, the first year for which AEO 2018 forecasts that the U.S. will stop being a net importer.[2900] CARB further argued that increased domestic oil production did *not* insulate the U.S. from risk, and that in fact "…current conditions are more prone to risk due to lower available spare oil production capacity in major oil producing countries, meaning that a supply disruption is more likely to have a more pronounced effect on oil prices and U.S. energy security."[2901]

Mr. Bordoff commented that geopolitical risk can still affect global oil prices, citing U.S. withdrawal from the Iran nuclear agreement and the reimposition of sanctions on Iranian oil sales; the collapse of Libyan oil production following conflict there; ongoing problems in Venezuela; a variety of short-term production outages in other producing areas; and even situations where geopolitics can result in lower prices rather than higher prices.[2902]

IPI stated that "…the *protective value* that the SPR offers given its size does automatically change as total U.S. petroleum consumption changes," and argued that it was not sufficient to consider only "the budgetary costs for maintaining [the size of] the SPR." IPI thus argued that "The agencies have failed to assess how much the relative protective value of the SPR will change as total U.S. consumption rises following the proposed rollback, and therefore have failed entirely to consider one important element of the national need to conserve energy."[2903]

Total energy independence for any country is only possible if it does not participate in the global energy markets, either because it consumes no energy (which is unrealistic) or because it produces enough energy to meet all of its energy needs and uses only energy that is produced domestically. As discussed above, NHTSA agrees with commenters that the oil market is global, and that events and situations abroad can affect oil prices even as U.S. oil production increases. The fact that the U.S. became a net oil exporter, at least on a weekly basis, in November 2019, and the evidence indicates that it will become a net oil exporter on a longer-term basis in MY 2020 does not change geopolitics in many parts of the world. Striving for energy independence in a global market necessarily means *reducing* risks, because even if the U.S. consumed only domestically-produced petroleum and continued to export, the U.S. economy would still be subject to oil price fluctuations due to external events and situations. The NPRM was clear on all of these points.[2904] The NPRM and PRIA repeatedly emphasized that changes in the oil

---

[2899] *Id*.
[2900] CARB, NHTSA-2018-0067-11783, at 317.
[2901] *Id*., at 319.
[2902] Bordoff, EPA-HQ-OAR-2018-0283-3906, at 3-4.

[2904] *See* 83 FR at 43213-15.

market meant that the risk of damage to the U.S. economy and of additional pain for U.S. drivers is *lower* than it was at the beginning of the CAFE program, not that it was eliminated entirely. NHTSA agrees with commenters that risk still exists, and that both production and consumption of oil are relevant to how big that risk might be. NHTSA simply believes, as explained in the NPRM and as explained again below, that the risk is lower than it would have been in the absence of the rapid growth in U.S. oil production, and that the lower risk means that the need of the U.S. to conserve energy, from this perspective, is less dire than it was at earlier points in the program.

The analyses for both the NPRM and the final rule account for the ongoing economic risk of participating in the global oil market by placing a value on energy security. The energy security value is made of several components. While commenters are correct that neither the NPRM nor the final rule analyses attributed a positive cost to the monopsony or military security components, the agencies do employ a cost for macroeconomic shock risk as part of energy security. Section VI discusses these estimates in more detail; for purposes of this discussion, NHTSA only notes that these issues are accounted for in the agencies' cost-benefit analysis, and to the extent that zero values are used for some elements, the reason for that is explained at length in those sections and public comments received on these issues did not present new information to change the agencies' minds on those values.

With regard to the comment that NHTSA should be accounting for the "protective value" of the SPR along with the literal cost of maintaining it, NHTSA is not in a position at this time to attempt to estimate such a value, and notes that the commenter provided no suggestions as to how to do so. The Department of Energy's website states that the maximum number of days of import protection provided by the SPR is 143 days, and that it takes 13 days from Presidential decision for SPR fuel to enter the market.[2905] The 1973 OPEC oil embargo lasted from October 1973 to March 1974, roughly 150 days. As explained, NHTSA continues to believe that the effect of increased U.S. oil production is to stabilize, broadly, global oil markets. The longer a sustained spike in prices due to geopolitical events continues, the greater incentive U.S. shale production has to respond. NHTSA believes that it is foreseeable that the SPR could be utilized to help mitigate a price shock in the interim, for the majority of foreseeable shock situations.

(5) Factors that NHTSA is Prohibited From Considering

The NPRM explained that EPCA also provides that in determining the level at which it should set CAFE standards for a particular model year, NHTSA may not consider the ability of manufacturers to take advantage of several EPCA provisions that facilitate compliance with CAFE standards and thereby reduce the costs of compliance.[2906] As discussed further in Section IX below, NHTSA cannot consider compliance credits that manufacturers earn by exceeding the CAFE standards and then use to achieve compliance in years in which their measured average fuel economy falls below the standards. NHTSA also cannot consider the use of alternative fuels by dual fuel vehicles nor the availability of dedicated alternative fuel vehicles—including

[2905] *See* https://www.energy.gov/fe/services/petroleum-reserves/strategic-petroleum-reserve/spr-quick-facts-and-faqs.
[2906] 49 U.S.C. 32902(h).

battery-electric vehicles—in any model year. EPCA encourages the production of alternative fuel vehicles by specifying that their fuel economy is to be determined using a special calculation procedure that results in those vehicles being assigned a higher equivalent fuel economy level than they actually achieve.

The NPRM further explained that the effect of the prohibitions against considering these statutory flexibilities in setting the CAFE standards is that the flexibilities remain voluntarily-employed measures. If NHTSA were instead to assume manufacturer use of those flexibilities in setting new standards, higher standards would appear less costly and therefore more feasible, which would thus effectively require manufacturers to use those flexibilities in order to meet higher standards. By keeping NHTSA from including them in our stringency determination, the provision ensures that these statutory credits remain true compliance flexibilities.

Additionally, for the non-statutory fuel economy improvement value program that NHTSA developed by regulation, the NPRM stated that NHTSA does not consider these subject to the EPCA prohibition on considering flexibilities. EPCA is very clear as to which flexibilities are not to be considered. When the agency has introduced additional flexibilities such as A/C efficiency and "off-cycle" technology fuel economy improvement values, NHTSA has considered those technologies as available in the analysis. Thus, today's analysis includes assumptions about manufacturers' use of those technologies, as detailed in Section VI.

Michalek and Whitefoot commented that "[w]e find [the statutory prohibition on considering certain flexibilities in determining maximum feasible CAFE standards] problematic because the automakers use these flexibilities as a common means of complying with the regulation, and ignoring them will bias the cost-benefit analysis to overestimate costs."[2907] IPI commented that "it is not clear that the statutory prohibition on considering credit availability was intended to apply to banked credits," because 49 U.S.C. 32902(h)(3) was

> added…as a 'conforming amendment' to EISA, which was the statute that gave NHTSA authority to allow credit trading and transferring; meanwhile, banking and borrowing have been part of NHTSA's authority since EPCA in 1975. In 1989, e.g., NHTSA explicitly relied on the availability of 'credit banks' to justify maintaining the MY 1990 standard at 27.5 mpg instead of lowering its stringency. NHTSA has not explained why it now believes it may not more fully consider banking.[2908]

NHTSA agrees, as explained in the NPRM, that if the agency was able to consider the compliance flexibilities in determining maximum feasible standards, more-stringent standards would appear less costly and therefore more feasible. NHTSA is nevertheless bound by the statutory prohibition on considering the above-mentioned flexibilities. As for IPI's disagreement that 32902(h)(3) should apply to banked credits because it was labeled a "conforming amendment," NHTSA looks to the specific statutory language provided, which prohibits "[consideration], when prescribing a fuel economy standard, [of] the trading, transferring or *availability* of credits. . . ." (Emphasis added.) IPI's suggested interpretation would render

---

[2907] Michalek and Whitefoot, NHTSA-2018-0067-11903, at 10-11.
[2908] IPI, NHTSA-2018-0067-12213, Appendix, at 19.

"availability" as surplusage. If Congress had meant the prohibition to apply only to traded and transferred credits, it would have said so. Instead, Congress also prohibited consideration of the "availability of credits," which must be read reasonably to refer to "what credits are available," i.e., banked credits. The fact that NHTSA considered the availability of banked credits in 1989, prior to establishment of this statutory prohibition, has no bearing in a post-EISA world.

Nonetheless, NHTSA notes that it is informed by the "real-world" analysis presented in the FRIA, which accounts for credit availability and usage, and manufacturers' ability to employ alternative fueled vehicles—for purpose of conformance with E.O. 12866. Under the real-world analysis, compliance does, in fact, appear less costly. For example, today's "real world" analysis shows manufacturers' costs averaging about $1,420 in MY 2029 under the final standards, as compared to the $1,640 shown by the "standard setting" analysis. However, for purposes of determining maximum feasible CAFE levels, NHTSA considers only the "standard-setting" analysis shown in the NPRM, consistent with Congress's direction.

f) EPCA/EISA Requirements that No Longer Apply Post-2020

The NPRM explained that Congress amended EPCA through EISA to add two requirements not yet discussed in this section relevant to determination of CAFE standards during the years between MY 2011 and MY 2020 but not beyond. First, Congress stated that, regardless of NHTSA's determination of what levels of standards would be maximum feasible, standards must be set at levels high enough to ensure that the combined U.S. passenger car and light truck fleet achieves an average fuel economy level of not less than 35 mpg no later than MY 2020.[2909] And second, between MYs 2011 and 2020, the standards must "increase ratably" in each model year.[2910] Neither of these requirements apply after MY 2020, so given that this rulemaking concerns the standards for MY 2021 and after, the NPRM stated that they are not relevant to this rulemaking.

CARB commented that because the proposal did not "provide for improved efficiency of motor vehicles" over the long term, "Stagnating the standards violates Congressional direction to ratably increase fuel economy when the technology for doing so has been demonstrated to exist (which it does…) or could be developed in the necessary time."[2911]

NHTSA notes, again, that the statutory language is clear that Congress only directed ratable increases in stringency through MY 2020. After MY 2020, the statutory language is clear that standards simply need be "maximum feasible, as determined by the Secretary." Some commenters may have disagreed that the proposal represented maximum feasible levels, but there is no statutory basis for arguing that the "ratable increase" requirement extends beyond MY 2020.

g) Other Considerations in Determining Maximum Feasible Standards

The NPRM explained that NHTSA has historically considered the potential for adverse safety consequences in setting CAFE standards. This practice has been consistently approved in case law. As courts have recognized, "NHTSA has always examined the safety consequences of the CAFE standards in its overall consideration of relevant factors since its earliest rulemaking under the CAFE program." *Competitive Enterprise Institute v. NHTSA*, 901 F.2d 107, 120 n. 11 (D.C. Cir. 1990) ("*CEI-I*") (citing 42 Fed. Reg. 33534, 33551 (June 30, 1977)). The courts have consistently upheld NHTSA's implementation of EPCA in this manner. *See, e.g., Competitive Enterprise Institute v. NHTSA*, 956 F.2d 321, 322 (D.C. Cir. 1992) ("*CEI-II*") (in determining the maximum feasible fuel economy standard, "NHTSA has always taken passenger safety into account") (citing *CEI-I*, 901 F.2d at 120 n. 11); *Competitive Enterprise Institute v. NHTSA*, 45 F.3d 481, 482-83 (D.C. Cir. 1995) ("*CEI-III*") (same); *Center for Biological Diversity v. NHTSA*, 538 F.3d 1172, 1203-04 (9th Cir. 2008) (upholding NHTSA's analysis of vehicle safety issues associated with weight in connection with the MYs 2008-2011 light truck CAFE rulemaking). Thus, NHTSA explained that in evaluating what levels of stringency would result in maximum feasible standards, NHTSA assesses the potential safety impacts and considers them in balancing the statutory considerations and to determine the maximum feasible level of the standards.

The attribute-based standards that Congress requires NHTSA to set help to mitigate the negative safety effects of the historical single number standards originally required in EPCA, and in past rulemakings, NHTSA constrained its modeling so as not to consider possible mass reduction in lower weight vehicles in its analysis, which affected the resulting assessment of potential adverse safety impacts. That analytical approach did not reflect, however, the likelihood that automakers may pursue the most cost-effective means of improving fuel efficiency to comply with CAFE requirements. For the NPRM, as for the final rule, the modeling did not limit the amount of mass reduction that is applied to any segment, but rather considered that automakers may apply mass reduction based upon cost-effectiveness, similar to most other technologies. NHTSA does not, of course, mandate the use of any particular technology by manufacturers in meeting the standards. The NPRM and today's final rule, like the Draft TAR, also considered the safety effect associated with the additional vehicle miles traveled due to the rebound effect.

NHTSA explained that the NPRM considered the safety effects of vehicle scrappage rates on the fleet as a whole. The NPRM also explained NHTSA's consideration of the effect of additional expenses in fuel savings technology on the affordability of vehicles—the likelihood that increased standards will result in consumers being priced out of the new vehicle market and choosing to keep their existing vehicle or purchase a used vehicle. Since new vehicles are significantly safer than used vehicles, slowing fleet turnover to newer vehicles results in older and less safe vehicles remaining on the roads longer. NHTSA stated that this significantly affects the safety of the United States light duty fleet, as described more fully in in the safety section of the NPRM and in Chapter 11 of the PRIA. Furthermore, as fuel economy standards become more stringent, and more fuel efficient vehicles are introduced into the fleet, fueling costs are reduced. This results in consumers driving more miles, which results in more crashes and increased highway fatalities.

A number of commenters disagreed with a variety of aspects of the NPRM's analysis of safety, and several also disagreed with how NHTSA considered safety along with the other factors in the proposal. The States and Cities commenters, for example, agreed that "NHTSA has historically considered safety impacts when setting maximum feasible standards," but argued that:

> in the Proposed Rollback, NHTSA departs from its past practice by relying on completely novel and unsupported theories regarding the linkages between fuel economy and safety that do not reflect reality. In the past, NHTSA has considered the safety of the technologies that improve fuel economy. [citations omitted] In the Proposed Rollback, however, NHTSA has linked safety concerns with rebound and scrappage effects of more stringent fuel economy standards. [citations omitted] As discussed [elsewhere], these theories are unsupported, implausible, and contradicted by numerous experts—rendering them arbitrary and capricious. The agency has also failed to acknowledge or adequately justify its break with past analyses of safety. *See Fox Television*, 556 U.S. at 515."[2912]

EDF commented that NHTSA cannot "…lawfully rely upon the repercussions of increased driving as a justification…. The fact that the standards do not 'compel' this driving prevents such reliance, and…[EPCA/EISA] nowhere indicate that [NHTSA] can refuse to comply with [its] statutory obligations by pointing to a projection that individuals might drive more and in doing so, some of them will get into traffic accidents.[2913] EDF further argued that:

> It is especially unlikely that Congress intended for NHTSA to consider potential increases in driving (or… 'VMT'). Under basic economic theory and under the Agency's traditional analysis (including their analysis of this proposal), an improvement in fuel economy—which makes driving cheaper—would be expected to lead to some increase in driving for households that are sensitive to and conscious of that effect on their budgets. Thus, consideration of VMT impacts could be used to undermine *any* fuel economy standard. Because VMT is 'a factor [that] is both so indirectly related to [fuel economy] and so full of potential for canceling the conclusions drawn from [a fuel economy analysis] . . . it would surely have been expressly mentioned in [the statute] had Congress meant it to be considered.' *Whitman v. Am. Trucking Associations*, 531 U.S. 457, 469 (2001)."[2914]

Other comments on safety as part of the legal justification varied. NESCAUM claimed that NHTSA's safety justification "is disputed by EPA's technical staff based on their identification of flaws in NHTSA's analysis," suggesting that it was therefore invalid and not a basis for decision-making.[2915] Global commented that there was no policy reason for freezing the level of standards due to mass reduction concerns (i.e., safety), given footprint standards.[2916]

[2912] States and Cities, NHTSA-2018-0067-11735, at 77.
[2913] EDF, NHTSA-2018-0067-12137, Supplemental Safety Comments, at 3.
[2914] *Id*.
[2915] NESCAUM, NHTSA-2018-0067-11691, at 3.
[2916] Global, NHTSA-2018-0067-12032, Attachment A, at A-32.

IPI argued that it was inappropriate to account for vehicle safety-related deaths and injuries "without an adequate discussion of the health and safety impacts of the Proposed Rule's increased emissions or without an accurate estimate of the actual safety impact of the rollback versus the 2012 standards."[2917]

NHTSA agrees with commenters that the safety analysis conducted to inform this rulemaking (both NPRM and final rule) is different from—broader than—past safety analyses conducted to inform CAFE and CO_2 rulemakings. NHTSA disagrees, however, that the agency failed to acknowledge or explain this fact. The NPRM directly acknowledges and explains the evolution of the safety analysis over time and why, specifically, the NPRM included the safety effects of rebound and scrappage phenomena.[2918] The NPRM also expressly sought comment on these elements of the safety analysis and the safety analysis generally, before explaining how they worked and describing their tentative findings in considerable detail. It is inaccurate for commenters to claim that the agency did not acknowledge or explain these changes. Commenters' disagreement with the substance of the safety analysis does not create a valid process complaint here. Section VI discusses in detail the comments received on the substance of the safety analysis, including a number of comments citing deliberative feedback provided by some members of EPA staff during NPRM development, and contains the agencies' responses. With regard to the comment from EDF, as explained above, the premise that vehicles may be driven more or less in response to more or less stringent CAFE (or CO_2) standards is called the rebound effect, and it is discussed at length in Section VI above. The rebound effect has been factored into rulemaking cost-benefit analyses and reduced CAFE and CO_2 standard benefits in such analyses for well over a decade,[2919] and EPA and NHTSA have written repeatedly about and considered the magnitude of this effect. NHTSA is aware that some commenters disagree that a rebound effect even exists for fuel economy, and understands how such commenters would correspondingly disagree that VMT-related safety effects could arise from differences in CAFE standards. But NHTSA does not agree that the rebound effect is zero, and correspondingly believes that safety effects from additional driving (due to exposure to crashes) exist and are capable of quantification for analytical purposes.

Moreover, if EDF were correct that agencies may consider only the behavior that regulations directly "compel," then CAFE analysis would be challenged to consider even fuel savings—the purpose of CAFE standards—because the standards do not compel Americans to drive, or to buy new vehicles, or to buy any vehicles at all. Reasonable assumptions about how much Americans drive (depending on how much it costs to drive, among other things), and what vehicles Americans buy and how often they buy them (depending on how much those vehicles cost, among other things), are useful and important for including in analyses that help decision-makers distinguish between different levels of potential CAFE standards. Circular A-4 additionally directs agencies to consider ancillary effects of rulemakings.[2920] NHTSA believes

that it is reasonable to consider these effects as part of the safety analysis, and to consider safety effects as part of its determination of maximum feasible standards.

2. Administrative Procedure Act

To be upheld under the "arbitrary and capricious" standard of judicial review in the APA, an agency rule must be rational, based on consideration of the relevant factors, and within the scope of the authority delegated to the agency by the statute. The agency must examine the relevant data and articulate a satisfactory explanation for its action including a "rational connection between the facts found and the choice made."[2921]

Statutory interpretations included in an agency's rule are subject to the two-step analysis of *Chevron, U.S.A. v. Natural Resources Defense Council*.[2922] Under step one, where a statute "has directly spoken to the precise question at issue," *id*. at 842, the court and the agency "must give effect to the unambiguously expressed intent of Congress."[2923] If the statute is silent or ambiguous regarding the specific question, the court proceeds to step two and asks "whether the agency's answer is based on a permissible construction of the statute."[2924]

If an agency's interpretation differs from the one that it has previously adopted, the agency need not demonstrate that the prior position was wrong or even less desirable. Rather, the agency would need only to demonstrate that its *new* position is consistent with the statute and supported by the record and acknowledge that this is a departure from past positions. The Supreme Court emphasized this in *FCC v. Fox Television*.[2925] When an agency changes course from earlier regulations, "the requirement that an agency provide a reasoned explanation for its action would ordinarily demand that it display awareness that it *is* changing position," but "need not demonstrate to a court's satisfaction that the reasons for the new policy are *better* than the reasons for the old one; it suffices that the new policy is permissible under the statute, that there are good reasons for it, and that the agency *believes* it to be better, which the conscious change of course adequately indicates."[2926] The APA also requires that agencies provide notice and comment to the public when proposing regulations,[2927] as the agencies did when publishing the NPRM for this rulemaking.

---

should include any important ancillary benefits and countervailing risks. An ancillary benefit is a favorable impact of the alternative under consideration that is typically unrelated or secondary to the purpose of the action (e.g., reduced refinery emissions due to more stringent fuel economy standards for light trucks). A countervailing risk is an adverse economic, health, safety, or environmental consequence that results from a regulatory action and is not already accounted for in the direct cost of the action (e.g., adverse safety impacts from more stringent fuel-economy standards for light trucks). As with other benefits and costs, an effort should be made to quantify and monetize both ancillary benefits and countervailing risks.")

a) Requests to Extend the Comment Period

On August 2, 2018, the agencies published the NPRM on the agencies' respective websites, soliciting public comments.[2928] On August 24, 2018, the *Federal Register* published the NPRM, which began a 60-day public comment period.[2929] The public comment period would have ended on October 23, 2018, but the agencies extended the comment period until October 26, 2018.[2930] In the *Federal Register* notice extending the comment period, the agencies explained that they were denying requests for an extension of the comment period by at least 60 days, explaining that "[a]utomakers will need maximum lead time to respond to the final rule[.]"[2931] Although the comment period ultimately closed on October 26, 2018, the agencies' dockets remained open, and the agencies continued to accept and consider comments, to the extent possible, for more than one year after the comment period began.[2932]

After publishing the NPRM, the agencies received a number of requests to extend the comment period, generally for an additional 60 days.[2933] For example, seventeen States and the District of Columbia jointly requested a 60-day extension of the comment period.[2934] That request cited the voluminous record, the complexity of the material, and the profound potential impact on human health and the environment, among other things.[2935] The City of Los Angeles and New York State Department of Environmental Conservation also requested a 60-day extension, for similar reasons.[2936] In addition, 32 United States Senators jointly requested a 60-day extension of the comment period.[2937] The Senators argued that an extension was appropriate to ensure adequate public participation with such an important rule.[2938] Several non-government organizations similarly requested a 60-day extension of the comment period due to the complexity of the issues and the importance of the proposed rule.[2939] Other organizations also requested a 60-day extension, stressing the complexity of the issues and the significance of the

proposed rule's impact on the environment.[2940] The American Lung Association also requested a 60-day extension of the comment period, asserting that it needed more time to analyze the impact of the proposed rule on human health.[2941] The California Air Resources Board (CARB) likewise requested a 60-day extension, in part, based on information that it asserted should have been included in the NPRM.[2942] New York University School of Law's Institute for Policy Integrity similarly requested a 60-day extension based on information that it contended should have been included in the NPRM's "sensitivity analysis table for the 'Cumulative Changes in Fleet Size, Travel (VMT), Fatalities, Fuel Consumption and C02 Emissions through MY2029.'"[2943]

The agencies do not believe a further extension of the comment period was warranted under the circumstances.[2944] The APA does not specify a minimum number of days for a comment period.[2945] Two Executive Orders also provide direction to Federal agencies with respect to the length of a comment period for a proposed rule.[2946] Executive Order 12,866 states that "[e]ach agency shall (consistent with its own rules, regulations, or procedures) provide the public with meaningful participation in the regulatory process . . . . In addition, each agency should afford the public a meaningful opportunity to comment on any proposed regulation, which in most cases should include a comment period of not less than 60 days."[2947] Additionally, Executive Order 13,563 reaffirmed Executive Order 12,866's directive that comment periods should generally not be less than 60 days, stating: "To the extent feasible and permitted by law, each agency shall afford the public a meaningful opportunity to comment through the Internet on any proposed regulation, with a comment period that should generally be at least 60 days."[2948] More recently, in December of 2018, the Department of Transportation implemented DOT Order 2100.6, which provides its operating administrations, including NHTSA, with direction on appropriate rulemaking processes and procedures.[2949] While not yet effective at the time the proposal was published, the Order provides that "the comment period for

[2947] Executive Order 12,866 § 6(a)(1).
[2948] Executive Order 13,563 § 2(b).
[2949] DOT Order 2100.6, "Policies and Procedures for Rulemakings," available at: https://www.transportation.gov/sites/dot.gov/files/docs/regulations/328561/dot-order-21006-rulemaking-process-signed-122018.pdf.

significant DOT rules should be at least 45 days."[2950] The 63 day comment period for the proposal far exceeded this amount.

Consistent with these principles, courts give broad discretion to agencies in determining the reasonableness of a comment period. Courts have frequently upheld comment periods that were significantly less than the 63-day comment period here. *See Connecticut Light & Power Co. v. Nuclear Regulatory Comm'n*, 673 F.2d 525, 534 (D.C. Cir. 1982) (upholding a 30-day comment period and stating that "neither statute nor regulation mandates that the agency do more"); *see also North American Van Lines v. ICC*, 666 F.2d 1087, 1092 (7th Cir. 1981) (upholding a 45-day comment period).[2951] In addition to the length of a comment period, courts consider the number of comments received and whether comments had an effect on an agency's final rule, in assessing whether the public had a meaningful opportunity to comment.[2952]

These principles are easily satisfied here. Here, the agencies initially provided a 60-day comment period and then further extended it to ensure compliance with the Clean Air Act. The Clean Air Act requires that the record of proceedings allowing oral presentation of data, views, and arguments on a proposed rule be kept open for 30 days after completion of a proceeding to provide an opportunity for submission of rebuttal and supplementary information.[2953] Because the final "proceeding allowing oral presentation of data, views, and arguments" was expected to be on September 26, 2018, the comment period for the proposed rule was extended by three days to meet that requirement.[2954]

The 63-day comment period was consistent with what the law requires.[2955] While the agencies understand and agree with commenters about the importance and complexity of the issues here, the public docket demonstrates that the public had a meaningful opportunity to comment on the proposed rule.[2956] The agencies received a total of more than 750,000 public comments, many of which commented on detailed, technical portions of the proposed rule. For instance, the California Air Resources Board provided 415 pages of detailed comments involving very specific aspects of the proposal,[2957] and the Auto Alliance filed 202 pages of detailed comments, and commissioned a separate econometric study analyzing the effects of multiple

alternatives.[2958] This is clear evidence that the public had not only the opportunity to review and comment on the proposal, but to do so with an extraordinary level of detail.

Finally, notwithstanding the sufficiency of the agencies' 63-day comment period, the agencies published their NPRM on their websites on August 2, 2018, more than three weeks before the comment period formally opened on August 24, and this effectively provided the public with 22 additional days in which to review the proposal and draft comments. The agencies' public dockets also remained open for more than one year after the start of the comment period, and the agencies considered late comments received, to the extent practicable.

b) Other Comments on Public Participation

Several commenters objected to NHTSA's 15-page limit on primary comments, asserting that it impacted the public's ability to meaningfully participate in the rulemaking process.[2959] However, as certain of the commenters acknowledged, the NPRM also explicitly stated that commenters could also submit attachments—without any page limit.[2960] Thus, the page limit on primary comments did not prevent commenters from presenting any information they deemed relevant to the agencies. Both primary comments and their attachments are available in the agencies' public dockets, and were considered by the agencies in this rulemaking as demonstrated by the responses to comments discussed throughout this final rule.

NHTSA's 15-page limit simply prescribed the form that comments should take: a concise summary comment of up to 15 pages, with optional attachments with no page limit. Many commenters submitted extensive attachments to their comments, including commenters that objected to the 15-page limit for primary comments. For example, several States and cities that jointly commented submitted a 13-page primary comment, accompanied by 145 pages of "detailed comments" and three appendices totaling 101 additional pages.[2961] The 15-page limit had the effect of creating executive summaries of otherwise voluminous comments, which increased efficiency during the rulemaking process. This was NHTSA's stated purpose for the 15-page limit. As explained in the NPRM: "NHTSA established this limit to encourage you to write your primary comments in a concise fashion."[2962] In any event, no commenter was prevented from submitting information to the agencies based on NHTSA's page limitation for primary comments. The agencies strongly disagree that public participation was impeded by NHTSA's specification that primary comments were limited to 15 pages.

On August 2, 2018, the agencies published a joint Notice of Proposed Rulemaking (NPRM) on the agencies' respective websites, which solicited public comments on "The Safer

Affordable Fuel-Efficient (SAFE) Vehicles Rule for Model Years 2021–2026 Passenger Cars and Light Trucks."[2963] The NPRM indicated that the public may submit written comments by any of the following methods: online through the Federal eRulemaking Portal at www.regulations.gov, by fax, by mail, or by hand delivery. The NPRM also notified the public that the agencies planned to hold three joint public hearings, and would accept oral and written comments at the hearings. The NPRM indicated that the agencies planned to hold the hearings in Washington, D.C.; the Detroit, Michigan area; and the Los Angeles, California area, but indicated that the specific addresses and dates for the hearings would be announced in a supplemental *Federal Register* notice.[2964] On August 24, 2018, the agencies published a notice in the *Federal Register*, which provided new locations for two of the three hearings and added dates for each hearing.[2965] That notice informed the public that the agencies planned to hold three joint public hearings during the comment period: 1) on September 24, 2018 in Fresno, California; 2) on September 25, 2018 in Dearborn, Michigan; and 3) on September 26, 2018 in Pittsburgh, Pennsylvania.[2966]

The agencies also received several comments with respect to the sufficiency of the agencies' public hearings during the comment period. For example, the South Coast Air Quality Management District asserted that EPA failed to meet its obligation to hold public hearings under the Clean Air Act, claiming that an EPA "political appointee" did not have the legal authority to change hearing locations.[2967] The comment also claimed that holding certain of the hearings in smaller metropolitan areas than originally announced resulted in 15 million fewer potential participants in the hearings.[2968] Additionally, the comment noted that the NPRM and the notice that set the new locations of two of the public hearings were both published in the Federal Register on the same day, yet those documents contained conflicting hearing locations (the NPRM listed the originally planned hearing locations).[2969]

Similarly, seventeen States and the District of Columbia submitted a joint comment requesting that the agencies reinstate the hearing locations that were initially listed in the NPRM, with the stated goal of maximizing the number of public participants.[2970] Similarly, a group of environmental organizations jointly submitted a comment stating that the new hearing locations failed to maximize the potential participants for the agencies' public hearings.[2971] That group

also asserted that the agencies failed to provide a reason for the agencies' denial of requests to hold more than three public hearings.[2972]

The agencies more than satisfied their legal obligation with respect to holding public hearings, and the three hearings provided substantial additional opportunity for public participation. While the agencies understand that some commenters were disappointed with some aspects of the process, those commenters did not demonstrate that the agencies' process was legally deficient, nor that any party suffered prejudice from the changes the agencies made to their public hearing arrangement.

The APA does not require agencies to hold public hearings during the rulemaking process, unless the opportunity for a public hearing is required by a governing statute.[2973] NHTSA's governing fuel economy statute does not require a public hearing during the rulemaking process.[2974] The Clean Air Act requires EPA to "give interested persons an opportunity for the oral presentation of data, views, or arguments, in addition to an opportunity to make written submissions . . . ." 42 U.S.C. 7607(d)(5)(ii). The agencies' three joint public hearings satisfied this statutory requirement.

The agencies note that it was clear from the NPRM that the hearings were not yet finalized. No addresses or dates were announced for the hearings, and the NPRM indicated that information on the hearings would be forthcoming in a supplemental *Federal Register* notice. The NPRM (signed by the EPA Administrator) indicated that three hearings would be held, and the fact that specific details about those hearings were announced in a later notice signed by a different political appointee does not itself make the hearings themselves invalid. The Clean Air Act does not mandate hearings in any particular location and the public was aware from the NPRM that additional information on the hearings would be forthcoming. To the extent that any individual person or group was inconvenienced by the change in location announced in the supplemental notice, they still had ample time to submit public comments through any of the multiple other available methods indicated in the NPRM.[2975]

[2973] *See* 5 U.S.C. 553(c). Absent a statutory requirement, the APA gives agencies the discretion whether or not to hold a public hearing, stating that "the agency shall give interested persons an opportunity to participate in the rule making through submission of written data, views, or arguments with or without opportunity for oral presentation." *Id.*

[2974] *See* 49 U.S.C. 32902.

[2975] Executive Order 13,563 offers guidance to agencies with respect to how to maximize public participation. The Executive Order states that agencies should "afford the public a meaningful opportunity to comment through the Internet on any proposed regulation . . . ." The vast majority of the comments the agencies received in this rulemaking were submitted through the internet.

The agencies regret any confusion that resulted from publication of the NPRM in the *Federal Register* on the same date as publication of the notice that updated the hearing locations and provided additional information, including hearing dates. However, because the NPRM did not include dates for the hearings, and the NPRM informed interested parties to look for an additional notice that would announce specific dates and addresses for the hearings, no one could have relied on the NPRM to the exclusion of the supplemental notice.[2976]

The agencies ultimately held three public hearings, as was originally announced. There is no Clean Air Act requirement for a particular number of hearings, and by holding the hearings in locations throughout the United States (including in California), the agencies offered a meaningful opportunity for participation. Moreover, the public docket remained open for two months subsequent to the announcement of the final hearing locations, providing any interested party who was unable to attend a public hearing ample opportunity to submit comments in writing. As evidence of this meaningful opportunity to comment on the proposed rule, the agencies received a total of more than 750,000 public comments.

Several commenters also asserted that the agencies delayed posting the hearing transcripts to the public docket until October 25, which was one day before the close of the public comment period.[2977] The Environmental Defense Fund claimed that this was inconsistent with the Clean Air Act's requirements that "'[t]he transcript of public hearings, if any, on the proposed rule shall also be included in the docket promptly upon receipt from the person who transcribed such hearings.' 42 U.S.C. 7607(d)(4)(B)."[2978] As one commenter acknowledged, the transcripts were certified by the reporters on September 26, 2018 (Pittsburgh hearing), September 27, 2018 (Dearborn hearing), and October 1, 2018 (Fresno hearing).[2979] The agencies made the transcripts publicly available within a reasonable period. Moreover, it was reasonable for the agencies to have an opportunity to review the transcripts for errors prior to making them publicly available. While the concern expressed by these commenters was an inadequate ability to offer responsive comments to the transcripts, the rulemaking process would be never-ending if every commenter had an opportunity to respond to every other commenter. There is no such requirement in the APA, the Clean Air Act, or otherwise. The public had sufficient opportunity to comment on the agencies' proposals, as described above.

A few commenters requested that the agencies host a workshop or webinar to help commenters better understand the agencies' modeling and analyses.[2980] The commenters pointed to similar activities undertaken by EPA for other complex rulemakings. While the agencies did not conduct a live workshop or webinar regarding the proposal, they did make extensive

---

[2976] Additionally, as a matter of fairness, the agencies gave interested parties notice about the change in public hearing locations one month prior to the first public hearing. *See* 83 FR 42817 (August 24, 2018).

information publicly available beyond the contents of the NPRM. To assist the public, NHTSA hosted a dedicated webpage with information on the modeling.[2981] The webpage included a video introduction to the CAFE model.[2982] The webpage enabled members of the public to download the model software, its system documentation, source code, and input files.[2983] Many commenters commented in detail on the modeling and analyses. However, the agencies recognize that public stakeholders vary in their experience and understanding of the modeling and analyses and will continue to consider ways to facilitate public participation in future rulemakings, which could include the use of workshops or webinars.

Some comments criticized the agencies for the agencies' untimeliness in adding materials to the rulemaking dockets, for example, identifying material "that was not added to the rulemaking docket until the end of the original comment period or, in some cases, added either after that period already had closed or not at all."[2984]

The critical question is "whether the final rule changes critically from the proposed rule rather than on whether the agency relies on supporting material not published for comment."[2985] In other words, "[t]he question is typically whether the agency's final rule so departs from its proposed rule as to constitute more surprise than notice."[2986] To that end, agencies are allowed—as the agencies here did—to rely on supplemental data that clarified, expanded on, or confirmed information in the proposed rule, even if that supplemental data was not disclosed in the proposed rule.[2987] In any event, the commenters have failed to show how they were prejudiced by any information posted later than they would have preferred.[2988]

Some commenters noted that certain aspects of the CAFE model used for the proposal were not previously subject to peer review.[2989] Certain commenters asserted that the proposal was legally flawed because the full CAFE model was not peer reviewed prior to the proposal.[2990] In support of this argument, commenters cited the Information Quality Act and related OMB guidance that states that "each agency shall have a peer review conducted on all influential

scientific information that the agency intends to disseminate."[2991] Commenters also cited EPA's Peer Review Handbook, which states: "For highly influential scientific assessments, external peer review is the expected procedure."[2992]

The agencies agree that peer review is appropriate for the CAFE model, and the CAFE model has been peer reviewed. As discussed in the NPRM, and as certain commenters acknowledged, the CAFE model was peer reviewed in 2017.[2993] NHTSA included peer review materials in the public docket as well as on its webpage regarding the model.[2994] As described in those materials: "In 2017, the Volpe Center arranged for a formal peer review of the version of the CAFE model released and documented in 2016 . . . . All of the peer reviewers supported much about the model's general approach, and supported many of the model's specific characteristics. Peer reviewers also provided a variety of general and specific recommendations regarding potential changes to the model, inputs, outputs, and documentation. NHTSA and Volpe Center staff agree with many of these recommendations and have either completed or begun work to implement many of them; implementing others would require further research, testing, and development not possible at this time, but we are considering them for future model versions."[2995]

However, certain new elements of the CAFE model were not completed at the time of the 2017 peer review.[2996] NHTSA subsequently obtained a peer review of significant new elements added to the model after the 2017 peer review.[2997] As described in the new peer review charge, included in a July 2019 report included in the rulemaking docket, NHTSA explained:

> To inform the proposed rule announced in August 2018, DOT staff introduced significant new elements to the model, including methods to estimate changes in vehicle sales volumes, vehicle scrappage, and automotive sector labor usage. Each of these regulatory actions involved consideration of and response to significant public comment on model results, as well as comments on the model itself. In addition to DOT staff's own observations, these comments led DOT staff to make a wide range of improvements to the model. Insofar as a formal peer review could identify additional potential opportunities to improve the model, DOT sponsored a review of the entire model in 2017. At this time, DOT seeks review of some of the significant new elements added to the model after that review.

[2991] *See* Center for Biological Diversity et al., NHTSA-2018-0067-12000.
[2992] *See* Center for Biological Diversity et al., NHTSA-2018-0067-12000.
[2993] 83 FR 43000 (Aug. 24, 2018) ("A report available in the docket for this rulemaking presents peer reviewers' detailed comments and recommendations, and provides DOT's detailed responses."); *see* Center for Biological Diversity et al., NHTSA-2018-0067-12000.
[2994] NHTSA-2018-0067-0055; https://www.nhtsa.gov/corporate-average-fuel-economy/compliance-and-effects-modeling-system.
[2995] NHTSA-2018-0067-0055.
[2996] NHTSA-2018-0067-0055 (explaining, in responses to 2017 peer review, that "[t]he model has been updated to including procedures to estimate impacts on new vehicle sales, and on older vehicle scrappage").
[2997] NHTSA-2018-0067-0055.

This subsequent peer review of the new elements was not complete at the time the proposal was published, and therefore materials concerning the peer reviewers' comments and NHTSA's responses were not available until later.[2998] Although the comment period on the proposal had closed at that time, the agencies continued to receive comments on the new peer review materials, which they have considered in issuing this final rule.[2999] Of course, the new elements of the modeling were also described in detail in the NPRM and commenters also directly commented on them in great detail. Thus, the public was fully apprised of all aspects of the modeling and had a robust opportunity to provide comment.

To the extent commenters are suggesting the Information Quality Act required a full peer review of all aspects of the CAFE model *prior* to the proposal, the agencies disagree.[3000] Peer review of the new elements of the CAFE model helped ensure that the model is scientifically sound, and the peer reviewers provided feedback that helped improve the model and may help develop additional improvements to the model in the future. In this sense, the peer review of the new elements of the model functioned similarly to public comments from commenters with specific scientific expertise. Much of the feedback from the peer reviewers were in fact similar in nature to comments received from public commenters on the model. By engaging in both peer review and notice-and-comment procedures, the agencies ensured that they had information from a wide variety of sources, including those with specific expertise, to validate and improve the model.[3001] The technical aspects of the model, including improvements made to the model following the proposal, are described in detail in this final rule. Moreover, as the Center for Biological Diversity noted, the Information Quality Act does not create third-party rights.[3002]

The agencies also disagree that EPA needed to obtain a separate peer review of the CAFE model.[3003] The peer review addressed aspects of the model relevant to the analysis by both agencies under their respective statutory schemes. The agencies have expertise in their statutory requirements and discussed in detail both in the proposal and this final rule how the CAFE model was used to inform the decision-making under both EPCA and the CAA.

c) Other APA Comments

Many commenters suggested that the record of evidence developed for the 2016 Draft TAR and EPA's Original Determination was a better basis for NHTSA to determine maximum feasible standards than the record of evidence for the current rulemaking. These commenters

---

[2998] NHTSA-2018-0067-0055 (July 2019 report).
[2999] *See, e.g.*, Center for Biological Diversity et al., NHTSA-2018-0067-12439; Environment America et al., NHTSA-2018-0067-12441.
[3000] *See, e.g.*, Center for Biological Diversity et al., NHTSA-2018-0067-12000; Environment America et al., NHTSA2018-0067-12441.
[3001] The timing of the peer review of new elements of the model also did not require a second cycle of notice and comment. *See, e.g.*, Alto Dairy v. Veneman, 336 F.3d 560, 569-70 (7th Cir. 2003) ("The law does not require that every alteration in a proposed rule be reissued for notice and comment. If that were the case, an agency could 'learn from the comments on its proposals only at the peril of subjecting itself to rulemaking without end.'").
[3002] Center for Biological Diversity et al., NHTSA-2018-0067-12000.
[3003] Center for Biological Diversity et al., NHTSA-2018-0067-12000.

also argued that, in the NPRM, NHTSA ignored the findings and analysis in the TAR and the Technical Support Document and contradicted the pre-existing record without explanation. Lastly, these commenters argued that the NPRM did not have a reasoned basis under the APA, particularly in light of the agency's change in position and the reliance interests at stake.

Agencies always have authority under the Administrative Procedure Act to revisit previous decisions in light of new facts, as long as they provide notice and an opportunity for comment—as the agencies did here. Indeed, it is the best practice to do so when changed circumstances so warrant.[3004]

"Changing policy does not, on its own, trigger an especially 'demanding burden of justification.'"[3005] "Agencies are free to change their existing policies as long as they provide a reasoned explanation for the change."[3006] Providing this explanation "would ordinarily demand that [the agency] display awareness that it *is* changing position."[3007] Beyond that, however, "[w]hen an agency changes its existing position, it 'need not always provide a more detailed justification than what would suffice for a new policy created on a blank slate.'"[3008] The agency "need not demonstrate to a court's satisfaction that the reasons for the new policy are *better* than the reasons for the old one."[3009] For instance, "evolving notions" about the appropriate balance of varying policy considerations constitute sufficiently good reasons for a change in position.[3010] A change in policy is "well within an agency's discretion:" agencies are permitted to conduct a "reevaluation of which policy would be better in light of the facts," without "rely[ing] on new facts."[3011]

To be sure, providing "a more detailed justification" is appropriate in some cases.[3012] But when "a more detailed justification" is needed, all that is required is for the agency to explain how "new information arising after" the previous determination "informed its conclusion" that a change was appropriate: "explanations relying on new data are sufficient to satisfy the more detailed explanatory obligation."[3013] As one of the critical comments itself noted, "[a]gencies must use 'the best information available' in reaching their conclusions, and cannot lawfully rely

3010 N. Am.'s Bldg. Trades Unions v. Occupational Safety & Health Admin., 878 F.3d 271, 303 (D.C. Cir. 2017) (quoting the agency's rule).
3011 Nat'l Ass'n of Home Builders v. E.P.A., 682 F.3d 1032, 1037-38 (D.C. Cir. 2012).
3012 FCC v. Fox Television Stations, Inc., 556 U.S. 502, 515 (2009) ("Sometimes [the agency] must [provide a more detailed justification than what would suffice for a new policy created on a blank slate]—when, for example, its new policy rests upon factual findings that contradict those which underlay its prior policy; or when its prior policy has engendered serious reliance interests that must be taken into account.").
3013 Mingo Logan Coal Co. v. Envtl. Prot. Agency, 829 F.3d 710, 727 (D.C. Cir. 2016).

on outdated information as circumstances change."[3014] Accordingly, when new information became available, the agencies relied on it expressly, resulting in a fully-explained change in their analysis and ultimately their conclusions.

While "[i]t would be arbitrary or capricious to ignore such matters,"[3015] the agencies have not ignored them. NHTSA has satisfied these standards. The NPRM expressly and repeatedly acknowledged that it represented a change from the 2012 final rule, the Draft TAR, and EPA's Original Determination, appropriately justifying the change by citing shifts in policy priorities or new facts and changed circumstances that became apparent since the Original Determination.[3016] The agencies are fully cognizant of the facts and circumstances that have changed since the Original Determination, expressly acknowledged them in the Revised Determination and SAFE Rule NPRM, and adapted to accept them now in the final rule.

Several commenters invoked requests to the agencies under the Freedom of Information Act ("FOIA") regarding material sought in connection with the rulemaking.[3017] These comments ranged from simple references to existing FOIA requests to the agencies, to the actual submission of the FOIA requests as a comment posted to the rulemaking docket.[3018] These commenters sought a variety of information, which included calendars and internal correspondence of specific agency personnel, communications with non-governmental stakeholders, and technical materials and clarifications relating to aspects of the agencies' analysis.[3019]

To the extent these requests sought substantive material, those matters are addressed in other sections herein that pertain to the respective underlying issues implicated. Although the submission of FOIA requests through an online rulemaking docket is a very unusual form of submitting a FOIA request to an agency, the agencies nevertheless processed the comments that requested materials by invoking FOIA as formal FOIA requests. As such, once identified, those comments were forwarded to the agencies' respective FOIA offices, which commenced the intake process of the letters as FOIA requests. In turn, the agencies' FOIA offices transmitted receipt acknowledgement letters to the requestors and conducted searches for the applicable material. The agencies responded to the requestors by producing the responsive non-exempt records identified, applying the appropriate FOIA standards applicable to the records and requests. Like all other typical FOIA requests, the requestors were provided with an opportunity

[3019] *See, e.g.*, Environmental Defense Fund, NHTSA-2018-0067-12397; Office of the Attorney General of the State of New York, NHTSA-2018-0067-3613; California Air Resources Board, NHTSA-2018-0067-4166.

to administratively appeal the FOIA decision and, if desired, subsequently seek judicial review of the agencies' decisions. Several commenters availed themselves of this procedure.[3020]

Thus, the agencies fully satisfied their obligations under the governing FOIA provisions. In fact, other commenters noted the agencies' responses to these FOIA requests and incorporated information disclosed in the responses into their comments.[3021] Moreover, several of the FOIA requests submitted as comments requested information that had already been published on the agencies' websites for the rulemaking or in the rulemaking dockets.

Although the agencies fulfilled their obligations under all applicable FOIA law, the agencies also stress that FOIA compliance is wholly irrelevant to conformity to governing APA standards in the rulemaking process. FOIA arises from an independent statutory framework, which contains unique provisions for judicial review.[3022] These provisions for judicial review provide "an adequate form of relief" such that the APA is not typically even an appropriate mechanism to seek the disclosure of further information requested under FOIA.[3023] Likewise, the APA's principles governing rulemaking procedures, including disclosures of information for such rulemakings, exist as autonomous statutory and jurisprudential concepts totally untethered from the principles of disclosure under FOIA.

Similarly, as an independent statutory framework from the APA, the susceptibility of materials and records for production under FOIA has no bearing on whether such materials should have been made public under the APA as part of a rulemaking. The scope of materials for production under FOIA arises from the Agency's reasonable interpretation of the language of the FOIA request, as well as the exemptions potentially applicable to the records under the applicable FOIA statutes and implementing regulations.[3024] In contrast, in an APA review of rulemaking procedures, separate standards exist to govern the scope of materials an agency must make available during the rulemaking process.[3025] Thus, records may be responsive to a FOIA request, but not appropriate for publication under the APA—even if the FOIA request concerns the proposed rule in question. The FOIA requests at issue here are illustrative of this distinction. For example, one of the specific FOIA requests identified by commenters describes the requests as pertaining to the NPRM, but seeks Outlook calendars of DOT and NHTSA personnel.[3026] While such materials may be responsive to the underlying FOIA requests, which expressly mention the calendars, an employee's entire list of calendar appointments—including

[3026] *See* Environmental Defense Fund, NHTSA-2018-0067-12397.

appointments unrelated to the rulemaking—is clearly not contemplated by the APA as material necessary for publication along with a proposed rule. Thus, while the agencies sought to comply with their independent statutory obligations under FOIA, to the extent commenters invoke purported FOIA noncompliance, the agencies consider such arguments irrelevant to the rulemaking analysis. Likewise, any production of records in connection with any FOIA request that invokes the proposed rule is not a recognition by the agencies that the material should have also been made available during the rulemaking under the APA.

Several commenters also criticized the agencies, and specifically the EPA, for not publishing an updated version of the Optimization Model for Reducing Emissions of Greenhouse Gases from Automobiles ("OMEGA") along with the proposed rule.[3027] As described in further detail in Section IV herein, OMEGA is a fleet compliance model developed by the EPA and used in previous rulemakings. While many commenters raised technical arguments comparing the OMEGA model to the CAFE Model utilized in this rulemaking, such technical analysis and comments are addressed elsewhere in this final rule analysis. *See* Section IV. Likewise, while several comments refer to FOIA requests for OMEGA model materials, the Agencies' discussion of FOIA comments are addressed above.

Most other commenters who raised more procedural arguments concerning the unavailability of an updated version of the OMEGA model argued that an updated version of the model should have been released because the EPA utilized the model during an interagency review of the proposed rule.[3028] In considering these comments, the agencies emphasize that neither NHTSA, the EPA, nor any other interagency reviewer relied upon the OMEGA model for the preparation of either the proposed or the final versions of the SAFE Vehicles Rule. Instead, as clearly expressed in rulemaking descriptions and documents accompanying both this final rule and the proposed rule, the agencies relied on a separate model to perform the analysis that helped to inform the agencies regarding potential effects of various fuel economy standards. This independent model, the CAFE Model, was developed by the Department of Transportation's Volpe National Transportation Systems Center.

In fact, most commenters discussing the OMEGA model understood and expressly acknowledged that the agencies relied upon the CAFE Model rather than the OMEGA model for this rulemaking.[3029] Several commenters even paradoxically argued *both* that the agencies unreasonably failed to utilize the OMEGA model *and* that the agencies denied meaningful opportunity for comment by utilizing but failing to publish an updated OMEGA model.[3030] Nevertheless, the analysis and universe of documents published for the proposed rule made abundantly clear that the CAFE Model—not the OMEGA model—performed the applicable analysis for this rulemaking. Likewise, the agencies' proposed rule published voluminous analyses and supporting documents to describe the CAFE Model and explain the underlying methodologies incorporated into the model's operation for this rulemaking. The agencies also

released the full version of the CAFE Model employed in this rulemaking, as well as its respective inputs and outputs, in order to provide commenters with ample opportunities to understand the model's function and operation.

The extensive comments on the modeling conducted for this rulemaking confirm that the agencies provided the public with sufficient information to comment on the modeling process for the rulemaking. Comments regarding the OMEGA and CAFE models were expansive, spanning hundreds of pages of technical analysis and submissions from a variety of commenters. Many of these comments even consisted of detailed and technical comparisons of the CAFE model used in this rulemaking with past versions of OMEGA models used for prior rulemakings.[3031] Even if certain of these commenters disagreed with the Agencies' ultimate approach to the modeling, they evidently understood the applicable methodologies and performance of the CAFE Model for this rulemaking sufficiently to substantively engage with the Agencies on these topics through their comments. Therefore, the agencies consider the detailed comments on the OMEGA and CAFE models as clear indicia that the extensive information, materials, and explanations provided by the agencies in the proposed rule enabled significant opportunity for the public to comment on the modeling for the rule.

To the extent that commenters allege an insufficient opportunity to comment by claiming that the EPA actually utilized the OMEGA model in the rulemaking process, the agencies consider such comments unfounded.[3032] The agencies did not rely on the OMEGA model during the rulemaking process, including during the analysis for the proposed and final rules. In past rulemakings, the EPA developed a complete final version of the OMEGA model to perform the rulemaking analysis. Here, the EPA did not even finalize a completed updated version of the OMEGA model, much less rely on such a model in the course of the rulemaking. Therefore, no completed version of an updated OMEGA model even existed for the agencies to publish as part of the notice of proposed rulemaking.

To the extent commenters argue that the EPA *should* have updated the model for this rulemaking, the APA's facilitation of a meaningful opportunity to comment neither requires nor contemplates a mandate that the agencies develop computational modeling alternatives for the public, which were not even incorporated into the agencies' own rulemaking analysis.[3033] In fact, doing so would actually detract from the notice and comment process because it would convolute the rulemaking docket and inhibit the public's ability to identify the modeling materials actually used in the rulemaking process. Thus, such extraneous materials would only dilute the rulemaking docket with voluminous and complex materials, such as modeling files, input files, and statistical figures, that had no influence on the rulemaking in question. Indeed, several commenters already claimed that the voluminous and complex supporting materials in

[3031] *See, e.g.*, California Air Resources Board, NHTSA-2018-0067-11873; Union of Concerned Scientists, NHTSA-2018-0067-12039; Alliance of Automobile Manufacturers, NHTSA-2018-0067-12073.
[3032] *See, e.g.*, Center for Biological Diversity, NHTSA-2018-0067-12000.
[3033] *See, e.g.*, Center for Biological Diversity et al., NHTSA-2018-0067-12000.

the rulemaking docket required significant time for review, so the introduction of extensive totally extraneous material would have been only counterproductive to the process.[3034]

Moreover, requiring the EPA to perform the work necessary to fully update the OMEGA model solely for a public release—when it did not otherwise intend to consider the model in the rulemaking—would divert valuable and finite agency resources away from actual rulemaking analyses in favor of efforts that further no progress in the rulemaking.[3035] Such an approach would detract from the agencies' opportunities to devote time to other considerations that actually influenced the rulemaking, such as the substantive analysis incorporated into the proposed rule and the drafting of extensive language to explain to the public the methodologies applied by the agencies for the proposal. Such an inefficient allocation of resources undermines both the rulemaking process envisioned by the APA and the very notice and comment procedures utilized by these commenters.

Several commenters also argued that even if the agencies did not rely on the model for this rulemaking, the OMEGA model still informed the EPA's analysis and interagency review by providing general background experience in regulating greenhouse gas emissions—either through the agency's work with prior versions of the model or ongoing efforts to update the OMEGA model for purposes unrelated to this rulemaking. However, even assuming the model provided background experience to the EPA in regulating in this arena, federal jurisprudence makes clear that "[t]he Administrative Procedure Act does not require that every bit of background information used by an administrative agency be published for public comment." *See B. F. Goodrich Co. v. Dep't of Transp.*, 541 F.2d 1178, 1184 (6th Cir. 1976). This is particularly the case when, as here, "[t]he basic data upon which the agency relied in formulating the regulation was available…for comment." *Id.*; *see also Am. Min. Cong. v. Marshall*, 671 F.2d 1251, 1261 (10th Cir. 1982) ("These documents consist of background information and data as well as several internal memoranda. There is nothing to indicate that the Secretary actually relied on any of these documents in promulgating the rule or that the data they contain was critical to the formulation of the rule."). In fact, publishing such background information not only exceeds the requirements of the APA, but would actually affirmatively undermine the APA's notice and comment procedure. If every piece of information ever referenced by the agencies or upon which the Agencies drew regulatory experience were required to be published, rulemaking dockets would expand to an absurd scope of nearly infinite materials, spanning arguably back to even the school textbooks the rulemaking personnel used to learn the underlying disciplines employed in the rulemaking analysis. Clearly such a scope would frustrate rather than further the provision of proper notice to the public about a proposed rule.[3036]

[3034] *See, e.g.*, Institute for Policy Integrity, NHTSA-2018-0067-5641; Northeast States for Coordinated Air Use Management, NHTSA-2018-0067-2158.
[3035] *See, e.g.*, Environmental Defense Fund, NHTSA-2018-0067-12108.
[3036] To the extent commenters seek to understand the manner in which the OMEGA model informed prior rulemaking efforts, the EPA has released the full versions of prior OMEGA models and applicable materials along with the prior rulemakings. In fact, several commenters referenced such materials in submitting detailed comments comparing the CAFE Model with the OMEGA model. Manufacturers of Emission Controls Association, NHTSA-

Moreover, even assuming the premise of several commenters' challenges—that the EPA consulted updates to the OMEGA model during the interagency review—such a predicate still would not require the publication of the model during the rulemaking process.[3037] As the agencies have made clear, the OMEGA model did not affect any part of the rule, including the methodologies and analysis underlying the formulation of the rule. Therefore, even if consulted, the OMEGA model would exist as, at most, supplementary material which had no influence on the rulemaking methodologies, all of which were fully disclosed. *See, e.g.*, *Chamber of Commerce of U.S. v. S.E.C.*, 443 F.3d 890, 900 (D.C. Cir. 2006) ("When the agency relies on supplementary evidence without a showing of prejudice by an interested party, the procedural requirements of the APA are satisfied without further opportunity for comment, provided that the agency's response constitutes a logical outgrowth of the rule initially proposed") (internal citations omitted).

3. National Environmental Policy Act

As discussed above, EPCA requires NHTSA to determine the level at which to set CAFE standards for each model year by considering the four factors of technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy. The National Environmental Policy Act (NEPA) directs that environmental considerations be integrated into that process.[3038] To explore the potential environmental consequences of this rulemaking action, NHTSA prepared a Draft Environmental Impact Statement ("DEIS") for the NPRM and a Final Environmental Impact Statement ("FEIS") for the final rule. The purpose of an EIS is to "provide full and fair discussion of significant environmental impacts and [to] inform decisionmakers and the public of the reasonable alternatives which would avoid or minimize adverse impacts or enhance the quality of the human environment."[3039]

As explained in the NPRM, NEPA is "a procedural statute that mandates a process rather than a particular result."[3040] The agency's overall EIS-related obligation is to "take a 'hard look' at the environmental consequences before taking a major action."[3041] Significantly, "[i]f the adverse environmental effects of the proposed action are adequately identified and evaluated, the agency is not constrained by NEPA from deciding that other values outweigh the environmental costs."[3042] The agency must identify the "environmentally preferable" alternative but need not adopt it.[3043] "Congress in enacting NEPA . . . did not require agencies to elevate environmental

---

2018-0067-11994. Thus, any commenters that were interested in such extraneous background information had ample opportunity to access the material.

[3037] *See, e.g.*, Environmental Defense Fund, NHTSA-2018-0067-12406.

[3038] NEPA is codified at 42 U.S.C. 4321–47. The Council on Environmental Quality (CEQ) NEPA implementing regulations are codified at 40 CFR parts 1500–08.

[3039] 40 CFR 1502.1.

[3040] Stewart Park & Reserve Coal., Inc. v. Slater, 352 F.3d 545, 557 (2d Cir. 2003).

[3043] 40 CFR 1505.2(b).

concerns over other appropriate considerations."[3044] Instead, NEPA requires an agency to develop and consider alternatives to the proposed action in preparing an EIS.[3045] The statute and implementing regulations do not command the agency to favor an environmentally preferable course of action, only that it make its decision to proceed with the action after taking a hard look at the potential environmental consequences and consider the relevant factors in making a decision among alternatives.[3046]

NHTSA received many comments on the DEIS. Among the comments received, many commenters stated that the baseline/no-action standards were the environmentally preferable alternative and argued that the environmental benefits of the proposal were (1) insufficient and/or (2) incorrectly assessed in a variety of ways. Comments regarding the environmental analyses presented in this FRIA are addressed in Section VI above, while those regarding the DEIS are addressed in Chapter 10 of the FEIS.

When preparing an EIS, NEPA requires an agency to compare the potential environmental impacts of its proposed action and a reasonable range of alternatives. In the DEIS, NHTSA analyzed a No Action Alternative and eight action alternatives. In the FEIS, NHTSA analyzed the same No Action Alternative and seven action alternatives, including a new alternative (the Preferred Alternative) within the range of the alternatives considered in the DEIS and FEIS.[3047] The alternatives represent a range of potential actions the agency could take, and they are described more fully in Section V above, below in this section, and Chapter 2 of the FEIS. The environmental impacts of these alternatives, in turn, represent a range of potential environmental impacts that could result from NHTSA's setting maximum feasible fuel economy standards for passenger cars and light trucks.

To derive the direct and indirect impacts of the action alternatives, NHTSA compared each action alternative to the No Action Alternative, which reflects baseline trends that would be expected in the absence of any further regulatory action other than finalizing the augural standards. More specifically, the No Action Alternative in the DEIS and FEIS assumed that NHTSA would not amend the CAFE standards for MY 2021 passenger cars and light trucks. In addition, the No Action Alternative assumed that NHTSA would finalize the MY 2022-2025 augural CAFE standards that were described in the 2012 final rule. Finally, for purposes of its analysis, NHTSA assumed that the MY 2025 augural standards would continue indefinitely. The augural standards also serve as a proxy for EPA's CO_2 standards for MYs 2022-2025, which were also finalized in the 2012 final rule. The No Action Alternative provides an analytical

[3044] Baltimore Gas, 462 U.S. at 97.
[3045] 42 U.S.C. 4332(2)(C)(iii).
[3046] 40 CFR 1505.2(b).
[3047] In its scoping notice, NHTSA indicated that the action alternatives analyzed would bracket a range of reasonable annual fuel economy standards, allowing the agency to select an action alternative in its final rule from any stringency level within that range. 82 FR 34740, 34743 (July 26, 2017).

baseline against which to compare the environmental impacts of other alternatives presented in the EIS.[3048]

For the DEIS, NHTSA analyzed eight action alternatives, Alternatives 1 through 8, which ranged from amending the MY 2021 standards to match the MY 2020 standards and holding those standards flat for passenger cars and light trucks through MY 2026 (Alternative 1) to maintaining the existing MY 2021 standards and subsequently requiring average annual increases in fuel economy by 2.0 percent (passenger cars) and 3.0 percent (light trucks) (Alternative 8). The action alternatives analyzed in the DEIS also reflected different options regarding air conditioning efficiency and off-cycle technology adjustment procedures, with some alternatives phasing out these adjustments in MYs 2022-2026. For the FEIS, NHTSA analyzed seven action alternatives, Alternatives 1 through 7, which range from amending the MY 2021 standards to match the MY 2020 standards and holding those standards flat for passenger cars and light trucks through MY 2026 (Alternative 1) to maintaining the existing MY 2021 standards and subsequently requiring average annual increases in fuel economy by 2.0 percent (passenger cars) and 3.0 percent (light trucks) (Alternative 7) from year to year. The primary differences between the action alternatives for the DEIS and FEIS is that the FEIS did not analyze alternatives that phased out the air conditioning efficiency and off-cycle technology adjustments (see Section V above for further discussion), and the FEIS added an alternative under which fuel economy increased at 1.5 percent per year for both cars and light trucks (Alternative 3). Both of the ranges of action alternatives, as well as the No Action Alternative, in the DEIS and FEIS encompassed a spectrum of possible standards NHTSA could determine was maximum feasible based on the different ways the agency could weigh EPCA's four statutory factors. Throughout the FEIS, estimated impacts were shown for all of these action alternatives, as well as for the No Action Alternative. For a more detailed discussion of the environmental impacts associated with the alternatives, *see* Chapters 3-8 of the FEIS, as well as Section VII above.

NHTSA's FEIS describes potential environmental impacts to a variety of resources, including fuel and energy use, air quality, climate, land use and development, hazardous materials and regulated wastes, historical and cultural resources, noise, and environmental justice. The FEIS also describes how climate change resulting from global carbon emissions (including CO_2 emissions attributable to the U.S. light duty transportation sector under the alternatives considered) could affect certain key natural and human resources. Resource areas are assessed qualitatively and quantitatively, as appropriate, in the FEIS, and the findings of that analysis are summarized here.[3049]

3048 *See* 40 CFR 1502.2(e), 1502.14(d). CEQ has explained that "[T]he regulations require the analysis of the no action alternative even if the agency is under a court order or legislative command to act. This analysis provides a benchmark, enabling decision makers to compare the magnitude of environmental effects of the action alternatives [*See* 40 CFR 1502.14(c).] . . . Inclusion of such an analysis in the EIS is necessary to inform Congress, the public, and the President as intended by NEPA. [*See* 40 CFR 1500.1(a).]" Forty Most Asked Questions Concerning CEQ's National Environmental Policy Act Regulations, 46 FR 18026 (Mar. 23, 1981).

3049 The impacts described in this section come from NHTSA's FEIS, which is being publicly issued simultaneously with this final rule. As described in Section VII.A.4.c.1 above, the FEIS is based on "unconstrained" modeling rather than "standard setting" modeling; NHTSA conducts modeling both ways in order to reflect the various statutory requirements of EPCA and NEPA. The preamble employs the "standard setting" modeling in order to

As the stringency of the alternatives increases, total U.S. passenger car and light truck fuel consumption for the period of 2020 to 2050 decreases. Total light-duty vehicle fuel consumption from 2020 to 2050 under the No Action Alternative is projected to be 3,371 billion gasoline gallon equivalents (GGE). Light-duty vehicle fuel consumption from 2020 to 2050 under the action alternatives is projected to range from 3,598 billion GGE under Alternative 1 to 3,456 billion gallons GGE under Alternative 7. Under the Alternative 3, light-duty vehicle fuel consumption from 2020 to 2050 is projected to be 3,571 GGE. All of the action alternatives would increase fuel consumption compared to the No Action Alternative, with fuel consumption increases that range from 226 billion GGE under Alternative 1 to 85 billion GGE under Alternative 7.

The relationship between stringency and air pollutant emissions is less straightforward, reflecting the complex interactions among the tailpipe emissions rates of the various vehicle types, the technologies assumed to be incorporated by manufacturers in response to the CAFE standards, upstream emissions rates, the relative proportions of gasoline and diesel in total fuel consumption, and changes in VMT from the rebound effect. In general, emissions of criteria and toxic air pollutants increase across all action alternatives, with some exceptions. Further, the action alternatives would result in increased incidence of $PM_{2.5}$-related adverse health impacts (including increased incidences of premature mortality, acute bronchitis, respiratory emergency room visits, and work-loss days) due to the emissions increases.[3050]

For CO (in 2025), NO_X (in 2025), and SO_2, emissions generally decrease under the action alternatives compared to the No Action Alternative. For CO in 2025, the largest decrease occurs under Alternative 1 and the emissions decreases get smaller from Alternative 1 through Alternative 7. For NO_x in 2025, the largest decrease occurs under Alternative 6. For SO_2 in 2025, the largest decrease occurs under Alternative 6; however, SO_2 emissions under Alternative 7 are greater than under the No Action Alternative. For SO_2 in 2035, the largest decrease occurs under Alternative 2. For SO_2 in 2050, the largest decrease occurs under Alternative 1 and the emissions decreases get smaller from Alternative 1 through Alternative 7. Across all criteria pollutants, action alternatives, and analysis years, the smallest decrease in emissions is less than 0.1 percent and occurs for NO_x under Alternative 7 in 2025; the largest decrease is 12 percent and occurs for SO_2 under Alternative 2 in 2050.

For CO (in 2035 and 2050), NO_X (in 2035 and 2050), $PM_{2.5}$, and VOCs, emissions show increases across action alternatives compared to the No Action Alternative, with the largest increases occurring under Alternative 1 (except CO in 2035, for which the largest increase occurs under Alternative 4). The emissions increases get smaller from Alternative 1 through Alternative 7. Exceptions to this trend are for $PM_{2.5}$ and VOCs in 2025, which show the smallest

ensure that the decision-maker does not consider things that EPCA/EISA prohibit, but as a result, the impacts reported here may differ from those reported elsewhere in this FRIA. However, NHTSA considers the impacts reported in the FEIS, in addition to the other information presented in this FRIA, as part of its decision-making process.

[3050] As discussed in Section X.E.1, NHTSA also performed a national-scale photochemical air quality modeling and health benefit assessment for the FEIS, which is included as Appendix E. This analysis affirms the estimates that appeared in the DEIS and explains conclusions that may be drawn from the FEIS air quality discussion.

emissions increase under Alternative 6. Across all criteria pollutants, action alternatives, and analysis years, the smallest increase in emissions is 0.1 percent and occurs for SO_2 under Alternative 7 in 2025; the largest increase is 12 percent and occurs for VOCs under Alternative 1 in 2050.

Under each action alternative in 2025 compared to the No Action Alternative, decreases in emissions would occur for all toxic air pollutants except for DPM, for which emissions would increase by as much as 2 percent. For 2025, the largest relative decreases in emissions would occur for 1,3,-butadiene, for which emissions would decrease by as much as 0.5 percent. Percentage reductions in emissions of acetaldehyde, acrolein, benzene, and formaldehyde would be less. Under each action alternative in 2035 and 2050 compared to the No Action Alternative, increases in emissions would occur for all toxic air pollutants. The largest relative increases in emissions would occur for DPM, for which emissions would increase by as much as 9 percent. Percentage increases in emissions of acetaldehyde, acrolein, benzene, 1,3,-butadiene, and formaldehyde would be less.

In addition, the action alternatives would result in increased incidence of $PM_{2.5}$-related adverse health impacts due to the emissions increases. Increases in adverse health outcomes include increased incidences of premature mortality, acute bronchitis, respiratory emergency room visits, and work-loss days. In 2025 and 2035, all action alternatives except for Alternative 6 would result in increased adverse health impacts nationwide compared to the No Action Alternative as a result of increases in emissions of NO_x, $PM_{2.5}$, and DPM. The increases in adverse health impacts are largest for the least stringent alternative (Alternative 1). The increases get smaller from Alternative 1 to Alternative 4, get larger from Alternative 4 to Alternative 5, then smaller from Alternative 5 to Alternative 6, and larger again from Alternative 6 to Alternative 7. In 2050, all action alternatives would result in decreased adverse health impacts nationwide compared to the No Action Alternative as a result of decreases in emissions of SOx. The decreases in adverse health impacts get smaller from Alternative 1 to Alternative 7.

The action alternatives would increase U.S. passenger car and light truck fuel consumption and CO_2 emissions compared with the No Action Alternative, resulting in minor increases to the anticipated increases in global CO_2 concentrations, temperature, precipitation, and sea level, and minor decreases in ocean pH that would otherwise occur, as described below. They could also, to a small degree, increase the impacts and risks of climate change. Uncertainty exists regarding the magnitude of impact on these climate variables, as well as to the impacts and risks of climate change. Still, the impacts of the action alternatives on global mean surface temperature, precipitation, sea level, and ocean pH would be extremely small in relation to global emissions trajectories. This is because of the global and multi-sectoral nature of climate change. These effects would be small, would occur on a global scale, and would not disproportionately affect the United States.

According to the FEIS, passenger cars and light trucks are projected to emit 85,900 million metric tons of carbon dioxide ($MMTCO_2$) from 2021 through 2100 under the No Action Alternative. Alternative 1 would increase these emissions by 10 percent through 2100 (approximately 8,800 $MMTCO_2$). Alternative 7 would increase these emissions by 4 percent through 2100 (approximately 3,100 $MMTCO_2$). Emissions increases would be highest under

Alternative 1 and would decrease across the action alternatives, with emissions being the lowest under the No Action Alternative.

In the FEIS, NHTSA presented two different analyses based on these emissions changes to illustrate potential impacts to certain climate variables. In the first analysis, to represent the direct and indirect impacts of this action, NHTSA used the Global Change Assessment Model (GCAM) Reference scenario (i.e., future global emissions assuming no additional climate policy [“business-as-usual”]) to represent the reference case emissions scenario. Under that analysis, total global CO_2 emissions from all sources are projected to be 4,950,865 $MMTCO_2$ under the No Action Alternative from 2021 through 2100, which means that the action alternatives are expected to increase global CO_2 emissions between 0.06 (Alternative 7) and 0.17 (Alternative 1) percent by 2100. The estimated CO_2 concentrations in the atmosphere for 2100 would range from 789.89 parts per million (ppm) under Alternative 1 to approximately 789.11 ppm under the No Action Alternative, indicating a maximum atmospheric CO_2 increase of approximately 0.78 ppm compared to the No Action Alternative.

Changes in CO_2 emissions translate to changes in global mean surface temperature, sea levels, global mean precipitation, and ocean pH, among other things. Under the first analysis, global mean surface temperature is projected to increase by approximately 3.48°C (6.27°F) under the No Action Alternative by 2100. Implementing the lowest-emissions action alternative (Alternative 7) would increase this projected temperature rise by 0.001°C (0.002°F), while implementing the highest-emissions alternative (Alternative 1) would increase projected temperature rise by 0.003°C (0.005°F). Projected sea-level rise in 2100 ranges from a low of 76.28 centimeters (30.03 inches) under the No Action Alternative to a high of 76.35 centimeters (30.06 inches) under Alternative 1. Alternative 1 would result in an increase in sea level equal to 0.07 centimeter (0.03 inch) by 2100 compared with the level projected under the No Action Alternative, compared to an increase under Alternative 7 of 0.02 centimeter (0.001 inch) compared with the No Action Alternative. Global mean precipitation is anticipated to increase by 5.85 percent by 2100 under the No Action Alternative. Under the action alternatives, this increase in precipitation would be increased further by 0.01 percent. Finally, ocean pH in 2100 is anticipated to be 8.2715 under Alternative 7, about 0.0001 less than the No Action Alternative. Under Alternative 1, ocean pH in 2100 would be 8.2712, or 0.0004 less than the No Action Alternative.

In the second analysis, NHTSA used the GCAM6.0 scenario instead of the default scenario to represent the reference case emissions scenario. The GCAM6.0 scenario assumes a moderate level of global GHG reductions and corresponds to stabilization, by 2100, of total radiative forcing and associated CO_2 concentrations at roughly 678 ppm. By assuming a moderate level of global GHG reduction, NHTSA attempts to capture the cumulative impacts of this action (i.e., the impact on the environment which results from the incremental impact of the action when added to other past, present, and reasonably foreseeable future actions). In the FEIS, NHTSA documented a number of domestic and global actions that indicate that a moderate reduction in the growth rate of global GHG emissions is reasonably foreseeable in the future.

Under the second analysis, compared with projected total global CO_2 emissions of 4,044,005 $MMTCO_2$ from all sources from 2021 to 2100, the incremental impact of this rulemaking is expected to increase global CO_2 emissions between 0.08 (Alternative 7) and 0.22 (Alternative 1) percent by 2100. Estimated atmospheric CO_2 concentrations in 2100 range from a low of 687.3 ppm under the No Action Alternative to a high of 688.04 ppm under Alternative 1. Alternative 7, the lowest CO_2 emissions alternative, would result in CO_2 concentrations of 687.55 ppm, an increase of 0.26 ppm compared with the No Action Alternative. Global mean surface temperature increases for the action alternatives compared with the No Action Alternative in 2100 range from a low of 0.001°C (0.002°F) under Alternative 7 to a high of 0.004°C (0.007°F) under Alternative 1. Global mean precipitation is anticipated to increase by 4.77 percent by 2100 under the No Action Alternative. Under the action alternatives, this increase in precipitation would be increased further by 0.01 percent. Projected sea-level rise in 2100 ranges from a low of 70.22 centimeters (27.65 inches) under the No Action Alternative to a high of 70.30 centimeters (27.68 inches) under Alternative 1, indicating a maximum increase of sea-level rise of 0.07 centimeter (0.03 inch) by 2100. Sea-level rise under Alternative 7 would be 70.25 centimeters (27.66 inches), a 0.03 centimeter (0.01-inch) increase compared to the No Action Alternative. Ocean pH in 2100 is anticipated to be 8.2721 under Alternative 7, about 0.0001 less than the No Action Alternative. Under Alternative 1, ocean pH in 2100 would be 8.2719, or 0.0004 less than the No Action Alternative.

For several other resources, NHTSA is unable to provide a quantitative measurement of potential impacts. Instead, the FEIS presents a qualitative discussion on potential impacts. In most cases, NHTSA presents the findings of a literature review of scientific studies, such as in Chapter 6, where NHTSA provides a literature synthesis focusing on existing credible scientific information to evaluate the most significant lifecycle environmental impacts from some of the fuels, materials, and technologies that may be used to comply with the alternatives. In Chapter 7, NHTSA discusses land use and development, hazardous materials and regulated waste, historical and cultural resources, noise, and environmental justice. Finally, in Chapter 8, NHTSA discusses cumulative impacts related to energy, air quality, and climate change, and provides a literature synthesis of the impacts on key natural and human resources of changes in climate change variables. In these chapters, NHTSA concludes that impacts would be proportional to changes in emissions that would result under the alternatives. As a result, among the action alternatives, Alternative 1 would have the highest impact on these resources while Alternative 7 would have the lowest.

Based on the foregoing, NHTSA concludes from the FEIS that the No Action Alternative is the overall environmentally preferable alternative because, assuming full compliance were achieved regardless of the agency's assessment of the costs to industry and society, it would result in the largest reductions in fuel use and CO_2 emissions among the alternatives considered. In addition, the No Action Alternative would result in the lowest overall emissions levels of criteria air pollutants (with the exception of sulfur dioxide) and of the toxic air pollutants studied by NHTSA. Impacts on other resources (especially those described qualitatively in the FEIS) would be proportional to the impacts on fuel use and emissions, as further described in the FEIS, with the No Action Alternative expected to have the fewest negative impacts.[3051] Although the CEQ regulations require NHTSA to identify the environmentally preferable alternative,[3052] the agency need not adopt it, as described above. The following section (Section VIII.B.4) explains how NHTSA balanced the relevant factors to determine which alternative represented the maximum feasible standards, including why NHTSA does not believe that the environmentally preferable alternative is maximum feasible.

4. Evaluating the EPCA Factors and Other Considerations to Arrive at the Proposed Standards

As discussed in this section, NHTSA is required to consider four enumerated factors when establishing maximum feasible CAFE standards under 49 U.S.C. chapter 329: "technological feasibility, economic practicability, the effect of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy."[3053] For this final rule, NHTSA has considered a wide range of potential CAFE standards (Baseline/No Action Alternative and Alternatives 1 through 7), ranging from the augural standards set forth in 2012 (Baseline/No Action Alternative), through a number of less stringent alternatives, including the proposed preferred alternative (Alternative 1, 0 percent per year stringency improvement) and what has been chosen as the final standards (Alternative 3, 1.5 percent per year stringency improvement). NHTSA has determined that Alternative 3, which would increase the stringency of the MY 2020 standards by 1.5 percent per year for both passenger cars and light trucks from MY 2021 through 2026, represents the maximum feasible CAFE standards under 49 U.S.C. 39202. In addition to technological feasibility, economic practicability, the effects of other motor vehicle standards of the Government on fuel economy, and the need of the United States to conserve energy, NHTSA has also considered the impact of the standards on safety and the environment.

How did the Agency Balance the Factors for the NPRM?

In the NPRM, NHTSA began its discussion of the tentative balancing of factors by explaining that "NHTSA well recognizes that the decision it proposes to make in today's NPRM is different from the one made in the 2012 final rule that established standards for MY 2021 and identified "augural" standard levels for MYs 2022-2025. Not only do we believe that the facts before us have changed, but we believe that those facts have changed sufficiently that the balancing of the EPCA factors and other considerations must also change. The standards we are proposing today reflect that balancing."[3054] NHTSA highlights this discussion at the outset in response to the number of commenters who claimed that NHTSA had not acknowledged or explained in the NPRM how or why the proposal was different from past work or policy decisions.

[3051] Among the action alternatives considered, Alternative 7 would be the environmentally preferable alternative, as it is closest in stringency to the No Action Alternative.

[3052] 40 CFR 1505.2(b).

[3053] 49 U.S.C. 32902(f).

[3054] 83 FR at 43213.

The NPRM balancing discussion went on to explore the definition of "to conserve" in the context of what "energy conservation" and "the need of the U.S. to conserve energy" should be interpreted to mean, in recognition of the major structural changes in global oil markets since EPCA was originally passed, and even since the 2012 final rule that set forth the augural standards. NHTSA examined these changes from both a demand perspective and a supply perspective. On the demand side, U.S. demand and global demand have both changed over time. The NPRM discussed the fact that the U.S. consumes a much smaller share of global oil output than it did at the CAFE program's outset, both because U.S. fleet fuel economy has improved, and because other countries that were not major petroleum consumers in the 1970s have rapidly increased their share of consumption, and continue to do so. A more globalized market means that risk of price spikes is spread around—making the U.S. in particular less likely to bear a disproportionate burden of price spikes. The NPRM also discussed the decreasing energy intensity of the U.S. economy over time and the improving balance of payments in petroleum, including the likelihood that the U.S. is poised to become a net petroleum exporter in the near future. Related to the decreasing energy intensity of the U.S. economy, on the demand side, the NPRM discussed the proliferation of fuel-efficient vehicle options in the market in response to CAFE increases over time, and the fact that consumers who wish to purchase more fuel efficient vehicles have largely done so, and may continue to do so over time if they wish.

On the supply side, the NPRM explained, vast increases in U.S. petroleum production, largely from shale formations, have introduced a major new stable supply into the global market. Shale oil production costs may be higher than the cost (for example, to OPEC members) to produce traditional oil, but that itself acts as a lever on global prices. Prices of goods like oil are affected by demand and supply—given that global demand trends increase relatively steadily, if OPEC States want to increase revenues by selling more of the total oil consumed globally, they have to try to control global supply volume by controlling production volumes (to avoid shale production increasing in response to higher prices). In short, the higher global prices trend, the more U.S. shale production increases in response, and as supply increases, prices fall. The NPRM discussed the responsiveness of U.S. shale production and suggested it could be higher than traditional producers in some instances. Traditional oil producers seeking to maintain market share have a new incentive to keep prices below a certain threshold, and U.S supply helps to buffer the impact of geopolitical events. The NPRM looked at then-current EIA oil price forecasts, under which U.S. gasoline prices were not forecast to exceed $4/gallon through 2050, and acknowledged that while price shocks could still occur, NHTSA tentatively concluded that from the supply side, it is possible that the oil market conditions that created the price shocks in the 1970s may no longer exist.

In light of these changes in global oil markets, the NPRM tentatively concluded that many aspects of the need of the U.S. to conserve energy had improved enough over time to merit further consideration of what the need of the United States is to conserve oil today and going forward. With regard to environmental considerations, the NPRM returned to the definition of "to conserve" and suggested that differences of thousandths of a degree Celsius in 2100 resulting from higher levels of carbon dioxide emissions under the proposal as compared to the augural standards might not rise to the level of "wasteful," given the other considerations discussed. With regard to consumer costs, the NPRM discussed the interplay of oil market conditions with prior arguments about consumer "myopia" with regard to the benefits of fuel savings, and tentatively concluded that U.S. consumers may be valuing fuel savings appropriately and purchasing the vehicles they want to purchase—i.e., that using CAFE standards as a tool to compel consumers to save money may not be necessary.

Given the discussion above, NHTSA tentatively concluded that the need of the U.S. to conserve energy may no longer function as assumed in previous considerations of what CAFE standards would be maximum feasible. In that discussion, NHTSA stated that the overall risks associated with the need of the U.S. to conserve oil have entered a new paradigm with the risks substantially lower today and projected into the future than when CAFE standards were first issued and in the recent past. NHTSA explained that the effectiveness of CAFE standards in reducing the demand for fuel combined with the increase in domestic oil production have contributed significantly to the current situation and outlook for the near- and mid-term future. NHTSA tentatively concluded that the world has changed, and the need of the U.S. to conserve energy, at least in the context of the CAFE program, has also changed.

Of two other factors under 32902(g), the NPRM explained that the changes were perhaps less significant. NHTSA suggested that all of the alternatives appear as though they could narrowly be considered *technologically* feasible, in that they could be achieved based on the existence or the projected future existence of technologies that could be incorporated on future vehicles. With regard to the effect of other motor vehicle standards of the Government on fuel economy, the NPRM explained that it was similarly not heavily limiting during this rulemaking time frame. The NPRM analysis projected that neither safety standards nor Tier 3 compliance obligations appeared likely to make it significantly harder for industry to comply with more stringent CAFE standards, and that EPA's CO_2 standards should have no greater effect on difficulty in meeting CAFE standards than already existed.

For economic practicability, the NPRM considered the traditional definition used by the agency, and expressed concern that all of the alternatives considered in the proposal could raise economic practicability concerns. NHTSA stated that it believed there could be potential for unreasonable elimination of consumer choice, loss of U.S. jobs, and a number of adverse economic consequences under nearly all if not all of the regulatory alternatives considered in the NPRM. NHTSA explored consumer choice issues given a foreseeable future of relatively low fuel prices and the likelihood that more stringent CAFE standards could cause automakers to add technology to new vehicles that consumers do not want, or prevent the addition of technology to new vehicles that consumers do want, and suggested that there could be risk that such elimination of consumer choice could be unreasonable. NHTSA explained its assumption, based on repeated manufacturer input, that fuel-saving technologies that paid for themselves within 2.5 years would be added regardless of CAFE stringency, meaning that the power of CAFE standards (by themselves) to compel fuel savings was reduced. NHTSA suggested that requiring more technology to be added than consumers were willing to pay for could have dampening effects on vehicle sales, particularly given forecasted relatively low gas prices, increasing the likelihood of automaker non-compliance with more stringent standards due to difficulty in selling higher-fuel-economy models. NHTSA examined the levels of electrification necessary to meet the various regulatory alternatives evaluated in the NPRM and compared them with information about consumers' willingness to purchase vehicles with these technologies and even to spend money on fuel economy improvements generally. NHTSA suggested that if the market for higher fuel-economy vehicles exists and is already possibly saturated, increasing fuel economy requirements could create economic practicability concerns by affecting sales and consumer choice.

NHTSA recognized that automakers cross-subsidize regulation-driven cost increases and expressed concern about their ability to do that under sustained, ongoing increases over many years, and the corresponding concern that continued cross-subsidizing could create affordability problems for lower-income consumers if manufacturers pass costs forward to consumers more broadly rather than concentrating them in high-volume, higher-profit vehicles. NHTSA suggested that higher vehicle prices and monthly vehicle payments could outweigh, for at least some new vehicle purchasers, the benefit of fuel savings, because vehicle payments are fixed costs and fuel costs may be less fixed. NHTSA expressed concern that as vehicles get more expensive in response to higher CAFE standards, it will become more and more difficult for finance companies and dealers to continue creating loan terms that keep monthly payments low and do not result in consumers' still owing significant amounts of money on the vehicle by the time they can be expected to be ready for a new vehicle. This situation may imply a bubble in new vehicle sales, the effects of which could fall disproportionately on new and low-income buyers. NHTSA suggested that these effects could impact both fleet-wide safety (by slowing fleet turnover) and consumer choice. The NPRM also expressed concern that the sales and employment analyses were unable to capture (1) the risk that manufacturers and dealers may not be able to continue keeping monthly new vehicle payments low, or (2) the risk that manufacturing could shift overseas as manufacturing costs rise.

NHTSA also examined the net benefits of the various regulatory alternatives, and noted that the analysis showed that consumers recoup only a portion of the costs associated with increasing stringency under all of the alternatives, because the fuel savings resulting from each of the alternatives was substantially less than the costs associated with the alternative, meaning that net savings for consumers improved as stringency decreased. NHTSA explained that it recognized that this was a significantly different analytical result from the 2012 rule, which showed the opposite trend, and explained that the result was different because the facts and analysis underlying the result were also different, and enumerated the noteworthy differences, such as payback assumptions; fleet composition; what levels of technologies had already been applied; the costs and effectiveness values for some of those technologies; fuel price forecasts; the value of the rebound effect; the value of the social cost of carbon; accounting for price impacts on fleet turnover; not limiting mass reduction to only the largest vehicles; and the value of a statistical life having increased. NHTSA explained that all of these changes, together, meant that the standards under any of the regulatory alternatives (compared to the preferred alternative) were more expensive and had lower benefits than if they had been calculated using the inputs and assumptions of the 2012 analysis. This assessment, in turn, contributed to the agency's decision to reevaluate what standards might be maximum feasible in the model years covered by the rulemaking. NHTSA explained that it had thus both relied on new facts and circumstances in developing the proposal and reasonably rejected prior analyses relied on in the 2012 final rule.[3055]

NHTSA then considered that "maximum feasible" may change over time as the agency assessed the relative importance of each factor that Congress requires it to consider, and tentatively concluded that proposing CAFE standards that hold the MY 2020 curves for passenger cars and light trucks constant through MY 2026 would be the maximum feasible standards for those fleets and would fulfill EPCA's overarching purpose of energy conservation in light of the facts before the agency and as the agency expected them to be in the rulemaking time frame. NHTSA recognized that this was a different interpretation from the 2012 final rule and explained that the context of that rulemaking was meaningfully different from the current context, because the facts had changed the importance of the need of the U.S. to conserve energy, and NHTSA recognized that under that circumstance, while more stringent standards may be possible, insofar as production-ready technology exists that the industry could physically employ to reach higher standards, it was not clear that higher standards would be economically practicable in light of current U.S. consumer needs to conserve energy. Therefore, NHTSA stated, it viewed the determination of maximum feasible standards as a question of the appropriateness of standards given that their need—either from the societal-benefits perspective in terms of risk associated with fuel price shocks or other related catastrophes, or from the private-benefits perspective in terms of consumer willingness to purchase new vehicles with expensive technologies that may allow them to save money on future fuel purchases—seems likely to remain low for the foreseeable future. NHTSA also considered the effects of the standards on highway safety and expressed concern that because more stringent standards could depress sales and slow fleet turnover, and because higher fuel economy leads to more driving and more exposure to crash risk, all regulatory alternatives would improve safety as compared to the augural standards.

b) What Comments did NHTSA Receive Regarding How it Balanced the Factors in the NPRM?

In addition to comments on each of the factors NHTSA considered discussed above, comments also were received on how NHTSA should balance these factors in determining the maximum feasible final standards. Hundreds of thousands of comments addressed stringency and, thus, the agency's evaluation of what standards were maximum feasible. Most of those focused on the augural standards: many individual commenters supported reducing the stringency of the standards from augural levels—some citing estimates of cost, and some citing concerns about consumer choice. Many comments by other individual commenters supported retaining stringency at augural levels or increasing stringency beyond that level—generally citing concerns about climate change and increased fuel costs under less stringent standards. A few commenters, like CEI, expressly supported the proposal, and even suggested that stringency should be decreased further. Many other commenters, including environmental and consumer

[3055] *See* FCC v. Fox Television Stations, 556 U.S. at 514-515; *see also* NAHB v. EPA, 682 F.3d 1032 (D.C. Cir. 2012).

groups, health advocacy organizations, and a number of State organizations, argued that the proposal was flawed and/or that the augural standards should be finalized because more stringent standards help to reduce climate change and address other air quality issues.[3056] The Congressional Tri-Caucus commenters supported maintaining the augural standards, stating that they contribute to employment and protect low income communities and communities of color.[3057]

The Alliance and Global Automakers both supported final standards that increased in stringency year over year. The Alliance stated that it could support stringency increases between 0 percent per year and 2-3 percent per year "along with the inclusion of appropriate flexibilities."[3058] Global stated that increases should be "meaningful"[3059] and suggested that "[i]n order for the U.S. auto industry to remain competitive and continue to export vehicles to the rest of the world, industry is best served by a reasonable, steady ramp rate that accounts for investments made and the global nature of the market. Steady increases allow for long-term planning and create an environment of security that fosters ongoing investment in vehicle technology and consumer confidence in purchasing new vehicles. It also provides a level playing field upon which automakers can compete."[3060] Toyota made similar points, and argued that while the standards set in 2012 are beyond maximum feasible today, the "statutes support an adjustment to those standards that reflect the realities of the market, consumer choice, and the pace of technological advancement acceptable to consumers."[3061] Mazda stated that it supported "increasing requirements for fuel efficiency…, if they are sensible and achievable under changing market conditions."[3062]

NADA commented that it was willing to support standards that increased in stringency (i.e., more stringent than the proposal) if they were economically practicable and technologically feasible, based on the evidence before the agencies; if they ensured consumer choice and "the strongest possible rate of fleet turnover;" and if passenger car and light truck standards increased at the same rate.[3063] The Alliance for Vehicle Efficiency (AVE) argued that compliance shortfalls are evidence that the current rate of stringency increase is beyond maximum feasible, and that the assumptions that enabled those rates to be chosen "are no longer feasible based on consumer adoption."[3064] AVE suggested that a rate of increase of 2.5 percent per year for both

cars and trucks, retroactively imposed beginning in MY 2018, would be feasible given sufficient flexibilities.[3065]

NADA also stressed the importance of flexibilities as a compliance tool for meeting standards that increase faster than the proposal.[3066] The Minnesota agencies supported maintaining standards at the augural levels, commenting that automakers has simply "requested additional flexibility…, not a wholesale rollback of the standards," and suggesting that additional flexibilities would enable augural levels.[3067] IPI disagreed with the suggestion in the NPRM that heavy automaker reliance on credits for compliance might indicate that standards were beyond maximum feasible, arguing that automakers must be either using credits about to expire, or counting on future standards being cheaper to meet due to rising consumer demand for fuel economy, technology costs decreasing over time, and the cost-effectiveness of EPA's EV multiplier incentive.[3068]

With regard to analysis of costs and benefits, IPI argued that the final rule needed, like the 2012 rule, to cite costs and benefit expressly in discussing balancing of statutory factors, but with a "proper" accounting of costs and benefits. IPI claimed that in the NPRM the factors were balanced "in a way that conflicts with the…controlling statute and weighed…without regard for the accuracy of the accompanying cost-benefit analysis."[3069] IPI stated that "…the agencies' analysis produced biased and irrational results at each of the steps in that causal chain, leading to a Proposed Rule that vastly overstates the benefits of the rollback and understates the benefits society foregoes with the rollback," and that "[a] full and balanced analysis of all the costs and benefits that the agencies are charged with considering would reveal—as the midterm review recently confirmed—that the baseline standards will deliver massive net social benefits, and the proposed rollback is unjustified."[3070]

With regard to net benefits, the States and Cities commenters stated that prior analyses had concluded that the net benefits of the augural standards were extremely high,[3071] while the Alliance stated that "[t]he NERA-Trinity Assessment confirms the Agencies' findings that Alternatives 1, 5, and 8 result in increased net benefits relative to the no-action alternative augural CAFE standards."[3072] Michalek and Whitefoot commented that "maximizing net benefits is among the most important factors to consider in policy selection because it is an effort to weigh a variety of policy implications on a common basis and seek decisions that are beneficial to society overall," but also cautioned that estimates are inherently uncertain and should be transparent and clearly justified; that sensitivity analysis is necessary; that a net benefits analysis will not be able to capture distributional effects or changes in behavior caused

by the policy; and that "it is not clear that there is necessarily any relationship between MNB and setting the 'maximum feasible' criteria while considering 'economic practicability.'"[3073] IPI disagreed with the NPRM's suggestion that feasibility concerns could lead NHTSA not to maximize net benefits, stating that "if a standard were truly not feasible, then its costs would be prohibitively high, and a full and fair cost-benefit analysis would reflect that."[3074]

CARB argued that "[a]lthough EPCA provides NHTSA with some discretion with respect to balancing the four factors, that discretion is nevertheless constrained by EPCA's overriding mandate of conserving energy."[3075] CARB further stated that EPCA "envision[s] the promulgation of increasingly stringent requirements to ensure the continued reductions of both emissions and fuel consumption from motor vehicles."[3076] Michalek and Whitefoot similarly commented that the requirement that standards be maximum feasible necessarily means that stringency must increase over time, because technology capabilities and cost are constantly improving; international regulations are constantly increasing in stringency; and if standards are held constant, automakers will always exceed them.[3077] The States and Cities commenters cited the *CAS* language from the D.C. Circuit that "[i]t is axiomatic that Congress intended energy conservation to be a long term effort that would continue through temporary improvements in energy availability," and argued that "[w]hile NHTSA purports to acknowledge this purpose and the importance of improving fuel economy over time, NHTSA proposes to do the opposite: roll back fuel economy standards for a period of at least *six years*."[3078] The States and Cities commenters further argued that NHTSA had "departed sharply from its past interpretations and practice without an adequate explanation, often without even an acknowledgement," citing *Fox Television*, insofar as the 2012 final rule justification had noted that less stringent regulatory alternatives would have conserved less energy than the then-finalized standards, as compared to "[w]ith the Proposed Rollback, NHTSA has radically changed positions—assuming energy conservation provides little, if any, benefits, for example—without explaining or even acknowledging this complete reversal of course."[3079] The States and Cities commenters concluded that it was "impermissible" for NHTSA to balance "the factors in a manner that contravenes EPCA's central purpose of energy conservation."[3080]

ACEEE commented that NHTSA did not have discretion to assess whether the need of the U.S. to conserve energy was as great as when EPCA was first passed, arguing that "[t]he statute does not ask for a determination on whether the nation needs to save energy. It assumes the need and directs that the need be taken into account along with other considerations."[3081] Securing America's Energy Future commented that the need of the U.S. to conserve energy

continued, and that "[a]lthough the nation is undoubtedly more energy secure than it was before the start of the U.S. shale oil revolution ten years ago,"[3082] "[u]ntil the U.S. transportation sector is no longer beholden to oil, the country will be vulnerable to oil price volatility. Improving the fuel efficiency of the U.S. vehicle fleet is a valuable insurance policy against this volatility."[3083] IPI also commented that fuel efficiency standards act as insurance, but against unpredictable future fuel prices.[3084] IPI stated that anticipating relatively low future fuel prices was not an appropriate basis for finalizing the proposal, both because fuel costs may rise in the future, and also because EPA's Final Determination "found that that even with the lowest prices projected in AEO 2016 of close to $2, the 'lifetime fuel savings significantly outweigh the increased lifetime costs' of the GHG standards."[3085] IPI further argued that "[i]n ignoring the [FD] analysis, the Proposed Rule has failed to provide a 'reasoned explanation' for dismissing the 'facts and circumstances that underlay' the original rule, rendering its analysis arbitrary and capricious."[3086] IPI also argued that NHTSA had not adequately explained its "shift since 2012 in its interpretation and application of the need to conserve energy factor," stating that "[a]ctual fuel savings, and the associated benefits to consumers, the environment, and society, were at the heart of NHTSA's analysis of the need to conserve energy factor back in 2012. Now the agency ignores those conclusions from 2012 and relies on mistaken and inconsistent interpretations of petroleum import projections and the urgency of climate change to justify ignoring this statutory factor and giving primacy instead to economic practicability and safety effects. The failure to explain this shift in approach is arbitrary."[3087]

UCS argued that the need of the United States to conserve energy is "the most important of the four required factors" according to *CBD v. NHTSA*, and claimed that "NHTSA has manipulated the evaluation of the factors to produce a result that supports the preferred option in the NPRM."[3088] The States and Cities commenters argued that it was "[c]ynical…" for NHTSA to justify the proposal on the basis that "the oil intensity of U.S. GDP has continued to decline" in part as a result of increasingly stringent CAFE standards, and on the basis that "[m]anufacturers have responded to fuel economy standards and to consumer demand over the last decade to offer a wide array of fuel-efficient vehicles in different segments and with a wide array of features."[3089]

CARB and CBD *et al.* argued that if NHTSA's analysis indicates that automakers will voluntarily exceed the standards, then the standards cannot be maximum feasible.[3090] Robertson commented relatedly that standards should not be set below augural levels because "Much higher fuel economy and reduced emissions have been achieved by several lower priced makes and

models using hybrid technology."[3091] Blue Planet Foundation stated that the augural standards are feasible because automakers have already invested in technologies, and electrification is projected to continue to grow cheaper over time, so that "even the up-front cost of an EV will begin to reach parity with gas-powered cars by 2024."[3092] ACEEE also cited the voluntary overcompliance in the NPRM analysis as evidence that there could not be diminishing returns from higher fuel efficiency standards, because "the list of [cost-effective] technology [must] continually regenerate itself" if manufacturers would continue applying it in the absence of future standards. Moreover, ACEEE argued, past analyses had always found plenty of available cost-effective technologies, and automakers would find a way to apply them.[3093]

c) How is NHTSA Balancing the Factors to Determine the Maximum Feasible Final CAFE Standards?

EPCA/EISA grants the Secretary (by delegation, NHTSA) discretion in how to balance the relevant statutory factors, while bearing in mind EPCA's overarching purpose of energy conservation. Many commenters cited the Ninth Circuit's language in *CBD v. NHTSA* that "the overarching purpose of EPCA is energy conservation,"[3094] and the D.C. Circuit's language in *CAS v. NHTSA* that "[i]t is axiomatic that Congress intended energy conservation to be a long term effort that would continue through temporary improvements in energy availability."[3095] NHTSA has considered those comments and those court decisions carefully as it made the decision set forth in the final rule. Based on the information before the agencies and considering carefully the comments received, NHTSA has determined that the preferred alternative identified in the proposal—amending the MY 2021 standards to match MY 2020, and holding those standards flat through MY 2026—does not represent the maximum feasible standards, and that the maximum feasible standards for MYs 2021-2026 passenger cars and light trucks increase in stringency by 1.5 percent per year from the MY 2020 standards. The following discussion walks through NHTSA's evaluation and balancing of the relevant factors in light of the information before it.

(1) Need of the U.S. to Conserve Energy

NHTSA agrees with commenters that energy conservation remains important, and that changed conditions, even significantly changed conditions, do not obviate NHTSA's obligation to set maximum feasible CAFE standards as directed by Congress. Many commenters disagreed strongly with NHTSA's suggestion in the NPRM that increased U.S. petroleum production, and the U.S.'s likely imminent status as a net petroleum exporter, decreased the need of the U.S. to conserve energy. NHTSA agrees that there is still a need to conserve energy, and oil in particular. Like an insurance policy or a savings account, continuing to move the needle forward on CAFE helps position Americans better to weather certain types of possible future uncertainty.

NHTSA believes that it is reasonable to be somewhat conservative about this risk, and thus to set CAFE standards that increase in stringency year over year through MY 2026.

That said, NHTSA believes that there are limits to how much uncertainty the CAFE program can mitigate—continuing to make progress is important, but it is also important to be transparent and realistic about what is being accomplished, even if NHTSA were able to set standards beyond levels that NHTSA considers maximum feasible. NHTSA also continues to believe that structural changes in global oil markets over the last 10 years, driven in part by changes in demand both in the U.S. and abroad, and in part by the significant growth in U.S. petroleum production, have led to a fundamental shift in the dynamics of global oil prices, which has in turn improved U.S. (and possibly, global) energy security. NHTSA believes that this shift is important to consider as NHTSA weighs the need of the Nation to conserve energy.

NHTSA acknowledges that price shocks can still happen. The large scale attack on Saudi Arabia's Abqaiq processing facility—the world's largest crude oil processing and stabilization plant—on September 14, 2019 caused "the largest single-day [crude oil] price increase in the past decade," of between $7 and $8, according to EIA.[3096] The Abqaiq facility has a capacity to process 7 million barrels per day, or about 7 percent of global crude oil production capacity. By September 17, however, also according to EIA,

> Saudi Aramco reported that Abqaiq was producing 2 million barrels per day, and they expected its entire output capacity to be fully restored by the end of September. In addition, Saudi Aramco stated that crude oil exports to customers will continue by drawing on existing inventories and offering additional crude oil production from other fields. Tanker loading estimates from third-party data sources indicate that loadings at two Saudi Arabian export facilities were restored to the pre-attack levels. Likely driven by news of the expected return of the lost production capacity, both Brent and WTI crude oil prices fell on Tuesday, September 17.[3097]

Thus, the largest single-day oil price increase in the past decade was largely resolved within a week, and assuming very roughly that average crude oil prices were $70/barrel in September 2019 (slightly higher than actual), an increase of $7/barrel would represent a 10 percent increase as a result of the Abqaiq attack. Contrast this with the 1973 Arab oil embargo, which lasted for months and raised prices 350 percent.[3098] Saudi Arabia could have benefited, revenue-wise, from higher prices following the Abqaiq attack, but instead moved rapidly to restore production and tap reserves to *control* the risk of resulting price increases, likely recognizing that long-term sustained price increases would reduce their ability to control global supply (and thus prices, and

[3097] *Id*.
[3098] *See* Jeanne Whalen, "Saudi Arabia's oil troubles don't rattle the U.S. as they used to," Washington Post, September 19, 2019, available at https://www.washingtonpost.com/business/2019/09/19/saudi-arabias-oil-troubles-dont-rattle-us-like-they-used/.

thus their own revenues) by relying on their lower cost of production.[3099] Even if the NPRM discussion was perhaps overconfident about the ability of U.S. shale producers to act as "swing" supply, as some commenters suggested, it seems clear from events that the *existence* of U.S. production has a stabilizing effect on global oil prices. This has played out in important ways in the first quarter of 2020, with the dissolution of the "OPEC+" coalition as Russia and Saudi Arabia compete for market share in response to U.S. shale production and also in the wake of global demand downturn.[3100]

Even though the effect of significant supply disruptions appears much lower than was the case several years ago, the analysis for this final rule (like the NPRM analysis) does, in fact, explicitly account for the possible occurrence of price shocks. The cost penalty used in the analysis to represent the consequences of those shocks attempts to quantify the negative impact on U.S. GDP created by abrupt, short-term increases in the world oil price. The values used in the NPRM were based on arguably outdated work, and commenters cited more recent studies of relevance in their comments on the NPRM – one of which formed the basis for the estimates in today's analysis. The final rule estimate of this cost are based on a recent study which states that "[i]n recent years, the United States has become much more self-reliant in producing oil, and a newer economics literature suggests that oil demand may be more elastic and U.S. GDP may be less sensitive to world oil price shocks than was previously estimated. These developments suggest somewhat lower security costs may be associated with U.S. oil consumption."[3101] These more recent studies concede that the fact that "the world has not seen a major oil supply disruption since 2003," and that therefore "we have no reliable method to quantify the effects of these disruptions,"[3102] but even the range of uncertainty suggests that the risk has decreased relative to prior estimates. The price shock cost estimate employed in the NPRM was at least twice as large as the upper bound of the range in Brown's new estimates, and consistently close to the upper bound of the range of his more conservative estimates. The approach taken today, which relies on median estimates in Brown's study, implies that risk is more properly estimated here than in the NPRM.

Commenters (Bordoff, SAFE, CARB, IPI) argued that increased U.S. petroleum production, which improves the stability of the global supply and reduces the probability of supply interruptions, does not reduce U.S. exposure to petroleum price shocks, which are still

determined by the dynamics of the global market. By reducing the probability of supply disruptions in the global market, the U.S. does reduce its vulnerability to price shocks. However, to the extent that the vulnerability to price shocks is a function of *exposure*, commenters are correct that looming petroleum independence does not entirely insulate the U.S. economy from the consequences of global oil price shocks. Some commenters further argued that the proposed standard would leave the U.S. more exposed to oil price shocks, which would harm consumers. Basic mathematics means that a less efficient on-road fleet necessarily would spend more on fuel than a more efficient on-road fleet in the event of a sudden, unexpected, and dramatic increase in oil price. The suggestion in these comments, however, is that finalizing the augural standards would sufficiently insulate U.S. consumers from harm during such an event, while finalizing any other regulatory alternative would not. NHTSA disagrees that finalizing the augural standards, as compared to the standards we are finalizing, would make a meaningful difference in this case.

A continuous, but slow, price increase over several years is fundamentally different from the kinds of acute price shocks over which commenters have expressed understandable concern. Long-term price increases signal consumers to make investments in fuel economy, in both the new and used vehicle markets, and to diversify the vehicles in their household fleets. In a side analysis using outputs from the CAFE Model, the agencies examined the consequences of a gasoline price spike in 2030—increasing the price from $3.40/gallon to $6/gallon for eight months, then reverting back to $3.40/gallon.[3103] By choosing a year so far in the future, the agencies consider a larger gap in fleet fuel efficiency than is attributable to this action. If the agencies increase stringency again after MY 2026, the efficiency gap between the on-road fleet in the final standards and baseline would be smaller than simulated here. This side analysis showed that even a nearly doubling of the fuel price, sustained for more than half a year, would result in less than 1 percent savings in fuel expenditures for that year under the final standards (relative to the proposal), compared to about 5 percent reduction in expenditures under the augural standards. This demonstrates that even though finalizing the augural standards would mitigate American drivers' increase in fuel expenditures by more than the standards the agencies are finalizing today, it would only do so by a few percent. This is important to understanding concerns about differences in the amount of fuel saved under today's final standards versus if the augural standards were finalized, as will be discussed more below. And as also discussed below, NHTSA believes the augural standards are beyond maximum feasible at this time.

Some commenters raised the possibility that the U.S. might ban fracking at some point in the future, and suggested that therefore the need of the U.S. to conserve energy could not be assumed away. NHTSA acknowledges that the future is uncertain. Without the supply of U.S. oil in the global market, NHTSA agrees that it is foreseeable that conditions could revert somewhat to how global oil market conditions were before the ramp-up in U.S. supply—i.e., that the global market as a whole could be somewhat less stable and thus fuel prices could be somewhat more prone to change unexpectedly and for longer periods. Pulling out of the market on the supply side means that the agencies would lose the ability to influence the market on that side. Presumably, part of the policy objective of banning fracking would be to accelerate a transition to a post-oil transportation system. In that scenario, presumably decision-makers

[3103] Docketed in NHTSA-2018-0067.

would consider higher fuel prices to be an acceptable tradeoff for less driving and lower emissions. That said, the availability of shale oil resources does exist today, and is not realistically in question. And, even if the future availability of that capacity was realistically doubtful, any increase in fuel economy above current levels, like the final rule will require, will help somewhat to mitigate the economic pain to drivers of that event were it to occur, as shown above.[3104] To the extent that current events cause pauses or consolidation in the shale industry's development, while that may lead to transitory difficulty for the shale industry, the resources will continue to exist, and U.S. shale will continue to be able to act as a lever to keep global prices from rising very high for very long.

As noted above, Securing America's Energy Future commented that "[a]lthough the nation is undoubtedly more energy secure than it was before the start of the U.S. shale oil revolution ten years ago,"[3105] *"[u]ntil the U.S. transportation sector is no longer beholden to oil*, the country will be vulnerable to oil price volatility. Improving the fuel efficiency of the U.S. vehicle fleet is a valuable insurance policy against this volatility."[3106] (Emphasis added.) NHTSA agrees fully with this comment. Energy security concerns were the driving force behind the creation of the CAFE program, as discussed in the NPRM. U.S. energy security has improved, but the only way to resolve petroleum-related energy security concerns entirely would be for the U.S. vehicle fleet to stop using oil. And doing so would not avoid energy-related concerns entirely, but rather shift them away from petroleum (and the Middle East) and toward battery-related security (and lithium-, nickel-, cobalt-, and other metals-producing countries).[3107]

Our relationship to the global energy market has changed significantly since the CAFE program was created, with most of this change occurring over the last decade. The United States has become energy independent, and is currently a net exporter of petroleum products. Rising world oil prices no longer only mean a financial burden on U.S. drivers and a wealth transfer to foreign nations. While rising prices continue to affect U.S. motorists, we have taken steps to insulate our transportation system from exogenous price shocks. CAFE standards (and, recently, CO_2 standards) have increased the efficiency of new vehicles for more than a decade, and these increasingly efficient vehicles are still working their way into the on-road fleet as older models are retired. Accompanying any increase in the global oil price is an increase in revenue to the

[3107] While progress is being made on developing and improving domestic sources for many of the minerals necessary for battery development, the U.S. is still heavily dependent on imports of both raw materials and batteries. Regarding minerals production and import dependence, *see* Schulz, K.J., DeYoung, J.H., Jr., Seal, R.R., II, and Bradley, D.C., eds., Critical mineral resources of the United States – Economic and environmental geology and prospects for future supply: U.S. Geological Survey Professional Paper 1802 (*see particularly* Chapter K, p. K1-K21 on lithium), available at https://www.commerce.gov/sites/default/files/2020-01/Critical_Minerals_Strategy_Final.pdf and https://pubs.usgs.gov/pp/1802/k/pp1802k.pdf. Regarding vehicle battery supply chains, *see* Coffin, D., and J. Horowitz, "The Supply Chain for Electric Vehicle Batteries," *Journal of International Commerce and Economics*, December 2018, available at https://www.usitc.gov/publications/332/journals/the_supply_chain_for_electric_vehicle_batteries.pdf.

U.S. oil industry. To the extent that motorists are spending more on oil everywhere, the dollars spent on domestically produced petroleum products stay within the U.S. and additional revenue from foreign buyers flows into our domestic energy industry. To the extent that the U.S. transportation system is able to further reduce its dependence on petroleum in a cost-effective manner, it is sensible to do so. But in the current environment, in which motorized transportation is increasingly energy efficient and U.S. energy producers are not only supplying our demand but exporting petroleum products to other nations, the nationwide benefits of reducing petroleum consumption are substantially diminished.

There is also the opposite concern to bear in mind – that energy security is not just about oil becoming more expensive, but also about other changes in oil prices. Major fluctuations in either direction, as well as oil price collapse, can potentially have seriously destabilizing geopolitical effects. Many major oil producing countries (some of whom are allies) rely heavily on oil revenues for public revenue, and sustained losses in public revenue in certain countries and regions can foreseeably create new energy-related security risks, not only for the U.S. As the world works toward transitioning away from oil for transportation, keeping prices reasonably stable may best help that transition remain peaceful and steady. In short, energy security can cut both ways, and the current estimates of price shock that we model inherently do not account for the longer-term stabilizing effect of steady global oil consumption (of which the U.S. is a part) on global security. Steady trends in consumption can facilitate steady changes in production, which can facilitate a steady security situation.

NHTSA does not interpret EPCA/EISA to mean that Congress expected the CAFE program to take the U.S. auto fleet off of oil entirely—indeed, EISA renders doing so impossible because it amended EPCA to prohibit NHTSA from considering the fuel economy of dedicated alternative fuel vehicles, including electric vehicles, when setting maximum feasible standards. This means that standards cannot be set that assume increased usage of full electrification for compliance. Reading that prohibition together with the obligation to set maximum feasible standards by considering (which is hard to do without balancing) factors like economic practicability with the need of the U.S. to conserve energy, NHTSA believes that Congress intended CAFE to try to mitigate the risk of gas lines, but not to shift the fleet entirely off of oil. Moreover, the EISA-added requirement that standards "increase ratably" for MYs through 2020 ceases to apply beginning in MY 2021. While NHTSA unquestionably has discretion to determine that standards should continue to increase post-MY 2020, NHTSA does not interpret EPCA/EISA as *requiring* that they do, as long as they are maximum feasible. Several commenters suggested that standards that do not continue to increase, by definition, cannot be maximum feasible, but NHTSA believes that this interpretation does not account for the clear requirement that maximum feasible standards be determined with reference to the four statutory factors. The statute does not preclude an interpretation that non-increasing standards could be maximum feasible, depending on the facts before the agency. Neither does the statute preclude an interpretation that amending standards downward can be maximum feasible, as has occurred in the past in response to changes in consumer demand.[3108]

[3108] *See*, Center for Auto Safety v. NHTSA (CAS), 793 F.2d 1322 (D.C. Cir. 1986).

Nevertheless, for purposes of this final rule, NHTSA does believe that standards that increase in stringency are maximum feasible; the question remains by how much those standards should increase. While NHTSA agrees that CAFE standards must conserve energy, the improvement in energy security discussed above is entirely relevant to *how much energy should be conserved*. If the marginal improvement in energy security of increasing CAFE stringency from one regulatory alternative to another is very small, as it appears to be based on the above discussion, then other aspects of the need of the U.S. to conserve energy must be considered next to see what effect they have.

Consumer costs, as discussed above, is another aspect of the need of the U.S. to conserve energy. The final rule analysis estimates that all alternatives besides the baseline/augural standards would result in higher fuel costs for consumers than the baseline/augural standards would result in, as follows:

Table VIII-6 – Estimated Average Fuel Costs Over the Useful Lives of MY 2029 Vehicles, Under Each Regulatory Alternative

Scenario Name	**Lifetime Fuel Expenditures (2018 $)***		**Lifetime Increase (2018 $)***	
	7% discount rate	3% discount rate	7% discount rate	3% discount rate
Augural Cafe Standards	13,525	17,300	-	-

*Rounded to nearest $25

A number of commenters stated that the 2012 rulemaking had relied on fuel savings as part of its justification, and argued that the NPRM had not adequately grappled with the fact that the proposal would have cost consumers more in fuel expenditures than if NHTSA finalized the augural standards. In fact, NHTSA explained in the NPRM that while fuel costs would be higher, NHTSA believed that the higher upfront (and ongoing, if financed) costs of new vehicles and associated taxes and registration fees—as well as the opportunity cost associated with those upfront costs—would outweigh, for many consumers, the additional fuel costs that would be incurred if standards were less stringent than augural. That continues to be the case under the final rule analysis, as discussed below. In addition, Section VI.D. discusses how past rulemaking analyses assumed that consumers were ‘myopic’ and/or did not have adequate information about the benefits of fuel savings, which led them to choose to purchase less efficient vehicles than they otherwise would if they better understood the costs or savings they would accrue. As Section VI.D. explains, the agencies are less certain today that consumers improperly value fuel savings. Vehicle buyers today have more information about fuel costs than ever before, including right on the window sticker when considering a new vehicle purchase, and it is ultimately a private choice whether consumers prefer improvements in other vehicle attributes over additional fuel economy. When fuel costs are expected to rise manageably over time, it may be that consumers are comfortable choosing to absorb an additional $1,375 over the vehicle's lifetime, the estimated difference in lifetime expenditures between the proposal and if NHTSA was choosing to finalize the augural standards, and are even more comfortable choosing to absorb an additional $1,125, the estimated difference in lifetime expenditures between the final standards and what the augural standards would have required. If fuel prices rise less than anticipated, as they have done since the 2012 final rule, or even decrease over time, buyers face an even smaller tradeoff between foregone fuel savings and the value of improvements in other aspects of new cars.

Consumer expenditures on fuel are important to understanding the benefits (and net benefits) of CAFE and CO_2 standards. Every analysis of CAFE/CO_2 standards relies on hundreds of assumptions, and estimates of costs and benefits developed as part of those analyses, by their very nature, depend on those assumptions. Specifically, the net benefits associated with each alternative result from the assumptions used and the relationships between vehicle production, ownership, and usage in which the assumptions interact. Put more simply, inputs affect outputs. As discussed in the section above on economic practicability, net benefits may be a consideration in the determination of maximum feasible standards, among the many other things the agency considers. While some commenters have asserted that the analysis for this rulemaking has "put a thumb on the scale by undervaluing the benefits and overvaluing the costs of more stringent standards,"[3109] this final rule has identified a number of critical assumptions in the 2012 final rule that were problematic in the other direction (i.e., undervaluing the costs and overvaluing the benefits), for a variety of reasons. For example, the projected fuel prices in the 2012 analysis inflated the value of fuel savings relative to what has actually occurred. That assumption about how fuel prices were projected to rise over time was solidly grounded at the time, but is no longer so, and continuing to use it would not be reasonable, even if that means that the benefits of all of the regulatory alternatives decrease as compared to what the 2012 analysis showed. Lower oil prices mean that fuel savings benefits for consumers are lower under any CAFE standards, whether the augural standards or the standard being finalized today – consumers may yet spend less on fuel under more stringent standards, but *how much less* matters.

Additionally, the assumption in 2012 that no market exists for fuel economy improvements at any fuel price or technology cost artificially inflated the value of fuel savings attributable to the standards in each regulatory alternative. The combination of assumptions and relationships (the examples above, and others) in the 2012 final rule produced estimates of net benefits that continued to increase with stringency from 1 percent per year through 6 percent per year.[3110] Under some alternatives, benefits actually would have appeared to be infinite, growing faster than the discount rate, if the analysis had been extended far enough into the future. No

[3109] *See* CBD v. NHTSA, 538 F.3d 1172, 1189 (9th Cir. 2008).

[3110] The 7 percent per year alternative happened to be indistinguishable from the 6 percent alternative in that analysis.

market works this way, and there is no reasonable set of assumptions under which costs could *never* exceed benefits no matter how much technology was deployed or how much stringency was required. Rather than demonstrating meaningfully that more stringent standards are always more beneficial to society, the result from the 2012 analysis suggests that that analysis was critically flawed. That said, while the 2012 analysis appeared to show that more technology, at a faster pace, is always preferable from the perspective of net benefits, the agencies ultimately relied on other features of the analysis and considerations of impacts in choosing a preferred alternative. While today's analysis produces an inflection point at a 3 percent discount rate—a level of stringency where further increases reduce net benefits as the tradeoff between regulatory costs and resulting net benefits tips the other way[3111]—the agencies similarly rely on considerations beyond net benefits in choosing the preferred alternative.[3112]

NHTSA also agrees with many commenters that environmental (both climate and air quality) concerns are relevant to the need of the U.S. to conserve oil, as explained above. As the Supreme Court stated in *Massachusetts v. EPA*, "[a] reduction in domestic emissions would slow the pace of global emissions increases,"[3113] and there is no question that CAFE standards directly affect CO_2 emissions. Besides providing information on differences between the regulatory alternatives in terms of million metric tons of CO_2 emitted, the NPRM also provided a chart illustrating the difference between the estimated atmospheric CO_2 concentration (789.76 ppm) in 2100 under the proposal as compared to the estimated level under the augural standards (789.11 ppm) in a scenario where no CO_2 emissions reduction measures are implemented throughout the planet.[3114] The NPRM noted that this translated to 3/1000ths of a degree Celsius increase in global average temperatures by 2100, relative to the augural standards. Many commenters strongly objected to the framing of these findings, as discussed above in the section on the environmental implications of the need of the U.S. to conserve energy. Changing the framing does not change the agency's findings.[3115] For this final rule, the Preferred Alternative would result in 922.5 million metric tons of CO_2 more than the estimated emissions if the augural standards were to be finalized (for MY 2017 – MY 2029 vehicles between calendar years 2017 and 2070), which is 160.2 million fewer tons than if the proposed Preferred Alternative were to be finalized. It is reasonable to consider these raw million-metric-ton estimates in terms of their effects, namely, on estimated temperature change and sea level rise, which are the primary climate effects referred to and estimated. The FEIS accompanying today's rule estimates that, by 2100, global mean surface temperature will increase by 3.487 degrees (Celsius) under either the proposed or final standards, versus 3.484 degrees under the augural standards. The FEIS shows corresponding sea level rise in 2011 reaching 76.34 cm under the final standards, 76.35 cm under

[3111] *See* Table VII-95.
[3112] *See* CBD v. NHTSA, 538 F.3d 1172, 1188 (9th Cir. 2008).
[3113] Mass. v. EPA, 549 U.S. at 526.
[3114] 83 FR at 42996-97 (Aug. 24, 2018).
[3115] In fact, NHTSA's analysis in Section 8.6.4.2 of the FEIS illustrates that the differences between alternatives are similar in reference to other GCAM scenarios. Regardless of whether there will be widespread global efforts to mitigate climate change, the impacts of this action are roughly the same.

the proposed standards, and 76.28 cm under the augural standards. This is accounted for in economic terms (i.e., translated from fractions of a degree temperature rise and from millimeters of sea level rise, among other things, into dollar-based effects) in the measure of the social cost of carbon, described in Section VI.D.1.b)(12).

NHTSA is mindful of the language in *Massachusetts v. EPA* that "[a]gencies … do not generally resolve massive problems in one fell regulatory swoop,"[3116] and acknowledges the concerns of many commenters that standards less stringent than augural may result in higher CO_2 emissions. In response, it is important to remember that even under the proposal, sales of new vehicles would, over time, have continued to improve the fuel economy and reduce the CO_2 emissions of the on-road fleet through fleet turnover effects, as discussed in Section IV. Under the final rule, those rates of improvement will likely be faster than they would have been if NHTSA were finalizing the proposal. Emissions are still being reduced under the final rule, and the on-road fleet will be less energy and carbon intensive than it is today. NHTSA is taking the impacts of CO_2 emissions into account, while also considering the other statutory factors in its balancing.

It is also important to note that the science of climate change and the models used to assess effects on climate variables (and other effects discussed in Section VII.A.4.b, and in the DEIS/FEIS) are subject to various types and degrees of uncertainty. In light of this, NHTSA also conducted climate sensitivity analyses in the FEIS.[3117] In these analyses, NHTSA considered a range of climate sensitivities (1.5°C, 2.0°C, 2.5°C, 3.0°C, 4.5°C, and 6.0°C) for a doubling of CO_2 compared to preindustrial atmospheric concentrations (278 ppm CO_2). Even under the least stringent alternative considered (the proposal) and assuming the highest level of climate sensitivity (6.0°C), the global mean surface temperature increase in 2100 was 0.006°C higher than under the augural standards. Thus, accounting for some of this uncertainty, impacts on global mean surface temperature resulting from this action remain very small.

NHTSA received many comments about the costs of delaying CO_2 emissions reductions and the potential of crossing climate tipping points and triggering abrupt climate change. Many of these costs and risks are factored in to the social cost of carbon, and are therefore considered as part of the agency's cost-benefit analysis. And many of these costs and risks cannot be quantified at all: the current state of science does not allow for quantifying how increased emissions from a specific policy or action might affect the probability and timing of abrupt climate change. However, NHTSA does recognize that while these costs cannot be quantified, they do exist and must also be taken into account. Ultimately, the costs of delaying CO_2 emissions reductions (both the ones that can be accounted for quantitatively and those that can only be considered qualitatively) must also be balanced against the costs associated with more stringent alternatives. Some of the costs associated with more stringent alternatives are direct, such as the additional costs passed on to consumers for technology that improves fuel economy.

[3116] Mass. v. EPA, 549 U.S. at 524.
[3117] *See* Sections 5.4.2.3 and 8.6.4.2 of the FEIS.

Other costs are indirect, such as environmental costs associated with more stringent fuel economy standards. For example, the increased electrification of motor vehicles can result in localized impacts associated with the production and recycling of lithium-ion batteries. Similarly, the increased reliance on material substitution for vehicle mass reduction could result in various environmental impacts associated with manufacture and recycling. Certainly, the benefits of these technologies in reducing carbon emissions outweighs the other life-cycle environmental impacts, but that does not mean NHTSA can just ignore those impacts, either.

Many commenters claimed that NHTSA ignored the effects of climate change or determined they were inevitable, not urgent enough to act upon, or not worth the effort to address at all. NHTSA makes none of those determinations here. On the contrary, NHTSA has considered the material on this subject in the administrative record and the plethora of public comments we received on the topic. The agency recognizes what is at stake, but we also recognize that NHTSA is not charged by Congress to single-mindedly address carbon emissions at the expense of all other considerations. The question before NHTSA is not whether to conserve energy (and thereby reduce carbon emissions, which drive climate change) but by how much each year. Taking climate change into account elevates the importance of the "need of the United States to conserve energy" criterion in NHTSA's balancing. However, in light of the limits in what the agency can achieve, the potential offsetting impacts to the environment, and the statutory requirement to consider other factors, the impacts of carbon emissions alone cannot drive the outcome of NHTSA's decision-making.

NHTSA also recognizes the potential impacts of this rulemaking on air quality. To be clear, this final rule does not directly involve the regulation of pollutants such as carbon monoxide, smog-forming pollutants (nitrogen oxides and unburned hydrocarbons), or "air toxics" (e.g., formaldehyde, acetaldehyde, benzene). Nevertheless, NHTSA recognizes that this rule is expected to impact such emissions indirectly (by reducing travel demand and accelerating fleet turnover to newer and cleaner vehicles on one hand while, on the other, increasing activity at refineries and in the fuel distribution system). Based on a review of Section VII.A.4.c. above and the FEIS, NHTSA believes these impacts are much smaller than impacts on fuel use and CO_2 emissions, and therefore factor in less to the need of the U.S. to conserve energy.[3118]

For criteria pollutants, NHTSA estimates that emissions over the lifetimes of vehicles through MY 2029 under the alternatives will not change significantly. Tailpipe emissions of most pollutants will generally decrease, while upstream emissions will generally increase. Overall emissions under the action alternatives for most pollutants will increase over time. Changes are not uniform year-to-year, however, reflecting the complex interaction of the amount of highway travel, the distribution of that travel among different vehicles, upstream processes, etc. Generally, tailpipe air toxic emissions decrease while upstream air toxic emissions increase. Over the long term, however, the upstream emissions increase further while the decreases in

[3118] For an explanation of how NHTSA considers environmental impacts and the differences between the preamble and FEIS analyses, *see* Section VII.A.4.c.1 above.

tailpipe emissions become less pronounced. Overall, NHTSA anticipates that air toxic emission will increase over time under the action alternatives. Most alternatives result in cumulative increases in adverse health impacts associated with total upstream and tailpipe pollutant emissions. Although some alternatives would have resulted in decreases, the differences among alternatives across the lifetime of vehicles through MY 2029 are not large.

NHTSA also considered the various impacts reported qualitatively in the FEIS and described briefly above in Section VIII.B.3. Although the agency cannot compare the impacts of the alternatives quantitatively (except to the degree that they are otherwise covered by the agency's monetary cost-benefit analysis, such as through the social cost of carbon), NHTSA recognizes that such impacts would generally increase under all the action alternatives compared to the augural standards. In Chapter 8 of the FEIS, for example, NHTSA provides a qualitative discussion of the long-term impacts of climate change on key natural and human resources. While these impacts would be expected to increase under the action alternatives, the change is expected to be very small. In contrast, the FEIS also discusses some environmental impacts that would decrease with the lower stringencies considered in this rulemaking. For example, in Chapter 6 of the FEIS, NHTSA provides a literature review of potential lifecycle impacts as a result of manufacturer use of various materials and technologies to meet the standards. NHTSA can account for the benefits to tailpipe emissions of these technologies as part of its evaluation of technology effectiveness. However, as discussed in the FEIS, accounting for the upstream emissions associated with the processes used in the manufacture of these technologies can be complicated. Because the adoption of these materials and technologies would vary across alternatives, and each has varying upstream impacts, the agency cannot provide meaningful comparisons across alternatives. Still, any benefit to tailpipe CO_2, criteria pollutant, or air toxic emissions of more stringent alternatives would be offset by the increased upstream impacts reported in that section.[3119]

In total, environmental impacts factor into the need of the U.S. to conserve energy and potentially elevate that criterion, but those impacts cannot be considered in isolation. While some impacts are more significant than others, NHTSA must consider how much weight to place on this factor as well as the relative weight of other factors.

Thus, even if the agency no longer interprets the need of the U.S. to conserve energy as necessarily boundless as it once did, as it explained in the NPRM and again in the discussion above, NHTSA continues to believe that the factor functions in the overall balancing to push toward increases in stringency, and notes that any increase in stringency over the last binding standards—not in question at this point, the standards for MY 2020—does conserve energy and reduce negative environmental impacts. In fact, fleet turnover over time means that less energy

---

[3119] In most cases, tailpipe emissions benefits offset upstream environmental impacts associated with materials and technologies NHTSA considered in its analysis. However, in some cases, results may not align with conventional wisdom. For example, while EVs can offer significant life-cycle GHG emissions savings over conventional vehicles, this is highly dependent on the time and location of charging. In some regions, life-cycle impacts are similar for EVs and conventional vehicles.

is being consumed by the fleet over time even if standards did *not* increase year over year. Even if new vehicles are not all as efficient as would have been required under more stringent standards, they are still more efficient on average than the older vehicles they are replacing, particularly after a decade of successive increases in CAFE standard stringency, as Section IV above discusses. The on-road fleet has well over 250 million vehicles, dwarfing the roughly 16 million new vehicles sold each year. Comprehensive energy savings come from turning over legacy vehicles in the fleet so that overall fleet fuel economy increases. If the NPRM's preferred alternative were finalized, the fuel consumption of the passenger car and light truck fleet would have fallen from roughly 8.5 million barrels per day (currently) to roughly 7 million barrels per day by 2050 as the fleet turned over. Finalizing the 1.5 percent alternative reduces that number to 6.3 million barrels per day. That breaks the trend of increasing oil consumption over time, and conserves energy.

(2) Technological Feasibility and the Effect of Other Motor Vehicle Standards of the Government on Fuel Economy

As in the 2012 final rule, technological feasibility and the effect of other motor vehicle standards of the Government on fuel economy do weigh in NHTSA's balancing of the relevant factors, but they play a less significant role because they vary less across regulatory alternatives than the other factors vary. Technological feasibility, as explained above and as similarly explained in 2012, relates to whether technologies exist and can be commercially applied during the rulemaking timeframe. None of the regulatory alternatives under consideration today would require brand new technologies to be invented – they can all be met with technology that exists currently. However, as recognized in the 2012 final rule, "some technologies that currently have limited commercial use cannot be deployed on every vehicle model in MY [2021], but require a realistic schedule for widespread commercialization to be feasible. …Any of the alternatives could thus be achieved on a technical basis alone if the level of resources that might be required to implement the technologies is not considered." As explained above in the discussion of economic practicability, however, resources must be, and are, considered. The 2012 final rule further explained that "If all alternatives are at least theoretically technologically feasible in the [rulemaking] timeframe, and the need of the nation is best served by pushing standards as stringent as possible, then the agency might be inclined to select the alternative that results in the very most stringent standards considered." The 2012 final rule stated, however, that such a selection would be inappropriate because "the agency must also consider what is required to practically implement technologies, which is part of economic practicability, and to which the most stringent alternatives give little weight."

NHTSA considers technological feasibility similarly to how it has long considered that factor—for the most part, the question of what standards are maximum feasible is less about technological feasibility than about economic practicability. All of the regulatory alternatives considered in this final rule are likely technologically feasible, but that does not mean that any of them could be maximum feasible, just as we concluded in evaluating alternatives in 2012. NHTSA must now account for how the need of the U.S. to conserve oil has changed, and this consideration tips our balancing away from the most stringent standards.

For the effect of other motor vehicle standards of the Government on fuel economy, there is relatively little variation across regulatory alternatives, as discussed in the FRIA. As in the 2012 final rule, in developing this final rule NHTSA considered the effects of compliance with known and possible NHTSA safety standards and known EPA emission standards in developing this final rule, and has accounted for those effects in the analysis. The effect of other motor vehicle standards of the Government does not, therefore, have a noticeable effect on NHTSA's balancing of factors to determine maximum feasible standards.

(3) Economic Practicability

Economic practicability remains a complex factor to consider and balance, as discussed above, encompassing a variety of different issues that are each captured to various degrees through the analysis. As NHTSA stated in the 2012 final rule, "The agency does not necessarily believe that there is a bright-line test for whether a regulatory alternative is economically practicable, but there are several metrics … that we find useful for making the assessment."[3120] In 2012, as today, NHTSA looks to factors like:

- Per-vehicle cost, in terms of "even if the technology exists and it appears that manufacturers can apply it consistent with their product cadence, if meeting the standards will raise per-vehicle cost more than we believe consumers are likely to accept, which could negatively impact sales and employment in this sector, the standards may not be economically practicable";[3121]

- Application rate of technologies, because "even if shortfalls are not extensive, whether it appears that a regulatory alternative would impose undue burden on manufacturers in either or both the near and long term in terms of how much and which technologies might be required" can be relevant to manufacturers' difficulty with meeting standards;[3122]

- Consumer demand, which NHTSA described in 2012 as "other … considerations related to the application rate of technologies, whether it appears that the burden on several or more manufacturers might cause them to respond to the standards in ways that compromise … other aspects of performance that are important to consumer acceptance of new products";[3123]

- Manufacturer compliance shortfalls, because "If it appears, in our modeling analysis, that a significant portion of the industry cannot meet the standards defined by a regulatory alternative in a model year, given that our modeling analysis accounts for manufacturers' expected ability to design, produce, and sell vehicles (through redesign cycle cadence,

---

[3120] 77 FR at 63038 (Oct. 15, 2012).
[3121] *Id*.
[3122] *Id*.
[3123] *Id*.

technology costs and benefits, etc.), then that suggests that the standards may not be economically practicable"[3124];

- Uncertainty and consumer acceptance of technologies, which the 2012 final rule said was "not accounted for expressly in our modeling analysis, but [was] important to an assessment of economic practicability given the time frame of this rulemaking."[3125]

Thus, estimated impacts on per-vehicle cost are one issue; estimated sales and employment impacts are issues; uncertainty surrounding future market conditions and consumer demand for fuel economy (versus consumer demand for other vehicle attributes) are other issues. Consumers may respond to per-vehicle cost increases by choosing to keep their current vehicle or buy used vehicles instead of new vehicles, with consequent effects on new vehicle sales and the overall fleet makeup; consumers may respond to new fuel-economy-improving technologies on certain models by choosing to buy other models, especially when fuel costs are not expected to increase significantly in the ownership timeframe and consumers value other vehicle attributes more than they value fuel economy. Either of these responses may cause manufacturers both to lose money and to face further difficulties in meeting the CAFE standards. While there are significant benefits for both manufacturers and consumers under attribute-based standards, manufacturers must still sell enough "target-beaters" to balance out sales of less-fuel-efficient vehicles and meet their overall fleet-average compliance obligations. If consumer demand shifts strongly away from target-beaters, CAFE compliance will be a struggle, even if the target-beaters are widely available. Section IV above discusses this phenomenon in more detail. And if consumers buy fewer new vehicles in response to per-vehicle cost increases, which the agencies are beginning to see already, [3126] the fleet as a whole will turn over more slowly, and fuel conservation gains may also be slowed. NHTSA does not believe that that is EPCA's goal. Manufacturers struggling to sell new vehicles will have less capital to devote to further technological improvements; may choose to move manufacturing jobs outside the U.S. to places with lower labor costs; and so forth. A net benefits analysis may be informative to attempting to quantify some of the issues described above, but not all of these issues lend themselves to clear quantification. The following discussion will evaluate what the agencies believe has been reasonably accounted for.

(a) Per-Vehicle Costs, Sales, and Employment as Part of Economic Practicability

Per-vehicle cost estimates are relevant to NHTSA's consideration of economic practicability because, when cost increases associated with more stringent standards are passed through to consumers as price increases, they affect consumers' willingness and ability to purchase new vehicles, and thus influence vehicle sales and fleet turnover. A similar effect occurs in reverse when stringency is decreased. Table VIII-7 below shows the estimated effects on per-vehicle costs by regulatory alternative in MY 2029:

[3124] *Id*.
[3125] *Id.*
[3126] *See, e.g.*, Jackie Charniga, "Prime buyers flood used-vehicle market in Q4," Automotive News, March 4, 2020, https://www.autonews.com/finance-insurance/prime-buyers-flood-used-vehicle-market-q4.

Table VIII-7 – Average Regulatory Costs (beyond MY 2017) in MY 2029

Scenario Name	Passenger Cars	Light Trucks	Combined
Augural Cafe Standards	2,325	3,275	2,775
0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	1,350	1,425	1,375
0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	1,375	1,450	1,400
1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	1,475	1,825	1,650
1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	1,450	1,950	1,675
1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	1,600	2,300	1,925
2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	1,650	2,400	2,000
2.00%/Y Pc And 3.00%/Y Lt During 2022-2026	1,775	2,750	2,225

*Rounded to nearest $25

Generally speaking, per-vehicle costs increase as stringency increases. The agencies estimate that, by MY 2029, costs for additional fuel-saving technology (beyond that present on vehicles in MY 2017) would average about $2,800 under the augural CAFE standards, as compared to about $1,400 under the proposed CAFE standards, and about $1,650 under the final CAFE standards for MYs 2021-2026. The next most stringent alternative beyond the 1.5 percent alternative is the "2%/3%" alternative. Under 2%/3%, the agencies estimate that costs would increase by $2,000 per vehicle on average. NHTSA understands that many readers may not find an extra $350 per vehicle to be a compelling reason to reject the 2%/3% alternative, or even find an additional $1,125 per vehicle a reason to reject the baseline/augural standards. As the NPRM discussed, "…the corresponding up-front and monthly costs may pose a challenge to low-income or credit-challenged purchasers. …such increased costs will price many consumers out of the market—leaving them to continue driving an older, less safe, less efficient, and more polluting vehicle, or purchasing another used vehicle that would likewise be less safe, less efficient, and more polluting than an equivalent new vehicle."[3127] This continues to be a concern: for example, the average MY 2025 prices estimated here under the baseline, final, and 2%/3% CAFE standards are about $38,100, $36,850, and $37,150, respectively. The buyer of a new MY 2025 vehicle might thus avoid the following purchase and first-year ownership costs under the final standards as compared to the baseline standards or 2%/3% standards:

[3127] 83 FR at 43222 (Aug. 24, 2018).

Table VIII-8 - Example Calculations of Transactional Costs Associated with New Vehicle Purchases Under Baseline, Final, and 2%/3% Standards

	Due at purchase					**Monthly**				
	Baseline	Final	2%/3%	Savings Final vs. Baseline	Savings Final vs. 2%/3%	Baseline	Final	2%/3%	Savings Final vs. Baseline	Savings Final vs. 2%/3%
Down payment[3128]	4,458	4,311	4,347	147	36					
Taxes and fees	2,080	2,012	2,028	68	16					
Loan payments						558	539	544	19	5
Collision and comp.						58	56	57	2	1
Total	6,538	6,323	6,375	215	52	616	595	601	21	6
Total (68 months)	6,538	6,323	6,375	215	52	41,888	40,460	40,868	1,428	408

While the buyer of the average vehicle would also purchase somewhat more fuel under the final standards than the baseline standards, this difference might average less than four gallons per month during the first year of ownership. Some purchasers may consider it more important to avoid these very certain (e.g., being reflected in signed contracts) cost savings than the comparatively uncertain (because, e.g., some owners drive considerably less than others, and may purchase fuel in small increments as needed) fuel savings. For some low-income purchasers or credit-challenged purchasers, the cost savings may make the difference between being able or not to purchase the desired vehicle. As vehicles get more expensive in response to higher CAFE standards, it will get more and more difficult for manufacturers and dealers to continue creating loan terms that both keep monthly payments low and do not result in consumers still owing significant amounts of money on the vehicle by the time they can be expected to be ready for a new vehicle. These considerations were discussed in the NPRM and they remain true for this final rule.

Per-vehicle cost and fuel economy both affect sales estimates in the final rule analysis. Table VIII-9 below shows the estimated effects on fleet-wide sales by regulatory alternative from 2017-2030, where the augural standards represent absolute sales and all other alternatives represent increases relative to the augural sales:

[3128] Edmunds estimates that the average down payment for a new vehicle in 2019 was 11.7% of the vehicle's price, see https://www.edmunds.com/car-buying/how-much-should-a-car-down-payment-be.html

Table VIII-9 – Estimated Sales Impacts by Alternative

Year	Augural Cafe Standards	0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	2.00%/Y Pc And 3.00%/Y Lt During 2022-2026

The final rule analysis indicates that industry sales decrease as stringency increases, and increase as stringency decreases. While sales under both the proposal and the final rule are comparable, each represents about a 1.5 percent reduction in total sales over the period from 2017 – 2030. In the context of 16-17 million new vehicle sales annually, NHTSA does not believe that the sales volume effects here, while significant, are necessarily determinative for economic practicability, even after accounting for fuel economy effects in the sales analysis as some commenters recommended. That said, NHTSA recognizes that the final rule sales analysis does not account for a number of factors that could cause differences between alternatives to result in changes in new vehicle sales (perhaps greater). For example, as explained above, NHTSA remains concerned that significant increases in fixed upfront prices (which for many people translate to monthly financing costs) are harder for certain segments of new vehicle buyers to manage than fuel costs, which can be managed to some extent through vehicle switching or travel decisions. The sales analysis for this final rule indicates that more stringent standards tend to result in higher light truck sales and lower passenger car sales. While NHTSA does not have specific information (or a vehicle choice model) to inform the agency about which consumers (by income) buy which vehicles, and while NHTSA acknowledges that it does not account for price cross-subsidization by manufacturers to keep "entry-level" new vehicle (often, passenger car) prices low, NHTSA continues to be concerned about the possibility of a bubble in the market for new vehicles. As the Wall Street Journal reported in November 2019, "Some 33% of people who traded in cars to buy new ones in the first nine months of 2019 had negative equity, compared with 28% five years ago and 19% a decade ago, according to car-shopping site Edmunds…. Rising car prices have exacerbated an affordability gap that is increasingly getting filled with auto debt."[3129] The sales analysis for this final rule does not directly account for these effects, but NHTSA is concerned that they may be considerable. NHTSA notes that this analysis does not take into account potential economic turmoil or recession, which may have a significant impact on vehicle sales and industry viability.[3130]

The final rule analysis also looked at employment effects under the different regulatory alternatives. A number of commenters argued that more stringent standards improved employment opportunities, as shown in the NPRM analysis and in other analyses, due to the need for workers to manufacture the additional technology needed to meet those more stringent standards. Similar to the NPRM analysis, the agencies' updated analysis shows labor utilization, on balance, increasing slightly with stringency, as this effect outweighs the opposing effect of changes in vehicle sales. Table VIII-11 below shows the estimated effects on U.S. auto industry employment by regulatory alternative in MY 2029:

[3129] AnnaMaria Andriotis and Ben Eisen, "A $45,000 Loan for a $27,000 Ride: More Borrowers are Going Underwater on Car Loans," Wall Street Journal, November 9, 2019.
[3130] Letter from Alliance for Automotive Innovation, NADA, and MEMA to Congress, Mar. 23, 2020, available at https://www.autosinnovate.org/wp-content/uploads/2020/03/COVID-19-Letter-to-Congress-NADA-MEMA-AAI-March-23.pdf.

Table VIII-10 - Estimated Industry Labor Utilization in 2029

Scenario Name	Person Years
Augural Cafe Standards	1,203,232
0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	1,185,903
0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	1,185,778
1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	1,189,758
1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	1,190,486
1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	1,194,963
2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	1,196,318
2.00%/Y Pc And 3.00%/Y Lt During 2022-2026	1,199,720

It is important to note, however, that the reduction in person-years described in this table merely reflects the fact that, when compared to the standards set in 2012, fewer jobs will be specifically created to meet infeasible regulatory requirements. It is also important to note that the $15 billion in avoided required technology costs (in MY 2029) can be invested by manufacturers into other areas, or passed on to consumers. Moreover, consumers can either take those cost savings in the form of a reduced vehicle price, or used toward the purchase of specific automotive features that they desire (potentially including a more-efficient vehicle or optional safety features that can reduce risk of injury or death for all vehicle occupants on the road), which would increase employment among suppliers and manufacturers.

Generally speaking, the agencies' analysis shows net labor utilization increasing with stringency, because the additional labor utilization involved with producing additional fuel-saving technology outweighs the foregone labor utilization involved with the foregone sales. As indicated above, for the scope of labor utilization accounted for in today's analysis, the agencies show about 1.20 million person-years under the augural CAFE standards and about 1.19 million person-years under either the proposed or final standards. As for sales, it is arguably instructive to consider these estimates in the broader context of U.S. employment. BLS data indicates that roughly 129 million people in the U.S. are employed full-time at the time of writing,[3131] and that roughly 1.4 million people were employed in motor vehicle and motor vehicle equipment manufacturing in 2018.[3132] The agencies estimate that, compared to the augural standards, the final standards will reduce automotive labor utilization associated with production of the MY 2029 fleet by about 1.1%, a slightly smaller reduction than the 1.4% estimated to occur under the proposed standards. For comparison, the Synapse Report cited often by commenters concluded that vehicle standards result in "nationwide employment increases of more than 100,000 in 2025 and more than 250,000 in 2035…these increases represent less than 0.2 percent of current U.S.

[3131] https://www.bls.gov/cps/cpsaat08.htm.
[3132] https://www.bls.gov/cps/cpsaat18b.htm.

employment levels."[3133] Even at these levels, which NHTSA does not necessarily agree are accurate, the employment effects of standards are in the range of the average of more than 216,000 jobs added to the U.S. economy *during each month* of 2018.[3134] That said, as for sales, NHTSA recognizes that the final rule labor utilization analysis does not account for a number of factors that could cause differences between alternatives to be different (perhaps greater), as discussed further below.

(b) Application Rates for New Technologies as Part of Economic Practicability

The sales analysis for this final rule also does not account for the potential consumer acceptance issue of more stringent standards effectively requiring the application of technologies not yet ready for widespread deployment. As widely noted, the 2012 rule assumed extremely high penetration of dual-clutch transmissions in response to standards. While the agencies stated throughout that final rule that the analysis was not meant to represent the expected response to the standards, Ford did apply DCTs to a number of vehicle models in its fleet, that resulted in major customer satisfaction issues and ultimately caused extensive buyback campaigns, customer service programs, and class-action litigation.[3135] Sales can be impacted as a result of standards if technologies applied in response to those standards have operational, maintenance, or customer acceptance problems, or if consumers are unwilling to pay for it. Manufacturer capital to develop and add new technologies and manage these rollout issues is finite, as discussed. Insufficient capital can also cause quality problems. The cost effects modeled in this final rule analysis, that drive the sales and scrappage analyses, only include technology costs and RPE—they do not include the cost of stranded capital or lost consumer surplus, which are things that could drive up costs, drive down benefits, and therefore impact sales and scrappage beyond what today's analysis shows.

As Section IV above notes, a great deal of fuel economy-improving technology has already been added to the fleet since 2012, which means that the amount of fuel economy-improving technology left to be added in response to higher standards is less than it was assumed to be in 2012. Looking at the technology penetration rates modeled in today's analysis, it appears that the augural standards are projected to require nearly 20 percent total electrification in MY 2029, while the proposal would have required nearly 7 percent and the final standards would require nearly 8 percent. Table VIII-11 below shows projected electrification rates by 2029 for the regulatory alternatives—electrification refers to all models with strong hybrids, PHEVs, or full EVs:

[3133] https://www.synapse-energy.com/sites/default/files/Cleaner-Cars-and%20Job-Creation-17-072.pdf, at ES-2.
[3134] Payroll employment increased by 2.6 million jobs in 2018, an average of 216,667 per month. "The Employment Situation – December 2018," Bureau of Labor Statistics, available at: https://www.bls.gov/news.release/archives/empsit_01042019.pdf.

Table VIII-11 – Electrification Rates by Alternative

Scenario Name	Strong Hybrid	Plug-In Hybrid	BEV	Total
Augural Cafe Standards	12.4%	6.5%	0.6%	19.6%
0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	4.4%	1.8%	0.7%	6.9%
0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	4.4%	1.9%	0.7%	6.9%
1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	5.3%	1.9%	0.7%	7.9%
1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	5.0%	1.9%	0.7%	7.6%
1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	7.0%	2.4%	0.7%	10.0%
2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	6.7%	2.5%	0.7%	9.9%
2.00%/Y Pc And 3.00%/Y Lt During 2022-2026	8.0%	3.4%	0.7%	12.1%

As the table shows, the analysis projects that meeting the augural standards could require over twice as much electrification as the final rule standards could require.[3136] The current market penetration for all such vehicles is only approximately 4 percent even though the technology is well-established, with hybrids having been first introduced with the Honda Insight in 1999 and Toyota Prius in 2000, plug in hybrids with the Chevrolet Volt in late-2010 and electric vehicles with the Tesla Roadster in 2008 and Nissan Leaf in late 2010. As Mr. Kreucher commented, and as Figure VIII-2 shows, consumers appear to be driven by fuel price. Given anticipated fuel prices during this timeframe and evidence in the market today of cannibalization within these vehicle segments (not to mention the continued phasing out of government incentives for these vehicles),[3137] NHTSA is concerned that there could be consumer acceptance

[3136] While NHTSA is prohibited by statute from considering battery electric vehicles as a compliance mechanism, we are aware that many OEMs will likely opt to produce a smaller number of fully electric vehicles rather than a large number of strong hybrid models.

[3137] 26 U.S.C. Section 30D provides for tax credits ranging from $2,500 to $7,500 for purchasers of qualifying plug-in hybrid (PHEV) and battery electric (BEV) vehicles, with a phaseout applying to vehicle manufactured by an automaker once they sell 200,000 qualifying vehicles. Both Tesla and General Motors have reached this threshold and the tax credit applicable to purchasers of new PHEV and BEV vehicles from those manufacturers has been reduced gradually and will phase out completely on January 1, 2020 for Tesla, and April 1, 2020 for General Motors.

The California Clean Vehicle Rebate Project was launched in 2010 to provide incentives of up to $5,000 for purchasers or lessees of qualifying PHEV, BEV, and certain other alternative fuel vehicles. Since then, the program has undergone significant changes, including the addition of income eligibility criteria for certain incentives, and excluding eligibility toward the purchase or lease of a vehicle with an MSRP exceeding $60,000.

Separately, in 2005, California passed a law allowing hybrid electric vehicle (HEV), plug in hybrid electric vehicle (PHEV), and battery electric vehicle (BEV), and other qualifying alternative fuel vehicle owners to apply for a sticker allowing single-occupant access to High Occupancy Vehicle (HOV) lanes. HEV access was phased out in 2011, with eligibility being limited to PHEV, BEV and other qualifying alternative fuel vehicle owners. Access is now limited to a four-year period, and only to individuals who do not receive a rebate under the California Clean Vehicle Rebate Project (unless meeting income eligibility requirements).

problems associated with further electrification under more stringent alternatives, which could have sales impacts.

We underscore that the table above simply shows the analytical results of the modeling for today's final rule based upon the most cost-effective means of achieving a given standard– it does *not* show how manufacturers would, or could, comply with the CAFE standards represented by the different regulatory alternatives. The discussion below covers the topic of manufacturer compliance shortfalls, and this discussion and that one are connected: the final rule analysis does not show significant compliance shortfalls under any regulatory alternative, but NHTSA believes that this is in large part because the CAFE model is not programmed with assumptions about consumer acceptance of strong hybrid technologies. In effect, the model lets manufacturers lean on hybridization to achieve compliance at a lower cost than if manufacturers instead pursued, for example, more advanced engine technologies. If cost-effectiveness is the only concern, that may be a valid compliance choice. If consumer acceptance of hybrid vehicles is accounted for, especially in a time of foreseeably low fuel prices, it may not be a valid compliance choice.

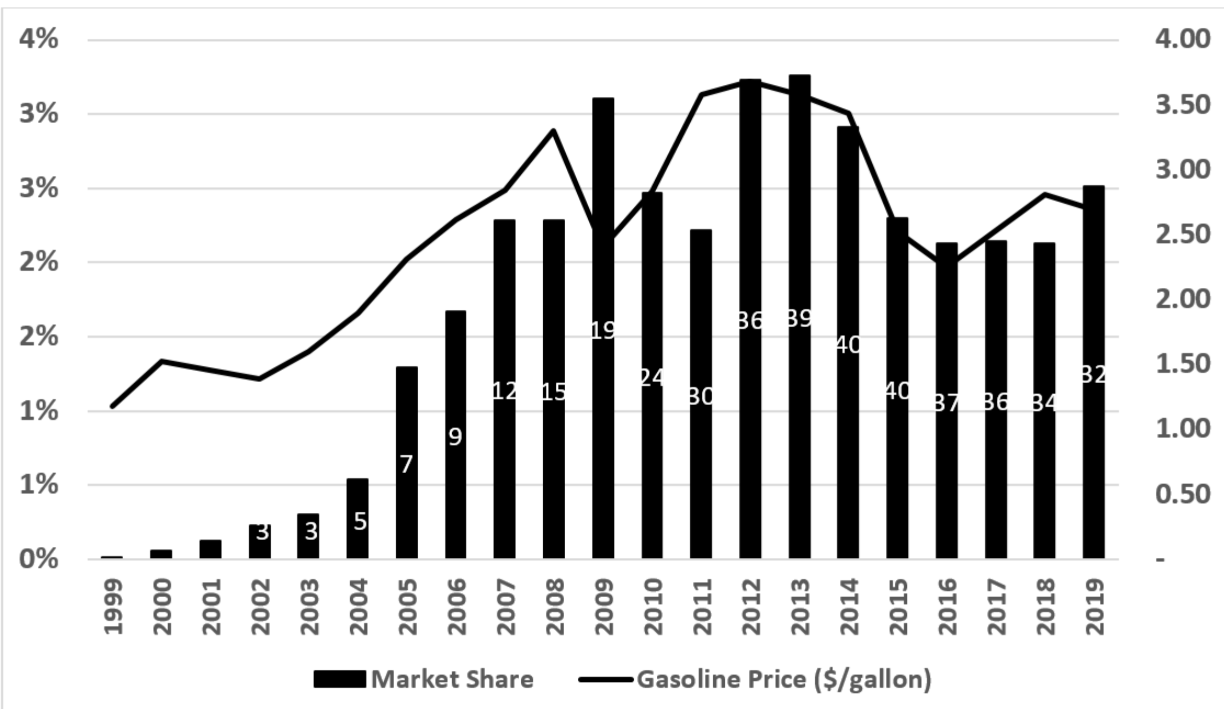

Figure VIII-2 – Strong Hybrid Market Share and U.S. Fuel Prices

As Figure VIII-2 illustrates, the market share of strong hybrids in the new vehicle market has mostly tracked fuel prices. The bars represent the market share (left axis) and the line tracks the price of fuel (on the right axis). The light numbers inside of each bar represent the number of unique strong hybrid models offered for sale in that year. Initially, we see rapid growth that continues during the fuel price increases of the mid-2000s and peaking at around 3.5 percent market share. The figure shows that neither the passage of time, where consumers become more familiar with the technology over successive vehicle purchases, nor the number of models offered for sale have much of an impact on the market share for strong hybrids. Despite a doubling of the number of models offered for sale in subsequent years, market share continued to track fuel price closely, and fell dramatically as prices fell in 2015 and 2016. At fuel prices at or above $3.50/gallon, strong hybrids were able to capture additional market share. However, the current projection does not show prices returning to those levels for quite some time – leaving manufacturers uncertain about their ability to sell strong hybrids in the numbers estimated to be needed to comply with CAFE and CO_2 standards before MY 2026.

The agencies conducted a sensitivity analysis to evaluate the impact of compliance pathways that did not rely on strong hybrids (see Chapter 7 of the FRIA). As we discuss in the sensitivity analysis, in the absence of strong hybrids, compliance pathways tend toward a greater reliance on advanced engines and transmissions, and more aggressive exploitation of opportunities to reduce vehicles' mass. These alternative technology pathways carry with them additional technology costs that increase compliance costs in the baseline and increase the savings associated with the preferred alternative.

Under the CAFE program, where battery electric vehicles are not a compliance option (due to statutory restrictions on their consideration for rulemaking), the additional cost of advanced engine technology in the baseline increases baseline technology cost by about $800 per vehicle, and increases the cost savings under the preferred alternative, which has a much smaller reliance on strong hybrids to achieve compliance, by about $600 per vehicle. This difference is sufficient to change the sign on net social benefits for the preferred alternative to being slightly negative, to being very positive (nearly $80 billion at a 3 percent discount rate). The magnitude of this impact is comparable to the impact of varying fuel price projections.

As shown in, Figure VIII-2 even the preferred alternative requires levels of strong hybridization (and PHEV share) that would be about twice what has been observed at the market, even at its peak. Both the baseline and the 2%/3% alternative have even greater reliance on hybridization – more than twice as much in the baseline. The compliance costs associated with each alternative in today's rule depend upon the estimated levels of hybridization in the compliance scenarios being possible to achieve in the new vehicle market. The sensitivity analysis shows that manufacturers can still reach comparable levels of fuel economy without additional reliance on hybridization, but at significantly higher per-vehicle costs. Those higher costs have implications for the sales response, vehicle retirement rates in the existing vehicle population, and the penetration rate of emerging safety features.

(c) Consumer Demand as Part of Economic Practicability

As discussed above, NHTSA's consideration of consumer demand as relevant to economic practicability has been upheld by the D.C. Circuit in *Center for Auto Safety v. NHTSA*. A number of commenters argued that consumers do, in fact, demand more fuel economy than the NPRM analysis assumed; that consumers will appreciate more widespread application of fuel economy-improving technologies that NHTSA appears to believe they will tolerate; that NHTSA was wrong to assume that fuel prices will remain relatively low in the future and continue to dampen consumer demand for fuel economy; and that vehicle manufacturers will not make tradeoffs between investments in fuel economy improvements and investments in other vehicle characteristics which consumers also demand, such that requiring manufacturers to meet more stringent standards will not impair consumer demand for new vehicles because less of those other characteristics will be available. Those commenters also often highlighted the *CAS* language stating that consideration of consumer demand may not undermine EPCA's goal of energy conservation.

NHTSA agrees with commenters that some consumers seek out vehicle models with higher fuel efficiency, and notes that those consumers have increasing numbers of relatively high-efficiency vehicle models to choose from in the current new-vehicle market, as shown in the previous section. CAFE does not affect fuel economy improvements that are supported by consumer demand—market forces will take care of that. Instead, it specifically addresses fuel economy improvements that are *not* preferred by consumers, and the agency sets standards that require manufacturers to make fuel economy improvements that consumers are not otherwise seeking. Section IV.B.3 discusses at some length the fact that alternative powertrains and higher fuel-efficiency vehicle models have proliferated widely since 2011—consumers no longer lack for choice if fuel economy is what they want. NHTSA's concern regarding consumer demand is that in an era of relatively low gasoline prices—as EIA currently projects and NHTSA has no basis to second-guess, and which may be even lower than currently projected—it does not appear likely that the market for higher fuel-economy vehicles and alternative powertrains in particular will increase significantly in the rulemaking timeframe, beyond the 30-month payback period that the agencies currently use as a proxy for market demand for fuel economy. It is worth citing the *CAS* case at greater length here in light of its parallels: as the D.C. Circuit stated in that case,

> [T]he petitioners do not challenge the consideration of consumer demand per se, but rather the weight the agency has given the factor in downgrading standards when, they argue, the principal impracticability is paying a civil penalty [*note: today, using or purchasing credits*]. Until the model years at issue here, there has been little tension between consumer demand and the fuel conservation goals of EPCA. The agency now relies on market projections in a setting in which falling gas prices have relaxed consumer demand for fuel efficiency. Earlier consideration of consumer demand in setting standards could not have alerted Congress to the agency's current application of this factor. Because Congress has not spoken clearly on the issue before us, it must be determined whether the agency's interpretation represents a reasonable accommodation of the policies embodied in the statute.
>
> . . .
>
> The agency concluded that if manufacturers had to restrict the availability of larger trucks and engines in order to adhere to CAFE standards, the effects "would go beyond the realm of 'economic practicability' as contemplated in the Act."[Citation omitted.] The original projections of technological feasibility for the 1985 model year standards were based on the assumption that gasoline prices would remain high and consumer demand for fuel-efficient vehicles would remain strong. No one disputes that actual circumstances have deviated from these assumptions. NHTSA acted within the reasonable range of interpretations of the statute in correcting the 1985 standards to account for these changed conditions. Consideration of product mix effects was also reasonable in setting the standards for 1986, as there is no evidence that the same trends in consumer demand will not continue.

. . .

> In short, while it may be disheartening to witness the erosion of fuel conservation measures in the face of changes in consumer priorities, this court is nonetheless compelled to uphold the agency's standards. They are the result of a balancing process specifically committed to the agency by Congress, and, in this case, the weight given to consumer demand was not outside the range permitted by EPCA.

CAS, 793 F.2d 1322, 1340-41 (D.C. Cir. 1986). As in the situation presented in the *CAS* case, the agencies believed in 2012 based on the evidence then before them that fuel prices would be significantly higher than the fuel prices currently projected today. Using the fuel prices currently projected, which are lower because of the structural changes to the global oil market described at length above, Figure VIII-3 shows the difference in annual fuel consumption for a typical driver under the augural standards, proposed standards, and final standards. As the figure shows, the difference in annual consumption (for a user that drives 14K miles per year[3138]) is fewer than 40 gallons by MY 2030—the largest difference between the alternatives. Rising fuel prices over time increase the value of those forty gallons, but the diminishing returns to successive increases in fuel economy are nonetheless evident.[3139]

[3138] Parts of the central analysis assume a typical new vehicle is driven 14,000 miles per year, for each of the first three years it is owned. In practice, the average is slightly higher, through affected by a smaller number of users that drive much more than average. There is no single value that is representative of all households, and the National Household Travel Survey has shown lower annual usage estimates than 14,000 miles per year for a typical new vehicle.

[3139] In general, because fuel savings are subject to diminishing returns as CAFE standards become more stringent, and per-vehicle costs increase as CAFE standards become more stringent, the relationship between per-vehicle costs and the value of fuel savings is more of a curve than a line, although the slope of the curve is reduced by the fact that we rely on EIA’s forecast of rising fuel prices over time.

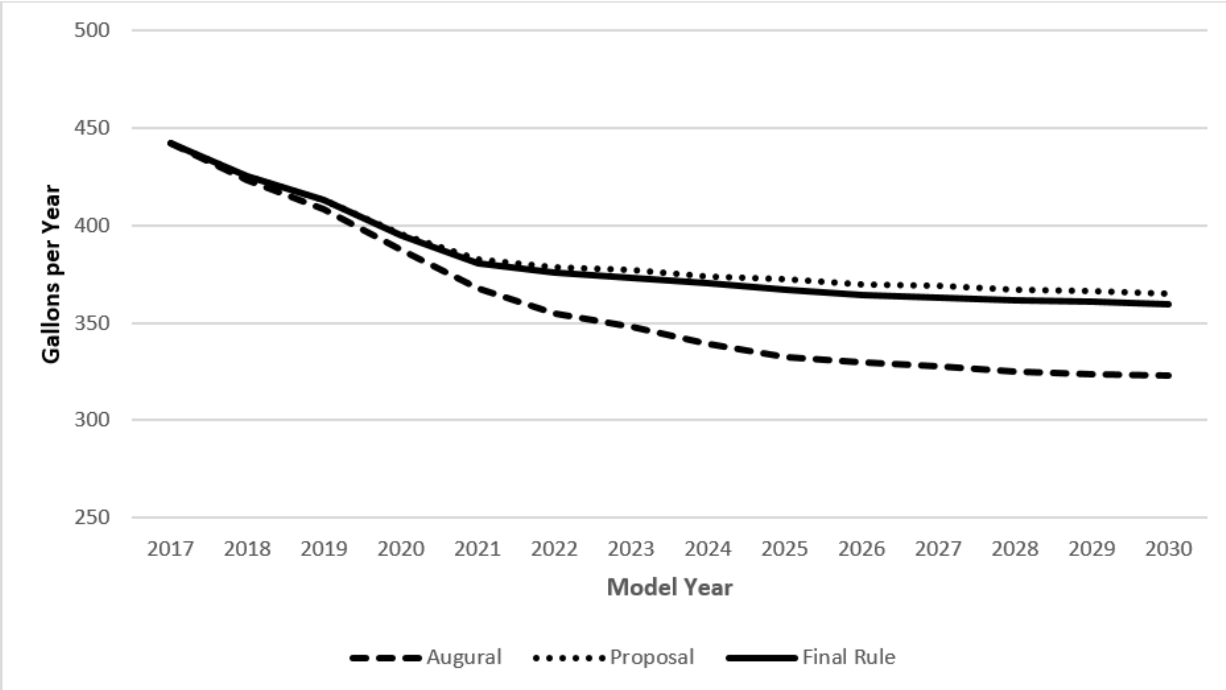

Figure VIII-3 – Annual Fuel Consumption for a Typical Driver

Thus, on the supply side, greater and more stable global oil supply, which reduces projected fuel prices, means that the benefits of more stringent CAFE standards are lower than they appeared to be in 2012 when the agencies believed oil supply would be scarcer and less stable, and projected fuel prices were consequently higher.

On the demand side, as already explained, while NHTSA agrees that some consumers do seek out higher fuel economy, those consumers have vastly more higher fuel-economy-vehicle options than they did when the agencies wrote the 2012 final rule, as shown in Section IV above. For the other consumers who are driven more by the economics of their vehicle-purchasing decisions, NHTSA believes that they are likely making reasonably informed decisions about the new vehicle attributes they want in light of expectations about future fuel costs. This can be illustrated by examining estimated payback periods under the different regulatory alternatives, because payback period directly compares estimated future fuel savings with estimated vehicle purchase and ownership costs. A number of commenters suggested that per-vehicle cost was not a meaningful metric in isolation, because consumers would also be saving money on fuel under more stringent standards. The agencies discuss affordability issues further below, but the rulemaking presents Table VIII-12 here as a comparison of per-vehicle costs to lifetime fuel savings to illustrate the point raised by commenters:

Table VIII-12 – Fuel Savings and Consumer Costs in MY 2029

Scenario Name	Lifetime Fuel Cost ($)*	Regulatory Cost (vs. 2017)	Registration Costs ($)	Payback Period (years)
Augural Cafe Standards	21,771	2,770	5,158	5.0
0.00%/Y Pc And 0.00%/Y Lt During 2021-2026	23,967	1,383	4,919	4.6
0.50%/Y Pc And 0.50%/Y Lt During 2021-2026	23,925	1,409	4,922	4.6
1.50%/Y Pc And 1.50%/Y Lt During 2021-2026	23,570	1,641	4,962	4.6
1.00%/Y Pc And 2.00%/Y Lt During 2021-2026	23,501	1,676	4,968	4.6
1.00%/Y Pc And 2.00%/Y Lt During 2022-2026	23,079	1,922	5,013	4.5
2.00%/Y Pc And 3.00%/Y Lt During 2021-2026	22,938	1,993	5,026	5.0
2.00%/Y Pc And 3.00%/Y Lt During 2022-2026	22,604	2,222	5,067	5.0

*Fuel savings are undiscounted for purposes of estimating payback period because payback periods and discount rates are interchangeable concepts, and today's analysis represents consumer wiliness-to-pay for fuel economy by a 2.5 year desired payback period.

Table VIII-12 shows the differences in regulatory costs, other registration costs (taxes and financing, though the cost of insurance also increases to cover more expensive vehicles), lifetime fuel savings, and the payback relative to a MY 2017 vehicle. It is important to compare apples to apples, so in this case, because the agencies are considering fuel costs over a vehicle's full lifetime, this rulemaking needs to compare that against a broader lifetime cost of ownership, instead of comparing it simply to the estimated increase in initial purchase price. Under the augural standards, the analysis projects that it would take a full five years for the undiscounted value of fuel savings to offset the estimated upfront increase in purchase cost (relative to a MY 2017 vehicle). For reference, the average new car buyer holds on to that car for about six or seven years.[3140] Naturally, this payback period, and the fuel savings on which it is based, depend upon fuel prices. Higher fuel prices shorten payback periods, while declining fuel prices lengthen them. For this analysis, the agencies have employed fuel prices estimated using the version of NEMS used to produce AEO 2019, as discussed in Section VI.

Thus, all of the regulatory alternatives considered in today's analysis result in significantly longer payback periods than the 2.5 years assumed by the agencies, the industry, and the NAS—i.e., while fuel economy would foreseeably improve in the rulemaking timeframe in the absence of regulation, it would do so at a rate slower even than the proposal would have

[3140] IHS Markit estimates the average length of new vehicle ownership at about 79 months, see https://www.forbes.com/sites/jimgorzelany/2018/01/12/the-long-haul-15-vehicles-owners-keep-for-at-least-15-years/#4e971b576237.

required.[3141] NHTSA thus does not expect that consumer demand for fuel-efficient vehicles will grow significantly in the rulemaking timeframe without regulation to prop up manufacturer sales of significantly larger volumes of more fuel-efficient models. This increases the economic practicability of regulatory alternatives that represent less stringent standards, as compared to those that represent more stringent standards.

(d) Manufacturer Compliance Shortfalls as Part of Economic Practicability

Manufacturer compliance shortfalls given the pace of increase in standard stringency over time are also relevant to economic practicability, and were considered as part of the 2012 final rule. Some commenters argued that it was not reasonable for NHTSA to interpret automakers' fuel economy improvements over time as evidence that less stringent standards might be maximum feasible, suggesting that evidence of improvements means that improvements are possible, and that automakers' stated difficulties with meeting more stringent standards may be overstated. Fleet fuel economy improvements over time have been possible, NHTSA agrees. NHTSA does not agree, however, that improvements thus far constitute *de facto* evidence of automakers' ability to meet rapidly increasing standards indefinitely into the future. Section IV above illustrates this clearly—many more very fuel-efficient models are available now than in 2012, while fuel prices have been trending downward on an absolute basis over the same time period. Simultaneously and relatedly, the rate at which various manufacturer fleets have been falling short of their standards has been increasing steadily. As Section IV explains, at the time of the 2012 analysis, most manufacturers were in reasonable shape in terms of compliance. The total fleet outperformed CAFE standards by a full mile per gallon—reflecting the historical trend that the full fleet *always* exceeds the average fuel economy target.[3142] Of the then 45 import passenger car, domestic passenger car, and light truck compliance fleets in the 2012 model year, 26 of the fleets exceeded their fuel economy targets, while 19 failed to meet their standard.[3143] Of those 19 fleets that failed to meet their standard, the total shortfall was 41,033,802 credits—the equivalent of $225,685,911 in penalties.[3144] That is no longer the case. 2016 marked the first model year in CAFE history that the entire light duty

---

[3141] While presented at the industry level, technology application and compliance simulation occur at the level of each individual manufacturer's respective fleets. Some OEMs and fleets are able to increase CAFE more easily than others—starting from more favorable positions and adding less expensive technology, or taking advantage of credit provisions, to improve the fuel economy of their fleets. However, for several OEMs, even the proposed standards are binding, and the costs associated with bringing their fleets into compliance are significant. At the level of the industry average, the cost of compliance with the proposal—and as a corollary, with the other alternatives—exceeds the 2.5 year payback for fuel economy technology, even while a small amount of overcompliance occurs at the industry level.

[3143] NHTSA MY 2011-2019 Industry CAFE Compliance, https://one.nhtsa.gov/cafe_pic/MY%202011-MY_2019_Credit_Shortfall_Report_v08.pdf.

[3144] *Id*. While we denominate shortfalls in terms of credits, that is simply for convenience, and any given manufacturer's shortfall is measured in tenths of a mile per gallon for compliance purposes.

fleet failed to meet its target.[3145] This continued in the 2017 model year (the most recent full model year of compliance data).[3146] In the 2017 model year, of the now 42 compliance fleets, only 14 fleets exceeded their targets.[3147] 25 failed to meet their target, with a total shortfall of 166,715,863 credits—the equivalent of $1,133,430,584 in penalties.[3148] Required manufacturer reporting data shows the situation continuing to get worse in the 2018 and 2019 model years,[3149] despite manufacturers' increasing ability to utilize generous credit provisions related to alternative fueled vehicles and A/C efficiency and off-cycle adjustments.

Although each year has continued to see improvements in fuel economy performance, each successive increase in stringency requires many fleets not only to achieve the new level from the resulting increase, but to resolve deficits from the prior year as well. The problem is particularly marked in the light truck fleet, where sales of lower fuel-economy vehicles have proliferated over this time period, despite availability of higher fuel-economy models. But the passenger car fleet is facing compliance challenges as well, as more consumers have shifted away from sedans and into crossover utility vehicles that are considered passenger cars for compliance purposes. While the agencies' move toward footprint based standards account for vehicle length and track width—which certainly affect fuel economy as described above—they do not account for mass-intensive increases in vehicle ride height that crossover purchasers value, the additional frontal area and higher drag at highway speeds, or the additional power required to achieve similar performance as the equivalent sedan. These issues are further exacerbated by the fact that consumers are demanding more powerful engines than the baseline efficient four cylinder versions the agencies assumed consumers would find acceptable, instead opting to upgrade to more powerful powertrains.[3150] If the augural standards were finalized and energy prices remain as currently projected, the shortfall situation could well erase large portions of assumed fuel savings/emissions reduction benefits from higher standards.

In the current analysis, gasoline prices are projected to rise steadily from about $2.50/gallon in 2017 to $3.5/gallon by 2035. While CAFE can provide some insurance against unexpected and sudden price increases, in the case of sustained, consistent increases in gasoline prices, market demand for fuel economy would outpace the standards over time. In an earlier analysis, the agencies considered the impact of a sudden gasoline price shock in a single year, where the price of gasoline jumped from $3.50/gallon to $6/gallon for most of a year. If instead of that one-year spike, the price of gasoline rose steadily from current levels to $6/gallon by 2040, the response of both consumers and manufacturers in the marketplace would cause the industry to consistently over-comply with even the augural standards.[3151] The payback

[3149] *Id*.
[3150] Mr. Rykowski's comments for EDF, for example, stated that EPA's recent Fuel Economy and CO_2 Trends Reports show clearly that manufacturers have been improving vehicle performance at the expense of fuel economy. *See* NHTSA-2018-0067-12018, at 31.
[3151] We simulated this response in the CAFE Model, where all other inputs were identical to the central analysis.

assumption in this analysis, where consumers are willing to pay for any fuel economy improvement that pays for itself in the first 2.5 years of vehicle usage, would likely be too short in a world with $6/gallon gasoline, where the cost of operating a vehicle consumed a larger share of a household's budget and even longer payback periods could be seen as sound investments. Thus, if it turns out that fuel prices rise steadily over the next decade, at a significantly faster rate than currently projected, the market will end up demanding more efficient vehicles and the gap between the baseline and the preferred alternative will shrink further. However, the agencies do not currently have information that projects $6/gallon fuel in 2040 is likely, for the reasons discussed at length above.

As also discussed above, while the analysis for this final rule does not show significant shortfalls under any regulatory alternative, that appearance of compliance is predicated on the assumption that automakers will be able to sell the hybrids that we simulate them producing in response to the standards. Again, given foreseeably low fuel prices going forward, it is also foreseeable that selling greater volumes of hybrid vehicles will be even more difficult than at present. It is very possible that manufacturer compliance shortfalls could end up being worse than the agency's analysis currently forecasts for the more stringent alternatives.

Given the ongoing shortfall problem illustrated above, and given the payback period estimates, the proposal might appear to be the correct answer in the absence of other considerations. NHTSA believes that the bubble concerns may be significant, and the diminishing returns of higher standards identified in Section IV above calls into question the value of pushing that bubble. Compliance shortfalls represent a growing problem with the current standards and will continue to be a problem if stringency does not converge at least somewhat more closely with what the market appears willing to bear. If industry is unable to comply with standards, that non-compliance means that the standards are not achieving what they set out to achieve in terms of fuel savings or emissions reductions, or at least they are not achieving what NHTSA estimated they would achieve. The NPRM disagreed with the idea that "if you build it, they will come"—that manufacturers would find a way to market higher fuel-economy vehicles, and consumers would eventually buy them. Comments on that topic were mixed: some commenters agreed with the NPRM's sentiment, while other commenters argued that manufacturers' past ability to exceed standards combined with consumers' growing interest in fuel economy/lower emissions meant that concerns about the market's ability to bear further increases were misplaced. The shortfall discussion above and in Section IV suggests that the NPRM's sentiment may be accurate, but this difference in perspective highlights the core philosophical question of the CAFE program—whether consumers should choose for themselves how much fuel economy they want, or whether the government should choose for them.

(4) Considering Safety Along with the Other Factors in Determining Maximum Feasible Standards

In addition to the above, as explained in the NPRM and as discussed extensively by commenters, NHTSA considers safety effects in determining maximum feasible CAFE standards. A number of commenters objected to aspects of the safety analysis, as discussed in Section VI above, and some made suggestions for improvement. In response to those comments, NHTSA took a very conservative approach in making a number of changes to the safety analysis for this final rule:

- Commenters disagreed with certain aspects of the sales and scrappage effects on the safety analysis; in response to those comments, changes have been made and the scrappage effect on fatalities is lower now than it was in the NPRM;
- Commenters disagreed with certain aspects of mass reduction; in response to those comments, changes have been made there;
- Commenters argued that additional technologies should be accounted for; in response to those comments, many of those technologies have been added;
- Commenters argued that the NPRM did not account for crash avoidance technologies; in response to those comments, the final rule accounts for the effects of crash avoidance technologies;
- Commenters argued that the NPRM did not account for the mortality/morbidity effects of criteria pollution differences between the alternatives; in response, the final rule accounts for these effects explicitly in these values.

Overall, the final rule analysis suggests that fatalities may be lower than the NPRM analysis showed; injuries may be greater; and the safety effects overall are less than the NPRM suggested, but they are still significant. Less-stringent standards remain better for safety and are projected to save thousands of lives and prevent tens of thousands of hospitalizations, even if the amount by which they are better is lower than previously estimated.

EPCA/EISA directs NHTSA to conserve energy and consider the need of the U.S. to conserve energy, while simultaneously directing NHTSA to set attribute-based standards whose outcome varies depending on what consumers choose to buy, and directing NHTSA to consider economic practicability. The greater the need of the U.S. to conserve energy, the more the government should decide for consumers how much fuel economy will be in their new vehicles. Based on the information before NHTSA in this final rule, NHTSA agrees with the commenters who suggested that increasing CAFE stringency can function as “insurance” against future oil price volatility, although as illustrated above, the short-term effects of that insurance may be relatively minor and the longer-term effects may be too uncertain to consider meaningfully. NHTSA also agrees that environmental considerations necessitate energy conservation, though the long-term benefits of emissions reductions (even accounting for the increased costs of delayed action) require consideration of the immediate costs to consumers, the industry, and the environment.

Balancing all of the factors and issues identified above, NHTSA concludes that standards that increase at 1.5% per year are the maximum feasible for passenger cars and light trucks for MYs 2021-2026, based on the information currently before the agency. We recognize that more stringent standards, including the baseline/augural standards, could conserve more energy and might be technologically feasible (in the narrowest sense), but the additional incremental fuel savings, emissions reductions, and environmental benefits of higher standards is not significant enough to outweigh the immediate economic costs. There is still risk to the U.S. from circumstances outside our control that the CAFE program may be able to mitigate, but there must also be recognition of the limited extent to which this program can address that risk, certainly without exacerbating considerable challenges currently being faced by automakers, dealers, and consumers. Economic practicability would be best served by slower increases, as discussed above. And while these two factors weigh in different directions, NHTSA has discretion to accommodate conflicting statutory priorities in a reasonable manner. Beginning with MY 2021, the first MY addressed by this rule, Congress eliminated the obligation to increase FE standards ratably.[3152] Thus, the appropriateness of an increase, if any, is within NHTSA's discretion based on its balancing of statutory factors.[3153]

In past rulemakings, as discussed above, NHTSA has expressly considered the point at which net benefits appear to be maximized as potentially relevant to determining maximum feasible CAFE standards.[3154] Whether the standards maximize net benefits has thus been a significant, but not dispositive, factor in the past for NHTSA's consideration of economic practicability. Executive Order 12866, as amended by Executive Order 13563, states that agencies should "select, in choosing among alternative regulatory approaches, those approaches that maximize net benefits. . ." In practice, however, NHTSA must consider that the modeling of net benefits does not capture all considerations relevant to the EPCA statutory factors. Additionally, nothing in EPCA or EISA mandates that NHTSA set standards at the point at which net benefits are maximized, and case law confirms that whether to maximize net benefits in determining maximum feasible standards is within NHTSA's discretion.[3155] As explained extensively in prior rulemakings, even if the agency believed it could quantify enough relevant factors to determine the CAFE levels at which net benefits were maximized with reasonable accuracy, there may be other considerations which lead the agency to conclude that maximum feasible CAFE standards are not the ones that maximize net benefits. For example, in 2012, NHTSA rejected the regulatory alternative that appeared to maximize net benefits (and all alternatives more stringent than that one) based on the conclusion that even though net benefits

---

[3152] Previously applied for MYs 2011-2020.
[3153] NHTSA also notes that it was expressly anticipated in the 2012 final rule that the current rulemaking could determine that the augural standards were not maximum feasible. NHTSA stated that "Whether different alternatives may be maximum feasible can also be influenced by differences and uncertainties in the way in which key economic factors (*e.g.*, the price of fuel and the social cost of carbon) and technological inputs could be assessed and valued. While NHTSA believes that our analysis for this final rule uses the best and most transparent technology-related inputs and economic assumption inputs that the agencies could derive for MYs 2017-2025, *we recognize that there is uncertainty in these inputs, and the balancing could be different if the inputs were different. When the agency undertakes the future rulemaking to develop final standards for MYs 2022-2025, for example, we expect that much new information will inform that future analysis, which may potentially lead us to choose different standards than the augural ones presented today*." (emphasis added) 77 FR at 63037 (Oct. 15, 2012).
[3154] *See*, *e.g.*, the 2006 final rule, which concluded that the point at which net benefits were maximized *was* the maximum feasible CAFE level (71 FR 17566 (Apr. 6, 2006)); the 2010 final rule, which considered among the regulatory alternatives one that maximized net benefits, but explained that nothing in EPCA or EISA mandated that NHTSA choose CAFE standards that maximize net benefits (75 FR 25324, at 25606, 25167 (May 7, 2010)); and the 2012 final rule, which also considered among the regulatory alternatives one that maximized net benefits, and also explained that nothing in EPCA or EISA mandated that NHTSA choose CAFE standards that maximize net benefits, in fact, directly rejecting the regulatory alternative that maximized net benefits as beyond maximum feasible for the MYs 2017-2025 timeframe (77 FR 62624 (Oct. 15, 2012)).
[3155] The Ninth Circuit has agreed with NHTSA that "EPCA neither requires nor prohibits the setting of standards at the level at which net benefits are maximized," stating further that "The statute is silent on the precise question of whether a marginal cost-benefit analysis may be used. See Chevron, 467 U.S. at 843, 104 S.Ct. 2778. Public Citizen and Center for Auto Safety persuade us that NHTSA has discretion to balance the oft-conflicting factors in 49 U.S.C. 32902(f) when determining "maximum feasible" CAFE standards under 49 U.S.C. 32902(a)." CBD v. NHTSA, 538 F.3d 1172, 1188 (9th Cir. 2008).

were maximized, the "resultant technology application and cost" were simply too high, and thus made those standards economically impracticable, and thus beyond maximum feasible.[3156]

Table VII-95 and Table VII-96 of the Preamble appear to suggest that net benefits would be maximized under a 3 percent discount rate by choosing the 2%/3% alternative, and under a 7 percent discount rate by choosing the 0% (proposed) alternative. Across all alternatives under either discount rate, the variation in net benefits is within $20 billion over the lifetimes of vehicles produced during the rulemaking timeframe. While $20 billion may seem like a large amount of money, it must be understood within context – the auto industry accounted for approximately $89 billion of U.S. GDP in 2018 alone,[3157] and Americans spent approximately $370 billion on gasoline in 2019 alone.[3158] For a program this large, if the difference between the net benefits created by different regulatory alternatives is within $20 billion (over the full lifetimes of six model years), the net benefits are relatively small. Furthermore, given how close together the net benefits are across the range of regulatory alternatives considered, NHTSA does not believe that the point at which net benefits are maximized is meaningful for determining maximum feasible CAFE standards in this final rule.

Important to that conclusion is the fact that the net benefits estimates produced by the analysis depend heavily on EIA's future forecasts of fuel prices, which were made prior to the recent collapse of oil prices. If the former OPEC+ members continue to pursue market share, fuel prices will likely continue to drop. If, instead of pursuing market share, they try to control prices by restricting supply, U.S. shale production can ramp back up and exert downward pressure on price. If fuel prices end up even lower than our analysis assumes, benefits from saving additional fuel will be worth even less to consumers. Our analysis captures none of these effects. Depending upon future fuel prices, net benefits estimates described above could foreseeably be overstated, possibly by a significant amount. It is possible, depending on future fuel prices, that the final rule 1.5 percent annual increase standards could end up being more stringent than standards that would maximize net benefits. Moreover, sustained low oil prices can be expected to have real effects on consumer demand for additional fuel economy, which will have real effects on sales, jobs, and many other things relevant to NHTSA's consideration of what standards would be maximum feasible. Choosing a regulatory alternative more stringent than the final rule's 1.5 percent annual increases could foreseeably either lead to more hybridization than the market is likely to bear given foreseeably low fuel prices, or lead to significantly more cost than the analysis currently suggests. Neither of those outcomes would be

---

[3156] 77 FR at 63050 (Oct. 15, 2012).
[3157] *See* Bureau of Economic Analysis, GDP by Industry, "Value Added by Industry," Oct. 29, 2019, https://apps.bea.gov/iTable/iTable.cfm?ReqID=51&step=1 (accessed Mar. 18, 2020)
[3158] Using EIA estimates of an average of $2.60/gallon gasoline cost in 2019 (https://www.eia.gov/todayinenergy/detail.php?id=42435) and EIA estimates of about 142 billion gallons total gasoline consumed (https://www.eia.gov/tools/faqs/faq.php?id=23&t=10).

beneficial for consumers or for industry, even considering the additional fuel savings for consumers.[3159]

NHTSA concludes that steady increases at 1.5 percent annually, with the same rate for cars and trucks as suggested by several commenters, are the optimal way to move the needle forward on fuel economy, fuel savings, and emissions reductions without imposing excessive cost on automakers and consumers and overly reducing vehicle sales. Requiring demand changes (through CAFE standards) much faster than what the market will bear creates a substantial likelihood of a mis-match between what companies produce and what consumers buy. While companies can manage that mis-match for short periods through incentivization and cross-subsidization, we have seen that over time automakers begin to fall short on fuel economy performance relative to the standards. Over time, if swaths of the industry continually fall short of fuel economy targets, and consumer demand for fuel economy does not significantly increase, then continuing to force technology into the fleet does not achieve the program's objectives (i.e., energy conservation). This is the case regardless of how much manufacturers spend manufacturing vehicles that consumers do not purchase (implicating concerns with economic practicability) to reduce their compliance liability. This is one part of why NHTSA believes that the 1.5 percent alternative is maximum feasible during the rulemaking timeframe.

While the 1.5 percent alternative being finalized is new for the final rule, it is responsive to comments requesting steady increases at the same rate for both cars and trucks, and it is within the range of rates of increase considered in the NPRM. As both the NPRM analysis and the final rule analysis show, after MY 2020 the proposed (0%) standards are not binding at the industry level (though some manufacturers, and fleets, remain below their standard after that model year) as a consequence of market demand for fuel economy at projected gasoline prices. However, the preferred (1.5% percent) alternative, while producing slightly higher achieved CAFE levels, tracks closely to the level produced by the combination of existing CAFE standards (through MY 2020) and subsequent market demand for fuel economy represented by the proposal. It is also

---

[3159] It is within NHTSA's discretion to adopt an alternative based on unquantified/unquantifiable benefits. *See, e.g.*, Inv. Co. Inst. v. Commodity Futures Trading Comm'n, 720 F.3d 370, 379 (D.C. Cir. 2013) ("The appellants further complain that CFTC failed to put a precise number on the benefit of data collection in preventing future financial crises. But the law does not require agencies to measure the immeasurable. CFTC's discussion of unquantifiable benefits fulfills its statutory obligation to consider and evaluate potential costs and benefits. *See Fox,* 556 U.S. at 519, 129 S.Ct. 1800 (holding that agencies are not required to 'adduce empirical data that' cannot be obtained). Where Congress has required 'rigorous, quantitative economic analysis,' it has made that requirement clear in the agency's statute, but it imposed no such requirement here. *American Financial Services Ass'n v. FTC,* 767 F.2d 957, 986 (D.C.Cir.1985); *cf., e.g.,* 2 U.S.C. § 1532(a) (requiring the agency to 'prepare a written statement containing ... a qualitative and quantitative assessment of the anticipated costs and benefits' that includes, among other things, 'estimates by the agency of the [rule's] effect on the national economy')."); BellSouth Corp. v. FCC, 162 F.3d 1215, 1221 (D.C.Cir.1999) ('When ... an agency is obliged to make policy judgments where no factual certainties exist or where facts alone do not provide the answer, our role is more limited; we require only that the agency so state and go on to identify the considerations it found persuasive')."

likely close to the point at which net benefits will be maximized, even if it remains unclear exactly where that point will end up.

As a kind of insurance policy against future fuel price volatility, standards that increase at 1.5 percent per year for cars and trucks will help to keep fleet fuel economy higher than they would be otherwise when fuel prices are low, which is not improbable over the next several years.[3160] These standards will also enable industry to choose how to spend the capital that would otherwise be spent meeting more stringent standards on more of what consumers are demanding, which could also include more fuel economy if the market heads unexpectedly in that direction. As explained above, even if more stringent standards might be technologically feasible in a narrow sense, and even if the effect of other motor vehicle standards of the Government does not vary significantly between regulatory alternatives, economic practicability concerns still counsel against more stringent standards, and the need of the U.S to conserve energy does not, at present, appear to counsel toward higher stringency. Standards that increase at 1.5 percent per year represent a reasonable balance of additional technology and required per-vehicle costs, consumer demand for fuel economy, fuel savings and emissions avoided given the foreseeable state of the global oil market and the minimal effect on climate between finalizing 1.5 percent standards versus more stringent standards. The final standards will also result in year-over-year improvements in fleetwide fuel economy, resulting in energy conservation that helps address environmental concerns, including criteria pollutant, air toxic pollutant, and carbon emissions. All things considered, NHTSA determines that an increase of 1.5 percent per year is maximum feasible for both passenger cars and light trucks for MYs 2021-2026.

IX. Compliance and enforcement

A. Introduction

1. Overview

The CAFE and CO_2 emissions standards are both fleet-average standards, and for both programs, determining compliance begins by testing vehicles on dynamometers in a laboratory over pre-defined test cycles under controlled conditions.[3161] A machine is connected to the

---

[3160] For example, EIA currently expects U.S. retail gasoline prices to average $2.14/gallon in 2020, compared to $2.69/gallon in 2019 (*see* https://www.eia.gov/outlooks/steo/archives/mar20.pdf), and $3.68/gallon in 2012 (*see* https://www.eia.gov/dnav/pet/hist/LeafHandler.ashx?n=PET&s=EMM_EPM0_PTE_NUS_DPG&f=A). While gasoline prices may foreseeably rise over the rulemaking time frame, it is also very foreseeable that they will not rise to the $4-5/gallon that many American saw over the 2008-2009 time frame, that caused the largest shift seen toward smaller and higher-fuel-economy vehicles. *See, e.g.*, Figure VIII-2 above.

[3161] For readers unfamiliar with this process, it is similar to running a car on a treadmill following a program—or more specifically, two programs. 49 U.S.C. 32904(c) states that, in testing for fuel economy, EPA must "use the same procedures for passenger automobiles [that EPA] used for model year 1975 (weighted 55 percent urban cycle and 45 percent highway cycle), or procedures that give comparable results." Thus, the "programs" are the "urban cycle," or Federal Test Procedure (abbreviated as "FTP") and the "highway cycle," or Highway Fuel Economy Test (abbreviated as "HFET"), and they have not changed substantively since 1975. Each cycle is a designated speed vehicle's tailpipe while it performs the test cycle, which collects and analyzes the resulting exhaust gases; a vehicle that has no tailpipe emissions has its performance measured differently, as discussed below. CO_2 quantities, as one of the exhaust gases, can be evaluated for vehicles that produce CO_2 emissions directly. Fuel economy is determined from the amount of CO_2 emissions, because the two are directly mathematically related.[3162] Manufacturers generally perform their own testing, and EPA confirms and validates those results by testing a sample of vehicles at the National Vehicle and Fuel Emissions Laboratory (NVFEL) in Ann Arbor, Michigan. The results of this testing form the basis for determining a manufacturer's compliance in a given model year, through the following steps:

- Each vehicle model's performance on the test cycles is calculated;
- The number of vehicles of that model that were produced is divided by the performance;
- That number, in turn is summed for all the manufacturer's model types;
- The manufacturer's total product volume is then divided by the summed value of all the model types; and
- That number represents the manufacturer's fleet harmonic average performance.

That performance is then compared to the manufacturer's unique compliance obligation (standard). This compliance obligation is calculated using the same approach that is used to determine performance, except that the fuel economy or CO_2 target value (based on the footprint of each vehicle model) is used instead of the model's measured performance value. The fuel economy or CO_2 target values for each of the vehicle models in the manufacturer's fleet and production volumes are used to derive the manufacturer's fleet harmonic average standard. Using fuel economy targets to illustrate the concept, the following figure shows two vehicle models produced in a model year for which passenger cars are subject to a fuel economy target function that extends from about 30 mpg for the largest cars to about 41 mpg for the smallest cars:

---

trace (of vehicle speed versus time) that vehicles must follow during testing—the FTP is meant roughly to simulate stop and go city driving, and the HFET is meant roughly to simulate steady flowing highway driving at about 50 mph. The 2-cycle dynamometer test results differ somewhat from what consumers will experience in the real world driving environment because of the lack of high speeds, rapid accelerations, and hot and cold temperatures evaluations with the A/C operation. These added conditions are more so reflected in the EPA 5-cycle test results listed on each vehicle's fuel economy label and on the fueleconomy.gov website.

[3162] Technically, for the CAFE program, carbon-based tailpipe emissions (including CO_2, CH_4, and CO) are measured, and fuel economy is calculated using a carbon balance equation. EPA uses carbon-based emissions (CO_2, CH_4, and CO, the same as for CAFE) to calculate the tailpipe CO_2 equivalent for the tailpipe portion of its standards.

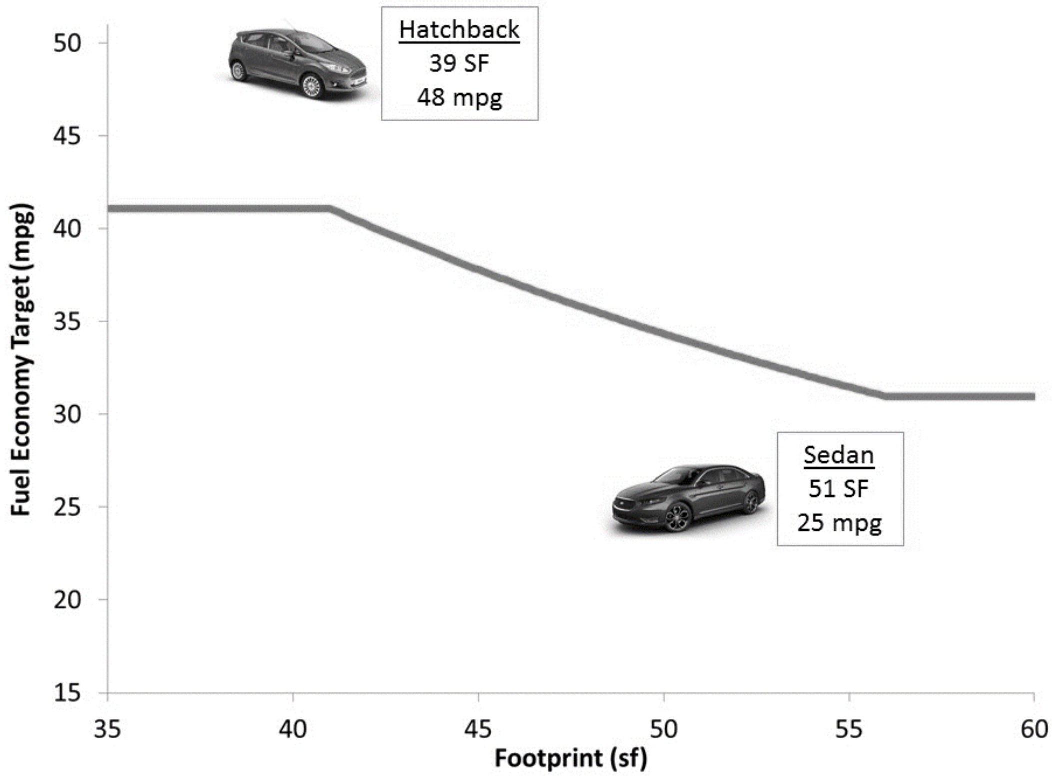

Figure IX-1 – Illustration of Vehicle Models vs. Fuel Economy Targets

If these are the only two vehicle models the manufacturer produces, the manufacturer's required CAFE obligation is determined by calculating the production-weighted harmonic average of the fuel economy target values applicable at the hatchback and sedan footprints (from the curve, about 41 mpg for the hatchback and about 33 mpg for the sedan). The manufacturer's achieved CAFE level is determined by calculating the production-weighted harmonic average of the hatchback and sedan fuel economy levels (in this example the values shown in the boxes in Figure IX-1, 48 mpg for the hatchback and 25 mpg for the sedan). Depending on the relative mix of hatchbacks and sedans the manufacturer produces, the manufacturer's fleet may meet the standard, or perform better than the standard (if required CAFE is less than achieved CAFE) and thereby earn credits or perform worse than the standard (if required CAFE is greater than achieved CAFE) and thereby have a shortfall that may be made up, in whole or in part, using CAFE credits, discussed below, or be subject to civil penalties. Although the arithmetic is different for CO_2 standards (which do not involve harmonic averaging), the underlying concept is the same.

There are thus two parts to the foundation of compliance with CAFE and CO_2 emissions standards: first, how well any given vehicle model performs relative to its target, and second, how many of each vehicle model a manufacturer produces. While no given model need precisely meet its target (and virtually no model exactly meets its target in the real-world), if a manufacturer finds itself producing large numbers of vehicles that fall well short of their targets, it will have to find a way of offsetting that shortfall, either by increasing production of vehicles that exceed their targets, or by taking advantage of compliance flexibilities and incentives, or the manufacturer will be subject to civil penalties. Given that manufacturers typically need to produce for sale vehicles that consumers want to buy, and not all consumers value fuel economy, their options for pursuing the former approach can often be limited.

The CAFE and CO_2 programs both offer a number of compliance flexibilities and incentives, discussed in more detail below. For example, starting in model year 2017, manufactures have flexibility to account for efficiency improvements in air conditioning (A/C) systems and/or for the application fuel economy improving technologies that increase fuel economy in the real-world, but that are, in whole or in part, not accounted for (e.g., stop-start technology, or high efficiency alternators) using the 1975-based 2-cycle compliance dynamometer test procedures.[3163] These fuel economy improvements are added to the 2-cycle performance results and are included in the calculation of a manufacturer's fuel economy in determining compliance relative to standards. In addition, for MYs 2017 – 2021, there are also two levels of compliance incentives for full-size pickup trucks with mild-HEV or strong-HEV technology or that overperform standards by 15 percent or more, or by 20 percent or more.[3164] This final rule removes this incentive starting in MY 2022, as discussed in more detail below. These fuel economy improvements are also included, for those model years and as earned, in the calculation of a manufacturer's fuel economy.[3165]

Some flexibilities and incentives are expressly provided for by statute, and some have been implemented by the agencies through regulations, consistent with the statutory scheme. Compliance flexibilities and incentives for the CAFE and CO_2 programs have a great deal of theoretical attractiveness: if designed properly, they can help to reduce overall regulatory costs, while maintaining or improving programmatic benefits. If designed poorly, they may create significant potential for market distortion (for instance, when manufacturers—in response to an incentive to deploy a particular type of technology—produce vehicles for which there is no natural market, such vehicles must be discounted in order to sell).[3166] Manufacturers' use of compliance flexibilities and incentives requires proper governmental and industry collaboration for manufacturers to achieve the most effective pathways to compliance.[3167] Overly-complicated

---

[3163] EPA regulations provided an equivalent program beginning in MY 2012.
[3164] Manufacturers also must apply the technology to a minimum percentage of their full-size pickup truck production.
[3165] NHTSA characterizes any programmatic benefit manufacturers can use to comply with CAFE standards that fully accounts for fuel use as a "flexibility" (e.g., credit trading) and any benefit that counts less than the full fuel use as an "incentive" (e.g., adjustment of alternative fuel vehicle fuel economy). NHTSA flexibilities and incentives are discussed further in Section IX.D.
[3166] While many manufacturers publicly discuss their commitment to certain technologies that reduce CO_2 emissions, consumer interest in them thus far remains low, despite often-large financial incentives from both manufacturers and the Federal and State governments in the form of tax credits (i.e., natural gas or fuel-cell vehicles). It is questionable whether continuing to provide significant compliance incentives for technologies that consumers appear not to want is an efficient means to achieve either compliance or national goals (*see, e.g.*, Congress' phase-out of the AMFA dual-fueled vehicle incentive in EISA, 49 U.S.C. 32906).
[3167] For these reasons, in this final rule, NHTSA is asking manufacturers to provide more detailed information on the new incentives allowed for A/C and off-cycle technologies and on credit trades for better collaboration in understanding the economic impact of these flexibilities and incentives and for the government to provide better oversight of the CAFE program.

flexibility and incentive programs can result in greater expenditure of both private sector and government resources to track, account for, and manage. Moreover, flexibilities or incentives that tend to favor specific technologies could distort the market. By these means, compliance flexibilities or incentives could create an environment in which entities are encouraged to invest in such favored technologies and, unless those technologies are independently supported by market forces, encourage rent seeking in order to protect, preserve, and enhance profits of companies that seek to take advantage of the distortions created by government mandate. Further, to the extent that there is a market demand for vehicles with lower CO_2 emissions and higher fuel economy, compliance flexibilities and incentives may cause some manufacturers to fall behind the industry's pace if they become overly reliant on them rather than simply improving the efficiency of their vehicles to meet that market demand.

If standards are maximum feasible levels, as required by statute, then the need for extensive compliance flexibilities and incentives should be low. The agencies sought comments in the NPRM on whether and how each agency's existing flexibilities and incentives might be amended, revised, or deleted to avoid the inefficiencies and market distortions discussed above. Specifically, comments were sought on the appropriate level of compliance flexibility, including credit trading, in a program that is correctly designed to be maximum feasible, in accordance with the statute. Comments were also sought on whether to allow *all* incentive-based adjustments, except those that are mandated by statute, to expire, in addition to other possible simplifications to reduce market distortion, improve program transparency and accountability, and improve overall performance of the compliance programs. The agencies considered comments on those issues in preparing the final rule. A summary of all the flexibilities for the CAFE and CO_2 programs finalized as a part of this final rule is provided in Table IX-1 though Table IX-4.

Table IX-1 – Statutory flexibilities for over-compliance with standards

Regulatory item	NHTSA			EPA		
	Authority	Current Program	Final Rule	Authority	Current Program	Final Rule
Credit Earning	49 U.S.C. 32903(a)	Yes, denominated in tenths of a mpg	No change	CAA 202(a)	Yes, denominated in g/mi	No change
Credit "Carry-forward"	49 U.S.C. 32903(a)(2)	5 MYs into the future	No change	CAA 202(a)	5 MYs into the future (except MYs 2010-2015 = credits may be carried forward through MY 2021)	No change
Credit "Carryback" (AKA "deficit carry-forward")	49 U.S.C. 32903(a)(1)	3 MYs into the past	No change	CAA 202(a)	3 MYs into the past	No change
Credit Transfer	49 U.S.C. 32903(g)	Up to 2 mpg per fleet; transferred credits may not be used to meet min DPC standard	No change; Alliance/Global request to reconsider prior interpretation is denied	CAA 202(a)	Unlimited	No change
Credit Trade	49 U.S.C. 32903(f)	Unlimited quantity; traded credits may not be used to meet min DPC standard	No change	CAA 202(a)	Unlimited	No change

Table IX-2 – Flexibilities that address gaps in compliance test procedures

Regulatory item	NHTSA			EPA		
	Authority	Current Program	Final Rule	Authority	Current Program	Final Rule
A/C efficiency	49 U.S.C. 32904	Allows mfrs to earn "fuel consumption improvement values" (FCIVs) equivalent to EPA credits starting in MY 2017	No change, except to add advanced A/C compressor technology to the pre-approved menu; (Alliance/ Global request to allow retroactive starting in MY 2012 is denied)	CAA 202(a)	"Credits" for A/C efficiency improvements up to caps of 5.0 g/mi for cars and 7.2 g/mi for trucks	No change, except to add advanced A/C compressor technology to the pre-approved menu.
Off-cycle	49 U.S.C. 32904	Allows mfrs to earn "fuel consumption improvement values" (FCIVs) equivalent to EPA credits starting in MY 2017	Add high efficiency alternators to the pre-approved menu; (Alliance/ Global request to allow retroactive starting in MY 2012 is denied).allow suppliers to begin petition process	CAA 202(a)	"Menu" of pre-approved credits (~10), up to cap of 10 g/mi for MY 2014 and beyond; other pathways require EPA approval through either 5-cycle testing or through public notice and comment	Add high efficiency alternators to the pre-approved menu; allow suppliers to begin petition process

	Authority	Current Program	Final Rule	Authority	Current Program	Final Rule
Full-size pickup trucks with HEV or overperforming target	49 U.S.C. 32904	Allows mfrs to earn FCIVs equivalent to EPA credits starting in MY 2017 and ending in MY 2025	Delete beginning with MY 2022	CAA 202(a)	10 g/mi for full-size pickups with mild hybrids OR overperforming target by 15% (MYs 2017-2021); 20 g/mi for full-size pickups with strong hybrids OR overperforming target by 20% (MYs 2017-2025)	Delete beginning with MY 2022

Table IX-4 – Incentives that encourage alternative fuel vehicles

Regulatory item	**NHTSA**			**EPA**		
	Authority	Current Program	Final Rule	Authority	Current Program	Final Rule
Dedicated alternative fuel vehicle	49 U.S.C. 32905(a) and (c)	Fuel economy calculated assuming gallon of liquid or gallon equivalent gaseous alt fuel = 0.15 gallons of gasoline; for EVs petroleum equivalency factor	No change	CAA 202(a)	Multiplier incentives for EVs and FCVs (each vehicle counts as 2.0/1.75/1.5 vehicles in 2017-2021), NGVs (1.6/1.45/1.3 vehicles); each EV = 0 g/mi upstream emissions through MY 2021 (then phases out based on per-mfr production cap of 200k vehicles)	Multiplier of 2.0 added for MY 2022-2026 NGVs. No change to EV and FCV multipliers that phase out after MY 2021. Electricity usage = 0 g/mi extended through MY 2026.
Dual-fueled vehicles	49 U.S.C. 32905(b), (d), and (e); 32906(a)	FE calc using 50% operation on alt fuel and 50% on gasoline through MY 2019. Starting with MY 2020, NHTSA will begin using the SAE defined "Utility Factor" methodology to account for actual potential use, and “F-factor” for FFV. NHTSA will continue to incorporate the 0.15 incentive factor.	No change	CAA 202(a)	Multiplier incentives for PHEVs and NGVs (each vehicle counts as 1.6/1.45/1.3 vehicles in 2017-2021); electric operation = 0 g/mi through MY 2021 (then phases out based on per-mfr production cap of 200k vehicles); “Utility Factor” method for use, and “F-factor” for FFV.	Multiplier of 2.0 added for MY 2022-2026 NGVs. No change to EV and FCV multipliers that phase out after MY 2021. Electricity usage = 0 g/mi extended through MY 2026.
Connected/ Automated Vehicles	n/a	n/a	n/a	CAA 202(a)	Mfrs can petition for off-cycle credits	No change
High-octane fuel blends	n/a	n/a	n/a	CAA 202(a)	No incentives or requirements	No change

2. Light-Duty CAFE Compliance Data for MYs 2011-2019

To understand manufacturers' potential approaches to using compliance flexibilities and incentives, CAFE compliance data for MYs 2011 through 2019 is discussed in this section. NHTSA believes that providing these data is important because it gives the public a better understanding of current compliance trends and the potential impacts that increasing CAFE standards have had on those model years and future model years addressed by this rulemaking.

NHTSA uses data from CAFE reports submitted by manufacturers to EPA or directly to NHTSA to evaluate compliance with the CAFE program. The data for MYs 2011 through 2017 include manufacturers' final compliance data that have been verified by EPA.[3168] The data for MYs 2018 and 2019 include the most recent projections from manufacturers' mid-model year and final-model year reports submitted to EPA and NHTSA, as required by 49 CFR Part 537 and 40 CFR 600.512-12.[3169] Because the projections do not reflect final vehicle production levels, the EPA verified final CAFE values may be slightly different than the manufacturers' projections. MY 2011 was selected as the start of the data because it represents the first compliance model year for which manufacturers were permitted to trade and transfer credits.[3170] MY 2019 is also important because it shows the projected performance of the fleet two years after manufacturers were allowed to use new flexibilities and incentives starting in MY 2017 to address increasing CAFE standards.

Figure IX-2 through Figure IX-5 provide a graphical overview of fuel economy performance and standards. Fuel economy performance includes three parts: (1) measured performance, on the 2-cycle dynamometer test; (2) performance increases for alternative fueled vehicles, under the Alternative Motor Fuels Act of 1988 (AMFA); and (3) performance adjustments for improved A/C systems and off-cycle technologies.[3171,3172,3173] These Figures do not account for credits earned or expected to be earned from overcompliance in prior or future

---

[3168] The data contain the latest information available from manufacturers except certain low volume manufacturers complying with standards under 49 CFR part 525.
[3169] MY 2018 data come from information received in manufacturers' final reports submitted to EPA according to 40 CFR 600.512-12 and MY 2019 data come from information received in manufacturers' mid-model year CAFE reports submitted to NHTSA according to 49 CFR part 537.
[3170] 49 CFR 535.6(c).
[3171] In the Figures, the label "CAFE with Capped AMFA" represents the maximum increase each year in the average fuel economy set to the limitation "cap" for manufacturers attributable to dual-fueled automobiles as prescribed in 49 U.S.C. 32906. The labels "A/C" and "off-cycle" represents the increase in the average fuel economy adjusted for A/C and off-cycle fuel consumption improvement values as prescribed by 40 CFR 600.510-12.
[3172] The Alternative Motor Fuels Act (AMFA) allows manufacturers to increase their fleet fuel economy performance values by producing dual-fueled vehicles. Incentives are available for building advanced technology vehicles such as hybrids and electric vehicles, compressed natural gas vehicles and for building vehicles able to run on dual-fuels such as E85 and gasoline. For MYs 1993 through 2014, the maximum possible increase in CAFE performance is "capped" for a manufacturer attributable to dual-fueled vehicles at 1.2 miles per gallon for each model year and thereafter decreases by 0.2 miles per gallon each model year through MY 2019. 49 U.S.C. 32906.
[3173] Consistent with applicable law, NHTSA established provisions starting in MY 2017 allowing manufacturers to increase fuel economy performance-based on fuel consumption benefits gained by technologies not accounted for during normal 2-cycle EPA compliance testing (called "off-cycle technologies" for technologies such as stop-start systems) as well as for A/C systems with improved efficiencies and for hybrid or electric full-size pickup trucks.

model years that were used or are available for complying with CAFE standards. Graphs are included for the total fuel economy performance (the combination of all passenger cars and light trucks produced for sale during the model year) as a single fleet, and for each of the three CAFE compliance fleets: domestic passenger car, import passenger car, and light truck fleets.

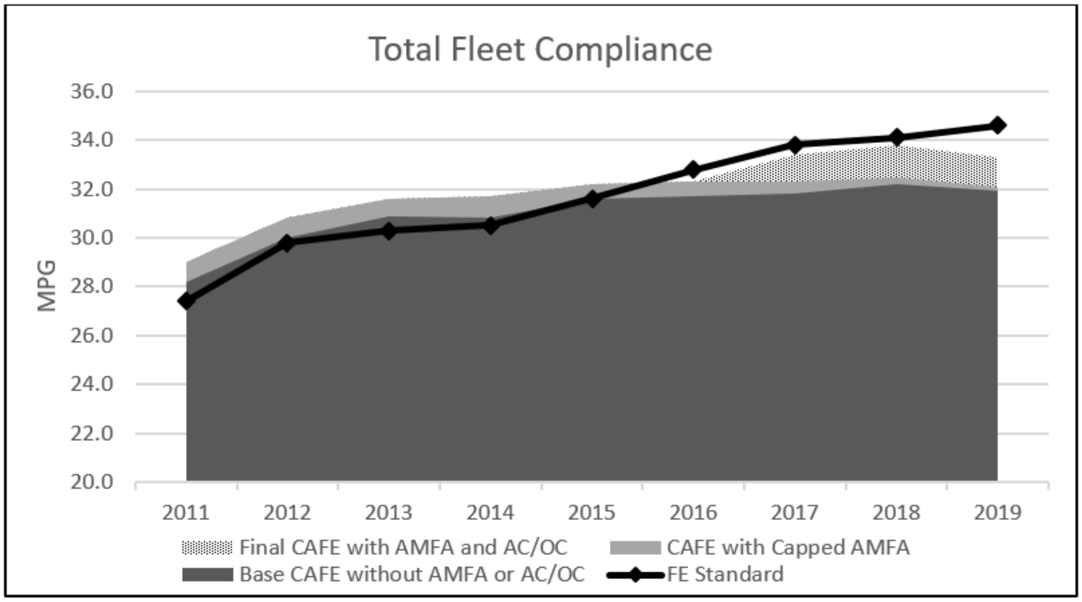

Figure IX-2 – Total Fleet Compliance Overview for MYs 2011 to 2019

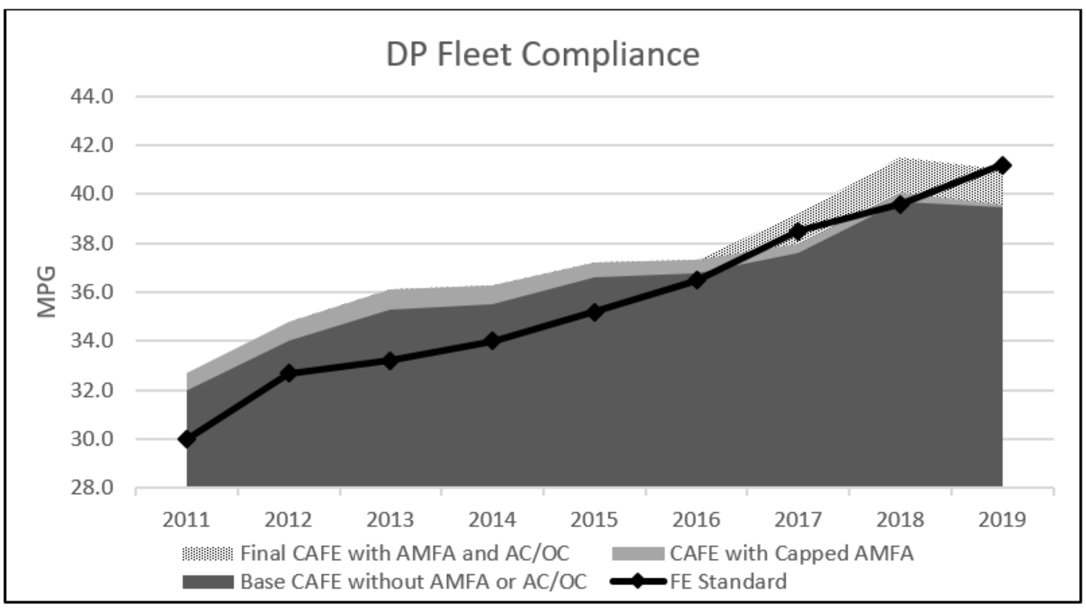

Figure IX-3 – Domestic Passenger Car Compliance Overview for MYs 2011 to 2019

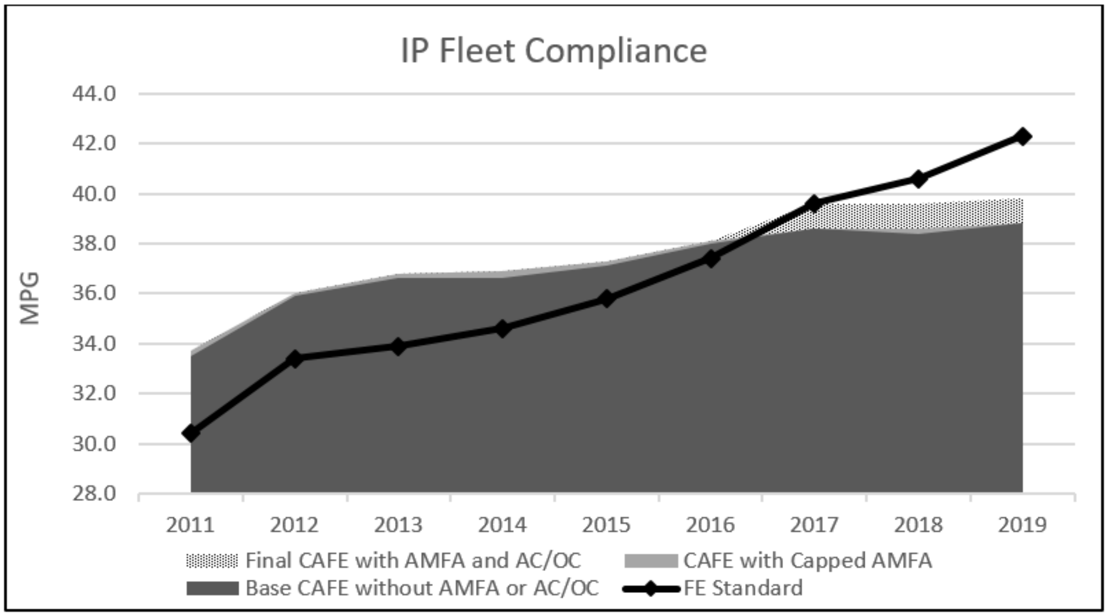

Figure IX-4 – Import Passenger Car Compliance Overview for MYs 2011 to 2019

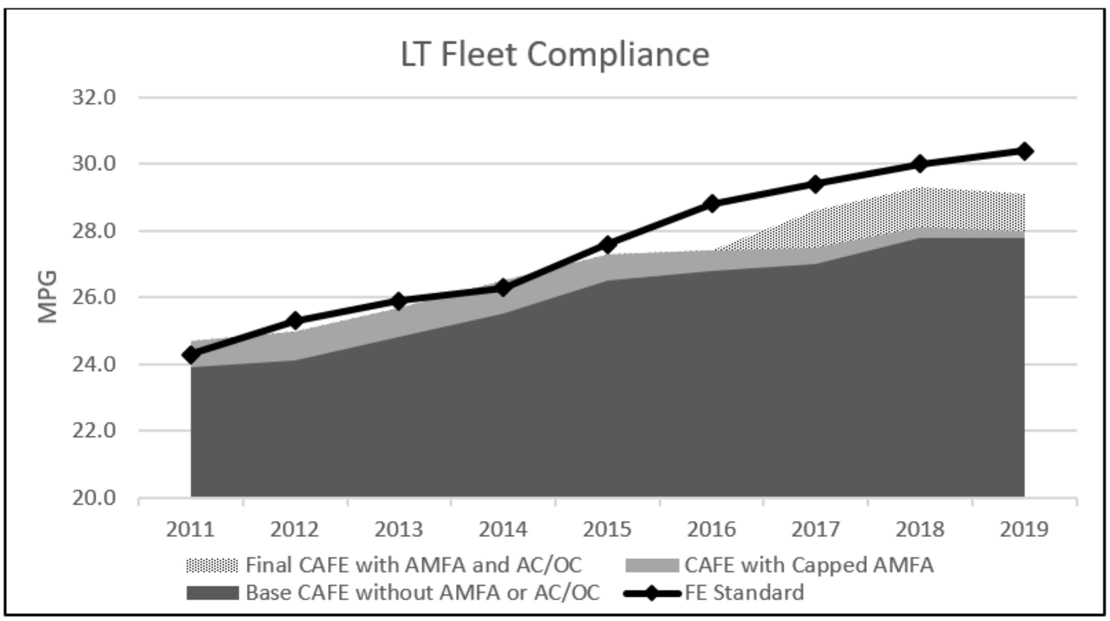

Figure IX-5 – Light Truck Compliance Overview for MYs 2011 to 2019

As shown in Figure IX-2, manufacturers' fuel economy performance for the total fleet was better than the overall CAFE standard through MY 2015. On average, the total fleet exceeded the overall CAFE standards by approximately 0.9 mpg for MYs 2011 to 2015. Comparatively, as shown in Figure IX-3 through Figure IX-5, for these same model years, domestic and import passenger cars exceeded standards on average by 2.1 mpg and 2.3 mpg, respectively. By contrast, for light trucks, manufacturers on average fell below standards by 0.3 mpg.

For MYs 2016 through 2019, as shown in the Figures, NHTSA has determined that the combined CAFE performance, including all flexibilities and incentives, of the total fleet has or is expected to be worse than the applicable CAFE standards, and increasingly so. The domestic passenger car fleet is the only compliance category expected to continue to be better than CAFE standards through MY 2018. But even the overall domestic passenger car fleet is expected to be worse than standards in MY 2019. The data show MYs 2016 through 2019 standards involve significant compliance challenges for many vehicle manufacturers. This is evident in the fact that the total fleet falls below the applicable CAFE standards on average by 0.6 mpg for these model years. Compliance challenges become even more substantial when observing individual compliance fleets. The largest individual performance shortfalls (i.e. the difference between CAFE performance values and standards) exist for import passenger car manufacturers, with an expected shortfall of 2.5 mpg in MY 2019, followed by light truck manufacturers, with a shortfall of 1.4 mpg in MY 2016.

Table IX-5 provides the numerical final CAFE performance values and standards for MYs 2004 to 2017. Notably, there was an increase in total fleet fuel economy of only 0.1 mpg for MY 2014, and no increase for MY 2016. In MY 2016, the total fleet's performance fell below the CAFE standard by 0.5 mpg. An increase in the total fleet's CAFE performance for MY 2017 was largely due to manufacturers gaining benefits from A/C and off-cycle technologies. For MY 2017, the total fleet's CAFE performance without A/C and off-cycle allowances increased by 0.1 mpg compared to MY 2016. However, even combined with new flexibilities, the total fleet's CAFE performance, for MY 2017, still falls below the CAFE standard by 0.4 mpg.

Table IX-5 – CAFE Performance and Standards for MYs 2004 to 2017

Model Year	**Domestic Passenger Car**		**Import Passenger Car**		**Light Truck**		**Total Fleet**	
	CAFE (mpg)	**Standard (mpg)**	**CAFE (mpg)**	**Standard (mpg)**	**CAFE (mpg)**	**Standard (mpg)**	**CAFE (mpg)**	**Standard (mpg)**
2017	39.2	38.5	39.7	39.6	28.6	29.4	33.4	33.8
2016	37.3	36.5	38.2	37.4	27.4	28.8	32.2	32.7
2015	37.2	35.2	37.3	35.8	27.3	27.6	32.2	31.6
2014	36.3	34.0	36.9	34.6	26.5	26.3	31.7	30.5
2013	36.1	33.2	36.8	33.9	25.7	25.9	31.6	30.3
2012	34.8	32.7	36.0	33.4	25.0	25.3	30.8	29.8
2011	32.7	30.0	33.7	30.4	24.7	24.3	29.0	27.4
2010	33.1	27.5	35.2	27.5	25.2	23.4	29.3	25.4
2009	32.1	27.5	33.8	27.5	24.8	23.0	29.0	25.4
2008	31.2	27.5	31.8	27.5	23.6	22.4	27.1	24.7
2007	30.6	27.5	32.2	27.5	23.1	22.2	26.6	24.6
2006	30.3	27.5	29.7	27.5	22.5	21.6	25.8	24.2
2005	30.5	27.5	29.9	27.5	22.1	21.0	25.4	23.7
2004	29.9	27.5	28.7	27.5	21.5	20.7	24.6	23.4

Figure IX-6 provides a historical overview of the industry's use of CAFE compliance flexibilities for addressing performance shortfalls.[3174] MY 2016 is the latest model year for which CAFE compliance determinations are complete, and credit application and civil penalty payment determinations made by the manufacturer. Historically, manufacturers have generally resolved credit shortfalls first by carrying forward any earned credits and then applying traded credits. In MYs 2014 and 2015, the amount of credit shortfalls is almost the same as the amount of carry-forward and traded credits. Manufacturers occasionally carryback credits or opt to transfer earned credits between their fleets to resolve performance shortfalls. Trading credits from another manufacturer and transferring them across fleets occurs far more frequently. Also, credit trading has generally taken the place of civil penalty payments for resolving performance shortfalls. Only a handful of manufacturers have made civil penalty payments since the implementation of the credit trading program.[3175] NHTSA expects there may be sufficient credits in manufacturers' credit accounts to resolve all import passenger car and light truck performance shortfalls expected through MY 2019. By statute, manufacturers cannot use traded or transferred credits to address performance shortfalls for failing to meet the minimum domestic passenger car standards.[3176] One domestic passenger car manufacturer paid civil penalties for failing to comply with the minimum domestic passenger car standards for MYs 2016 and 2017.[3177] Additional manufacturers are expected to pay civil penalty payments for failing to comply with the minimum domestic passenger cars standards for MYs 2018 through 2019.

[3174] The Figure includes all credits manufacturers have used in credit transactions to date. Credits contained in carryback plans yet to be executed or in pending enforcement actions are not included in the Figure.
[3175] Six manufacturers have paid CAFE civil penalties since credit trading began in 2011. Fiat Chrysler paid the largest civil penalty total over the period, followed by Jaguar Land Rover and then Volvo. *See* Summary of CAFE Civil Penalties Collected, CAFE Public Information Center, https://one.nhtsa.gov/cafe_pic/CAFE_PIC_Fines_LIVE.html.
[3176] Congress prescribed minimum domestic passenger car standards for domestic passenger car manufacturers and unique compliance requirements for these standards in 49 USC 32902(b)(4) and 32903(f)(2).
[3177] Fiat Chrysler paid $77,268,702.50 in civil penalties for MY 2016 and $79,376,643.50 for MY 2017 for failing to comply with the minimum domestic passenger car standards for those MYs.

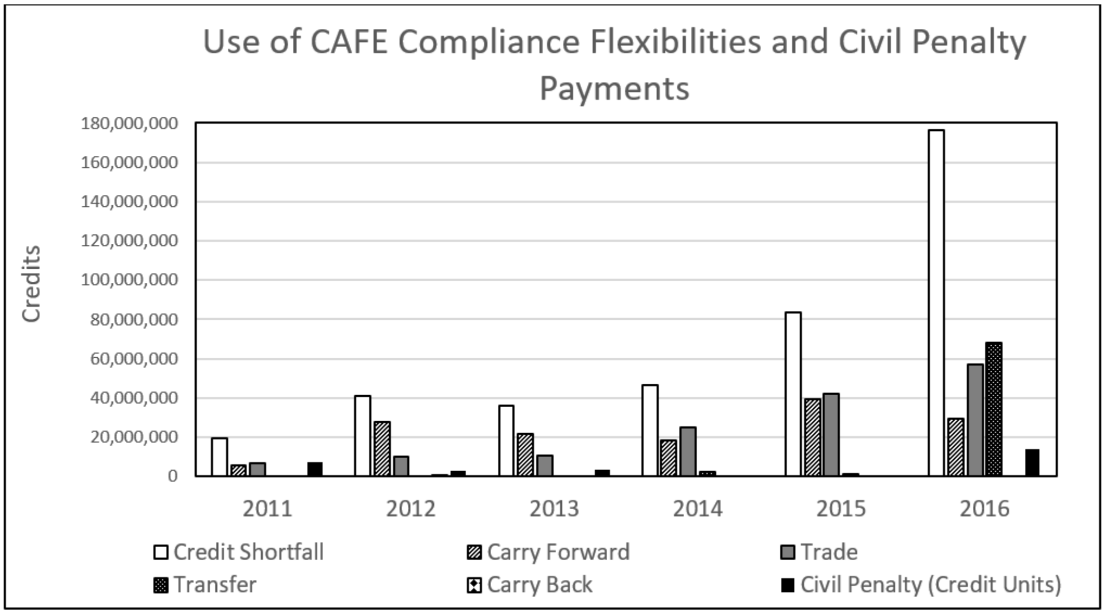

Figure IX-6 – Industry Use of Compliance Flexibilities and Civil Penalty Payments

The compliance data show that the rate at which industry has been increasing fuel economy, as shown by the actual fuel economy of the overall fleet, has not kept pace with the year-over-year increases in the stringency of the standards since MY 2010. The margin of CAFE overcompliance diminished steadily through MY 2015. In MY 2016, the fuel economy of the fleet was worse than standards, and the margin of the shortfall has or is projected to become worse through MY 2019. Manufacturers have increasingly used CAFE compliance flexibilities and paid more in civil penalties to address the growing CAFE shortfalls. The data show use of these flexibilities is likely to increase at least through 2019.

3. Shift in Sales Production from Passenger Cars to Light Trucks

The notable trend in the stagnant growth in the automotive industry's CAFE performance is likely related to an increase in the purchase of light trucks beginning with MY 2013. Light trucks had a sharp spike in sales, increasing by a total of 5 percent from MYs 2013 to 2014. In MY 2014, light trucks comprised approximately 41 percent of the total sales production volume of automobiles and has continued to grow ever since. In comparison, for model year 2014, domestic passenger cars represented 36 percent of the total fleet and import passenger cars represented 23 percent. Both domestic and import passenger car sales have continued to fall every year since MY 2013. Figure IX-7 shows the sales production volumes of light trucks and domestic and import passenger cars for MYs 2004 to 2017. The proportion of light trucks in the fleet, being driven by consumer demand and lower fuel prices, raises some concern for the ability of that fleet to comply with future CAFE standards. Historically, light truck fleets have fallen below their associated CAFE standards and have had larger performance shortages than either import and domestic passenger car fleets. This trend is expected to continue, even with allowance for A/C and off-cycle flexibilities. For MY 2019, NHTSA expects even greater CAFE performance shortages in the light truck and import passenger car fleets than in prior model years, based upon manufacturer's MMY reports. The combined effect of these fuel economy shortages will require manufacturers to rely heavily on compliance flexibilities or pay civil penalties.

Another important factor in automobile sales production impacting CAFE performance values involves increasing trends in the volume of small SUVs and pickup trucks. These vehicles as a percentage of total fleet increased from approximately 52 percent in MY 2012 to 63 percent in MY 2017. As shown in Figure IX-8, small SUVs, with 4WD and 2WD drivetrains, in particular have surpassed the sales production volumes of all other vehicle classes over these the given model years. The number of small and standard SUVs sold in the U.S. for MY 2017 nearly doubled compared to sales in the U.S. for MY 2012. During that same period, passenger car sales production as a total of vehicle sales production decreased by approximately 11 percent. The combination of low gas prices and the increased utility that SUVs provide may explain the shift in sales production. Nonetheless, if the sales of these small SUVs and pickup trucks continue to increase, NHTSA expects there will be continued stagnation in the CAFE performance of the overall fleet.

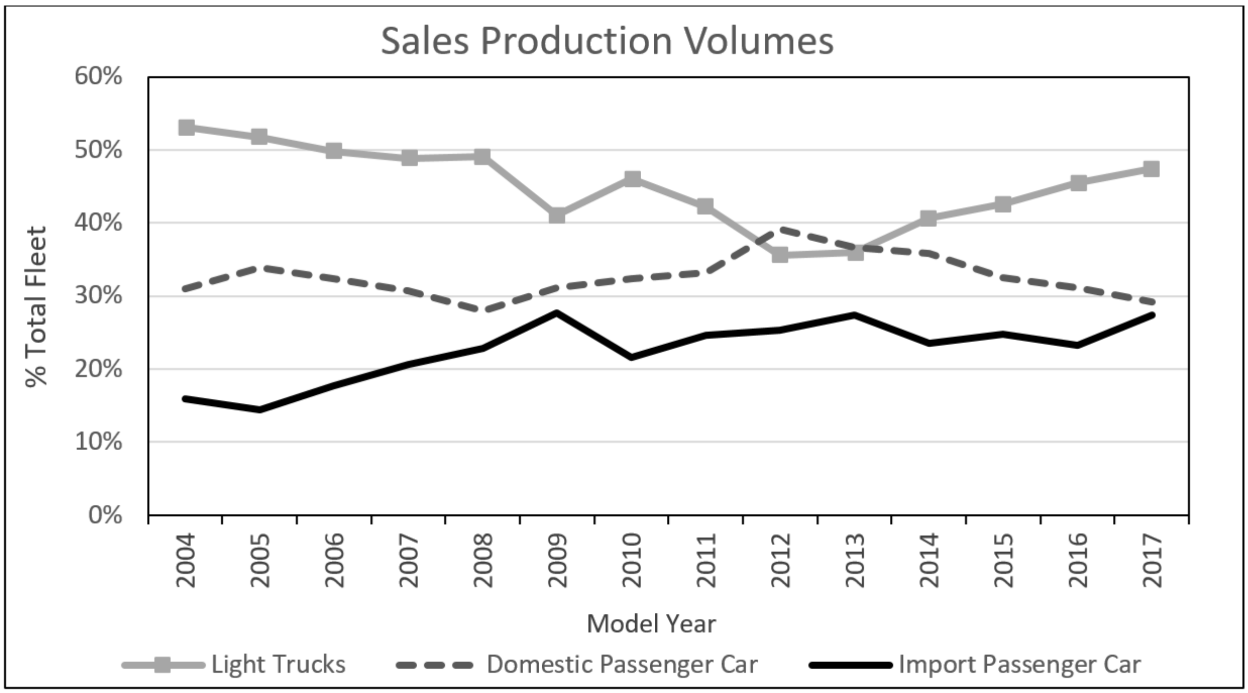

Figure IX-7 – Sales Production Volumes for MYs 2004 to 2017

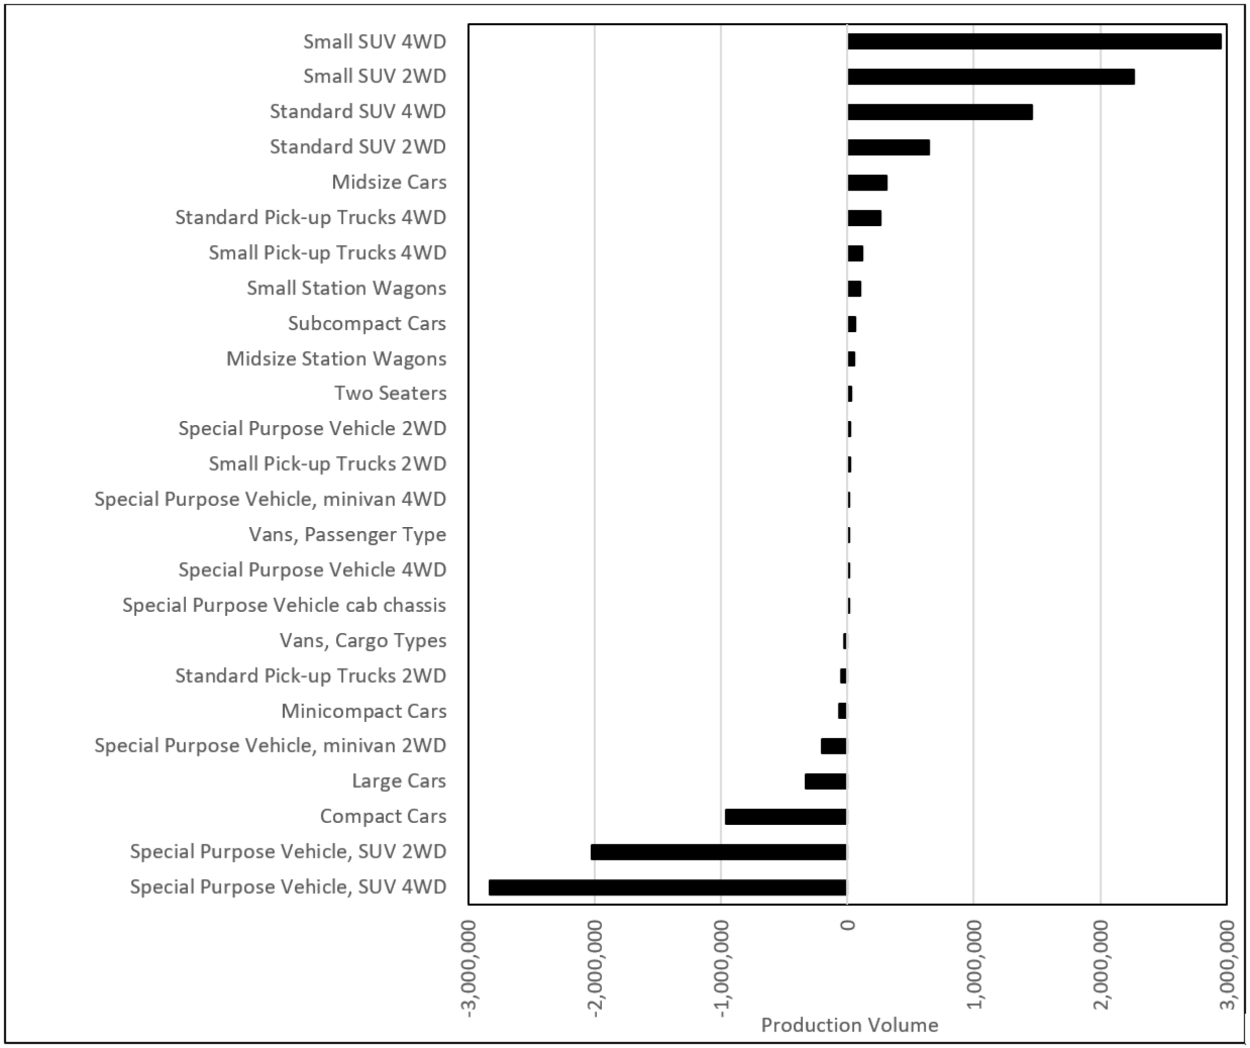

Figure IX-8 – Vehicle Class Production Changes for MYs 2012 to 2017

4. Vehicle Classification

Before manufactures can comply with CAFE and CO_2 standards, they must first determine how a vehicle is classified in accordance with 49 CFR Part 523, "Vehicle Classification." In EPCA, Congress designated some vehicles as passenger automobiles and some as non-passenger automobiles. Vehicle classification, for purposes of the light-duty CAFE and CO_2 programs, refers to whether a vehicle is classified as a passenger automobile (car) or a non-passenger automobile (light truck).[3178, 3179] As discussed previously, passenger cars and light trucks are subject to different fuel economy and CO_2 standards, and light trucks have less stringent standards to accommodate their utility usage.

Under EPCA and NHTSA's current regulations, vehicles are classified as light trucks either on the basis of off-highway capability or on the basis of having truck-like (utility) characteristics.[3180, 3181, 3182] Determining whether a vehicle is capable of "off-highway operation" is a two-part determination: first, does the vehicle either have 4-wheel drive or a gross vehicle weight rating (GVWR) over 6,000 pounds, and second, does the vehicle (that has either 4-wheel drive or over 6,000 pounds GVWR) also have "a significant feature … designed for off-highway operation."[3183] NHTSA's current regulations specify that this "significant feature" requires the vehicle to meet at least four out of five ground clearance dimensions.[3184] Further, to be classified as a light truck on the basis of having truck-like characteristics instead, NHTSA regulations also require the vehicle to perform at least one of the following functions: carry more than 10 persons, provide temporary living quarters, have an open bed (*i.e.*, a pickup truck), provide more cargo-carrying volume than passenger-carrying volume, or permit expanded cargo volume capacity by the removal or stowing of rear seats.[3185]

Over time, NHTSA has revised its light truck vehicle classification regulations and issued legal interpretations to address changes in vehicle designs. Based upon agency observations of current vehicle design trends, compliance testing and evaluation, and discussions with stakeholders, NHTSA has become aware of certain additional design changes that further complicate light truck classification determinations for the CAFE and CO_2 programs. NHTSA discussed several classification issues in the NPRM and sought comments on potential resolutions. Only a few comments were received, primarily from vehicle manufacturers, and they were aimed generally at requesting flexibility in how NHTSA applies the existing classification criteria. A summary of the comments received and NHTSA's responses for the final rule are explained in the following sections.

[3178] *See* 40 CFR 86.1803-01. For the MYs 2012–2016 standards, the MYs 2017–2025 standards, and this rule, EPA uses NHTSA's regulatory definitions for determining which vehicles would be subject to which CO_2 standards.
[3179] EPCA uses the terms "passenger automobile" and "non-passenger automobile;" NHTSA's regulation on vehicle classification, 49 CFR part 523, further clarifies the EPCA definitions and introduces the term "light truck" as a plainer language alternative for "non-passenger automobile."
[3180] 49 USC 32901(a)(18); 49 CFR part 523.
[3181] 49 CFR 523.5(b).
[3182] 49 CFR 523.5(a).
[3183] 49 U.S.C. 32901(a)(18).
[3184] The ground clearance dimensions are: (i) approach angle of not less than 28 degrees; (ii) breakover angle of not less than 14 degrees; (iii) departure angle of not less than 20 degrees; (iv) running clearance of not less than 20 centimeters; and/or (v) front and rear axle clearances of not less than 18 centimeters each.
[3185] By statute, vehicles that NHTSA, on behalf of the Secretary of DOT, "decides by regulation [are] manufactured primarily for transporting not more than 10 individuals" are passenger automobiles. 49 U.S.C. 32901(a)(18).

a) *Classification Based on "Truck-Like Characteristics"*

One of the "truck-like characteristics" that allows manufacturers to classify vehicles as light trucks is having at least three rows of seats as standard equipment, as long as the design also "permit[s] expanded use of the automobile for cargo-carrying purposes or other non-passenger-carrying purposes through the removal or stowing of foldable or pivoting seats so as to create a flat, leveled cargo surface extending from the forwardmost point of installation of those seats to the rear of the automobile's interior."[3186] Typically, most minivans qualify under the provision by expanding the cargo area through removable or stowable seats, and a small percentage of sports utility vehicles qualify through folding seats that use the seat backs to form a secondary "raised" cargo floor.[3187] NHTSA identified two issues with this criterion that various manufacturers appear to be approaching differently. Both relate to how expanded cargo area is provided when seats are removed or stowed in the vehicle.

The first issue is how to identify the "forwardmost point of installation" and how the location impacts the available cargo floor area and volume behind the seats. Seating configurations have evolved considerably over the last twenty years, as minivan seats are now very complex in design, providing far more ergonomic functionality. For example, the market demand for increased rear seat leg room has resulted in adjustable second row seats mounted to sliding tracks. Earlier seating designs had fixed attachment points on the vehicle floor, and it was easy to identify the "forwardmost point of installation" because it was readily observable and did not change. When seats move forward and backward on sliding tracks, however, the "forwardmost point of installation" is less readily identifiable. To avoid this complication, most manufacturers maintain light truck qualification by using adjustable seats that can be removed from the vehicle and having a flat floor rearward of the front seats.[3188] For others, the qualification is not as apparent because new adjustable seats have been introduced that remain within vehicle to accommodate side airbags. Manufacturers designate various positions for the forwardmost point of installation in vehicles where the seat in the sliding track can be moved far enough forward to allow the entire seat to compress against the back of the front seat where it can be stowed beyond the forwardmost point of installation, while the seat cushion bottom folds towards the seatback. In some cases, manufacturers designate the forwardmost point of installation at a location in the sliding track where the seat is positioned at its *rearmost* position in the track. In others, the initial point of installation is designated at a location in the sliding track accommodating the seating position of a 75-percentile male test dummy. The amount of the flat floor surface area and cargo volume behind the seats can vary depending on which approach a manufacturer adopts.

[3186] 49 CFR 523.5(a)(5)(ii).

[3187] All minivans and a small percentage of sports utility vehicles that qualify as light trucks do so by meeting the characteristic for third row seats. As more advanced seating designs are introduced in minivans, manufacturers that wish to retain this status will need to avoid losing the expanded cargo characteristics that are the basis for the allowing minivans to be qualified as light trucks.

[3188] NHTSA notes that to qualify as a light truck, a vehicle still requires a flat floor from the forwardmost point of installation of removable second row seats to the rear of the vehicle.

NHTSA sought public comments in the NPRM to explore potential options for establishing the forwardmost point of installation for adjustable second row seats and to evaluate whether an additional classification criteria could be required, specifying a minimum amount of cargo volume behind the seats. Comments were received from the Auto Alliance and Fiat Chrysler.[3189] Both the Auto Alliance and Fiat Chrysler commented that some flexibility is needed in determining the forwardmost point of installation that allows manufacturers to set the location of the seat attachment point to the sliding track in any manufacturer-designated position that allows for customer-ergonomics and safety, while still meeting the spirit of the expanded cargo-carrying requirement.[3190] The Auto Alliance further commented that the forwardmost attachment point of the seat structure to the floor is still a viable method of measurement, even when there is a sliding track between the floor attachment point and the seat.[3191]

NHTSA did not propose any vehicle reclassifications and is not adopting a regulatory change at this time. Based on its review of the comments, NHTSA agrees that flexibility is warranted to accommodate safety and customer demand but clarifies that the regulation requires seats that are not removed to be stowed—that is, moved so as to form a cargo area behind the seats. Manufacturers can freely designate the seating location in the sliding track to establish the forwardmost point of installation. At that seat location, the forwardmost point of installation is the forwardmost attachment point of the seat structure (including any carriage structures) to the floor in the sliding track. Vehicles will be considered to meet the characteristic provided the rear of the seats can be moved forward beyond that point and the seats articulate to an unusable stowed position either in the floor of the vehicle or at the front perimeter of expanded cargo area.[3192]

The second issue concerns the "flatness" and "levelness" of folded rear seats that use the seat backs to form a raised cargo surface and whether the seats must form a continuous flat, leveled surface. Many SUVs have three rows of designated seating positions, where the second row has "captain's seats" (*i.e.*, two independent bucket seats), rather than the traditional bench-style seating more common when the provision was added to NHTSA's regulation. When captain's seats are folded down, the seatback can form a flat surface for expanded cargo-carrying purposes, but the surface of the seatbacks may be angled (*i.e.*, at some angle slightly greater than 0°), or may be at a different level with the rest of the cargo area (*i.e.*, horizontal surface of folded seats is 0° at a different height from horizontal surface of cargo area behind the seats). Captain's seats, when folded flat, may also leave significant gaps around and between the seats. Some manufacturers have opted to use plastic panels to level the surface and to covers the gaps between seats, while others have left the space open and the surface angled or at different levels.

[3189] The National Automobile Dealers Association commented generally that it does not support any substantial modifications to the existing passenger car and light truck fleet definitions.
[3190] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.
[3191] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3192] The front perimeter of the cargo area is the plane formed behind the front seats and extending from one side of the vehicle to the other.

NHTSA sought comments in the NPRM on the following questions related to the requirement for a flat, leveled cargo surface:

- Does the cargo surface need to be flat and level in exactly the same plane, or does it fulfill the intent of the criterion and provide appropriate cargo-carrying functionality for the cargo surface to be other than flat and level in the same plane?
- Does the cargo surface need to be flat and level across the entire surface, or are (potentially large) gaps in that surface consistent with the intent of the criterion and providing appropriate cargo-carrying functionality? Should panels to fill gaps be required?
- Certain third row seats are located on top the rear axle causing them to sit higher and closer to the vehicle roof. When these seats fold flat the available cargo-carrying volume is reduced. Is cargo-carrying functionality better ensured by setting a minimum amount of useable cargo-carrying volume in a vehicle when seats fold flat?

The Auto Alliance, Fiat Chrysler, Hyundai, Kia, and one individual, Walter Kreucher, commented on these seating issues. The Auto Alliance, Fiat Chrysler, and Walter Kreucher believed that the criteria for a "flat, leveled cargo surface" should not be interpreted to mean that a cargo surface must be flat and level in exactly the same plane.[3193] The comments noted that a surface that is not exactly flat and level in the same plane can still provide substantial cargo-carrying capacity, while allowing manufacturers to provide ergonomically comfortable seats that meet safety requirements.[3194] The comments stated that NHTSA should not establish a minimum amount of cargo surface area for seats that remain within the vehicle.[3195] Instead, they preferred that manufacturers should be allowed to determine the methodology for providing appropriate cargo-carrying functionality without NHTSA stipulating additional requirements for flat and level surfaces or gaps and gap-filling panels.[3196]

The Auto Alliance and Fiat Chrysler argued that area or volume requirements are not needed, as those attributes speak to overall vehicle size and shape, which should remain a consumer choice.[3197] The requirements for expanded cargo- or other non-passenger-carrying purposes are fully met in the existing regulation, which requires a flat, leveled cargo surface with two rows of seats that are folded or stowed. Fiat Chrysler also commented that potential new requirements would likely be interpreted and executed differently across manufacturers and could narrow the choice of engineering solutions and negatively affect other important vehicle attributes.[3198]

[3193] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Walter Kreucher, Detailed Comments, NHTSA-2018-0067-0444.

[3197] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.
[3198] Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.

Hyundai and Kia commented that instead of requiring panels, NHTSA could limit the size of the gaps around and between folded seats.[3199] In that case, manufacturers would have flexibility to use panels if they wish but could take other measures to narrow gaps. On the other hand, Walter Kreucher stated that NHTSA should allow gaps of any size and not require the use of panels to cover them.[3200]

NHTSA is not adopting a regulatory change at this time. NHTSA agrees with commenters that it should not require a minimum amount of cargo surface area or volume for seats that remain within the vehicle, which could be difficult to meet for certain vehicle sizes and shapes that would otherwise be considered non-passenger vehicles. NHTSA agrees that the amount of cargo volume should be a consumer choice. Setting a minimum amount of cargo area or volume could have an adverse effect on potential new car buyers.

NHTSA notes that there may also be safety considerations involved with the requirement to have a flat, leveled cargo surface area formed by seat backs. A flat, leveled cargo surface area could prevent objects from having a ramp-like surface to gain momentum in rolling backwards into the tailgate's interior surface, potentially causing stress or damage on the tailgate's latching mechanism. For these reasons, several standards exist in the industry for preventing objects from sliding, such as standards from the American Disability Act (ADA) that specify floor and ground design requirements for protecting wheelchair seated occupants. In addition, objects resting on the tailgate could become a hazard or source of injury for individuals opening the tailgate. At this time, NHTSA accepts the commenters' position that having a cargo surface area that is exactly flat and level in the same plane may not be necessary. Comments did not provide enough information for NHTSA to identify any changes to the existing requirements. Therefore, at this time, NHTSA will retain its existing provisions for the stowing of foldable or pivoting seats to create a flat, leveled cargo surface, but NHTSA may consider conducting research in the future regarding these issues. NHTSA has also determined that it should set not a limit on the size of the gaps between folded seats at this time, although it may consider adopting such limits in the future. NHTSA continues to encourage manufacturers to consider the safety implications of all aspects of their vehicle designs, including any angling of the seat back cargo surface and whether it is appropriate to offer panels as optional equipment for covering any large gap openings.

b) Issues that NHTSA has Observed Regarding Classification Based on "Off-Road Capability"

(1) Measuring Vehicle Characteristics for Off-Highway Capability

For a vehicle to qualify as off-highway capable, in addition to either having 4WD or a GVWR more than 6,000 pounds, the vehicle must have four out of five characteristics indicative of off-highway operation.[3201] These characteristics are:

- An approach angle of not less than 28 degrees
- A breakover angle of not less than 14 degrees
- A departure angle of not less than 20 degrees
- A running clearance of not less than 20 centimeters
- Front and rear axle clearances of not less than 18 centimeters each

NHTSA's regulations require manufacturers to measure these characteristics when a vehicle is at its curb weight, on a level surface, with the front wheels parallel to the automobile's longitudinal centerline, and the tires inflated to the manufacturer's recommended cold inflation pressure.[3202] Given that the regulations describe the vehicle's physical position and characteristics at time of measurement, NHTSA previously assumed that manufacturers would use physical measurements of vehicles. In practice, NHTSA has instead received from manufacturers a mixture of angles and dimensions from design models (*i.e.*, the vehicle as designed, not as actually produced) and/or physical vehicle measurements.[3203] When appropriate, the agency will verify reported values by measuring production vehicles in the field. NHTSA currently requires that manufacturers use physical vehicle measurements as the basis for values reported to the agency for purposes of vehicle classification. NHTSA sought comment on whether regulatory changes are needed with respect to this issue.

(2) Approach, Breakover, and Departure Angles

Approach angle, breakover angle, and departure angle are relevant to determining off-highway capability. Large approach and departure angles ensure the front and rear bumpers and valance panels have sufficient clearance for obstacle avoidance while driving off-road. The breakover angle ensures sufficient body clearance from rocks and other objects located between the front and rear wheels while traversing rough terrain. Both the approach and departure angles are derived from a line tangent to the front (or rear) tire static loaded radius arc extending from the ground near the center of the tire patch to the lowest contact point on the front or rear of the vehicle. The term "static loaded radius arc" is based upon the definitions in SAE J1100 and

---

[3201] 49 CFR 523.5(b)(2).
[3202] *Id*.
[3203] NHTSA previously encountered a similar issue when manufacturers reported CAFE footprint information. In the October 2012 final rule, NHTSA clarified manufacturers must submit footprint measurements based upon production values. 77 FR 63138 (October 15, 2012).

J1544. The term is defined as the distance from wheel axis of rotation to the supporting surface (ground) at a given load of the vehicle and stated inflation pressure of the tire (manufacturer's recommended cold inflation pressure).[3204]

The static loaded radius arc is easy to measure, but the imaginary line tangent to the static loaded radius arc is difficult to ascertain in the field. The approach and departure angles are the angles between the line tangent to the static loaded radius arc and the level ground on which the test vehicle rests. Simpler measurements that provide good approximations for the approach and departure angles involve using either a line tangent to the outside diameter or perimeter of the tire or a line that originates at the geometric center of the tire contact patch and extends to the lowest contact point on the front or rear of the vehicle. The first method provides an angle slightly greater than, and the second method provides an angle slightly less than, the angle derived from the true static loaded radius arc. Both approaches can be used to measure angles in the field to verify data submitted by the manufacturers used to determine light truck classification decisions.

NHTSA sought comment on what the effect would be if it replaced reference to the "static loaded arc radius" with a different term like "outside perimeter of the tire" or "geometric center of the tire contact patch." The Auto Alliance and Fiat Chrysler offered comments. The Auto Alliance and Fiat Chrysler commented that only a measurement using the static loaded arc radius reasonably reflects the tire condition during off-road events that approach, breakover, and departure angles are quantifying. They also stated the static loaded arc radius best reflects the actual condition that exists versus the outside tire diameter.[3205] Finally, the Auto Alliance commented the static loaded arc radius is easy to measure; therefore, the off-road criteria should remain tied to the static loaded arc radius.[3206]

After reviewing the comments, NHTSA agrees that the static loaded arc radius is the most accurate way to account for the condition of the tire and the vehicle-to-ground interaction during off-road events. NHTSA has decided to accept the Auto Alliance's and Fiat Chrysler's views and will retain the existing definitions for off-road angles based upon the static loaded arc radius.

(3) Running Clearance

NHTSA regulations define "running clearance" as "the distance from the surface on which an automobile is standing to the lowest point on the automobile, excluding unsprung weight."[3207] Unsprung weight includes the components (*e.g.*, suspension, wheels, axles, and other components directly connected to the wheels and axles) that are connected and translate with the wheels. Sprung weight, on the other hand, includes all components fixed underneath the

[3204] 49 CFR 523.2.

[3206] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3207] *Id*.

vehicle and translate with the vehicle body (*e.g.*, mufflers and subframes). To clarify these requirements, NHTSA previously issued a letter of interpretation stating that certain parts of a vehicle—such as tire aero deflectors that are made of flexible plastic, bend without breaking, and return to their original position—would not count against the 20-centimeter running clearance requirement.[3208] The agency explained that this does not mean a vehicle with less than 20-centimeters running clearance could be elevated by an upward force that bends the deflectors and still be considered compliant with the running clearance criterion, as it would be inconsistent with the conditions listed in the introductory paragraph of 49 CFR 523.5(b)(2). Further, NHTSA explained that without a flexible component installed, the vehicle must meet the 20-centimeter running clearance along its entire underside. This 20-centimeter clearance is required for all sprung weight components.

The agency is aware of vehicle designs that incorporate rigid (*i.e.*, inflexible) air dams, valance panels, exhaust pipes, and other components, equipped as manufacturers' standard or optional equipment (*e.g.*, running boards and towing hitches), that likely do not meet the 20-centimeter running clearance requirement. Despite these rigid features, it appears manufacturers are not taking these components into consideration when making measurements. Additionally, NHTSA believes some manufacturers may provide dimensions for their base vehicles without considering optional or various trim level components that may reduce the vehicle's ground clearance. Consistent with our approach to other measurements, NHTSA believes that ground clearance, as well as all the other off-highway criteria for a light truck determination, should use the measurements from vehicles with all standard and optional equipment installed, at the time of the first retail sale.[3209] The agency reiterates that the characteristics listed in 49 CFR 523.5(b)(2) are characteristics indicative of off-highway capability. A fixed feature—such as an air dam that does not flex and return to its original state or an exhaust that could detach—inherently interferes with the off-highway capability of these vehicles. If manufacturers seek to classify these vehicles as light trucks under 49 CFR 523.5(b)(2) and the vehicles do not meet the four remaining characteristics to demonstrate off-highway capability, they must be classified as passenger cars.

In the NPRM, NHTSA sought public comments on how to consider components such as air dams, exhaust pipes, and other hanging component features—especially those that are inflexible—as relates to running clearance and whether the agency should consider amending its definition in Part 523 to account for these components. The Auto Alliance and three automobile manufacturers—Fiat Chrysler, Hyundai, and Kia—commented on the questions. The Auto Alliance and Fiat Chrysler commented that no change is needed for the 20-centimeter running clearance requirement for fixed features of the vehicle; all fixed components must have 20-centimeter of running clearance.[3210] They agreed that flexible components that bend without

breaking and return to their original position do not count against the 20-centimeter running clearance requirement.[3211] They disagreed with NHTSA's position that these requirements should apply to all vehicles with standard and optional equipment installed at the time of the first retail sale and proposed instead that the requirement should be "as shipped to the dealer."[3212] Additionally, the Auto Alliance asked NHTSA to make a specific allowance for vehicles that have adjustable ride height, such as air suspension, and permit the running clearance and other off-road clearance measurements to be made in the lifted or off- road mode.[3213] Hyundai and Kia urged NHTSA not to modify the definition of "running clearance," which currently is defined as "the distance from the surface on which an automobile is standing to the lowest point on the automobile, excluding unsprung weight."[3214]

Based upon the comments above, NHTSA has decided to retain its running clearance requirements for qualifying light trucks without change. First, running clearance means the distance from the surface on which an automobile is standing to all fixed components under the vehicle, excluding unsprung components, axle clearance components and flexible components that bend without breaking and returning to their original position as explained in NHTSA's previous interpretation. Second, NHTSA acknowledges that at this time, during validation testing for running clearance, a vehicle with optional equipment installed will only be tested "as shipped to the dealer." NHTSA has found that optional equipment can impact a vehicle's ability to comply with running clearance requirements, while optional equipment must be considered for other light truck agency validation tests unless the equipment has no impact on the outcome of the test.

(4) Front and Rear Axle Clearance

NHTSA regulations state that front and rear axle clearances of not less than 18 centimeters are another criterion that can be used for designating a vehicle as off-highway capable.[3215] The agency defines "axle clearance" as the vertical distance from the level surface on which an automobile is standing to the lowest point on the axle differential of the automobile.[3216]

The agency believes this definition may be outdated because of vehicle design changes, including axle system components and independent front and rear suspension components. In the past, traditional light trucks with and without 4WD systems had solid rear axles with center-mounted differentials on the axle. For these trucks, the rear axle differential was closer to the ground than any other axle or suspension system component. This traditional axle design still

---

[3216] 49 CFR 523.2.

exists today for some trucks with a solid chassis (also known as body-on-frame configuration). Today, however, many SUVs and CUVs that qualify as light trucks are constructed with a unibody frame and have unsprung (*e.g.*, control arms, tie rods, ball joints, struts, shocks, etc.) and sprung components (*e.g.*, the axle subframes) connected together as a part of the axle assembly.[3217] These unsprung and sprung components are located under the axles, making them lower to the ground than the axles and the differential, and were not contemplated when NHTSA established the definition and the allowable clearance for axles. The definition also did not originally account for 2WD vehicles with GVWRs greater than 6,000 pounds that had one axle without a differential, such as the model year 2018 Ford Expedition. Vehicles with axle components that are low enough to interfere with the vehicle's ability to perform off-road would seem inconsistent with the regulation's intent of ensuring off-highway capability, as Congress required.[3218]

In light of these issues, comments were sought in the NPRM on whether (and if so, how) to revise the definition of axle clearance. NHTSA sought comments on what unsprung axle components should be considered when determining a vehicle's axle clearance. The agency questioned whether the definition for axle clearance should be modified to account for axles without differentials. NHTSA also sought comment on whether the axle subframes surrounding the axle components but affixed directly to the vehicle unibody as sprung mass (lower to the ground than the axles) should be considered in the allowable running clearance discussed above. Finally, NHTSA sought comments on whether it should consider replacing both the running and axle clearance criteria with a single ground clearance criterion that considers all components underneath the vehicle that impact a vehicle's off-road capability.

Comments were received from the Auto Alliance, Fiat Chrysler, Hyundai, and Kia. All the manufacturers that commented claimed no change is needed to the current definition, regardless of whether the axle components are sprung or unsprung masses, as the bottom of the differential is the vulnerable component.[3219] The Auto Alliance also stated there is no need to further modify the definition to account for axles without differentials. Further, the Auto Alliance does not think a single criterion that considers all components under the axle is needed and prefers to keep the existing regulation.[3220] Fiat Chrysler and the Auto Alliance also recommended that 2WD SUVs and CUVs be reclassified back into the truck fleet, where they had been placed prior to the 2011 MY. Their position is that 2WD SUVs are designed to meet the "off-road-capable" definition in NHTSA's rules by having the required running and/or axle clearances as well as meeting other off-road dimensional criteria.[3221] Hyundai stated that changing the point of measurement now would have significant development and economic

impacts.[3222] Kia stated that it has designed its vehicles and developed product plans in reliance on the current definitions, and those designs and product plans cannot be modified cheaply or quickly.[3223]

NHTSA already addressed the comments on 2WD SUVs in a previous rulemaking, and NHTSA has no additional response at this time.[3224] Upon review of other comments, manufacturers did not clearly distinguish which parts of the axle sub-frames should be considered as sprung masses in order for NHTSA to understand if modifications are needed to its axle clearance requirements. Therefore, at this time, NHTSA is retaining its axle clearance requirements as currently specified. However, NHTSA still believes it is beneficial to continue efforts at defining those axle components that are sprung or unsprung masses before considering any changes to its regulatory provisions. In addition, NHTSA needs to understand any significant developmental and economic impacts that might be associated with any possible changes to its requirements. Therefore, NHTSA will consider collecting further information on these issues and may take further action related to this issue in the future.

B. EPA Compliance and Enforcement

1. Overview of the EPA Compliance Process

EPA established comprehensive vehicle certification, compliance, and enforcement provisions for the GHG standards as part of the rulemaking establishing the initial GHG standards for MY 2012-2016 vehicles.[3225] Manufacturers have been following these provisions since MY 2012 and EPA did not propose or seek comments on changing its compliance and enforcement program.

a) What Compliance Flexibilities and Incentives are Currently Available Under the CO_2 Program and How do Manufacturers Use Them?

Under EPA's regulations, manufacturers can use credit flexibilities to comply with CO_2 standards for passenger car or light truck compliance fleets. Similar to the CAFE program, manufacturers gain credits when the performance of a fleet exceeds its required CO_2 fleet average standard which can be carried forward for five years. EPA also allows a one-time credit carry-forward exceeding 5 years, allowing MY 2010-2015 to be carried forward through MY2021. A manufacturer's fleet performance that does not meet the fleet average standard generates a credit deficit. Manufacturers can carry credit deficits forward up to three model years before having to resolve the shortfall.

[3222] Hyundai, Detailed Comments, EPA-HQ-OAR-2018-0283-4411.
[3223] Kia, Detailed Comments, EPA-HQ-OAR-2018-0283-4195.
[3224] No new arguments have been raised beyond those already considered in the April 6, 2006, final rule (*see* 71 FR 17566).
[3225] *See* 75 FR 25468-25488 and 77 FR 62884-62887 for a description of these provisions. *See also* "The 2018 EPA Automotive Trends Report, Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975," EPA-420-R-19-002 March 2019 for additional information regarding EPA compliance determinations."

NHTSA's program continues the 5-year carry-forward and 3-year carryback, as required by statute. Credit "transfer" means the ability of manufacturers to move credits from their passenger car fleet to their light truck fleet, or vice versa. As part of the EISA amendments to EPCA, NHTSA was required to establish by regulation a CAFE credit transferring program, now codified at 49 CFR part 536, to allow a manufacturer to transfer credits between its car and truck fleets to achieve compliance with the standards. For example, credits earned by over-compliance with a manufacturer's car fleet average standard could be used to offset debits incurred because the manufacturer did not meet the truck fleet average standard in a given year.

Under Section 202(a) of the CAA, there is no statutory limitation on car/truck credit transfers, and EPA's CO_2 program allows unlimited credit transfers across a manufacturer's car and light truck fleets to meet CO_2 standards.

EPA requested comment on a variety of "enhanced flexibilities" whereby EPA could make adjustments to current incentives and credit provisions and potentially add new flexibility opportunities to expand the means by which manufacturers may satisfy standards. Some of these additional flexibilities would not result in a reduction in program stringency, while others would incentivize technologies that could realize greater CO_2 emissions reductions over a longer term, but would result in a loss of emission benefits in the short-term, as discussed below. EPA requested comments on these topics to support the increased application of technologies that the automotive industry is developing and deploying that could potentially lead to further long-term emissions reductions and allow manufacturers to comply with standards while reducing costs.

EPA explained that one category of flexibilities, such as off-cycle credits and credit banking, involve credits that are based on real world emissions reductions and do not represent a loss of overall emissions benefits or a reduction in program stringency, yet offer manufacturers potentially lower-cost or more efficient path to compliance. Another category of flexibilities, such as incentives for battery electric vehicles, hybrid technologies, and alternative fuels, do result in a loss of emissions benefit and represent a reduction in the effective stringency of the standards to the extent the incentives are used by manufacturers. These incentives would help manufacturers meet a numerically more stringent standard, but would not reduce real-world CO_2 emissions in the short term compared to a lower stringency option with fewer such incentives. EPA's policy rationale for providing such incentives, as articulated in the 2012 rulemaking, was that such programs could incentivize the development and deployment of advanced technologies with the potential to lead to greater CO_2 emissions reductions in the longer-term, where such technologies today are limited by higher costs, market barriers, infrastructure, and consumer awareness.[3226] Such incentive approaches would also result in rewarding automakers who invest in certain technological pathways, rather than being technology neutral.

Prior to the proposal, automakers and other stakeholders expressed support for this type of compliance flexibility. For example, in March 2018, Ford stated, "We support increasing clean car standards through 2025 and are not asking for a rollback. We want one set of standards

[3226] *See* 77 FR 62810-62826 (Oct. 15, 2012).

nationally, along with additional flexibility to help us provide more affordable options for our customers."[3227] Honda, in April 2018, also expressed its support for an approach that retained the existing standards while extending the advanced technology multipliers for electrified vehicles, eliminated automakers' responsibility for the impact of upstream emissions from the electric grid, and accommodated more off-cycle technologies.[3228]

EPA's request for comments was largely based on its consideration of input from automakers and other stakeholders, including suppliers and alternative fuels industries, supporting a variety of program flexibilities.[3229] The following provides an overview of EPA's request for comments on several flexibility concepts, the comments EPA received, and the agency's response to those comments. After considering comments, EPA is not adopting new incentives in the areas of credit multipliers (with the exception of multipliers for natural gas vehicles), new incentives for hybrid vehicles, incentives for autonomous or connected vehicles, or alternative fueled vehicles other than natural gas, as part of this final rule. EPA is finalizing program changes for the treatment of upstream emissions for electric vehicles, the treatment of natural gas vehicles, the treatment of hybrid and target-beating full-size pickup trucks, and off-cycle credits, as discussed below.

(1) *Credit Flexibilities*

Under the EPA program, CO_2 credits may be carried forward, or banked, for a period of five years, with the exception that MY 2010-2015 credits may be carried forward and used through MY 2021. CO_2 credits may also be traded between manufacturers and transferred between passenger car and light truck fleets similar to the CAFE program, but without any adjustment for fuel savings. Under Section 202(a) of the CAA, there is no statutory limitation on credit transfers between a manufacturer's passenger car and light truck fleets, and EPA's CO_2 program allows unlimited credit transfers across a manufacturer's passenger car and light truck fleets to comply with CO_2 standards. This flexibility is based on the expectation that it will help facilitate manufacturer compliance with CO_2 standards in the lead time provided, and allow CO_2 emissions reductions to be achieved in the most cost effective way.

Automakers suggested, prior to the NPRM proposal, a variety of ways in which CO_2 credit life could be extended under the CAA, like allowing automakers to carry-forward MY 2010 and later banked credits to MY 2025, extending the life of credits beyond five years, or even unlimited credit life where credits would not expire. EPA requested comments in the NPRM on extending credit carry-forward under the CO_2 program beyond the current five years, including unlimited credit life.

[3227] "A Measure of Progress" Bill Ford, Executive Chairman, Ford Motor Company, and Jim Hackett, President and CEO, Ford Motor Company, March 27, 2018, https://medium.com/cityoftomorrow/a-measure-of-progress-bc34ad2b0ed.
[3228] Honda Release "Our Perspective – Vehicle Greenhouse Gas and Fuel Economy Standards," April 20, 2018, http://news.honda.com/newsandviews/pov.aspx?id=10275-en.
[3229] Memorandum to docket EPA-HQ-OAR-2018-0283 regarding meetings with the Alliance of Automobile Manufacturers on April 16, 2018 and Global Automakers on April 17, 2018. EPA-HQ-OAR-2018-0283-0022.

General comments were received in response to the NPRM from the National Automobile Dealers Association and Volkswagen. They commented that credit carry-forward and carryback options help with annual compliance with the CO_2 program.[3230] They stated that these mechanisms allow manufacturers to become compliant over the course of the time a credit is usable in the market.[3231] Toyota, General Motors, Fiat Chrysler, the Auto Alliance, and the Global Automakers each commented that CO_2 credits earned by manufacturers need a longer life so they may be carried forward further than the current five-year limitation.[3232] They asked for an unlimited period for using CO_2 credits without restrictions, since they argue that automakers have earned those credits and should be allowed to use them however they see fit.[3233] They also stated that this would incentivize manufacturers to make early reductions in CO_2 emissions.[3234] Furthermore, it was noted that credits are earned when manufacturers achieve lower CO_2 fleet average emissions than otherwise required by regulation in any given model year. They stated that this typically results from actions taken by a manufacturer to deploy specific models or more efficient technology than required, often at a higher cost. Such technologies reduce the amount of CO_2 emissions released into the atmosphere over the life of the vehicle, which could be over several decades. Therefore, the resulting credit earned by a manufacturer for having made the product or technology investment that resulted in the reduced emissions should not be limited to five years.

Global Automakers, the Auto Alliance, Fiat Chrysler, and Toyota requested a one-time expiration date extension through 2026 for CO_2 credits earned in MYs 2010-2015.[3235] They asserted that earned credits represent actual CO_2 reductions and increasing their lifespan will allow for better compliance. Conversely, Honda disagreed with the extension of MY 2010-2015 credits through 2026 because they have been selling their credits under the assumption that they would expire.[3236] Honda stated that shorter life (soon to expire) credits are worth less than longer life credits, leading to a disadvantage for manufacturers who have already sold these credits at a lower price. Honda asserted that the one-time extension would benefit only a few automakers.[3237] However, Honda did agree that a one-time extension through 2026 for MYs 2016-2020 CO_2 credits would assist with compliance because these credits have yet to be involved in trades.[3238]

[3238] Honda, Detailed Comments, NHTSA-2018-0067-11818.

In sum, commenters requested either unlimited allowances to carry-forward surplus credits without any expiration date, a one-time expiration date extension through 2026 for CO_2 credits earned from MY 2010 and later, or consideration for extending credit life longer than the current five-year provision. After considering the comments received, EPA has decided not to change its credit carry-forward provisions at this time, and will retain the credit carry-forward period under the CO_2 program at five years for credits generated in MYs 2016 and later. EPA does not believe any changes to its credit carry-forward provisions are warranted. EPA notes that NHTSA's CAFE program is constrained by statute to a five-year carry-forward so if EPA adopted a longer carry-forward period, it might be of limited use since the level of stringency of the CO_2 and CAFE standards is similar across the programs. Also, the analysis on which the tailpipe CO_2 emissions standards finalized today are based, assumed a five-year carry-forward period for credits.

Another reason for denying manufacturers' requests is the potential inequitable advantage a longer credit life could have for manufacturers with surplus credits, especially those with significant amounts of credits currently banked for multiple model years. Manufacturers without credits, or manufacturers who have already sold their credits at current market values based on the present five-year carry-forward credit lifespan, as Honda discussed, will be significantly disadvantaged.[3239] These manufacturers are unlikely to be able to renegotiate the price of credit trades already made. Manufacturers with large amounts of credits would clearly be advantaged and able to distort the market in ways unfavorable to the goal of reducing emissions. EPA is concerned that these manufacturers will be able to create uncertainties in the market by being able to infuse large volumes of credits into future model years where it may even be possible to delay some cost-effective technologies from entering production because manufacturers are relying upon these credits as an alternative pathway to compliance.

(2) *Advanced Technology Incentives*

The existing EPA CO_2 program provides incentives for electric vehicles, fuel-cell vehicles, plug-in hybrid vehicles, and natural gas vehicles. The 2012 rulemaking allowed manufacturers to use a 0 grams/mile emissions factor for all electric powered vehicles rather than having to account for the CO_2 emissions associated with upstream electricity generation, up to a per-manufacturer cumulative production cap for MYs 2022-2025. The program also includes multiplier incentives that allow manufacturers to count advanced technology vehicles as more than one vehicle in the compliance calculations. The multipliers began with MY 2017 and end after MY 2021.[3240] Prior to the proposal, stakeholders suggested that these incentives should be expanded to support further the production of advanced technologies by allowing manufacturers to continue to use the 0 grams/mile emissions factor for electric powered vehicles rather than having to account for upstream electricity generation emissions and by extending and potentially increasing the multiplier incentives.

[3239] Honda, Detailed Comments, NHTSA-2018-0067-11818.

[3240] The multipliers are for EV/FCVs: 2017–2019—2.0, 2020—1.75, 2021—1.5; for PHEVs and dedicated and dual-fuel CNG vehicles: 2017–2019—1.6, 2020—1.45, 2021—1.3.

First, EPA requested comments on extending the use of 0 grams/mile emissions factor for electric powered vehicles.

The Auto Alliance, Global Automakers, and several manufacturers commented that upstream utility emissions come from power plants, not vehicle tailpipes, and manufacturers have no control over the feedstock used by those power plants and should not be held responsible for their upstream electricity emissions.[3241] The Auto Alliance further commented that removing upstream accounting is not an incentive for advanced technology vehicles; rather, it should be seen as a correction to remove responsibility for emissions over which the automakers have no control.[3242] Fiat Chrysler commented that "requiring upstream accounting could impede development of BEVs or PHEVs, as accounting of upstream emissions degrades the CO_2 performance of BEVs to the level of PHEVs, and PHEVs to the level of a conventional hybrid electric vehicle. This, in effect, disincentivizes the technology."[3243]

Several other commenters also supported not counting upstream emissions and instead only counting electric powered vehicle tailpipe emissions of 0 grams/mile.[3244] These commenters included NCAT, SAFE, BorgWarner, CALSTART, Eaton, and Edison Electric Institute.

API did not support continuing the 0 grams/mile emission factor for electricity use, commenting that by failing to factor the real contribution of upstream CO_2 emissions from electric generation, the regulatory agencies would distort the market for developing transportation fuel alternatives.[3245] API commented that EPA should not ignore the environmental burden of upstream emissions in granting production incentives to automakers.

Manufacturers of Emission Controls Association (MECA) commented that "with the growing emphasis on real-world emission reductions, it becomes increasingly important to consider all emissions to the environment, including upstream emissions. Numerous studies have shown that in many parts of the country, the temporary 0 grams/mile upstream emissions factor is not delivered in the real-world … MECA believes that EPA should continue to set performance-based standards that assess technology pathways based on delivering the intended emission reductions over the full well-to-wheels vehicle life cycle in the real-world."[3246] Motor & Equipment Manufacturers Association (MEMA) also supported a well-to-wheel fuel lifecycle approach, commenting that without this type of comprehensive assessment on the fuel impacts and comprehensive CO_2 costs, policies improperly "slant toward preferred technologies."[3247]

[3241] *See, e.g.*, Volkswagen, Detailed Comments, NHTSA-2017-0069-0583.

[3246] MECA, Detailed Comments, NHTSA-2018-0067-11994.
[3247] MEMA, EPA-HQ-OAR-2018-0283-5692. *See* https://www.mema.org/sites/default/files/resource/MEMA%20CAFE%20and%20GHG%20Vehicle%20Comments%20FINAL%20with%20Appendices%20Oct%2026%202018.pdf.

Nonetheless, MEMA commented that it is not opposed to continuing to allow 0 grams/mile emissions factor for electric powered vehicles through 2026.

The Union of Concerned Scientists (UCS) commented that not accounting for upstream emissions combined with the multipliers has a significant impact on the efficacy of the standard, and extending these regulatory incentives is more likely to result in a credit giveaway than to drive additional deployment of electric vehicles.[3248] UCS further commented that, to date, more than half of the electric vehicles sold have been in California and the states that have adopted California's ZEV standards; however, UCS asserted, federal standards ignore the upstream emissions for all vehicles sold.

After carefully considering the wide range of comments on whether to include upstream emissions associated with electricity use in the compliance calculations for electrified vehicles, EPA has decided to allow the continued use of the 0 grams/mile emissions factor with no per-manufacturer production caps or other limitations. EPA is revising its regulations to remove the production caps and related provisions. When EPA initially adopted a production cap for manufacturers that use the 0 grams/mile emissions factor, in the rulemaking to establish CO_2 standards for MY 2012-2016 vehicles, there were no controls in place for CO_2 emissions from electricity production.[3249] This was also the case when EPA extended the 0 grams/mile upstream provision and revised the production caps in the rule establishing MY 2017-2025 standards.[3250] However, since then, EPA has adopted a program to control CO_2 emissions from power plants.[3251] Emissions from the power sector have been declining and that trend is projected to continue.[3252] For these reasons, EPA no longer views the upstream emissions factor as an incentive in the same way it views a multiplier incentive which provides bonus credits. EPA agrees that, at this time, manufacturers should not account for upstream utility emissions. Therefore, EPA is adopting regulatory changes consistent with its historical practice of basing compliance with vehicle emissions standards on tailpipe emissions through model year 2026. EPA may choose to reconsider this decision in a future CO_2 rulemaking, and will reexamine the issue when establishing standards commencing with the 2027 model year[3253].

Second, EPA requested comments on extending or increasing advanced technology incentives, including multiplier incentives, with multipliers in the range of 2.0-4.5. EPA

[3248] UCS, Detailed Comments, NHTSA-2018-0067-12039.
[3249] 75 FR 25341, May 7, 2010.

[3251] 84 FR 32520, July 8, 2019.
[3252] 84 FR 32561.
[3253] By comparison, the CAFE program uses an energy efficiency metric instead of an emissions metric, and standards that are expressed in miles per gallon. For PHEVs and BEVs, to determine gasoline the equivalent fuel economy for operation on electricity, a Petroleum Equivalency Factor (PEF) is applied to the measured electrical consumption. The PEF for electricity was established by the Department of Energy, as required by statute, and includes an accounting for upstream energy associated with the production and distribution for electricity relative to gasoline. Therefore, the CAFE program includes upstream accounting based on the metric that is consistent with the fuel economy metric. The PEF for electricity also includes an incentive that effectively counts only 15 percent of the electrical energy consumed.

received a wide range of comments both for and against increasing the multiplier incentives. The MY 2017-2025 CO_2 program finalized in 2012 included incentive multipliers for certain advanced technologies for MY 2017-2021 vehicles.

The Auto Alliance, Global Automakers, and several individual manufacturers commented in support of continued and increased multipliers. The Auto Alliance commented that EPA should extend and significantly expand multipliers "to encourage a transition to these technologies while cost, range, and infrastructure challenges are addressed to encourage ongoing investments in advanced technologies."[3254] Global Automakers commented that multipliers should be included through MY 2026, set at values that encourage ongoing investment in advanced technologies, without diluting overall efficiency improvements in the program.[3255] NCAT, Eaton, Plug-in America, Alliance to Save Energy, SAFE, and MEMA also supported additional multiplier incentives to encourage further the production and sale of advanced technology vehicles.[3256]

EPA also received comments against extending the multiplier credits. UCS commented that reducing the stringency of the standards lessens the need for the adoption of these vehicles and undermines the initial rationale for these credits, resulting in a significant bank of credits which would further erode the benefits of these standards.[3257] American Council for an Energy-Efficient Economy (ACEEE) commented that providing multiplier incentives for any longer period, or at a greater rate than those currently in place, would create windfall credits for manufacturers given the industry's current product plans.[3258] Fiat Chrysler commented generally in support of a multiplier incentive, but noted that since multipliers are a CO_2-only flexibility not present in the CAFE program, greater use of multipliers would result in further disharmonizing the programs.[3259] API commented against multipliers, stating that the program should be technology neutral and that regulatory agencies should not incentivize either producer or consumer investments in government-selected technologies applied to government-selected vehicle categories.[3260]

In this final rule, EPA is neither adopting any additional EV or FCV multipliers nor extending the existing multipliers scheduled to phase out after MY 2021 for EVs, PHEVs, and FCVs. EPA is concerned that additional multiplier incentives beyond those already in place for these vehicles which are currently available to consumers would reduce the emissions benefits associated with the program. As discussed below in section IX.B.1.a.(3)(b), EPA is providing an additional multiplier for dedicated and dual-fuel NGVs, which are not currently produced by

auto manufacturers, for MYs 2022-2026. The CO_2 program already provides a significant incentive for PHEVs, EVs, and FCVs by only counting tailpipe emissions (not accounting for upstream emissions).

(3) Special Considerations

(a) Incentives for Connected or Automated Vehicles

Connected and automated (including autonomous) vehicles have the potential to impact significantly vehicle emissions in the future, with their aggregate impact being either positive or negative, depending on a large number of vehicle-specific and system-wide factors. EPA noted in the proposal that connected or automated vehicles would be eligible for credits under the off-cycle program if a manufacturer provides data sufficient to demonstrate the real-world emissions benefits of such technology applied to its vehicles. However, demonstrating the incremental real-world benefits of these emerging technologies will be challenging. Prior to the proposal, stakeholders suggested that EPA should consider an incentive for these technologies without requiring individual manufacturers to demonstrate real-world emissions benefits of the technologies. A number of stakeholders also requested that EPA consider credits for automated and connected vehicles that are placed in ridesharing or other high mileage applications, where any potential environmental benefits could be multiplied due to the high utilization of these vehicles. EPA requested comment on such incentives as a way to facilitate increased use of these technologies, including some level of assurance that they will lead to future additional emissions reductions. For example, EPA stated in the proposal that any near-term incentive program should include some demonstration that the technologies will be both truly new and have some connection to overall environmental benefits. EPA further outlined and sought comment on several approaches to incentivize automated and connected vehicle technologies.

EPA received comments supporting and opposing incentives for automated and connected vehicles. The Auto Alliance commented that the agencies should incentivize the adoption of these technologies and provide for possibly additional credit once the benefits beyond the credit values have been confirmed.[3261] It further commented that a growing body of modeling results, as well as real-world driving statistics, show that current automated driving technologies improve real-world fuel efficiency and reduce CO_2 emissions. SAFE commented that connected automated vehicles have tremendous potential to save lives, and when combined with ride-sharing and electric powertrains, they can also increase efficiencies and save fuel.[3262] SAFE argued that an initial review of the literature shows the potential for these technologies to improve fuel economy by up to 25 percent when they are optimized and aggregated alongside other traditional efficiency technologies. Toyota commented that automated vehicles, and possibly new mobility models such as ridesharing, can help attain societal goals concerning climate change, energy security, traffic congestion, and safety.[3263] Ford commented that it is supportive of credits for future connected and automated vehicles and that autonomous vehicles

[3261] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3262] SAFE, Detailed Comments, NHTSA-2018-0067-11981.
[3263] Toyota, Detailed Comments, NHTSA-2018-0067-12150.

are considered the future of personal mobility, with many manufacturers announcing plans to release autonomous-capable vehicles in the near term.[3264] Ford added that these vehicles have the potential to not only provide meaningful real-world CO_2 and fuel economy benefits, but also add true societal benefit for the public good by providing transportation to those who would otherwise not have access. General Motors and Jaguar Land Rover commented in favor of additional credits for vehicles placed in ride-sharing or high mileage applications.[3265]

SAFE commented that autonomous vehicles will lead to new jobs and better worker productivity. It stated that these vehicles will also reduce congestion and lead to safer travel.[3266]

Other commenters opposed incentives for automated and connected vehicles, generally commenting that while the technologies are promising, the impacts of the technologies remain highly uncertain and therefore incentives are not appropriate. ACEEE commented that EPA should not incentivize technologies such as automated vehicle technology or ridesharing services, unless and until it can be demonstrated that such an incentive will result in emissions reduction benefits and will not undermine the existing standards.[3267] ACEEE believes that there currently exists no real-world data to justify granting of off-cycle credits for automated vehicle technologies, and that providing automakers credits for deploying technologies which are driven by demands other than fuel savings and emissions reduction only allows them to make fewer real-world emissions reductions elsewhere. ACEEE further stated that while automated vehicles promise all-new possibilities and efficiencies in transportation and the use of infrastructure, the net impact on transportation sector energy use and emissions is unknown.

UCS commented that the "evidence to-date does not warrant incentivizing such technologies—there is no provable environmental benefit of such technologies, and the agencies have previously correctly acknowledged that any such potential impacts would be related to indirect benefits, which raise serious concerns about compliance and enforcement to ensure the integrity of the program."[3268] Honda commented that there remains considerable uncertainty in the literature regarding the energy and environmental benefits (or negative benefits) of connected/automated vehicle technology.[3269] Honda commented that if technology benefits can be verified under robust, repeatable conditions, they should warrant off-cycle credits under the existing off-cycle program. Honda does not believe credits should be granted for application of technology alone.

CARB commented that new compliance flexibilities (or off-cycle credit categories) for automated vehicles are not appropriate at this time.[3270] CARB believes that, although the technology is widely expected to provide safety and mobility benefits, automakers are expected

[3264] Ford, Detailed Comments, NHTSA-2018-0067-11928.
[3265] General Motors, Detailed Comments, NHTSA-2018-0067-11858; Jaguar Land Rover, Detailed Comments, NHTSA-2018-0067-11916.
[3266] SAFE, Detailed Comments, NHTSA-2018-0067-11981.

[3270] CARB, Detailed Comments, NHTSA-2018-0067-11873.

to bring the technology to market regardless, so incentives are unnecessary, and it is not established that these technologies will reduce emissions given their potential for high annual mileage. Resources for the Future commented they do not see a rationale for providing special credits to automated vehicles since such vehicles could increase or decrease emissions.[3271] Competitive Enterprise Institute (CEI) commented that some connected and/or automated vehicle technology applications—namely platooning—may improve fuel efficiency through improved aerodynamics and thus reduce CO_2 emissions; however, such applications to date are limited to heavy-vehicle prototypes beyond the scope of this rulemaking and in any event should be subject to verification prior to any award of off-cycle credits.[3272] CEI commented further: "We urge EPA to preserve the existing off-cycle program requirement that manufacturers demonstrate CO_2 emissions reductions prior to the award of credits, rather than picking technology winners and losers that have nothing to do with fuel economy or emissions." National Association of Truck Stop Operators (NATSO) commented against incentives, stating that although automated vehicles have the potential positively to transform transportation (and indeed day-to-day life) in the U.S., there are also a number of complexities and potential costs associated with them.[3273]

EPA is not adopting new incentives for automated and connected vehicles. While EPA agrees there may be potential for such technologies to reduce emissions long-term, depending on how the technologies are developed, implemented, and used, EPA remains concerned about the high degree of uncertainty regarding the impacts of the technologies and potential loss of emissions reductions associated with such incentives. EPA agrees with the comments that, at this time, it is more appropriate for manufacturers to seek credits through the existing off-cycle credits program where manufacturers would be required to provide data demonstrating direct emissions improvements for the technologies.

(b) Natural Gas Vehicle (NGV) Credits

Vehicles that are able to run on compressed natural gas (CNG) are eligible for an advanced technology multiplier credit for MYs 2017-2021, as discussed in the Advanced Technology Incentives section above. Dual-fueled natural gas vehicles, which can run either on natural gas or on gasoline, also may use utility factors higher than 0.5 when weighting tailpipe emissions measured over the test procedures while operating on natural gas and gasoline test fuels if the vehicles meet minimum design criteria, including minimum CNG range requirements. Prior to the proposal, EPA received input from several industry stakeholders that supported expanding these incentives to stimulate production of vehicles capable of operating on natural gas, including treating incentives for natural gas vehicles on par with those for electric vehicles and other advanced technologies, and adjusting or removing the minimum range requirements for dual-fueled CNG vehicles. EPA requested comments on these potential additional incentives for natural gas fueled vehicles.

[3271] Resources for the Future, Detailed Comments, NHTSA-2018-0067-11789.
[3272] CEI, Detailed Comments, EPA-HQ-OAR-2018-0283-4166.
[3273] NATSO, Detailed Comments, EPA-HQ-OAR-2018-0283-5484.

Among comments received regarding incentives for NGVs, Ariel Corporation and VNG together commented that NGVs can be effectively promoted by providing a level playing field and regulatory parity with EVs.[3274] They stated, "an effective alternative compliance pathway for NGVs can be established with a few simple changes to the regulations including applying the '0.15 divisor' to emissions calculations, which would harmonize EPA's regulations with the statutory CAFE program, and recognize the real-world emissions benefits of RNG [renewable natural gas], and provide NGVs with reasonable parity with EVs." Ariel and VNG commented also that EPA should offer advanced technology production multipliers for NGVs on par with EVs and FCVs, with NGVs receiving these incentives at the same level and for the same duration as electric and fuel-cell vehicles. These commenters believe that while NGVs have lower technology hurdles than these vehicles, they face similar infrastructure challenges and offer similar or superior emissions benefits through the use of RNG.

Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association commented in a joint submission that NHTSA and EPA should use this rulemaking opportunity to expand incentives for NGVs and thereby increase the availability of NGVs in the light-duty sector, particularly for pickup trucks, work vans, and sport utility vehicles.[3275] These commenters also submitted comments supporting additional incentives for full-size pickup NGVs and incentives for vehicles equipped to be converted to operate on natural gas. Coalition for Renewable Natural Gas, et al., commented that allowing 0 grams/mile accounting for electricity use is favorable to electric vehicles because it allows electric vehicle manufacturers to take credit for anticipated improvements in emissions associated with the electric grid resulting from increased use of natural gas and renewable energy.[3276] It further commented that given the significant amount of renewable natural gas currently being used and projected to be used in future years, using a factor of 0.15 or even greater to offset NGV emissions is warranted because RNG use reduces carbon dioxide emissions by 85 percent or more in most cases. Ingevity similarly commented in support of EPA including a 0.15 multiplier incentive for purposes of CO_2 compliance parity between natural gas and electric dual-fuel vehicles as necessary and critical to promote the commercialization of light-duty natural gas vehicles and stimulate the increased utilization of RNG. Ingevity added that growth in the natural gas vehicle market is necessary to meet future RFS obligations.[3277]

United States Senator James M. Inhofe commented that "even if all current incentives for EVs are eliminated, EVs still have a compliance advantage going forward. This is because the policy and technical approaches underlying the [CO_2] regulations embedded preferential treatment for the previous administration's favored technology. I respectfully ask you not to give NGVs preferential treatment, but to level the playing field to allow the marketplace to determine

[3274] Joint Submission from Ariel Corp. and VNG.co, Detailed Comments, NHTSA-2018-0067-7573.
[3275] Joint Submission from the Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association, Detailed Comments, NHTSA-2018-0067-11967.
[3276] Joint Submission from the Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association, Detailed Comments, NHTSA-2018-0067-11967.
[3277] Ingevity, Detailed Comments, NHTSA-2018-0067-8666.

the future of NGV adoption and not the federal bureaucracy. To achieve this parity, reinstating the 0.15 [CO_2] multiplier is essential."[3278]

In addition to supporting the application of a 0.15 factor, some in the natual gas industry also commented in support of production multipliers for NGVs. Ariel and VNG commented that EPA should offer advanced technology production multipliers for NGVs on par with EVs and FCVs, with NGVs receiving these incentives at the same level and for the same duration as electric and fuel cell vehicles. Ingevity commented that dual-fuel and dedicated NGV multipliers should be extended through 2025 as an effective way to promote the commercialization of these kinds of vehicles by the automakers. NGV America et al. commented that "NGVs, both dedicated and dual-fuel, should be provided with the same vehicle production multiplier credits as have previously been, and continue to be, provided to EVs and FCVs. Given that the expected and likely range capabilities of NGVs will generally exceed EV ranges (including natural gas dual-fuel vehicles that significantly outperform the range capabilities of PHEVs which justifiably enjoy a lower multiplier as compared to EVs), the vehicle production multipliers that are used for EVs should be applied to NGVs, including dual fuel NGVs. Specifically, dedicated and dual-fuel NGVs (or all covered advanced technology vehicles) should receive a base multiplier of 2.0 (or any such higher multiplier afforded to EVs/FCVs) for at least model years 2019 through 2021 and the same multipliers afforded to EVs/FCVs thereafter through 2025."

National Association of Convenience Stores (NACS) and the Society of Independent Gasoline Marketers of America (SIGMA) commented, "the Associations urge you to treat all fuels and technologies equally, including NGVs, EVs, and petroleum-based motor fuels. It is the role of the Agencies to set performance specifications via notice-and-comment rulemaking to ensure that they are appropriate. Once the specifications are set, however, it should be up to the market to determine how best to meet them."[3279]

UCS commented that natural gas is a potent greenhouse gas, and any direct emissions of methane pose a significant threat to any effort to limit climate change.[3280] UCS stated, "these direct emissions upstream significantly undermine any potential benefit that could come from the pump-to-wheel benefits of displacing gasoline or diesel with natural gas." UCS also commented, "furthermore, the technology underpinning any natural gas-powered vehicle is exceptionally mundane—natural gas has been deployed previously in vehicles like the Honda Civic, and aftermarket CNG conversions have long been available on the market. Again, there is no critical hurdle to overcome with CNG powered vehicles, and there is little if any benefit to any such incentives. We strongly recommend that EPA eliminate all incentives for natural gas vehicles and instead ensure such vehicles are credited commensurate with their impact on the environment." CARB also commented that new compliance flexibilities for NGVs are not appropriate at this time.[3281]

[3279] Joint submission on behalf of NACS and SIGMA, Detailed Comments, EPA-HQ-OAR-2018-0283-5824.
[3280] UCS, Detailed Comments, NHTSA-2018-0067-12039.
[3281] CARB, Detailed Comments, NHTSA-2018-0067-11873.

The Natural Gas Vehicles of America (NGVAmerica) commented that there is no incentive under existing EPA and NHTSA regulations for an automaker to sell vehicles equipped to be converted to operate on natural gas (so-called "gaseous-prep vehicles"), even though selling such vehicles often results in the increased availability of alternative fuel vehicles. Today, most alternative fuel conversions are performed on newly manufactured gaseous-prep vehicles or vehicles that have been equipped by the original equipment manufacturers with hardened valves, valve seats, pistons, and piston rings. As an example, most of Ford's commercial truck line-up is available as gaseous-prep, and many such vehicles are converted to natural gas or propane by qualified vehicle manufacturers. Converting these vehicles, producing an assembly-line gaseous-prep vehicle, and sharing diagnostic information are critical to ensuring that aftermarket conversions perform well in-use and do not degrade the vehicle's emission control equipment. Given the complexity of today's automobiles, it is virtually impossible to legally convert new vehicles without this level of cooperation from vehicle manufacturers.

NGVAmerica further commented that providing a regulatory incentive for automakers to sell these vehicles would expand the availability of gaseous-prep vehicles and increase consumer choice for alternative fuel vehicles. EPA, therefore, should provide a credit for selling such vehicles if the automaker can verify that the vehicles were subsequently upfitted or converted using an EPA certified alternative fuel system. Given the significant cost associated with certifying vehicles and installing natural gas tanks, there is very little likelihood that such an incentive would be abused by automakers. As with credits for original equipment manufactured vehicles, the utility factor for these vehicles would be based on the range of the vehicle when operating on natural gas. In this way, vehicles with larger range would earn more credit and vehicles with reduced range would earn less credit.

Regarding comments that EPA should provide additional credits to auto manufacturers for the potential use of RNG due to upstream benefits associated with the production of RNG by applying a 0.15 factor, EPA disagrees because auto manufacturers would not be required to ensure such fuels are used in the vehicles they produce over the life of those vehicles. Commenters provided a rationale for why they believe all NGVs produced in the future will be fueled with RNG, but EPA believes there is no assurance that this would be the case. If fossil fuel-based natural gas is used in the vehicles, the environmental benefits asserted by the commenters would not exist and the substantial vehicle incentives recommended by the commenters would result in a loss of environmental benefits. EPA does not believe it is appropriate to attribute most or all of the potential benefits of the production and use of RNG to the vehicle manufacturer. EPA's Renewable Fuel Standards (RFS) already appropriately credit RNG use as compared to fossil fuel-based natural gas. The RFS program provides a substantial incentive for RNG production, and those incentives may lead to even lower fuel pricing and greater demand for RNG as vehicle fuel, and for NGVs in the future. The RFS program also can provide incentives for liquid cellulosic fuels, advanced bio-diesel, and other types of renewable transportation fuels. Consistent with EPA's decision not to include upstream emissions associated with electricity use for EVs and PHEVs discussed above, EPA believes it is appropriate at this time to maintain the focus of the light-duty vehicle GHG standards on the capabilities of the vehicle to control emissions, and not rely on lifecycle fuel characteristics as a basis for developing specific vehicle incentives, particularly where those fuels are already incentivized by the RFS program.

After considering comments regarding incentive multipliers for NGVs and the current lack of light-duty NGV offerings by OEMs in the market, EPA has decided to include a multiplier incentive of 2.0 for MY 2022-2026 dedicated and dual-fuel NGVs. This multiplier will go into effect when the previously established multipliers expire, thus extending the mulipler for NGVs for 5 years beyond those previously established for NGVs. While other alternative fuel vehicles that were provided multiplier incentives are increasingly available in the light-duty marketplace, no OEM is currently offering light-duty NGVs. Since Honda ended production of the CNG version of the Honda Civic at the end of MY 2015, there have been no OEM NGV offerings available to consumers. EPA continues to believe that NGVs could be an important part of the overall light-duty vehicle fleet mix, and such offerings would enhance the diversity of potentially cleaner alternative fueled vehicles available to consumers.[3282] EPA believes it is appropriate to extend the availability of a production multiplier through MY 2026 for both dual-fuel and dedicated NGVs to potentially help spur their re-introduction by OEMs in the light-duty vehicle market.

EPA also received comments on the application of the regulatory utility factor. For dual-fuel vehicles, emissions are measured on both fuels (e.g., gasoline and natural gas) and weighted using a factor referred to in the regulations as a utility factor. To use a utility factor for natural gas greater than 0.5, a dual-fuel NGV must meet design criteria requiring the vehicle to have a natural gas to gasoline driving range of 2:1. The vehicle must also preferentially operate on natural gas until the natural gas tank is empty. EPA adopted these design criteria as part of the 2012 final rule to help ensure vehicles using a utility factor of higher than 0.5 would likely be fueled with and use natural gas most of the time on the road. At that time, EPA was concerned that natural gas refueling may be much more inconvenient for drivers relative to electric charging for PHEVs due to a lack of CNG refueling stations (or home refueling, compared to the availability of home chargers for many PHEVs) and, therefore, dual-fuel vehicles with limited driving range on natural gas would likely frequently operate on gasoline.

EPA received comments regarding the design criteria. Ingevity commented that it has developed a low-pressure (900 psi) adsorbed natural gas (ANG) fuel storage technology that allows vehicles to be refueled using an affordable and reliable low-pressure natural gas fueling appliance.[3283] Ingevity commented that ANG will allow for a distributed refueling network at users' homes and businesses, just like electrical recharging equipment has been installed for PHEVs over the last several years. Ingevity commented that the design criteria for dual-fuel NGVs that were established in the MYs 2017-2025 final rule "make it impossible to reasonably and affordably manufacture a dual-fuel NGV that can fully utilize the utility factor (UF) approach for determining fuel economy and [CO_2] emissions." Ingevity recommended that the design criteria for dual-fuel NGVs be removed and that the utility factor be based only on the range of the NGV on natural gas, equivalent to the treatment of PHEVs. MECA submitted similar comments regarding ANG technology.[3284]

[3282] The CNG Honda Civic had approximately 20 percent lower CO_2 than the gasoline Civic in MY 2015.
[3283] Ingevity, Detailed Comments, NHTSA-2018-0067-8666.
[3284] *See* MECA, Detailed Comments, NHTSA-2018-0067-11999.

Ariel and VNG also commented that design criteria imposed on dual-fuel NGVs add unnecessary costs and complexity, and currently are arbitrarily applied only to dual-fuel NGVs, and not to their dual-fuel hybrid counterparts.[3285] NACS, SIGMA, and NATSO also recommended that EPA remove eligibility requirements associated with the utility factor.[3286]

After considering the comments, EPA is removing the design criteria from the regulations and thereby allowing higher utility factors to be used for dual-fuel natural gas vehicles based solely on driving range on natural gas, as is the case for PHEVs. The utility factor represents a reasonable way of weighting the emissions of a dual-fuel vehicle on each fuel to derive a single emissions value when including the dual-fuel vehicles in a manufacturer's fleet average compliance determination. Ideally, the utility factor would match the use of each fuel in real-world vehicle operation. The utility factor is not meant to incentivize the adoption of a particular technology, so it differs fundamentally from incentives such as multipliers. With the development of low-pressure natural gas vehicle fueling system technology since the 2012 final rule, EPA's concerns regarding limited fueling infrastructure that led the agency to adopt the design criteria in the 2012 rule are significantly diminished. EPA believes that low-pressure fueling is a new advancement that offers the potential for more convenient refueling for individuals or businesses similar to that for PHEVs. EPA expects owners of dual-fuel CNG vehicles preferentially to seek to refuel and operate on CNG fuel as much as possible, both because the owner would have to pay a higher vehicle price for the dual-fuel capability, and because CNG fuel is considerably cheaper than gasoline. With the opportunity for relatively low-cost on-site refueling at homes or businesses, EPA expects such vehicles to be refueled with natural gas similar to how people refuel PHEVs. Vehicle purchasers that choose high pressure vehicle systems over low pressure systems would likely do so only if they have ready access to a high pressure refueling system, for example, at a fleet's central fueling location. Removing the design criteria for dual-fuel natural gas vehicles also addresses the concerns of some commenters regarding the differing treatment of PHEVs and dual-fuel NGVs.

EPA believes that with the advancement of technology offering the potential for more flexible refueling of NGVs, removing the design criteria is a reasonable change to the regulations. This regulatory change will apply starting with MY 2021. MY 2021 will provide sufficient time for orderly implementation and EPA is not aware of any dual-fuel NGVs emissions certified for MYs 2019-2020 that would otherwise be affected if this change were to be implemented sooner.

EPA received comments that vehicle conversions and "gaseous-prep" vehicles should be eligible for credits. In response to comments on vehicle conversions, alternative fuel converters are not required to meet fleet average standards but instead may comply with 40 CFR part 85 subpart F regulations providing a tampering exemption. Fleet average standards are generally not appropriate for fuel conversion manufacturers because the "fleet" of vehicles to which a conversion system may be applied has already been accounted for under the OEM's fleet average standard. Alternative fuel converters are not manufacturing new vehicles, but are converting

[3285] Joint Submission from Ariel Corp. and VNG, Detailed Comments, NHTSA-2018-0067-7573.

[3286] Joint submission on behalf of NACS and SIGMA, Detailed Comments, EPA-HQ-OAR-2018-0283-5824; NATSO, Detailed Comment, EPA-HQ-OAR-2018-0283-5484.

existing vehicles that have already been certified by the OEM. CO_2 credits are available to OEMs based on fleet emissions performance compared to the fleet average standards and therefore conversions are not eligible for these credits. EPA did not propose to change and is not changing the exemption process promulgated in 40 CFR part 85 subpart F. Because fuel conversions are not required to meet the fleet average standards, credits generated under those standards are not available. Regarding gaseous-prep vehicles, these vehicles are not NGVs at initial sale and therefore are not eligible for NGV incentives. Instead, they are included in the OEM's fleet as gasoline-only vehicles. EPA disagrees with the commenters that such vehicles should be eligible for NGV incentives at time of initial sale if the vehicle is later converted to natural gas since the OEM does not measure the emissions of the vehicle on natural gas at time of certification and is not responsible for the emissions performance of the vehicle on natural gas over the life of the vehicle.

C. NHTSA Compliance and Enforcement

1. Overview of the NHTSA Compliance Process

Consumer choice drives the mixture of automobiles on the road. Manufacturers largely produce a mixture of vehicles to meet consumer demand and address compliance with CAFE standards though the application of fuel economy improving technologies to those vehicles, and by using compliance flexibilities and incentives that are available in the CAFE program. As discussed earlier in this notice, each vehicle manufacturer is subject to separate CAFE standards for passenger cars and light trucks, and for the passenger car standards, a manufacturer's domestically-manufactured and imported passenger car fleets are required to comply separately.[3287] Additionally, domestically-manufactured passenger cars are subject to a statutory minimum standard.[3288] CAFE program flexibilities are largely provided for in statute. Credits for air conditioning efficiency, off-cycle, and pickup truck advanced technologies are not expressly specified by CAFE statute, but are "implemented consistent with EPCA's provisions regarding calculation of fuel economy" as discussed in section C.2 below.

Compliance with the CAFE program begins with manufacturers submitting required reports to NHTSA in advance and during the model year that contain information, specifications, data, and projections about their fleets.[3289] Manufacturers report early product projections to NHTSA describing their efforts to comply with CAFE standards per EPCA's reporting requirements.[3290] Manufacturers' early projections are required to identify any of the flexibilities and incentives manufacturers plan to use for air-conditioning (A/C) efficiency, off-cycle and, through MY 2021, full-size pickup truck advanced technologies. EPA consults with NHTSA when reviewing and considering manufacturers' requests for fuel consumption improvement

[3287] 49 U.S.C. 32904(b).
[3288] 49 U.S.C. 32902(b)(4).
[3289] 49 U.S.C. 32907(a); 49 CFR 537.7.
[3290] 49 U.S.C. 32907(a).

values for A/C and off-cycle technologies that improve fuel economy. NHTSA evaluates and monitors the performance of the industry using the information provided. NHTSA also audits manufacturers' projected data for conformance and verifies vehicle design data through testing to ensure manufacturers are complying as projected. After the model year ends, manufacturers submit final reports to EPA, including final information on all the flexibilities and incentives allowed or approved for the given model year.[3291] EPA then calculates the fuel economy level of each fleet produced by each manufacturer, and transmits that information to NHTSA.[3292]

NHTSA notes that some manufacturers have submitted and/or resubmitted requests for A/C and off-cycle benefits after EPA final reports are completed or nearly completed and, in those cases, such submissions are causing considerable delays in EPA's ability to finalize CAFE reports. Late and revised submissions can place significant burdens on the government in order to reassess a manufacturer's CAFE performances and standards and can also cause significant impacts on previous compliance model years. In the following sections, EPA and NHTSA are incorporating regulatory modifications or providing guidance to help manufacturers expedite approvals and to facilitate the governments processing of the flexibilities and incentives.

NHTSA determines each manufacturer's obligation to comply with applicable model year's CAFE standards and notifies the manufacturer if any of its fleet performances fall below standards. Manufacturers must submit plans detailing the compliance flexibilities to be used to resolve any possible noncompliances or may pay civil penalties to address any deficits for falling below standards. NHTSA periodically releases data and reports to the public through its CAFE Public Information Center (PIC) based on information in the EPA final reports for the given compliance model year, and based on the projections manufacturers provide to NHTSA for the next two model years.[3293]

2. NHTSA's CAFE Program Compliance

EPCA and EISA specify several flexibilities and incentives that are available to help manufacturers comply with CAFE standards. Some flexibilities are defined, and sometimes limited by statute—for example, while Congress allowed manufacturers to transfer credits earned for over-compliance from their car fleet to their truck fleet and vice versa, Congress also limited the amount by which manufacturers could increase their CAFE levels using those transfers.[3294] Consistent with the limits Congress placed on certain statutory flexibilities and incentives, NHTSA crafted and implements the credit transfer and trading regulations authorized by EISA to

---

[3291] For example, alternative fueled vehicles get special calculations under EPCA (49 U.S.C. 32905-06), and fuel economy levels can also be adjusted to reflect air conditioning efficiency and "off-cycle" improvements, as discussed below.

[3292] 49 U.S.C. 32904(c)-(e). EPCA granted EPA authority to establish fuel economy testing and calculation procedures; EPA uses a two-year early certification process to qualify manufacturers to start selling vehicles, coordinates manufacturer testing throughout the model year, and validates manufacturer-submitted final test results after the close of the model year.

[3293] NHTSA CAFE Public Information Center, https://one.nhtsa.gov/cafe_pic/CAFE_PIC_Home.htm.

[3294] *See* 49 U.S.C. 32903(g).

help ensure that total fuel savings are preserved when manufacturers exercise statutory compliance flexibilities.

NHTSA and EPA have previously developed other compliance flexibilities and incentives for the CAFE program consistent with the statutory provisions regarding EPA's calculation of manufacturers' fuel economy levels. As discussed previously, NHTSA finalized in the 2012 final rule, for MYs 2017 and later, an approach for manufacturers' "credits" under EPA's program to be applied as fuel economy "adjustments" or "improvement values" under NHTSA's program for: (1) technologies that cannot be measured or cannot be fully measured on the 2-cycle test procedure, i.e., "off-cycle" technologies; and (2) A/C efficiency improvements that also improve fuel economy but cannot be measured on the 2-cycle test procedure. Additionally, both agencies' programs give manufacturers compliance incentives through MY 2021 for utilizing specified technologies on pickup trucks, such as pickup truck hybridization.

The following sections outline how NHTSA determines whether manufacturers are in compliance with the CAFE standards for each model year, and how manufacturers may use compliance flexibilities, or address noncompliance by paying civil penalties. As addressed above, some compliance flexibilities are expressly prescribed in statute and some are implemented consistent with EPCA's provisions regarding calculation of fuel economy. NHTSA proposed new language updating and clarifying existing regulatory text in this area as part of the NPRM. NHTSA also sought comments in the NPRM on these changes, as well as on the general efficacy of these flexibilities in the fuel economy and CO_2 programs.

Moreover, the following sections explain how manufacturers submit data and information to the agency. As part of the NPRM, NHTSA proposed to implement a new standardized template for manufacturers to use to submit CAFE data to the agency, as well as a standardized template for reporting credit transactions. Additionally, NHTSA proposed adding requirements that specify the precision of the fuel savings adjustment factor in 49 CFR 536.4. These new requirements are intended to streamline reporting and data collection from manufacturers, in addition to helping the agency use the best available data to inform CAFE program decision makers. The comments received to these proposals are included in Section IX.C.2.a)(2)(d) along with NHTSA's responses to the comments and final resolutions established in the final rule.

NHTSA also sought comments on removing or modifying certain CAFE program flexibilities. The comments received and NHTSA's responses to those comments are discussed below.

a) How does NHTSA Determine Compliance?

(1) Manufacturers Submit Data to NHTSA and EPA and the Agencies Validate Results

EPCA, as amended by EISA, requires a manufacturer to submit reports to the Secretary of Transportation explaining whether the manufacturer will comply with an applicable CAFE standard for the model year for which the report is made; the actions a manufacturer has taken or intends to take to comply with the standard; and other information the Secretary requires by regulation.[3295] A manufacturer must submit a report containing the above information during the 30-day period before the beginning of each model year, and during the 30-day period beginning the 180th day of the model year.[3296] When a manufacturer determines it is unlikely to comply with a CAFE standard, the manufacturer must report additional actions it intends to take to comply and include a statement about whether those actions are sufficient to ensure compliance.[3297]

To implement these reporting requirements, NHTSA issued 49 CFR Part 537, "Automotive Fuel Economy Reports," which specifies three types of CAFE reports that manufacturers must submit. A manufacturer must first submit a pre-model year (PMY) report containing the manufacturer's projected compliance information for that upcoming model year. By regulation, the PMY report must be submitted in December of the calendar year prior to the corresponding model year.[3298] Manufacturers must then submit a mid-model year (MMY) report containing updated information from manufacturers based upon actual and projected information known midway through the model year. By regulation, the MMY report must be submitted by the end of July for the applicable model year.[3299] Finally, manufacturers must submit a supplementary report to supplement or correct previously submitted information, as specified in NHTSA's regulation.[3300]

If a manufacturer wishes to request confidential treatment for a CAFE report, it must submit both a confidential and redacted version of the report to NHTSA. CAFE reports submitted to NHTSA contain estimated sales production information, which may be protected as confidential until the termination of the production period for that model year.[3301] NHTSA temporarily protects each manufacturer's competitive sales production strategies, but does not permanently exclude sales production information from public disclosure. Sales production volumes are part of the information NHTSA routinely makes publicly available through the CAFE PIC.

The manufacturer reports provide information on light-duty automobiles such as projected and actual fuel economy standards, fuel economy performance values, and production volumes, as well as information on vehicle design features (e.g., engine displacement and transmission class) and other vehicle attribute characteristics (e.g., track width, wheelbase, and other off-road features for light trucks). Beginning with MY 2017, to obtain credit for fuel economy improvement values attributable to additional technologies, manufacturers must also provide information regarding A/C systems with improved efficiency, off-cycle technologies (e.g., stop-start systems, high-efficiency lighting, active engine warm-up), and full-size pickup trucks with hybrid technologies or with emissions/fuel economy performance that is better than

[3295] 49 U.S.C. 32907(a).
[3296] *Id*.
[3297] *Id*.
[3298] 49 CFR 537.5(b).
[3299] *Id.*
[3300] 49 CFR 537.8.
[3301] 49 CFR part 512, appx. B(2).

footprint-based targets by specified amounts. This includes identifying the makes and model types equipped with each technology, the compliance category those vehicles belong to, and the associated fuel economy improvement value for each technology.[3302] In some cases, NHTSA may require manufacturers to provide supplementary information to justify or explain the benefits of these technologies and their impact on fuel consumption or to evaluate the safety implication of the technologies. These details are necessary to facilitate NHTSA's technical analyses and to ensure the agency can perform enforcement audits as appropriate.

NHTSA uses manufacturer-submitted PMY, MMY, and supplementary reports to assist in auditing manufacturer compliance data and identifying potential compliance issues as early as possible. Additionally, as part of its footprint validation program, NHTSA conducts vehicle testing throughout the model year to confirm the accuracy of the track width and wheelbase measurements submitted in the reports.[3303] These tests help the agency better understand how manufacturers may adjust vehicle characteristics to change a vehicle's footprint measurement, and ultimately its fuel economy target. NHTSA also includes a summary of manufacturers' PMY and MMY data in an annual fuel economy performance report made publicly available on its PIC.

NHTSA uses EPA-verified final-model year (FMY) data to evaluate manufacturers' compliance with CAFE program requirements, and draws conclusions about the performance of the industry. After manufacturers submit their FMY data, EPA verifies the information, accounting for NHTSA and EPA testing, and subsequently forwards the final verified data to NHTSA.

(2) Changes to CAFE Reporting Requirements Made by This Final Rule

NHTSA proposed changes to its CAFE reporting requirements with the intent of streamlining data collection and reporting for manufacturers while helping the agency obtain the best available data to inform CAFE program decision-makers. The agency developed two new standardized reporting templates for manufacturers and proposed to start using the templates beginning in the 2019 compliance model year. In the NPRM, NHTSA sought comments on the templates. NHTSA's responses to the comments received and the changes to the templates for the final rule are presented below.

(a) Standardized CAFE Reporting Template

When NHTSA received and reviewed manufacturers' projection reports for MYs 2013 – 2015, the agency observed that most did not conform to the requirements specified in 49 CFR Part 537. For example, NHTSA identified several instances where manufacturers' CAFE reports included a "yes" or "no" response to a request for a vehicle's *numerical* ground clearance values.

[3302] NHTSA collects model type information based upon the EPA definition for "model type" in 40 CFR 600.002.
[3303] U.S. Department of Transportation, NHTSA, Laboratory Test Procedure for 49 CFR Part 537, Automobile Fuel Economy Attribute Measurements (Mar. 30, 2009), *available at* http://www.nhtsa.gov/DOT/NHTSA/Vehicle%20Safety/Test%20Procedures/Associated%20Files/TP-537-01.pdf.

In a 2015 notice of proposed rulemaking, NHTSA proposed to amend 49 CFR Part 537 to require a new data format for manufacturers' light-duty vehicle CAFE projection reports.[3304] In response to the proposal, some manufacturers commented that the previous changes in reporting requirements generated confusion and led to reporting errors. NHTSA recognized that the modification to the base tire definition in the 2012 final rule for MYs 2017 and later seemed to make some manufacturers uncertain about what footprint data was required in the reports.[3305] Specifically, certain manufacturers did not understand that the modified base tire definition required them to provide estimated attribute-based target standards for each unique model type/footprint combination beginning with MY 2013. NHTSA discovered cases where manufacturers only provided target or vehicle data for certified vehicle configurations, and did not report information for each of the unique model type/footprint combinations for their available production vehicles in the market. However, NHTSA did not adopt the proposed data format from the 2015 proposed rule after receiving adverse comments from manufacturers.[3306]

Since the issuance of the final rule in 2016, NHTSA has continued to receive projection reports that contain inaccurate and/or missing data. These noncompliant reports impede NHTSA's ability to audit manufacturer compliance data, identify potential compliance issues, and analyze industry trends. Problems with inaccurate or missing data has become an even greater issue for manufacturers reporting on the new MY 2017 incentives for efficient A/C systems, off-cycle technologies, and full-size pickup trucks with hybrid technologies/improved exhaust emission performance.[3307] These incentives are explained in Section IX.C.2.c). Manufacturers seeking to take advantage of these new benefits must provide information at the model-type level; however, many manufacturers did not submit the required information in their PMY reports for MYs 2017, 2018, and 2019. This caused NHTSA's Office of Enforcement to send letters reminding manufacturers of their obligation to submit accurate and complete CAFE reports. NHTSA will continue to monitor the accuracy, completeness, and timeliness of manufacturers' CAFE reports and may take additional action as appropriate.

In the NPRM, NHTSA proposed a new standardized template for reporting PMY and MMY information, as specified in 49 CFR 537.7(b) and (c), as well as supplementary information required by 49 CFR 537.8. The template allows manufacturers to build out the required confidential versions of CAFE reports specified in 49 CFR Part 537 and to produce automatically the required non-confidential versions by clicking a button within the template. While NHTSA recognizes that modifications to the reporting requirements may initially be a slight inconvenience to manufacturers, the number of noncompliant reports the agency continues to receive justifies development of a uniform reporting method to help ensure compliance with CAFE regulations. Adopting a standardized template will assist manufacturers in providing the agency with all necessary data, thereby helping manufacturers to ensure they are complying with CAFE regulations. The template organizes the required data in a manner consistent with

[3304] 80 FR 40540 (Jul. 13, 2015).
[3305] 49 CFR 523.2.
[3306] 81 FR 73958 (Oct. 25, 2016).
[3307] NHTSA allows manufacturers to use these flexibilities and incentives for complying with standards starting in MY 2017; the FCIV for full-size pickup trucks with hybrid technologies/improved exhaust emission performance applies only through MY 2021, as discussed further below.

NHTSA and EPA regulations and simplifies the reporting process by incorporating standardized responses consistent with those provided to EPA. The template collects the relevant data, calculates intermediate and final values in accordance with EPA and NHTSA methodologies, and aggregates all the final values required by NHTSA regulations in a single summary worksheet. Thus, NHTSA believes that the standardized templates will benefit both the agency and manufacturers by helping to avoid reporting errors, such as data omissions and miscalculations, and will ultimately simplify and streamline reporting.

NHTSA proposed to require that manufacturers use the standardized template for all PMY, MMY, and supplementary CAFE reports. NHTSA observed that a significant number of manufacturers submit their MMY reports as updated PMY reports—using the same amount of information, despite fewer data requirements. To conform with this method, NHTSA designed the template based on one standardized format that uses the same data requirements for all CAFE reports. This approach will further simplify CAFE projection reporting for manufacturers. The template contains a few additional data fields for certain vehicle characteristics; however, the inclusion of model type indexes will limit the number of required entries by populating a number of pre-entered data fields based on one value.

The standardized template will also allow NHTSA to modify its existing compliance database to accept and import uniform data and automatically aggregate manufacturers' data. This will allow NHTSA to execute its regulatory obligations more efficiently and effectively. Overall, the template will help to ensure compliance with data requirements under EPCA/EISA and drastically reduce the industry and government's burden for reporting in accordance with the Paperwork Reduction Act.[3308] NHTSA made the template available through its docket as well as its PIC, and sought comment on the regulatory changes to the reporting process.

Comments on the template were received from the Auto Alliance, Global Automakers, Ford, Mercedes-Benz, Toyota, Volvo and Volkswagen. The Auto Alliance, Toyota, and Volkswagen opposed adopting the proposed template; however, Global Automakers agreed with the appropriateness of a standardized template that combines credit trading information with a data reporting template.[3309] Global Automakers also made two recommendations: (1) combine EPA's AB&T template with NHTSA's CAFE Projections Reporting Template to streamline reporting and reduce burden; and (2) add an FMY report requirement as an update to the MMY report submission.[3310]

Mercedes-Benz, Ford, and Volkswagen commented about data fields they believed were outdated, or not relevant to fuel economy testing or projecting fuel economy performance.[3311] Mercedes-Benz stated that some required data fields are not currently collected as a part of the

[3308] 44 U.S.C. 3501 *et seq.*

[3311] Daimler Mercedes, Detailed Comments, EPA-HQ-OAR-2018-0283-4182; Ford, Detailed Comments, NHTSA-2018-0067-11928; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583.

fuel economy testing process, and their capture would require additional burden.[3312] Mercedes-Benz believes those data fields should be an optional requirement. Additionally, Mercedes-Benz recommended that NHTSA omit certain data fields, and stated that it would be helpful if NHTSA clarified its intention for the information in others.[3313] The specific data fields mentioned by Mercedes-Benz are in Table IX-6. Ford stated that many of the data fields are outdated, have no bearing on compliance assessments, and are misaligned with the current reporting structure, which is dictated by model type index.[3314] Similarly, Volkswagen stated that the proposed reporting template is populated with many fields that do not immediately appear relevant to projecting CAFE performance, align with the existing requirements in 49 CFR 537.7, or seem relevant in the space of automotive technology.[3315]

Table IX-6 – Suggested Data Fields to Omit

Worksheet(s)	**Data Field**	**Mercedes-Benz Recommendation**
Footprint - DP, Footprint - IP, and Footprint - LT	Type of Overdrive	Omit
	Type of Torque Converter	
	Catalyst Usage	
	Electric Traction Motor	Provide Clarification
	Motor Controller	
	Battery Configuration	
	Electrical Charging System	
	Energy Storage Device	
Fuel Economy - DP, Fuel Economy - IP, and Fuel Economy - LT	Calibration	Omit
	Distributor Calibration	
	Choke Calibration	
	Basic Vehicle Frontal Area	
	Optional Equipment	

The Auto Alliance and Mercedes-Benz noted the differences in how NHTSA and EPA request data on A/C efficiency and off-cycle technologies. Mercedes-Benz highlighted the difficulty in predicting the projected sales production of the technologies, and the Auto Alliance cautioned that the number of reporting entries would increase by a factor of ten or more.[3316] The Auto Alliance stated its belief that the change in reporting requirements would cost its members more than $1 million in information technology changes and that the changes could not be

[3312] Daimler Mercedes, Detailed Comments, EPA-HQ-OAR-2018-0283-4182.

[3315] Volkswagen, Detailed Comments, NHTSA-2017-0069-0583.
[3316] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Daimler Mercedes, Detailed Comments, EPA-HQ-OAR-2018-0283-4182.

completed prior to MY 2021.[3317] Likewise, Ford contended that an implementation date for MY 2019 is aggressive and does not provide manufacturers with adequate lead time.[3318]

The Auto Alliance emphasized that the templates lack common reporting standardization with submissions to EPA.[3319] The Auto Alliance, Global Automakers, Toyota, and Volvo all requested that NHTSA and EPA accept a single, common reporting format to satisfy reporting for both agencies.[3320] Mercedes-Benz and Volkswagen requested stakeholder workshops to review the template with agency staff, with the former recommending that NHTSA host the workshops in partnership with EPA.[3321]

Ford requests that NHTSA re-examine the proposed required submission methods and reconsider current electronic submission methods.[3322] Ford expressed concern about the efficiency and security issues involved in submitting data on a CD through the mail containing confidential business information.[3323] Ford identified what it believes are better available avenues for submission, such as secured email or online portals like EPA's Central Data Exchange.[3324]

NHTSA disagrees with many of the manufacturers' assertions. Differences in EPA and NHTSA regulations prevent establishing a single reporting format for CAFE purposes. For example, EPA only needs early model year information for manufacturers' applications for certification required under 40 CFR 86.1843-01. Manufacturers submit a single application with extensive details for each certified vehicle within a test group (i.e., the certified vehicle represents all the vehicles within the test group with similar technologies and performance characteristics). In comparison, NHTSA's required early model year information is far less detailed and is aggregated for model types and compliance categories. However, NHTSA and EPA already share all the relevant CAFE FMY information pursuant to an interagency agreement. This arrangement not only benefits manufacturers but also reduces the burden on the Federal government. Since much of the required data in NHTSA's projections template is already contained in EPA final reports, manufacturers would not be required to generate additional information but simply to provide estimates along the way to finalizing the data. NHTSA plans to release a data matrix that maps data elements between the CAFE template and the EPA final CAFE reports. NHTSA will notify the public when the matrix will be available on its website. Consequently, there is no need to create an additional final report as an updated version of NHTSA's MMY report, as suggested by Global Automakers. Once NHTSA configures its CAFE database to accept the reporting template via file upload, the agency will be

able to use the model type index data field to connect data values from the template to corresponding values in EPA's final CAFE report. Manufacturers should note that CAFE reports are estimated projections of the EPA final CAFE compliance data. Contrary to Mercedes concerns about the difficulty in predicting the projected sales production of the technologies, NHTSA only expects manufacturers to provide the most up-to-date information available 30 days before a report is required to be submitted to the Administrator as specified in 49 CFR Part 537.5(d). While manufacturer PMY reports may be limited in certain instances (excluding vehicles already in sales distribution), the MMY reports should be more inclusive and closer to the final values reported to EPA. Manufacturers should also be submitting supplementary reports to NHTSA if they believe there will be significant differences between CAFE MMY reports and the EPA final reports.

Commenters also stated that the A/C and off-cycle information reported in the NHTSA template is inconsistent with the EPA EV-CIS.[3325] NHTSA notes that the inconsistency between the agencies is intentional and necessary. NHTSA's off-cycle and A/C information must be collected in greater detail than that reported to the EPA EV-CIS. NHTSA collects detailed information on A/C and off-cycle technologies for determining penetration rates of specific technologies in the market, as well as analyzing the types of technologies as equipped on specific model types. In comparison, EPA aggregates the data for calculating credits, which allows for combining the benefits for all the technologies equipped on a model type. NHTSA also will use the detailed information for public disclosure and for auditing purposes. However, NHTSA acknowledges the Auto Alliance's concerns about the burden placed on the industry for providing more detailed data and therefore will not require manufacturers to start using the templates for reporting until MY 2023. NHTSA also agrees with Ford that it is important to consider the issues of security and efficiency with respect to the submission of confidential information to the agency, and the agency will consider possible changes to its procedures relating to the receipt and handling of confidential information to ensure streamlined, secure, and efficient submission of confidential information, including CAFE reports.[3326]

Secondly, NHTSA agrees with Mercedes-Benz and Volkswagen that workshops will aid in implementing the templates by providing instruction on how to complete them. NHTSA plans to host a workshop for manufacturers to discuss the implementation process. NHTSA believes finalizing the template in this rulemaking is important to address continuing concerns with reporting noncompliance (i.e., missing, incomplete, or inaccurate submissions) with the existing provisions in Part 537. Ultimately, establishing the new templates and holding educational workshops will be more effective in achieving industry compliance than imposing penalties on a case-by-case basis for failure to comply with reporting provisions.

Finally, NHTSA is also adopting changes to the proposed template in response to comments from Mercedes-Benz, Ford, and Volkswagen. NHTSA made changes to several of the data fields discussed by Mercedes-Benz. NHTSA does not agree with Mercedes-Benz's recommendation to omit the "Type of Overdrive" or "Type of Torque Converter" data fields;

[3325] *See, e.g.*, Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3326] *See* 49 CFR part 512, 537.5.

however, the agency does believe the proposed data to be inserted into those fields may be too specific for CAFE purposes. Therefore, the agency is finalizing a requirement that manufacturers identify whether vehicles are equipped with overdrive or a torque converter by selecting "Yes" or "No" from a dropdown list. The agency has also changed the "Calibration" field to "Other Calibration" to clarify the data being requested, and changed the "Auxiliary Emission Control Device" in the "Fuel Economy" worksheets to a dropdown that allows users to select multiple emission control systems. NHTSA believes that adding dropdown lists in the template creates uniformity in the reported information and makes the information more relevant to current vehicles.

The agency agrees with the essence of Volkswagen's assertion that some of the required data fields may no longer be as common on contemporary vehicles, and therefore, may not apply to all manufacturers. As suggested by Mercedes-Benz, NHTSA has decided to make the "Catalyst Usage," "Distributor Calibration," "Choke Calibration," and "Other Calibration" data fields optional with a default value of "N/A." NHTSA does not agree with Mercedes-Benz's recommendation that NHTSA provide a better understanding of its intention for the information in certain data fields. "Electric Traction Motor, Motor Controller," "Battery Configuration," "Electrical Charging System," and "Energy Storage Device" are the data fields that characterize the basic powerplant for electric vehicles. Basic Engine, along with Carline and Transmission Class, make up a model type for light-duty vehicles. Therefore, those five fields are used to group vehicles by model type in accordance with EPA regulations. Fuel economy performance is calculated by Subconfiguration, which is a subset of a model type. As such, those five data fields are an integral part of grouping vehicles for fuel economy testing purposes in accordance with EPA regulations. NHTSA also does not agree with Volkswagen's assertion that the template is populated with many fields that do not appear relevant to projecting CAFE performance. As previously mentioned, many of the data fields are used to arrange vehicles into groups for calculating fuel economy performance in accordance with 49 CFR 537.7.

Furthermore, NHTSA has re-engineered the template in a few areas to include additional supporting data elements used in calculating other data fields required by Part 537. These fields may not directly align with the existing requirements in Part 537 but are necessary for validation purposes. For this reason, NHTSA is also finalizing its proposal in the NPRM to remove the optional provisions for reporting the data fields for determining the CAFE model type target standards, making the information mandatory in the template. Additional changes have been made to the template to improve fuel economy calculations. NHTSA edited the template to include the calculation procedure for alternative-fuel vehicles and corrected the test procedure adjustment (TPA) calculation to align the fleet average fuel economy calculation methodology with 40 CFR 600.510-12. Several expanded worksheets and functional features were also added to the template to improve the usability of the templates for manufacturers. These changes include modifications such as adding the estimated credits and a minimum domestic passenger shortfall calculator as the last fields to the "Summary" worksheet. Other functional changes include protecting users from changing the formatting or data validation in each cell and allowing columns to be widened by users.

(b) Standardized Credit Documents

A credit "[t]rade" is defined in 49 CFR 536.3 as "the receipt by NHTSA of an instruction from a credit holder to place its credits in the account of another credit holder."[3327] "Traded credits are moved from one credit holder to the recipient credit holder within the same compliance category for which the credits were originally earned. If a credit has been traded to another credit holder and is subsequently traded back to the originating manufacturer, it will be deemed not to have been traded for compliance purposes."[3328] NHTSA does not administer trade negotiations between manufacturers and when a trade document is received the agreement must be issued jointly by the current credit holder and the receiving party.[3329] NHTSA does not settle contractual or payment issues between trading manufacturers.

NHTSA created its CAFE database to maintain credit accounts for manufacturers and to track all credit transactions. A credit account consists of a balance of credits in each compliance category and vintage held by the holder. While maintaining accurate credit records is essential, it has become a challenging task for the agency given the recent increase in credit transactions. Manufacturers have requested that NHTSA approve trade or transfer requests not only in response to end-of-model year shortfalls, but also, during the model year, when purchasing credits to bank.

To reduce the burden on all parties, encourage compliance, and facilitate quicker NHTSA credit transaction approval, the agency proposed in the NPRM to add a required template to standardize the information parties submit to NHTSA in reporting a credit transaction. Presently, manufacturers are inconsistent in submitting the information required by 49 CFR 536.8, creating difficulty for NHTSA in processing transactions. The template NHTSA proposed is a simple spreadsheet that trading parties fill out. When completed, parties will be able to click a button on the spreadsheet to generate a credit transaction summary and if applicable credit trade confirmation, the latter of which shall be signed by both trading entities. The credit trade confirmation serves as an acknowledgement that the parties have agreed to trade credits. The completed credit trade summary and a PDF copy of the signed trade confirmation must be submitted to NHTSA. Using the template simplifies CAFE compliance aspects of the credit trading process, and helps to ensure that trading parties follow the requirements for a credit transaction in 49 CFR 536.8(a).[3330]

Additionally, the credit trade confirmation includes an acknowledgement of the "error or fraud" provisions in 49 CFR 536.8(f)-(g), and the finality provision of 49 CFR 536.8(g). NHTSA sought comment on this approach, as well as on any changes to the template that may be necessary to facilitate manufacturer credit transaction requests. The agency uploaded the

[3327] 49 CFR 536.3(b).
[3328] *Id.*
[3329] *See* 49 CFR 536.8(a).
[3330] Submitting a properly completed template and accompanying transaction letter will satisfy the trading requirements in 49 CFR part 536.

proposed template to the NHTSA's docket and the CAFE PIC site for manufacturers to download and review.

Only Global Automakers commented on the proposed credit transaction template, and Global Automakers supported adopting a uniform template. Global Automakers stated that, in theory, it agrees that a standardized template with credit trading information is appropriate, and a similar template is already in use for these types of reporting requirements by its members that could be integrated into the end of the year EPA final report. Global Automakers believes the use of similar templates have been well-established, and such a template could be implemented across multiple agencies (i.e. NHTSA and EPA) with very little lag time in learning.[3331] No comments were received on the transaction letter generated by the template.

For the final rule, NHTSA is finalizing the proposed requirements for its credit templates to be incorporated into provisions for Part 536. NHTSA understands that manufacturers may be using similar credit reporting templates as part of their current business processes but has decided to adopt the template proposed in the NPRM. The NHTSA credit templates are an integral part of a long-range technology deployment that is already underway and will automate the NHTSA's CAFE database and web portal systems. When complete, the systems and portals will receive information directly from manufacturers and enable manufacturers, independently, to confirm credit trades and receive real-time credit balances. For this reason, diverging from the proposed templates for the final rule would impose unnecessary costs upon NHTSA. In the interest of accommodating the transition by manufacturers from other standardized templates, the agency will delay mandatory use of the CAFE credit template until January 1, 2021. Manufacturers may deviate from the generated language in the NHTSA credit trade confirmation by adding additional qualifications but, at a minimum, must include the core information generated by the template.

(c) Credit Transaction Information

Credit trading among entities commenced in the CAFE program starting in MY 2011.[3332] To date, NHTSA has received numerous credit trades from manufacturers but has only made limited information publicly available.[3333] As discussed earlier, NHTSA maintains an online CAFE database with manufacturer and fleetwide compliance information that includes year-by-year accounting of credit balances for each credit holder. While NHTSA maintains this database, the agency's regulations currently state that it does not publish information on individual transactions, and NHTSA has not previously required trading entities to submit information regarding the compensation (whether financial, or other items of value)

[3331] Global Automakers, Detailed Comments, NHTSA-2018-0067-12032.
[3332] 49 CFR 536.6(c).
[3333] Manufacturers may generate credits, but non-manufacturers may also hold or trade credits. Thus, the word "entities" is used to refer to those that may be a party to a credit transaction.

manufacturers receive in exchange for credits.[3334, 3335] Thus, NHTSA's PIC offers sparse information to those looking to determine the value of a credit.

The lack of information regarding credit transactions means entities wishing to trade credits have little, if any, information to determine the value of the credits they seek to buy or sell. It is widely assumed that the civil penalty for noncompliance with CAFE standards largely determines the upper value of a credit, because it is logical to assume that manufacturers would not purchase credits if it cost less to pay civil penalties instead, but it is unknown how other factors affect the value. For example, a credit nearing the end of its five-model-year lifespan would theoretically be worth less than a credit within its full five-model-year lifespan. In the latter case, the credit holder would likely value the credit more, as it can be used for compliance purposes for a longer period of time.

In the interest of facilitating a transparent and efficient credit trading market, NHTSA stated in the NPRM that consideration is being given to modifying its regulations for credit trade information. NHTSA sought comment in the NPRM about the feasibility of requiring more information disclosure around trades, including price information, noting that neither the public, shareholders, competitors, nor even the agencies themselves know the price of credit transactions. More specifically, NHTSA proposed requiring trading parties to submit information disclosing the identities of the parties to credit trades, the number of credits traded, and the amount of compensation exchanged for credits. Furthermore, NHTSA proposed that regulations would also permit the agency to publish information about specific transactions on the PIC.

NHTSA received comments from Volkswagen, Honda, Fiat Chrysler, Toyota, Global Automakers, the Auto Alliance, UCS, and from one private citizen, Mr. Jason Schwartz, regarding the scope of available credit information. All auto associations and manufacturers requested that NHTSA maintain the confidentiality of credit trades and transactions. The remaining commenters felt increased transparency would benefit the market.

Global Automakers, the Auto Alliance, Fiat Chrysler, and Volkswagen stated that credit trades are business-to-business, contain internal information and can involve both financial and non-financial compensation between parties.[3336] They stated credit transactions should be viewed as being similar to other competitive purchase agreements, which include non-disclosure terms and strict confidentiality with regard to cost and compensation.[3337] They contended that negotiations must remain confidential to protect the sensitive business practices for both the buyer and seller, and that revealing purchasing terms could result in a competitive disadvantage

---

[3334] 49 CFR 536.5(e)(1).

[3335] NHTSA understands that not all credits are exchanged for monetary compensation. The proposal that NHTSA is adopting in this final rule requires entities to report compensation exchanged for credits, and is not limited to reporting monetary compensation.

[3336] Global Automakers, Detailed Comments, NHTSA-2018-0067-12032; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583.

[3337] *See, e.g.*, Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

for both.[3338] Further, it was stated that certain transactions may not happen if they are publicized for fear of public criticism, making the program less efficient.[3339]

Honda added that disclosing trading terms may not be as simple as a spot purchase at a given price.[3340] Honda explained that it has undertaken a number of transactions for both CAFE and CO_2 credits, and there has been a range of complexity in these transactions due to numerous factors that are reflective of the marketplace, such as the volume of credits, compliance category, credit expiration date, a seller's compliance strategy, and even the CAFE penalty rate in effect at that time.[3341] In addition, Honda stated that automakers have a range of partnerships and cooperative agreements with their own competitors.[3342] Honda commented that credit transactions can be an offshoot of these broader relationships, and difficult to price separately and independently.[3343] Thus, Honda believes there may not be a reasonable, or even meaningful, presentation of "market" information in a transaction "price."[3344] Finally, Honda concluded by stating that information on pricing terms and business partner pairings is highly competitive and, if made public, could divulge to competitors a buyer's and/or seller's future compliance strategy.[3345] For these reasons, Honda believes it is appropriate to maintain the confidentiality of trade terms, pricing information, and of trading partner identification.[3346]

Fiat Chrysler stated that revealing credit transaction information would reveal highly confidential business information.[3347] It stated that credit transaction information may reveal the technology that is most valued by a company and the value of putting certain technology into a vehicle.[3348] It believed that credit trades are complex business transactions made at arm's length.[3349] As such, they may include monetary and non-monetary compensation, non-disclosure provisions, and other sensitive terms.[3350] Fiat Chrysler commented that publicizing such sensitive information could stifle the credit market and potentially result in uncompetitive outcomes, and could also decrease the efficiency in the credit trading marketplace.[3351] Fiat Chrysler further stated that the NPRM's justifications for requiring the disclosure of credit transaction information is unfounded and the government has no need of this information in the regular course of doing business.[3352]

[3352] Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.

The Auto Alliance, Honda, Toyota, and Volkswagen argued against NHTSA publishing credit movements each model year on its PIC. They stated that detailed credit banks by account holder are available to the public or entities wishing to engage in the credit market and that information is already sufficient.[3353] Global Automakers further contended that the agencies know which companies are trading and how those credits are being used, which is all that should be required for administering the program.[3354] The Auto Alliance argued that in private markets, trades and prices often are not made public; this privacy does not mean that the markets operate any less effectively, nor that the public at large does not benefit from the transactions that lower costs for all parties.[3355]

Volkswagen further commented that revealing confidential purchase terms has no precedent in the automotive industry. Volkswagen's position is that it does not disclose contract pricing for purchasing fuel saving technologies from suppliers, such as for turbochargers or battery packs. Therefore, Volkswagen does not believe it is appropriate to disclose the purchase price for CAFE credits.[3356]

Opposite views from those expressed by automobile manufacturers were received in the comments from UCS and Jason Schwartz. Both commenters strongly supported an increase in information regarding credit trading in the CAFE program.[3357] They argued that more information will allow manufacturers to make better informed decisions and lead to greater industry efficiency in general.[3358] UCS added that while the PIC does have some information, it is difficult to discern how the manufacturers are dividing credits to offset shortfalls.[3359] It requested NHTSA disclose at least as much information as EPA provides from its program, if not providing more information on transaction price and compliance category.[3360] Jason Schwartz had similar arguments for more transparency. Mr. Schwartz added that the agencies can assume that credits may be traded at prices similar to the civil penalty rate for noncompliance under the CAFE standards, but not knowing the actual prices greatly complicates the agencies' estimations of the costs of complying with the standards.[3361] Schwartz used several examples to explain and justify the need for making data on credit transactions, prices, and holdings publicly available to help the agency and the public assess the efficacy of the program.[3362] He also explained that such information will enable the smooth operation of the credit market by enabling credit buyers to better evaluate the value of credits and placing all

players on equal informational footing which facilitates price discovery, and assists buyers and sellers in reaching terms.[3363] He added that regulators should require greater transparency to facilitate oversight.[3364] He asserted his belief that greater transparency in tracking transactions and credits helps regulators detect fraud, manipulation, market power, abuse, and to enforce compliance.[3365]

In response to these comments, NHTSA has decided not to share detailed information on credit transactions or the cost of individual credit transactions with the public. NHTSA agrees with manufacturers that revealing confidential purchase terms could result in a competitive disadvantage for both credit buyers and sellers, as well as harm to companies revealing highly confidential business materials. However, NHTSA believes that greater government oversight is needed over the CAFE credit market. NHTSA needs to understand more information surrounding trades, including costing information. As Honda recognized in its comments, NHTSA needs to understand the full range of complexity in transactions, monetary and non-monetary, in addition to the range of partnerships and cooperative agreements between credit account holders—which may impact the price of credit trades.[3366] NHTSA also believes, as mentioned by commenters, that disclosure of information concerning credit trades is important for facilitating government oversight for protecting against fraud, manipulation, market power, and abuse which may occur in the credit market.

NHTSA is adopting new reporting provisions in this final rule. Starting January 1, 2021, manufacturers will be required to submit all credit trade contracts, including costing and transactional information, to the agency. This information may be submitted confidentially, in accordance with 49 CFR part 512.[3367] NHTSA will use this information to determine the true cost of compliance for all manufacturers. This information will allow NHTSA to assess better the impact of its regulations on the industry, and provide more insightful information to use in developing future rulemakings. This confidential information will be held by secure electronic means in NHTSA's database systems. As for public information, NHTSA will include more information on the PIC on aggregated credit transactions, such as the combined flexibilities all manufacturers used for compliance as shown in Figure IX-6, or information comparable to the credit information EPA makes available to the public. In the future, NHTSA will consider what information, if any, can be meaningfully shared with the public on credit transactional details or costs, while accounting for the concerns raised by the automotive industry.

(d) Precision of the CAFE Credit Adjustment Factor

EPCA, as amended by EISA, required the Secretary of Transportation to establish an adjustment factor to ensure total oil savings are preserved when manufacturers trade credits.[3368]

[3363] Jason Schwartz, Detailed Comments, NHTSA-2018-0067-12162.
[3364] Jason Schwartz, Detailed Comments, NHTSA-2018-0067-12162.
[3365] Jason Schwartz, Detailed Comments, NHTSA-2018-0067-12162.

[3367] *See also* 49 U.S.C. 32910(c).
[3368] 49 U.S.C. 32903(f)(1).

The adjustment factor applies to credits traded between manufacturers and to credits transferred across a manufacturer's compliance fleets.

In establishing the adjustment factor, NHTSA did not specify the exact precision of the output of the equation in 49 CFR 536.4(b). NHTSA's standard practice has been round to the nearest four decimal places (e.g., 0.0001) for the adjustment factor. However, in the absence of a regulatory requirement, many manufacturers have contacted NHTSA for guidance, and NHTSA has had to correct several credit transaction requests. In some instances, manufacturers have had to revise signed credit trade documents and submit additional trade agreements to properly address credit shortfalls.

NHTSA proposed in the NPRM to add requirements to 49 CFR 536.4 specifying the precision of the adjustment factor by rounding to four decimal places (e.g., 0.0001). NHTSA has also included equations for the adjustment factor in its proposed credit transaction report template, mentioned above, with the same level of precision. NHTSA sought comment on this approach but received no comments, and therefore is finalizing this approach in this final rule.

(3) NHTSA then Analyzes EPA-Certified CAFE Values for Compliance

After manufacturers complete certification testing and submit their final compliance values to EPA, EPA verifies the data and issues final CAFE reports to manufacturers and NHTSA. NHTSA then evaluates whether the manufacturers' compliance categories (i.e., domestic passenger car, imported passenger car, and light truck fleets) meet the applicable CAFE standards. NHTSA uses EPA-verified data to compare fleet average standards with actual fleet performance values in each compliance category. Each vehicle a manufacturer produces has a fuel economy target based on its footprint (footprint curves are discussed above in Section II.C), and each compliance category has a CAFE standard measured in miles per gallon (mpg). The manufacturer's fleet average CAFE standard is calculated based on the fuel economy target value and production volume of each vehicle model. The CAFE performance is calculated based on the compliance value and production volume of each vehicle model. A manufacturer complies with the CAFE standard if its fleet average performance is greater than or equal to its required standard, or if it is able to use available compliance flexibilities, described below in Section IX.C.2.c. to resolve any shortfall.

If the average fuel economy level of the vehicles in a compliance category falls below the applicable fuel economy standard, NHTSA provides written notification to the manufacturer that it has not met that standard. The manufacturer is then required to confirm the shortfall and either submit a plan indicating how it will allocate existing credits, or if it does not have sufficient credits available in that fleet, how it will earn, transfer, and/or acquire credits, or pay the appropriate civil penalty. The manufacturer must submit a credit allocation plan or payment within 60 days of receiving agency notification.

NHTSA approves a credit allocation plan unless it finds the proposed credits are unavailable or that it is unlikely that the plan will result in the manufacturer earning sufficient credits to offset the projected shortfall. If a plan is approved, NHTSA revises the manufacturer's credit account accordingly. If a plan is rejected, NHTSA notifies the manufacturer and requests a revised plan or payment of the appropriate civil penalty. Similarly, if the manufacturer is delinquent in submitting a response within 60 days, NHTSA takes action to collect a civil penalty. If NHTSA receives and approves a manufacturer's plan to carryback future earned credits within the following three years in order to comply with current regulatory obligations, NHTSA will defer levying civil penalties for noncompliance until the date(s) when the manufacturer's approved plan indicates that the credits will be earned or acquired to achieve compliance. If the manufacturer fails to acquire or earn sufficient credits by the plan dates, NHTSA will initiate noncompliance proceedings to collect civil penalties.[3369]

(4) Civil Penalties for Noncompliance

In the event that a manufacturer does not comply with a CAFE standard, EPCA provides that the manufacturer is potentially liable for a civil penalty.[3370] The manufacturer determines whether to use available credits to reduce or offset its potential penalty.[3371] This penalty rate is $5.50 for each tenth of a mpg that a manufacturer's average fuel economy falls short of the standard for a given model year multiplied by the total volume of those vehicles in the affected compliance category manufactured for that model year.[3372] A person (or manufacturer) that violates 49 U.S.C. 32911(a), including general CAFE violations other than those for failing to comply with CAFE standards (i.e., fuel economy labeling violations), is also liable to the United States Government for a civil penalty of not more than $42,530 for each violation. A separate violation occurs for each day the violation continues. All penalties are paid to the U.S. Treasury and not to NHTSA.[3373]

$$
\begin{aligned}
&Potential\ Civil\ Penalty \\
&\qquad = \$5.50\ \times\ (Avg.FE\ Performance - Avg.FE\ Standard)\ \times 10 \\
&\qquad \times\ Total\ Production
\end{aligned}
$$

Since the inception of the CAFE program, the U.S. Treasury has collected a total of $1,049,355,116 in CAFE civil penalty payments. Generally, import manufacturers have paid significantly more in civil penalties than domestic manufacturers, with the majority of payments made by import manufacturers for passenger cars and not light trucks. Over the total program

[3369] *See generally* 49 CFR part 536.

[3370] 49 U.S.C. 32911-12.

[3371] *See* 49 U.S.C. 32912.

[3372] NHTSA finalized a retaining the $5.50 civil penalty rate in an April 2018 NPRM. *See* 83 FR 13904 (Apr. 2, 2018).

[3373] 49 USC 32912(e) allows for fiscal year 2008 and each fiscal year thereafter, the total amount deposited in the general fund of the Treasury during the preceding fiscal year from fines, penalties, and other funds obtained through enforcement actions conducted pursuant to EISA and EPCA (including funds obtained under consent decrees), the Secretary of the Treasury, subject to the availability of appropriations, shall: (1) transfer 50 percent of such total amount to the account providing appropriations to the Secretary of Transportation for the administration of this chapter, which shall be used by the Secretary to support rulemaking under this chapter; and (2) transfer 50 percent of such total amount to the account providing appropriations to the Secretary of Transportation for the administration of this chapter, which shall be used by the Secretary to carry out a program to make grants to manufacturers for retooling, reequipping, or expanding existing manufacturing facilities in the United States to produce advanced technology vehicles and components.

lifetime, import manufacturers paid a total of $1,048,896,676 in CAFE penalties while domestic manufacturers paid a total of $458,440.[3374]

Prior to the CAFE credit trade and transfer program, several manufacturers opted to pay civil penalties instead of complying with CAFE standards. Since NHTSA introduced trading and transferring, manufacturers have largely traded or transferred credits to achieve compliance, rather than paying civil penalties for noncompliance. NHTSA therefore assumes that buying and selling credits is a more cost-effective strategy for manufacturers than paying civil penalties, in part, because it seems logical that the price of a credit is directly related to the civil penalty rate and decreases as a credit's life diminishes.[3375] Prior to trading and transferring, on average, manufacturers paid $28,073,281.93 in civil penalty payments annually (a total of $814,125,176 from MYs 1982 to 2010). Since trading and transferring began, manufacturers now pay an average of $26,136,660 each model year. The agency notes that six manufacturers have paid civil penalties since 2011 totaling $235,229,940; Fiat Chrysler paid a civil penalty in MY 2016 equal to $77,268,720.50 and in MY 2017 equal to $79,376,643.50 for for failing to meet the minimum domestic passenger car standards for those MYs. NHTSA expects that, over the next several years, manufacturers will face challenges in avoiding paying further civil penalties as standards increase in stringency. Compared to the current $5.50 CAFE civil penalty rate, a rate of $14 would cause manufacturers that do not comply with CAFE to pay significantly higher civil penalties, potentially in the magnitude of hundreds of millions of dollars annually beyond current projections. Additionally, although NHTSA has not historically been privy to the monetary terms of credit trades, NHTSA expects that the price of credits would increase in line with any increase in the CAFE civil penalty rate.

b) What Exemptions and Exclusions does NHTSA Allow?

(1) Emergency and Law Enforcement Vehicles

Under EPCA, manufacturers are allowed to exclude emergency vehicles, which include law enforcement vehicles, from their CAFE fleet.[3376] All manufacturers that produce emergency vehicles have historically done so. NHTSA did not propose any changes to this exclusion and therefore is retaining the provision without change for the final rule.

(2) Small Volume Manufacturers

Per 49 U.S.C. 32902(d), NHTSA established requirements for exempted small volume manufacturers in 49 CFR part 525, "Exemptions from Average Fuel Economy Standards." The small volume manufacturer exemption is available for any manufacturer whose projected or actual combined sales (whether in the U.S. or not) are fewer than 10,000 passenger automobiles

[3374] These totals include penalties associated with all fleets for these manufacturers. For example, the total penalties paid by import manufacturers includes penalties associated with shortfalls in those manufacturers' domestic passenger car fleets.
[3375] *See* 49 CFR 536.4 for NHTSA's regulations regarding CAFE credits.
[3376] 49 U.S.C. 32902(e).

in the model year two years before the model year for which the manufacturer seeks an exemption.[3377] The manufacturer must submit a petition with information stating that the applicable CAFE standard is more stringent than the maximum feasible average fuel economy level that the manufacturer can achieve.[3378] NHTSA must then issue by *Federal Register* notice, a proposed decision granting or denying the petition and inviting public comment.[3379] If the agency proposed to grant the petition, the notice includes an alternative average fuel economy standard for the passenger automobiles manufactured by the manufacturer.[3380] After conclusion of the public comment period, the agency publishes a final decision in the *Federal Register*.[3381] If the agency grants the petition, it establishes an alternative standard, which is the maximum feasible average fuel economy level for the manufacturers to which the alternative standard applies.[3382] NHTSA did not propose and is not making any changes to the small volume manufacturer provision or alternative standards regulations in this rulemaking.

c) What Compliance Flexibilities and Incentives are Currently Available Under the CAFE Program and How do Manufacturers Use Them?

There are several compliance flexibilities and incentives that manufacturers can use to achieve compliance with CAFE standards beyond applying fuel economy-improving technologies. Some compliance flexibilities and incentives are statutorily mandated by Congress through EPCA and EISA. These specifically include program credits generated from overcompliance, including the ability to carry-forward, carryback, trade and transfer credits, and special fuel economy calculations for dual- and alternative-fueled vehicles (discussed in turn, below). However, 49 U.S.C. 32902(h) expressly prohibits NHTSA from considering the availability of statutorily established credits (either for building dual- or alternative-fueled vehicles or from accumulated transfers or traders) in setting the level of the standards. Thus, NHTSA may not raise CAFE standards because manufacturers have enough credits to meet higher standards, or because alternative fuel vehicles (including electric vehicles) are available to help manufacturers achieve compliance. This is an important difference from EPA's authority under the CAA, which does not contain such a restriction, and which flexibility EPA has utilized in the past in determining appropriate levels of stringency for its program.

Generating, trading, transferring, and applying CAFE credits is governed by statute.[3383] Program credits are generated when a vehicle manufacturer's fleet over-complies with its standard for a given model year, meaning its vehicle fleet achieved a higher corporate average fuel economy value than the amount required by the CAFE program for that fleet in that model year. Conversely, if the fleet average CAFE level does not meet the standard, the fleet would

3383 49 U.S.C. 32903.

incur debits (also referred to as a shortfall). A manufacturer whose fleet generates a credit shortfall in a given model year can resolve its shortfall using any one or combination of several credits flexibilities, including credit carryback, credit carry-forward, credit transfers, and credit trades.

NHTSA also has promulgated compliance flexibilities and incentives consistent with EPCA's provisions regarding calculation of fuel economy levels for individual vehicles and for fleets.[3384] These compliance flexibilities and incentives, which were first adopted in the 2012 rule for MYs 2017 and later, include A/C efficiency improvement and off-cycle adjustments, and adjustments for advanced technologies in full-size pickup trucks, including adjustments for mild and strong hybrid electric full-size pickup trucks and performance-based incentives in full-size pickup trucks. The fuel consumption improvement benefits of these technologies measured by various testing methods can be used by manufacturers to increase the CAFE performance of their fleets. As discussed below, the adjustments for advanced technologies in full-size pickup trucks will no longer be available beginning in MY 2022.

Under NHTSA regulations, credit holders (including, but not limited to manufacturers) have credit accounts with NHTSA where they can, as outlined above, hold credits, and use them to achieve compliance with CAFE standards, by carrying forward, carrying back, or transferring credits across compliance categories. Manufacturers with excess credits in their accounts can also trade credits to other manufacturers, who may use those credits to resolve a shortfall currently or in a future model year. A credit may also be cancelled before its expiration date if the credit holder so chooses. Traded and transferred credits are subject to an "adjustment factor" to ensure total oil savings are preserved.[3385] Credits earned before MY 2011 may not be traded or transferred.[3386]

Credit "carryback" means that manufacturers are able to use credits to offset a deficit that had accrued in a prior model year, while credit "carry-forward" means that manufacturers can bank credits and use them towards compliance in future model years. EPCA, as amended by EISA allows manufacturers to carryback credits for up to three model years, and to carry-forward credits for up to five model years.[3387] Credits expire the model year after which the credits may no longer be used to achieve compliance with fuel economy regulations.[3388] Manufacturers seeking to use carryback credits must have an approved carryback plan from NHTSA demonstrating their ability to earn sufficient credits in future MYs that can be carried back to resolve the current MY's credit shortfall. .

Credit "trading" refers to the ability of manufacturers or persons to sell credits to, or purchase credits from, one another. EISA gave NHTSA discretion to establish by regulation a CAFE credit trading program, to allow credits to be traded between vehicle manufacturers, now

[3384] 49 U.S.C. 32904.

[3388] 49 CFR 536.3(b).

codified at 49 CFR part 536.[3389] EISA prohibited manufacturers from using traded credits to meet the minimum domestic passenger car CAFE standard.[3390]

As mentioned previously, the agencies sought comments in the NPRM on whether and how each agency's existing flexibilities and incentives might be amended, revised, or deleted to avoid the inefficiencies and market distortions as discussed earlier. NHTSA was concerned with the potential for unintended consequences. Specifically, comments were sought on the appropriate level of compliance flexibilities, including credit trading, in a program that is correctly designed to follow statutory direction to create maximum feasible fuel economy standards. Given that the credit trading program is discretionary under EISA, NHTSA also sought comments on whether the credit trading provisions in 49 CFR part 536 should cease to apply beginning in MY 2022. Comments were sought on whether to allow all incentive-based adjustments, except those that are mandated by statute, to expire, in addition to other possible simplifications to reduce market distortion, improve program transparency and accountability, and improve overall performance of the compliance programs.

The comments received from the public and NHTSA's responses to those comments are discussed below. A summary of all the flexibilities and incentives, and information on whether they were either retained or modified for the final rule, is presented in Table IX-1 through Table IX-4.

(1) Credit Carry-Forward and Back

Under the CAFE program, when the average fuel economy of a compliance fleet manufactured in a particular model year exceeds its applicable average fuel economy standard, the manufacturer earns credits.[3391] The credits may be applied to: (1) any of the 3 consecutive model years immediately before the model year for which the credits are earned; and (2) any of the 5 consecutive model years immediately after the model year for which the credits are earned. For example, a credit earned for exceeding model year 2017 standards will be usable for compliance purposes through and including the 2022 compliance model year. NHTSA did not seek comment on or propose changes to any of the aspects of its lifespan for CAFE credits because of the existing statutory limitation set forth by Congress. The public offered no comments on such flexibilities under the CAFE program.

(2) Credit Trading

All commenters responding to the NPRM on this issue favored retaining the existing CAFE credit trading program. Comments on credit trading were received from Volkswagen, Honda, General Motors, CARB, BorgWarner, Jaguar Land Rover, Fiat Chrysler, Global Automakers, the Auto Alliance, the Institute for Policy Integrity, Toyota, and academic

[3391] 49 U.S.C. 32903 and 49 CFR 536.

commenters, Jeremy Michalek and Jason Schwartz. No comments were received supporting the idea of changing the existing credit trading program.

In general, manufacturers' comments centered around problems in predicting whether consumers will purchase the fuel efficient vehicles necessary for manufacturers to meet their compliance obligations. They stated that continuing the credit trading program allows manufacturers to address uncertainty in the market better.[3392] The Auto Alliance, Volkswagen, Fiat Chrysler, and Honda commented that credit flexibilities allow manufacturers to comply with the program even when faced with market uncertainties.[3393] Honda stated that credit trading allows the government to set reasonable standards without fear of having to cater to the least-capable manufacturer.[3394] Jaguar Land Rover stated the removal of NHTSA's credit trading programs would increase and intensify the dis-harmonization between the CO_2 and CAFE programs.[3395]

Global Automakers, Fiat Chrysler, Jason Schwartz, and Jeremy Michalek each commented that the credit trading program allows for a more efficient compliance process given that more fuel-efficient manufacturers can sell their credits to manufacturers who fall short.[3396] These commenters and BorgWarner stated that the program lowers the overall cost of reducing fuel consumption.[3397] Likewise, Jaguar Land Rover, Fiat Chrysler, and General Motors argued compliance flexibilities, like trading, increase the ability to achieve higher fuel economy and reduced CO_2 emissions. They found that the credit trading flexibility allows them to invest more money in technologies that will lead to future increases in their fuel economy.[3398] Similarly, CARB argued credit flexibilities have been shown to be successful in reducing emissions and spurring innovation. It saw no reason to remove a successful program.[3399]

Fiat Chrysler stated that credit trading allows manufacturers to provide more choices for consumers since manufacturers are not required to meet the standard exactly, but rather, they can purchase traded credits and then provide vehicles the public is demanding while still complying with fleet average standards.[3400] They stated that this leads to the overall compliance of the U.S. fleet while allowing for more consumer choices. They further added that if the program is removed, manufacturers that currently generate credits from their fuel-efficient fleet may find it

more profitable to begin producing less fuel-efficient vehicles, perhaps even halting the current improvements in fuel efficiency across the industry.[3401]

Honda commented that regulatory flexibilities, such as credit trading, built into the CO_2 and CAFE programs have become critical elements to the programs' success, especially in the face of product cadences with uneven sales that do not always match compliance obligations.[3402] General Motors stated its belief that program flexibilities will continue to play an increasingly important role in reducing CO_2 emissions and increasing fuel economy through technologies and innovations.[3403] CARB stated that existing flexibilities create consistency in compliance planning for automakers for model years in the existing program.[3404] Fiat Chrysler added that each of the CAFE and CO_2 programmatic tools and flexibilities should be retained, improved and strengthened. Fiat Chrysler opined that this is a chance for the agencies to make better policies that work more efficiently and as intended, and cautioned that eliminating them now could have the serious negative impact of making the standards more stringent and costlier for manufacturers.[3405]

NHTSA is not making changes to its credit trading provisions in the final rule. NHTSA sought comments on removing the optional credit trading program to explore public views on market distortions or windfalls that occur as a result of the credit trading program. However, commenters consistently opined that removing existing flexibilities might result in manufacturers not building certain types of vehicles. This could adversely impact compliance plans over multiple model years. NHTSA concurs with those views, and since this final rule adopts CAFE standards that continuously increase through MY 2026, understands the importance of allowing for credit trading to provide additional means of achieving compliance for manufacturers who face varying degrees of difficulty in achieving the standards the agencies are finalizing today. With increasing standards, credit trading flexibilities help to compensate for the possibility of an uneven sales mix of vehicle types and to aid with compliance planning. Final sales volumes, as presented earlier, show a shift over the past several years in consumers purchasing more small SUVs subject to passenger car standards, and these vehicles are less fuel efficient than the compact and mid-sized passenger cars that previously dominated the market. The need to ensure consumer choice is adequately considered drives the need for NHTSA to provide credit trading flexibility to manufacturers. For example, even with increasing standards, a manufacturer could continue to sell certain types of vehicles with lower mpg performance over a longer period of time to satisfy its consumers by purchasing credits or carrying credits back from future model years to address the mpg fleet shortages caused by these vehicles, before ultimately having to introduce more fuel-efficient technologies. NHTSA believes that these types of scenarios are consistent with the purpose of the CAFE credit program, as adopted by Congress.

(3) Credit Transferring

Credit "transfer" means the ability of manufacturers to move credits from their passenger car fleet to their light truck fleet, or vice versa. As part of the EISA amendments to EPCA, NHTSA was required to establish by regulation a CAFE credit transferring program, now codified at 49 CFR part 536, to allow a manufacturer to transfer credits between its car and truck fleets to achieve compliance with the standards.[3406] For example, credits earned by overcompliance with a manufacturer's car fleet average standard may be used to offset debits incurred because of that manufacturer's failed to meet the truck fleet average standard in a given year. However, EISA imposed a cap on the amount by which a manufacturer could raise its CAFE performance through transferred credits: 1 mpg for MYs 2011-2013; 1.5 mpg for MYs 2014-2017; and 2 mpg for MYs 2018 and beyond.[3407] These statutory limits will continue to apply to the determination of compliance with CAFE standards. EISA also prohibits the use of transferred credits to meet the minimum domestic passenger car fleet CAFE standard.[3408]

In the NPRM, NHTSA responded to the 2016 petition for rulemaking from the Auto Alliance and Global Automakers (Alliance/Global or Petitioners) asking to amend the regulatory definition of "transfer" as it pertains to compliance flexibilities.[3409] In particular, Alliance/Global requested that NHTSA add text to the definition of "transfer" stating that the statutory transfer cap in 49 U.S.C. 32903(g)(3) applies when the credits are transferred. Alliance/Global assert that adding this text to the definition is consistent with NHTSA's prior position on this issue in the MYs 2012-2016 final rule, in which NHTSA stated:

> *NHTSA interprets EISA not to prohibit the banking of transferred credits for use in later model years. Thus, NHTSA believes that the language of EISA may be read to allow manufacturers to transfer credits from one fleet that has an excess number of credits, within the limits specified, to another fleet that may also have excess credits instead of transferring only to a fleet that has a credit shortfall. This would mean that a manufacturer could transfer a certain number of credits each year and bank them, and then the credits could be carried forward or back 'without limit' later if and when a shortfall ever occurred in that same fleet.*[3410]

NHTSA clarified in the NPRM, based upon a previous interpretation, that the transfer cap from EISA does not limit how many credits may be *transferred* in a given model year, but it

[3406] *See* 49 U.S.C. 32903(g)(1).
[3407] 49 U.S.C. 32903(g)(3).
[3408] 49 U.S.C. 32903(g)(4).
[3409] Auto Alliance and Global Automakers Petition for Direct Final Rule with Regard to Various Aspects of the Corporate Average Fuel Economy Program and the Greenhouse Gas Program (June 20, 2016) at 13, *available at https://www.epa.gov/sites/production/files/2016-09/documents/petition_to_epa_from_auto_alliance_and_global_automakers.pdf* [hereinafter Alliance/Global Petition].
[3410] 75 FR 25666 (May 7, 2010).

does limit the *application* of transferred credits to a compliance category in a model year.[3411] The interpretation concludes by stating that, "Thus, manufacturers may transfer as many credits into a compliance category as they wish, but transferred credits may not increase a manufacturer's CAFE level beyond the statutory limits."[3412]

NHTSA maintains its views that the transfer caps in 49 U.S.C. 32903(g)(3) are properly read to apply to the application of credits. As NHTSA explained in the NPRM, it understands that the language in the MYs 2012-2016 final rule could be read to suggest that the transfer cap applies at the time credits are transferred. However, NHTSA believes its existing interpretation — that the transfer cap applies at the time the credits are used — is a more appropriate, plain language reading of the statute. While manufacturers have approached NHTSA with various interpretations that would essentially allow them to circumvent the EISA transfer cap, NHTSA believes such interpretations are improper because they would not give effect to the statutory transfer cap. Therefore, NHTSA proposed in the NPRM to deny Alliance/Global's petition to revise the definition of "transfer" in 49 CFR 536.3, and is now finalizing that denial.

In response to the tentative denial of the petition above in the NPRM, comments were received from the Global Automakers and Toyota asking NHTSA to reconsider applying the transfer cap of 2.0 mpg per year when credits are transferred rather than when they are applied.[3413] They reiterated that imposing the cap when applying the credits is overly burdensome, but did not provide any new information that has persuaded NHTSA to change its view that the petition should be denied. The Auto Alliance also stated that NHTSA should revise its definition of "transfer" to be more consistent with EPA.[3414]

Other more general comments to the NPRM were also received from Walter Kreucher, Jeremy Michalek, Global Automakers, the Auto Alliance, and Toyota, regarding the use of the credit transfer flexibility. These commenters generally appreciated the transfer flexibility for its ability to reduce compliance costs.[3415] More specifically, Walter Kreucher commented that the ability to transfer credits between compliance categories was beneficial for manufacturers and allowed for efficiency in the markets and reduce compliance costs.[3416]

For the final rule, NHTSA is not making any changes to the existing provisions regarding transferring credits. NHTSA's position remains unchanged that the transfer cap in 49 U.S.C. 32903(g)(1) clearly limits the amount of performance increase for a manufacturer's fleet that fails to achieve the prescribed standards. The same statutory provision prevents NHTSA from changing its definition for transfer to be consistent with EPA. Consequently, NHTSA is not changing its definition or its previous interpretation that the application of transfer caps applies at

the time the credits are used and not when transferred. Therefore, NHTSA is finalizing its decision to deny the Auto Alliance and Global Automakers petition.

(4) Minimum Domestic Passenger Car Standard

EPCA, as amended by EISA, addresses the minimum domestic passenger car standard (MDPCS), clearly stating that any manufacturer's domestically-manufactured passenger car fleet must meet the greater of either 27.5 mpg on average, or 92 percent of the average fuel economy projected by the Secretary for the combined domestic and non-domestic passenger automobile fleets manufactured for sale in the U.S. by all manufacturers in the model year, which projection shall be published in the Federal Register when the standard for that model year is promulgated in accordance with 49 U.S.C. 32902(b).[3417] Since that requirement was added to the statute, NHTSA has always calculated the "92 percent" as greater than 27.5 mpg. NHTSA published the 92 percent MDPCS for MYs 2017–2025 at 49 CFR 531.5(d) as part of the 2012 final rule. 49 CFR 531.5(e) explains that the published MDPCS for MYs 2022–2025 are not final and may change when NHTSA sets standards for those model years. This is consistent with the statutory requirement that the 92 percent standards must be determined at the time an overall passenger car standard is promulgated and published in the Federal Register.[3418] Any time NHTSA establishes or changes a passenger car standard for a model year, the MDPCS for that model year must also be evaluated or re-evaluated and established accordingly. Thus, this final rule establishes the applicable MDPCS for MYs 2021-2026.

NHTSA considered comments received about the MDPCS, and discusses the comments and the agency's assessment in Section VIII.B.1.b).

Table IX-7 lists the minimum domestic passenger car standards and compares them to standards that would correspond to each of the other regulatory alternatives considered. NHTSA has updated these to reflect its overall analysis and resultant projection for the CAFE standards finalized today, highlighted below as "Preferred (Alternative 3)," and has calculated what those standards would be under the no action alternative (as issued in 2012, as updated for the NPRM, and as further updated by today's analysis) and under the other alternatives described and discussed further in Section V, above.

(5) Fuel Savings Adjustment Factor

Under NHTSA's credit trading regulations, a fuel savings adjustment factor is applied when trading occurs between manufacturers or when a manufacturer transfers credits between its fleets, but not when a manufacturer carries credits forward or carries back credits within the same fleet.[3419] The Alliance/Global requested in their 2016 petition that NHTSA require manufacturers to apply the fuel savings adjustment factor when credits are carried forward or carried back within the same fleet, including for existing, unused credits.

Per EISA, total oil savings must be preserved in NHTSA's credit trading program.[3420] The statutory provisions for credit transferring within a manufacturer's fleet do not explicitly include the same requirement; however, NHTSA prescribed a fuel savings adjustment factor that applies to both credit trades between manufacturers and credit transfers between a manufacturer's compliance fleets.[3421, 3422]

When NHTSA initially considered the preservation of oil savings, the agency explained how one credit is not necessarily equal to another. For example, the fuel savings lost if the

[3419] *See* 49 CFR 536.4(c).
[3420] 49 U.S.C. 32903(f)(1).
[3421] 49 U.S.C. 32903(g).
[3422] *See* 49 CFR 536.5; *see also* 74 FR 14430 (Mar. 30, 2009) (Per NHTSA's final rule for MY 2011 Average Fuel Economy Standards for Passenger Cars and Light Trucks, "There is no other clear expression of congressional intent in the text of the statute suggesting that NHTSA would have authority to adjust transferred credits, even in the interest of preserving oil savings. However, the goal of the CAFE program is energy conservation; ultimately, the U.S. would reap a greater benefit from ensuring that fuel oil savings are preserved for both trades and transfers. Furthermore, accounting for traded credits differently than for transferred credits does add unnecessary burden on program enforcement. Thus, NHTSA will adjust credits both when they are traded and when they are transferred so that no loss in fuel savings occurs.").

average fuel economy of a manufacturer falls one-tenth of an mpg below the level of a relatively low standard are greater than the average fuel savings gained by raising the average fuel economy of a manufacturer one-tenth of a mpg above the level of a relatively high CAFE standard.[3423] The effect of applying the adjustment factor is to increase the numerical value of credits for compliance accounting that are earned for exceeding a CAFE standard, that are applied to a compliance category with a higher CAFE standard. Likewise, the adjustment factor has the effect of decreasing the numerical value of credits for compliance accounting that are earned for exceeding a CAFE standard, that are applied to a compliance category with a lower CAFE standard. While applying the adjustment factor impacts the compliance accounting value of credits which are denominated in miles per gallon, the adjustment maintains the real world value of credits from the perspective of the actual amount of fuel consumed or saved.

Alliance/Global stated, in its 2016 petition, that while carry-forward and carryback credits have been used for many years, the CAFE standards did not change during the Congressional CAFE freeze, meaning credits earned during those years were associated with the same amount of fuel savings from year to year.[3424] Alliance/Global suggest that because there is no longer a Congressional CAFE freeze, NHTSA should apply the adjustment factor when moving credits within a manufacturer's fleet (i.e. carry-forward or carryback) beginning retroactively in MY 2011.[3425]

In the NPRM, NHTSA tentatively denied Alliance/Global's request to apply the fuel savings adjustment factor to credits that are carried forward or carried back within the same fleet to the extent that the request would impact credits carried forward or back retroactively within manufacturers' compliance fleets (i.e., credits that were generated prior to MY 2021 when the standards set by this rule first apply). NHTSA tentatively determined that applying the adjustment factor to credits earned in prior model years would be inequitable to apply retroactively. There would be an advantage for manufacturers carrying credits into future model years with higher CAFE standards. Manufacturers have historically planned compliance strategies based, at least in part, on the existing rules for how credits could be carried forward and back, including the lack of an adjustment factor when credits are carried forward or back within the same fleet. Thus, retroactively requiring an adjustment factor could disadvantage certain manufacturers without credits, and result in windfalls for other manufacturers.

To explore the impact on future model years, NHTSA sought additional comments in the NPRM on the feasibility of applying the fuel savings adjustment factor to credits carried forwards or back starting in MY 2021. Global Automakers submitted new comments arguing that the application of fuel savings adjustment factors to credits carried forward or back would not result in a credit windfall. They believed this practice would ensure that credits have a consistent value over time.[3426]

[3423] 74 FR 14432 (Mar. 30, 2009).
[3424] Alliance/Global Petition at 10.
[3425] Alliance/Global Petition at 4.
[3426] Global Automakers, Detailed Comments, NHTSA-2018-0067-12032.

Comments from Global Automakers provided no further justification that would persuade NHTSA to consider changing its position on denying the application of the adjustment factor to carry-forward and carryback credits beginning with MY 2011. NHTSA continues to be concerned about the inequitable outcome retroactive adjustments would have on the credit market. Therefore, NHTSA is finalizing its decision to deny the Alliance/Global request to apply the adjustment factor to credits carried forward or carried back within a compliance category retroactively beginning as early as MY 2011.

Congress expressly required that DOT establish a credit "transferring" regulation, to allow individual manufacturers to move credits from one of their fleets to another (e.g., using a credit earned for exceeding the light truck standard for compliance with the domestic passenger car standard). Congress also gave DOT discretion to establish a credit "trading" regulation so that credits may be bought and sold between manufacturers.[3427] Congress specified that trading was for earned credits "to be sold to manufacturers whose automobiles fail to achieve the prescribed standards such that the total oil savings associated with manufacturers that exceed the prescribed standards are preserved."[3428] NHTSA established 49 CFR part 536 believing it was consistent with the statute for transferred credits to be subject to the same "adjustment factor" to ensure total oil savings are preserved.[3429] NHTSA believed that no further application of the adjustment factor to other credit flexibilities would be appropriate at that time. NHTSA sought comments in the NPRM to explore the consequences associated with applying the adjustment factor to credits carried forward and back starting in MY 2021, but no further insight was gained from the comments received. Therefore, NHTSA is retaining its existing requirements for the adjustment factor to be applied to transferred and traded credits only. NHTSA will continue considering potential application of the adjustment factor for all types of credit flexibilities in the future, and may consider regulatory changes in subsequent rulemakings.

(6) VMT Estimates for Fuel Savings Adjustment Factor

NHTSA uses the vehicle miles traveled (VMT) estimate as part of its fuel savings adjustment equation to ensure that when traded or transferred credits are used, fuel economy credits are adjusted to ensure fuel oil savings is preserved.[3430] For MYs 2017-2025, NHTSA finalized VMT values of 195,264 miles for passenger car credits, and 225,865 miles for light truck credits.[3431] These VMT estimates harmonized with those used in EPA's CO_2 program. For MYs 2011-2016, NHTSA estimated different VMTs by model year.

In the NPRM, NHTSA explained that Alliance/Global requested in their 2016 petition that NHTSA apply fixed VMT estimates to the fuel savings adjustment factor for MYs 2011-2016 similar to how NHTSA handled VMT values for MYs 2017-2025.[3432] NHTSA rejected a

[3430] *See* 49 CFR 536.4(c).
[3431] 77 FR 63130 (Oct. 15, 2012).
[3432] Alliance/Global Petition at 5, 11.

similar request from the Auto Alliance in the MY 2017 and later rulemaking, citing lack of scope, and expressing concern about the potential loss of fuel savings.[3433]

The Alliance/Global argued that data from MYs 2011-2016 demonstrate that no fuel savings would have been lost, as was NHTSA's concern.[3434] Alliance/Global asserted that by not revising the MY 2012-2016 VMT estimates, credits earned during that timeframe were undervalued.[3435] Therefore, Alliance/Global argued that NHTSA should retroactively revise its VMT estimates to "reflect better the real-world fuel economy results."[3436]

Such retroactive adjustments could have unfair adverse effects upon manufacturers for decisions they made based on the regulations as they existed at the time. As Alliance/Global acknowledged, adjusting VMT estimates would disproportionately affect manufacturers that have a credit deficit and were part of EPA's Temporary Lead-time Allowance Alternative Standards (TLAAS). The TLAAS program sunsets for MYs 2021 and later. Given that some manufacturers would be disproportionately affected were NHTSA to adopt Alliance/Global's proposal, in the NPRM, NHTSA tentatively denied Alliance/Global's request to change the agency's VMT schedules for MYs 2011-2016 retroactively. Alliance/Global's suggestion that a TLAAS manufacturer should be allowed to elect either approach does not change the fact that manufacturers in the TLAAS program made production decisions based on the regulations as understood at the time.[3437] NHTSA sought comments on the Alliance/Global requests in the NPRM.

However, no further comments were received on this issue in response to the NPRM. Therefore, NHTSA is finalizing its decision to deny the Alliance/Global request to modify the VMT schedules for MYs 2011-2016.

(7) Special Fuel Economy Calculations for Dual and Alternative Fueled Vehicles

As discussed at length in prior rulemakings, EPCA, as amended by EISA, encouraged manufacturers to build alternative-fueled and dual- (or flexible-) fueled vehicles by providing special fuel economy calculations for "dedicated" (that is, 100 percent) alternative fueled vehicles and "dual-fueled" (that is, capable of running on either the alternative fuel or gasoline/diesel) vehicles.

Dedicated alternative-fuel automobiles include electric, fuel cell, and compressed natural gas vehicles, among others. The statutory provisions for dedicated alternative fuel vehicles in 49 U.S.C. 32905(a) state that the fuel economy of any dedicated automobile manufactured after MY 1992 shall be measured "based on the fuel content of the alternative fuel used to operate the automobile. A gallon of liquid alternative fuel used to operate a dedicated automobile is deemed

---

[3437] *See id.* at 11-12, n.12.

to contain 0.15 gallon of fuel." Under EPCA, for dedicated alternative fuel vehicles, there are no limits or phase-out for this special fuel economy calculation, unlike for duel-fueled vehicles, as discussed below.

EPCA's statutory incentive for dual-fueled vehicles at 49 U.S.C. 32906 and the measurement methodology for dual-fueled vehicles at 49 U.S.C. 32905(b) and (d) expire after MY 2019; therefore, NHTSA had to examine the future of these provisions in the MY 2017 and later CAFE rulemaking. NHTSA and EPA concluded that it would be inappropriate to measure duel-fueled vehicles' fuel economy like that of conventional gasoline vehicles with no recognition of their alternative fuel capability, which would be contrary to the intent of EPCA/EISA. The agencies determined that for MY 2020 and later vehicles, the general statutory provisions authorizing EPA to establish testing and calculation procedures provide discretion to set the CAFE calculation procedures for those vehicles. The methodology for EPA's approach is outlined in the 2012 final rule for MYs 2017 and later at 77 FR 63128 (Oct. 15, 2012). In the NPRM, NHTSA sought comments on that current approach.

NHTSA received comments from the Coalition for Renewable Natural Gas, NGV America, the American Gas Association, the American Public Gas Association, CARB, Ingevity Corporation, Fuel Freedom Foundation, UCS, National Farmers Union, Indiana Corn Growers Association, Volkswagen, and a joint submission from Ariel Corp. and VNG.co.

Fuel Freedom Foundation and the National Farmers Union asserted that the agencies should continue offering incentives for emerging technology vehicles including natural gas vehicles, internal combustion engine (ICE) vehicles that encourage renewable fuel use, electric and hydrogen fuel cell vehicles, flex-fuel vehicles (FFVs), and dedicated high-octane vehicles designed for compatibility with mid-level ethanol blends.[3438]

Indiana Corn Growers Association and Fuel Freedom Foundation specified that FFVs, as well as vehicles that run on mid-level ethanol blends, should receive credit for the petroleum reduction value.[3439] For vehicles using higher-ethanol blends, these commenters stated that the agencies should establish more accurate petroleum equivalency factors for the proportion of ethanol versus gas.[3440] Clean Fuels Development Coalition requested credits for producing "Engines Optimized for High-Octane" be reinstated.[3441] Volkswagen made the same request and added that a pathway to higher-octane fuel is important to it.[3442]

Ariel Corp. and VNG.co, the Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association commented that the agencies should expand incentives for natural gas vehicles in the light-duty sector especially for

pick-up trucks, work vans, and sport utility vehicles.[3443] They argued that current incentives are not strong enough to induce manufacturers to produce natural gas vehicles. They further requested that the market penetration rates be removed for light-duty trucks.[3444]

The Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association argued that an AMFA factor of 0.15 is low and because some natural gas vehicles can operate at 100 percent natural gas, a higher fuel economy credit is justified. They further supported a permanent use of the 0.15 factor for dual-fuel vehicles.[3445] Similarly, Ingevity Corporation, and Ariel Corp. and VNG.co argued that natural gas vehicle emissions should return to the 0.15 divisor.[3446]

Ingevity Corporation, Ariel Corp. and VNG.co, the Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association requested that the agencies remove the minimum driving range of natural gas compared to gasoline and "drive to empty" design requirements for dual-fueled natural gas vehicles and allow higher utility factors based on driving range only, so that dual-fuel NGVs are treated similarly to PHEVs. They stated a belief that the design constraints for dual-fuel NGVshold NGVs to an unfairly higher standard.[3447] As discussed above in Section IX.B, EPA is removing these design constraints for dual-fuel NGVs.

CARB argued that flexibilities for natural gas vehicles and high-octane blend vehicles are not yet warranted.[3448] Similarly, UCS argued that natural gas is a greenhouse gas and benefits from natural gas vehicles are undermined by their costs. UCS further commented that natural gas vehicle technology does not need any incentives since it has already been deployed and in the market.[3449]

In response to comments, NHTSA has determined that EPCA and EISA prescribe the incentive that is used for dedicated liquid and gaseous alternative fuel vehicles, and the CAFE program will continue to use those statutory incentives. For dedicated alternative fuel vehicles, the statute provides a significant incentive that only counts 15 percent of the actual energy

[3443] Joint submission from Ariel Corp and VNG.co LLC, Detailed Comments, NHTSA-2018-0067-7573; Joint submission from the Coalition for Renewable Natural Gas, NVG America, the American Gas Association, and American Public Gas Association, Detailed Comments, NHTSA-2018-0067-11967.

used.[3450] For dual fuel vehicles, NHTSA has determined that, for the portion of operation that occurs on an alternative fuel, it is consistent to use the same incentive that is specified by EPCA and EISA for dedicated fuel vehicles. For example, for the hypothetical case of a vehicle that operates 99 percent of the time on an alternative fuel, it would be appropriate for that vehicle to receive nearly the same incentive as a dedicated alternative fuel vehicle that operates 100 percent of the time on alternative fuel. Applying the same 15 percent of energy used incentive for both dedicated and duel fuel vehicles remains appropriate. NHTSA therefore is not adopting any new incentives for any alternative fueled vehicles.

D. Compliance Issues that Affect Both the CO_2 and CAFE Programs

Because the real world CO_2 emissions reduction benefits of certain technologies cannot be measured or fully measured using 2-cycle test procedures, EPA established new compliance flexibilities under its CAA authority, starting in MY 2012, that allow manufacturers credit for emission compliance for installing these technologies. Those flexibilities are designed to recognize improvements in A/C systems with greater efficiency and other "off-cycle" technologies that reduce real world tailpipe CO_2 emissions. More specifically, real world improvements that cannot be measured or fully measured on 2-cycle tests are determined and used to calculate additional CO_2 credits (in Megagrams (Mg)) for each model type that has the technologies. Because these tailpipe CO_2 improving technologies also impact fuel economy, NHTSA adopted the same flexibilities and incentives beginning in MY 2017. EPA and NHTSA also established incentives for both the CO_2 and CAFE programs that give added compliance credits and fuel consumption improvement values for the production of strong and mild hybrid full-size pickup trucks beginning in MY 2017.[3451] EPA adjusts manufacturers' CAFE performance values using the emissions benefits or incentives provided for these technologies. EPA developed a methodology for manufacturers to increase their passenger car and light truck fuel economy performance in accordance with procedures set forth by EPA in 40 CFR part 600. For the NHTSA CAFE program, the CO_2 reductions (in grams per mile) are converted to fuel consumption improved values (FCIVs, gallons per mile) and then the benefits are summed for all the model types in the manufacturer's fleets. The total FCIVs are used to adjust and increase manufacturers' CAFE (mpg) performance values.

It is important to note that while these flexibilities and incentives have similar value for compliance in the CAFE and CO_2 programs, there are differences in how they are accounted for in each of the programs due to differences in the structure of the programs. The CAFE program accounts for A/C efficiency and off-cycle improvements through EPA measurement procedures that determine *fuel consumption improvement values* (FCIVs). The CAFE A/C efficiency and

[3450] 32905(a) "... A gallon of a liquid alternative fuel used to operate a dedicated automobile is deemed to contain .15 gallon of fuel." 32905(c) "... One hundred cubic feet of natural gas is deemed to contain .823 gallon equivalent of natural gas. The Secretary of Transportation shall determine the appropriate gallon equivalent of other gaseous fuels. A gallon equivalent of gaseous fuel is deemed to have a fuel content of .15 gallon of fuel."
[3451] *See* 40 CFR 86.1867-86.1868, 86.1870.

off-cycle provisions do not involve manufacturer *credits*.[3452] There are no bankable, tradable, or transferrable credits earned by a manufacturer for implementing more efficient A/C systems or installing an off-cycle technology. In fact, the only credits provided for in NHTSA's CAFE program are those earned by overcompliance with a standard.[3453] As discussed above, EPA adjusts CAFE performance values based on the FCIVs generated through the use of these technologies. Off-cycle technologies and A/C efficiency improvements represent adjustments to individual vehicle compliance values based on the fuel consumption improvement values of these technologies.

Illustrative of this confusion, in the 2016 Alliance/Global petition, the petitioners asked NHTSA to avoid imposing unnecessary restrictions on the use of credits. Alliance/Global referenced language from an EPA report that stated compliance is assessed by measuring the tailpipe emissions of a manufacturer's vehicles, and then reducing vehicle CO_2 compliance values depending on A/C efficiency improvements and off-cycle technologies.[3454] This language is consistent with NHTSA's statement in the MY 2017 and later final rule, which explained how the agencies coordinate and apply off-cycle and A/C adjustments. "There will be separate improvement values for each type of credit, calculated separately for cars and for trucks. These improvement values are subtracted from the manufacturer's 2-cycle-based fleet fuel consumption value to yield a final new fleet fuel consumption value, which would be inverted to determine a final fleet fuel CAFE value."[3455]

In the NPRM, NHTSA proposed to deny Alliance/Global's request because what the petitioners refer to as "technology credits" are actually FCIVs applied to the fuel economy performance of individual vehicles.[3456] Thus, these adjustments are not actually "credits," per the usage of "credit" in EPCA/EISA and are not subject to the "carry-forward" and "carryback" provisions in 49 U.S.C. 32903. To alleviate confusion, and to ensure consistency in nomenclature, NHTSA proposed to update language in its regulations to reflect that the use of the term "credits" to refer to A/C efficiency and off-cycle technology adjustments should actually be termed fuel consumption improvement values (FCIVs). No further comments were received on this issue in response to the NPRM. For the final rule, NHTSA is finalizing the proposed changes in its regulations to remove the term "credits" and to replace it with the term "adjustments" for the FCIV benefit for A/C and off-cycle technologies in the CAFE program.

Manufacturers seeking to use these flexibilities and incentives start the process each model year by submitting information to EPA and seeking any necessary approvals, as appropriate. The use of certain technologies only requires submitting information to EPA, whereas others require a formal request process for approval. The differences are explained in

---

[3452] This is not to be confused with EPA's parallel program, which refers to the GHG's consideration of A/C improvements and off-cycle technologies as "credits."
[3453] 49 U.S.C. 32903.
[3454] *See* Alliance/Global Petition at 15.
[3455] 77 FR 62726 (Oct. 15, 2012).
[3456] The agencies also refer to A/C and off-cycle technology improvement values as "credits" sporadically throughout their regulations. NHTSA is amending its regulations to reflect these are adjustments and not actual credits that can be carried forward or back. For a further discussion, see above.

the following sections. The compliance information manufacturers must submit to EPA describes the technologies, the flexibilities or incentives being used, and the testing approach for deriving benefits. Initial information is required as a part of the EPA certification process, as specified by 40 CFR 86.1843-01 in advance of each model year. For technologies requiring approvals, EPA must confirm the manufacturer's testing approach, receive test results to assess the benefit of the technology, and then where applicable issue a *Federal Register* notice that invites public comment. EPA review and determination usually occurs before the end of the compliance model year, if manufacturers provide information to EPA on a timely basis. To receive the benefit under the CAFE program for technologies that require approvals, manufacturers must concurrently submit to NHTSA the same information that is sent to EPA. EPA consults with NHTSA in reviewing A/C efficiency and off-cycle adjustments to fuel economy performance values that require approval. NHTSA provides EPA its assessment of the suitability of a technology considering: (1) whether the technology has a direct impact upon improving fuel economy performance; (2) whether the technology is related to crash-avoidance technologies, safety critical systems or systems affecting safety-critical functions, or technologies designed for the purpose of reducing the frequency of vehicle crashes; (3) information from any assessments conducted by EPA related to the application, the technology, and/or related technologies; and (4) any other relevant factors.

EPA and NHTSA sought comments on several aspects of the shared flexibilities and incentives in the NPRM. Presented in the following sections is a summary of the comments received and the agencies final decisions for the final rule.

1. Incentives for Advanced Technologies in Full-Size Pickup Trucks

In the 2012 rulemaking for MYs 2017 and beyond, EPA and NHTSA created incentives to encourage implementation of hybrid electric full size pickup trucks for both the CO_2 and CAFE programs. CO_2 credits and CAFE FCIVs were made available for manufacturers that produce full-size pickup trucks with Mild HEV or Strong HEV technology, provided the percentage of production with the technology is greater than specified percentages.[3457] In addition, CO_2 credits and CAFE FCIVs were made available for manufacturers that produce full-size pickups with other technologies that enables full size pickup trucks to exceed performance of their CO_2 or CAFE targets based on footprints by specified amounts.[3458] These performance-based incentives created a technology-neutral path (as opposed to the other technology-encouraging path) to achieve the CO_2 credits and CAFE FCIVs, which would encourage the development and application of new technological approaches.

EPA and NHTSA established limits on the vehicles eligible to qualify for these incentives; a truck must meet minimum criteria for bed size and towing or payload capacity, and meet minimum production thresholds (in terms of a percentage of a manufacturer's full-size pickup truck fleet) in order to qualify for the incentives. As designed, the strong hybrid credit is 20 grams/mile per vehicle, available through MY 2025, if installed on at least 10 percent of the

[3457] 77 FR 62651 (Oct. 15, 2012).
[3458] *Id*.

manufacturer's full-size pickup truck fleet in the model year. The program also included an incentive for mild hybrids of 10 grams/mile per vehicle during MYs 2017–2021. To be eligible the manufacturer would have to show that the mild hybrid technology is utilized in a specified portion of its truck fleet beginning with at least 20 percent of a company's full-size pickup production in MY 2017 and ramping up to at least 80 percent in MY 2021.[3459]

At present, no manufacturer has qualified to use the full-size pickup truck incentives. One vehicle manufacturer introduced a mild hybrid pickup truck for MY 2019 but did not meet the minimum production threshold. Others have announced potential collaborations, or have already started production on future hybrid or electric models.[3460]

Prior to the NPRM, the agencies received input from automakers that these incentives should be extended and available to all light-duty trucks (e.g., cross-over vehicles, minivans, sport utility vehicles, and smaller-sized pickups) and not only full-size pickup trucks.[3461] Automakers also recommended that the program's eligibility production thresholds should be removed because they discourage the application of technology since manufacturers cannot be confident of achieving the thresholds. Some stakeholders have also suggested an additional incentive for strong and mild hybrid passenger cars. In the proposal, the agencies sought comment on whether these incentives should be expanded along the lines suggested by stakeholders, on the basis that perhaps these incentives could lead to additional product offerings of strong hybrids, and technologies that offer similar emissions reductions, which could enable manufacturers to achieve additional long-term CO_2 emissions reductions. In addition, the agencies sought comment on whether to extend either the incentive for hybrid full-size pickup trucks or the performance-based incentive past the dates that EPA specified in the 2012 final rule for MY 2017 and later. The agencies also sought comment on eliminating incentive programs, as discussed above.

The agencies received a variety of comments on the full-size pickup truck incentives. Comments were received from General Motors, Volkswagen, Honda, BorgWarner, Fiat Chrysler, Toyota, DENSO International, Ford, CARB, Global Automakers, UCS, Electric Drive Transportation Association, the Auto Alliance, Ariel Corp. and VNG.co, ACEEE, the Coalition

---

3459 77 FR 62651-2 (Oct. 15, 2012).

3460 Chrysler released the 2019 Dodge Ram 1500 "eTorque" (*see* https://www.fueleconomy.gov/feg/Find.do?action=sbs&id=40736&id=40737&id=40394&id=40397) which qualifies as a mild hybrid pickup truck by replacing the traditional alternator on the engine with a 48-volt Li-on battery-powered, belt-driven motor generator that improves performance, efficiency, payload, towing capabilities and drivability. The production volume of these vehicles did not qualify for the full-size pickup truck electric/hybrid incentive for MY 2019. Other vehicle models are currently in research or in development for future years but it is uncertain whether they will reach the required sales volumes to qualify for incentives. For example, *the hybrid and battery-electric versions of the F-150 pickup,* see https://www.trucks.com/2019/09/18/ford-truck-engineer-explains-electric-f-150-pickup-plans (September 18, 2019), or the new electric pickup truck manufactured by Rivian, https://www.trucks.com/2019/04/24/ford-plans-new-electric-truck-rivian-invests-500-million/ (April 24, 2019); or the Tesla all electric pickup truck (https://www.cnn.com/2019/11/08/success/tesla-pickup-reveal/index.html) (November 8, 2019).

3461 83 FR 43461 (Aug. 24, 2018).

for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association.

The Auto Alliance, Toyota, General Motors, BorgWarner, Global Automakers, and Volkswagen advocated to expand the full-size pickup truck hybrid incentives to all hybrid vehicles.[3462] They argued that prices for all hybrid-drive technologies are projected to remain high and consumer demand for these vehicles is still slow to increase.[3463] They asserted that expanding the full-size pickup truck hybrid incentive to all hybrid vehicles will help encourage investments in hybrid technology and continue to help manufacturers address their compliance challenges.[3464] Similarly, these commenters reported that the current market, fueled by consumer demand for SUVs and lower than expected gas prices, is not conducive to consumer acceptance of or demand for electric vehicles.[3465] For these reasons, they stated their belief that it is important to support adjustments and expansion of the current incentives to promote hybrid technologies.

The Auto Alliance, DENSO International, Global Automakers, Fiat Chrysler, and Honda also argued for alternative pathways for the agencies to consider allowing the full-size pickup truck hybrid incentives to be expanded to the light-duty truck segment, but not to all passenger vehicles. They argued that hybrid technology has been slow to be applied in the light-duty truck segment, but has been broadly applied to passenger cars.[3466]

Toyota, Global Automakers, and the Auto Alliance suggested the incentives for light-duty trucks should amount to 20 grams/mile.[3467] Global Automakers added that in addition to expanding full-size pickup truck hybrid incentives to light trucks, the agency should consider a smaller incentive for hybrid electric passenger vehicles as well.[3468] The Auto Alliance and Toyota suggested a 10 grams/mile credit for passenger cars.[3469] Volkswagen further requested the hybrid pickup credit to be expanded to all hybrid cars and trucks.[3470]

Toyota, the Auto Alliance, Electric Drive Transportation Association, Ford, DENSO International, Global Automakers, Fiat Chrysler, and BorgWarner commented that having

minimum production percentages for hybrid pickup trucks discourages manufacturers from investing in hybrid technologies. They requested that the agencies consider eliminating the percentage of production requirement and provide incentives in proportion to the value of the technology.[3471] Ford stated that the minimum production percentages unfairly penalize larger manufacturers who must produce more pickup trucks to claim the incentives than a smaller volume manufacturer.[3472]

Ariel Corp. and VNG.co, the Coalition for Renewable Natural Gas, NGVAmerica, the American Gas Association, and the American Public Gas Association commented the pickup truck incentives should be expanded to include natural gas vehicles.[3473] They suggested a "Natural Gas Pickup" incentive like the hybrid-electric and performance-based pickup credits, but no minimum production requirement.[3474]

ACEEE and UCS commented that hybrid technology has been around for quite a while and has been applied in every vehicle class. They discouraged the agencies from applying more incentives to these vehicles.[3475] Specifically, UCS stated that incentives for electric vehicles are mostly driven by state regulation, and EPA and NHTSA policies are rewarding manufacturers for meeting standards they were already required to meet.[3476] UCS commented that hybrids are not innovators or game-changing vehicles—they are simply one of many strategies by which manufacturers can reduce emissions and should not receive special treatment.[3477]

CARB commented that incentives for full-size hybrid pickup trucks should remain limited in their scope and that increasing or expanding those incentives can erode emissions benefits.[3478] CARB further commented that hybrid electric vehicles (HEVs) are widely available at varying levels of power and performance across vehicle sizes, and CARB does not believe HEVs deserve special treatment in the CO_2 vehicle regulations.

After carefully considering the comments received, EPA and NHTSA are not adopting any new or expanded incentives for hybrid vehicles or full-size pickup trucks, and are removing these incentives beginning in MY 2022 (the incentive for mild hybrids expires after MY 2021 regardless, so that does not change). The agencies believe any new or expanded incentives would likely not result in any further emissions benefits or fuel economy improvements since an

increase in sales volume would not be expected. The agencies agree with CARB and ACEEE, and UCS that hybrids are a well-established technology that has already been applied to a wide range of vehicles and, as such, no further incentives are warranted at this time. Further, the agencies believe that incentivizing manufacturers to implement specific technologies is inappropriate, as manufacturer fuel economy performance should represent actual fuel consumption. The agencies believe any new or expanded incentives for hybrids would likely not result in any further emissions benefits or fuel economy improvements beyond those measured during testing; to the extent that manufacturers choose to build full-size pickup trucks that exceed their targets, those will reap the benefits of target exceedance in the overall fleet averaging. Manufacturers did not provide sufficient evidence to support their position in a manner that leads the agencies to conclude otherwise, and there does not appear to be any likelihood that manufacturers will be able to take advantage of these flexibilities beyond MY 2021 that makes it necessary to retain them. Therefore, the agencies are removing these flexibilities from the program starting with MY 2022.

2. Flexibilities for Air Conditioning Efficiency

A/C systems are virtually standard automotive accessories, and more than 95 percent of new cars and light trucks sold in the U.S. are equipped with mobile A/C systems. A/C system usage places a load on an engine, which results in additional tailpipe CO_2 emissions and fuel consumption; the high penetration rate of A/C systems throughout the light-duty vehicle fleet means that efficient systems can significantly impact the total energy consumed and CO_2 emissions. A/C systems also have non-CO_2 emissions associated with refrigerant leakage.[3479] Manufacturers can improve the efficiency of A/C systems though redesigned and refined A/C system components and controls.[3480] That said, such improvements are not measurable or recognized using 2-cycle test procedures, since A/C is turned off during 2-cycle testing. Any A/C system efficiency improvements that reduce load on the engine and improve fuel economy is therefore not measurable on those tests.

The CO_2 and CAFE programs include flexibilities to account for the real world CO_2 emissions and fuel economy improvements associated with improved A/C systems and to include the improvements for compliance.[3481] The total of A/C efficiency credits is calculated by

---

[3479] *See* Section V for further details. Notably, manufacturers cannot claim CAFE-related benefits for reducing A/C leakage or switching to an A/C refrigerant with a lower global warming potential. While these improvements reduce GHG emissions consistent with the purpose of the CAA, they generally do not impact fuel economy and, thus, are not relevant to the CAFE program.

[3480] The approach for recognizing potential A/C efficiency gains is to utilize, in most cases, existing vehicle technology/componentry, but with improved energy efficiency of the technology designs and operation. For example, most of the additional A/C-related load on an engine is because of the compressor, which pumps the refrigerant around the system loop. The less the compressor operates, the less load the compressor places on the engine resulting in less fuel consumption and CO_2 emissions. Thus, optimizing compressor operation with cabin demand using more sophisticated sensors, controls, and control strategies is one path to improving the efficiency of the A/C system. For further discussion of A/C efficiency technologies, see Section II.D of the NPRM and Chapter 6 of the accompanying PRIA.

[3481] *See* 40 CFR 86.1868-12.

summing the individual credit values for each efficiency improving technology used on a vehicle, as specified in the A/C credit menu. The total A/C efficiency credit sum for each vehicle is capped at 5.0 grams/mile for cars and 7.2 grams/mile for trucks. Additionally, the off-cycle credit program contains credit earning opportunities for technologies that reduce the thermal loads on a vehicle from environmental conditions (solar loads or parked interior air temperature).[3482] These technologies are listed on a thermal control menu that provides a predefined improvement value for each technology. If a vehicle has more than one thermal load improvement technology, the improvement values are added together, but subject to a cap of 3.0 grams/mile for cars and 4.3 grams/mile for trucks.

EPA requested comment on the A/C caps and on whether A/C efficiency technologies and off-cycle thermal control technologies should be combined under a single cap, since the technologies directly interact with each other. That is, improved thermal control results in reduced A/C loads for the more efficient A/C technologies. If the thermal credits were removed from the off-cycle menu, they would no longer be counted against the 10 grams/mile menu cap discussed above, representing a way to provide more room under the menu cap for other off-cycle technologies. Specifically, EPA sought comment on replacing the current off-cycle thermal efficiency capped value of 10 grams/mile, with separate caps of 8 grams/mile for cars and 11.5 grams/mile for trucks.

Comments concerning the A/C caps were received from the Auto Alliance, DENSO, Fiat Chrysler, and Volkswagen. DENSO commented that A/C efficiency credits earned through the off-cycle petition process should not count toward the A/C credit cap. If A/C credits granted through the off-cycle petition process are no longer counted toward the A/C credit cap, it stated that manufacturers would be significantly incentivized to develop new and innovative technologies.[3483] Fiat Chrysler requested that certain A/C credits for electrical technologies (*i.e.*, A/C blower motor controls that limit wasted electrical energy) be transferred to the off-cycle credit list.[3484] Volkswagen further supported the removal of the thermal control technology credit caps and suggested that implementing caps at the fleet average level, rather than per-vehicle, could be less constraining.[3485] DENSO pointed to an NREL study which found that A/C improvements were greater than previously thought possible. Therefore, it requested the agencies consider increasing the A/C credit cap.[3486]

Similarly, the Auto Alliance and Fiat Chrysler suggested raising the cap on A/C efficiency and thermal control technology by 64 percent and combine them under a single cap.[3487] Additionally, they proposed increasing A/C efficiency and thermal control technology

---

credits by up to 64 percent.[3488] They also proposed that the agencies create new regulatory provisions to handle additional new A/C and thermal technologies.[3489]

As with increasing the credit caps, manufacturers and suppliers were generally supportive of higher credit caps, or no caps at all, for this combined technology group. However, EPA has decided not to adopt any changes to the caps, including combining the A/C efficiency and thermal controls menu, due to the uncertainty regarding the menu credit values. Additional uncertainty exists for these technology groups because there are likely synergistic effects between A/C efficiency and thermal technologies that would need to be further considered in determining appropriate credit levels if the two groups of technologies are combined under a single cap. Data is not currently available to consider these effects. Therefore, the agencies are not making any changes to the flexibilities for A/C efficiency improvements in the CO_2 or CAFE program, but may perform research to understand better the relationship between A/C efficiency and thermal technologies for consideration in future rulemakings.

3. Flexibilities for Off-Cycle Technologies

"Off-cycle" technologies are those that reduce vehicle fuel consumption and CO_2 emissions in the real world, but for which the fuel consumption reduction benefits cannot be measured or cannot be fully measured under the 2-cycle test procedures (city, highway or correspondingly FTP, HFET) used to determine compliance with the fleet average standards. The CAFE city and highway test cycles, collectively referred to as the 2-cycle laboratory compliance tests (or 2-cycle tests), were developed in the early 1970s. The city test simulates city driving in the Los Angeles area at that time. The highway test simulates driving on secondary roads (not expressways). The cycles are effective in measuring improvements in most fuel economy improving technologies; however, they are unable to measure or underrepresent certain fuel economy improving technologies because of limitations in the test cycles. For example, off-cycle technologies that improve emissions and fuel economy at idle (such as "stop start" systems) and those technologies that improve fuel economy to the greatest extent at expressway speeds (such as active grille shutters which improve aerodynamics) receive less than their real-world benefits in the 2-cycle compliance tests.

Starting with MY 2008, EPA began employing a "five-cycle" test methodology to measure fuel economy for the purpose of improving new car window stickers (labels) and giving consumers better information about the fuel economy they could expect under real-world driving conditions.[3490] However, for CO_2 and CAFE compliance, EPA continues to use the established "two-cycle" test methodology.[3491] As learned through development of the "five-cycle" methodology and prior rulemakings, there are technologies that provide real-world CO_2 emissions and fuel consumption improvements, but those improvements are not fully reflected

---

[3488] *See, e.g.*, Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.
[3489] *See, e.g.*, Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3490] https://www.epa.gov/vehicle-and-fuel-emissions-testing/dynamometer-drive-schedules.
[3491] The city and highway test cycles, commonly referred to together as the 2-cycle tests are laboratory compliance tests required by law for CAFE and are also used for determining compliance with the GHG standards.

on the “two-cycle” test. EPA established the off-cycle credit program to provide an appropriate level of CO_2 credit for technologies that achieve CO_2 reductions, but are normally not chosen as a CO_2 control strategy because their CO_2 benefits are not measured on the specified 2-cycle test.

Currently, EPA has three compliance pathways. The first approach allows manufacturers to gain credits without having to prove the benefits of the technologies on a case-by-case basis. A predetermined list or “menu” of credit values for specific off-cycle technologies exists and became effective starting in MY 2014.[3492] This pathway allows manufacturers to use credit values established by EPA for a wide range of off-cycle technologies, with minimal or no data submittal or testing requirements.[3493] Specifically, EPA established a menu with a number of technologies that have real-world CO_2 and fuel consumption benefits not measured, or not fully measured, by the two-cycle test procedures, and those benefits were reasonably quantified by the agencies at that time. For each of the pre-approved technologies on the menu, EPA established a quantified default value that is available without additional testing. Manufacturers must demonstrate that they were in fact using the menu technology, but not required to conduct testing to quantify the technology’s effects, unless they wish to receive a credit larger than the default value. The default values for these off-cycle credits were largely determined from research, analysis, and simulations, rather than from full vehicle testing, which would have been both cost and time prohibitive. EPA generally used conservative predefined estimates to avoid any potential credit windfall.[3494]

For off-cycle technologies not on the pre-defined technology list, or obtained through petitioning, EPA created a second pathway which allows manufacturers to use 5-cycle testing to demonstrate and justify off-cycle CO_2 credits.[3495] EPA established this alternative for a manufacturer to demonstrate the benefits of the technology using 5-cycle testing. The additional emissions tests allow emission benefits to be demonstrated over some elements of real-world driving not captured by the CO_2 compliance tests, including high speeds, rapid accelerations, and cold temperatures. Under this pathway, manufacturers submit test data to EPA, and EPA determines whether there is sufficient technical basis to approve the off-cycle credits. No public

---

[3492] *See* 40 CFR 86.1869-12(b).

[3493] The Technical Support Document (TSD) for the 2012 final rule for MYs 2017 and beyond provides technology examples and guidance with respect to the potential pathways to achieve the desired physical impact of a specific off-cycle technology from the menu and provides the foundation for the analysis justifying the credits provided by the menu. The expectation is that manufacturers will use the information in the TSD to design and implement off-cycle technologies that meet or exceed those expectations in order to achieve the real-world benefits of off-cycle technologies from the menu.

[3494] While many of the assumptions made for the analysis were conservative, others were “central.” For example, in some cases, an average vehicle was selected on which the analysis was conducted. In that case, a smaller vehicle may presumably deserve fewer credits whereas a larger vehicle may deserve more. Where the estimates are central, it would be inappropriate for the agencies to grant greater credit for larger vehicles, since this value is already balanced by smaller vehicles in the fleet. The agencies take these matters into consideration when applications are submitted for credits beyond those providedon the menu.

[3495] *See* 40 CFR 86.1869-12(c). EPA proposed a correction for the 5-cycle pathway in a separate technical amendments rulemaking. *See* 83 FR 49344 (Oct. 1, 2019). EPA is not approving credits based on the 5-cycle pathway pending the finalization of the technical amendments rule.

comment period is required for manufacturers seeking credits using the EPA menu or using 5-cycle testing.

The third pathway allows manufacturers to seek EPA approval, through a notice and comment process, to use an alternative methodology other than the menu or 5-cycle methodology for determining the off-cycle technology CO_2 credits.[3496] Manufacturers must provide supporting data on a case-by-casebasis demonstrating the benefits of the off-cycle technology on their vehicle models. Manufacturers may also use the third pathway to apply for credits and FCIVs for menu technologies where the manufacturer is able to demonstrate credits and FCIVs greater than those provided by the menu.

Due to the uncertainties associated with combining menu technologies and the fact that some uncertainty is introduced because off-cycle credits are provided based on a general assessment of off-cycle performance, as opposed to testing on the individual vehicle models, EPA established caps that limit the amount of credits a manufacturer may generate using the EPA menu. Off-cycle technology is capped at 10 grams/mile per year on a combined car and truck fleet-wide average basis. No caps were established for technologies gaining credits through the petitioning or 5-cycle approval methodologies.

a) Consideration of Eliminating A/C and Off-Cycle Adjustments in the CO_2 and CAFE Programs

The agencies sought comments in the NPRM on whether to remove the A/C and off-cycle flexibilities from the CAFE program and adjust the stringency levels accordingly based upon concern that the flexibilities might distort the market. Several commenters provided responses concerning the feasibility of removing any of these flexibilities. Commenters included the Auto Alliance, the National Automobile Dealers Association, Global Automakers, the Alliance for Vehicle Efficiency, ACEEE, BorgWarner, Fiat Chrysler, General Motors, International Council on Clean Transportation, Toyota, and UCS. Other comments were received requesting that the agencies look into expanding the flexibilities by including more technologies.

There was widespread support from commenters for retaining these flexibilities for A/C and off-cycle technologies in the CO_2 and CAFE programs. Commenters preferred that the agencies continue to include the flexibilities, believing them to enable real world fuel economy improvements and compliance with CO_2 and CAFE standards with a more cost effective combination of technologies. The agencies agree that these programs achieve real world fuel economy improvements and that keeping the flexibilities may enable more cost effective technology combinations to achieve those real world fuel economy improvements. For MY 2017, manufacturers introduced a wide variety of low-cost technologies through the A/C and off-cycle flexibilities that increased the overall industry's CAFE performance by 1.1 mpg. The agencies also acknowledge that the continued use of these flexibilities under the EPA program since 2012 warrants consideration due to automakers' and suppliers' significant investments in developing the technologies, which could result in stranded capital should the agencies

[3496] *See* 40 CFR 86.1869-12(d).

discontinue them and manufacturers choose to remove the technologies. For these reasons, the agencies have decided to continue allowing manufacturers to use the existing flexibilities for A/C efficiency and off-cycle technologies for future model years.

b) Final Decisions in Response to Manufacturers' and Suppliers' Requests

Automakers, trade associations, and auto suppliers recommended several changes to the current off-cycle credit program.[3497] Prior to the NPRM, automakers and suppliers suggested changes to the off-cycle program, including:

- Streamlining the program in ways that would give auto manufacturers more certainty and make it easier for manufacturers to earn credits;
- Expanding the current pre-defined off-cycle credit menu to include additional technologies and increasing credit levels where appropriate;
- Eliminating or increasing the credit cap on the pre-defined list of off-cycle technologies and revising the thermal technology credit cap; and
- Creating a role for suppliers directly to seek approval of their technologies.

EPA requested comments on several aspects of the off-cycle credits program and, as discussed below, both EPA and NHTSA are adopting some modest changes, primarily to help streamline and clarify their programs, and to ease the implementation burden for manufacturers and the government. The agencies are not adopting a significant expansion of the programs in this rule, as also discussed below. EPA and NHTSA are taking this relatively conservative approach for their off-cycle programs due to the uncertainty that remains in estimating off-cycle benefits of technologies and the need to remain cautious to help ensure that emissions and fuel economy benefits expected through the off-cycle flexibility are realized in the real-world.

(1) Program Streamlining

EPA requested comments on changes to the off-cycle process that would streamline the program. Currently, under the third pathway, manufacturers submit an application that includes the methodology they used to determine the off-cycle credit value and data, which then undergoes a public notice and comment process prior to an EPA decision regarding the application. Each manufacturer separately submits an application to EPA that must undergo a public notice and comment process even if the manufacturer uses a methodology previously approved by EPA for another manufacturer. For example, under the current program, multiple manufacturers have separately submitted applications for high-efficiency alternators and advanced A/C compressors using similar methodologies and producing similar levels of credits. If manufacturers also seek fuel economy improvement values for the CAFE program, they are also required to send the submissions to NHTSA, as EPA consults with NHTSA in its determinations for the CAFE program. NHTSA's involvement is discussed in more detail in Section IX.D.3.b).

[3497] *See generally* Alliance/Global Petition.

EPA requested comment on revising the regulations to allow all auto manufacturers to make use of a methodology once it has been approved by EPA under the public process, without subsequent applications from other manufacturers having to undergo the same process. This would reduce redundancy in the current program. Manufacturers would need to provide EPA with at least the same level of data and detail for the technology and methodology as the manufacturer that went through the initial public notice and comment process.

EPA received supportive comments for streamlining the approval process from auto manufacturers and suppliers. The Auto Alliance commented that it supports all actions that would shorten the time it takes EPA to evaluate and reach decisions on applications through the off-cycle alternative methodology pathway, and that manufacturers should be allowed to use common data from applications that have already been approved.[3498] Such common data would include ambient conditions, general consumer behavior data, and general operating and performance data for the same off-cycle technologies. Global Automakers also commented that EPA should streamline efforts to avoid reduplication of applications in situations where multiple automakers have submitted petitions for the same technology and recommended blanket approval for applications using the same specific technologies and calculation and measurement procedures.[3499] General Motors commented that when a credit for a new technology is approved for one manufacturer, the EPA decision document announcing that approval can serve as a guidance document that assigns a credit value or calculation methodology for the technology for all manufacturers without requiring duplicative testing.[3500] MEMA commented that it would be sufficient to uphold the integrity of the off-cycle program to require the next vehicle manufacturer's application to provide at least the same level of data and details as the original vehicle manufacturer application and to validate the level of credit the next vehicle manufacturer is applying for based on how the technology is applied in its fleet.[3501]

ACEEE commented that any streamlining of the process by which automakers petition for off-cycle credits must maintain the requirement that a thorough methodology show real-world benefits and ensure adequate opportunity for public review.[3502] International Council on Clean Transportation (ICCT), while not commenting on this specific request for comment, commented that the program should remain unchanged until potential changes can be further analyzed.[3503]

After considering the comments, consistent with its request for comment, EPA is streamlining the approval process as follows: once a methodology for a specific off-cycle technology has gone through the public notice and comment process and is approved for one manufacturer, other manufacturers may follow the same methodology to collect data on which to

[3503] International Council on Clean Transportation, Detailed Comments, NHTSA-2018-0067-11741.

base their off-cycle credits. Once a methodology is approved, other manufacturers may submit applications citing the approved methodology, but those manufacturers must provide their own necessary test data, modeling, and calculations of credit value specific to their vehicles, and any other vehicle-specific details pursuant to that methodology, to assess an appropriate credit value. This is similar to what occurred, for example, with the advanced A/C compressor, where one manufacturer applied for credits with data collected through bench testing and vehicle testing and subsequent manufacturers applied for credits following the same methodology, but by submitting test data specific to their vehicle models. However, those subsequent applications previously required a public notice and comment process. For future applications, as long as the testing is conducted using the previously-approved methodology, EPA will evaluate the credit application and issue a decision with no additional notice and comment, since the first application that established the methodology was subject to notice and comment.

EPA is not providing blanket approval for a specific credit value, nor amending the requirement that manufacturers collect necessary data or perform modeling or other analyses on their specific vehicle models as the basis for the credit. However, once a methodology has been fully vetted and approved through the public process, EPA believes additional public review of the identical methodology is unnecessarily duplicative. In EPA's experience thus far (for example with high-efficiency alternators and advanced A/C compressors for which EPA has received applications from several manufacturers based on the same methodology), additional public review has yielded no additional substantive public comments. EPA believes this change in the program will help reduce the time necessary for review of applications. EPA will maintain the option to seek additional public comment in cases where the agency believes a new application deviates from a previously approved methodology or raises new issues on which the agency believes it is prudent to seek comment.

EPA also requested comment on revising the regulations to allow EPA to, in effect, add technologies to the pre-approved credit menu without going through a subsequent rulemaking. For example, if one or more manufacturers submit applications with sufficient supporting data for the same or similar technology, the data from that application(s) could potentially be used by EPA as the basis for adding technologies to the menu. EPA requested comment on revising the regulations to allow EPA to establish through a decision document a credit value, or scalable value as appropriate, and technology definitions or other criteria to be used for determining whether a technology qualifies for the new menu credit. As envisioned in the NPRM, this streamlined process of adding a technology to the menu would involve an opportunity for public review but not a formal rulemaking to revise the regulations, allowing EPA to add technologies to the menu in a timely manner, where EPA believes that sufficient data exist to estimate an appropriate credit level for that technology across the fleet.

EPA received supportive comments regarding this request for comments from auto manufacturers and suppliers who believe that the change would help streamline the program. EPA also received comments from environmental NGOs suggesting that the program should not be changed at this time. After consideration of these comments, the agencies are not revising the regulations to allow technologies to be added to the menu without a rulemaking because EPA believes that menu-based off-cycle credits should be based on a robust demonstration of the technology, consistent with the regulations. The agencies will retain the option to add technologies to the menu through a rulemaking, similar to the approach being taken for high-efficiency alternators and advanced A/C compressors as discussed below, where sufficient data has been collected from multiple manufacturers and vehicle models on which to base a menu credit. The menu credits are meant to be conservative. The agencies are concerned that basing a menu credit on data from only one or a few manufacturers does not guarantee a robust and accurate credit level representing vehicles across the fleet. At this time, the agencies continue to believe a rulemaking process with full opportunity for public comment remains the best approach for adding technologies to the menu. A rulemaking ensures that all stakeholders including automakers have an opportunity to provide data to support an appropriate and conservative credit level for the fleet. This approach also provides an incentive for manufacturers to, in the meantime, continue to perform testing and provide actual data that could eventually be used to inform a rulemaking process to add a technology to the menu. The agencies want to preserve that element of the program to maintain the integrity of off-cycle credits representing real-world reductions.

(2) A/C and Off-Cycle Application Process

The agencies received several comments, in addition to those received in the petitions from the Auto Alliance and Global Automakers, discussed below, on the application process for approving additional A/C and off-cycle credits. Commenters included the Global Automakers, the Auto Alliance, Volkswagen, Edison Electric Institute, Ford, Fiat Chrysler, NCAT, Toyota, General Motors, and DENSO International.

Fiat Chrysler, Ford, Volkswagen, DENSO International, Global Automakers, and the Auto Alliance requested that the agencies respond more quickly to applications for A/C and off-cycle technologies.[3504] They prefer that petitions be addressed before the close of a model year so manufacturers can have a better idea of what credits they will earn.

The agencies agree that responding to petitions before the end of a model year is beneficial to manufacturers and the government. Manufacturers would have a better idea of the approved credits, and the government could carry-out its compliance processes more efficiently. EPA structured the A/C and off-cycle programs to make it possible to complete the processes by the end of the model year so manufacturers could submit their final reports within the required deadline, 90 days after the calendar year. However, delays currently exist due to the timing needed to review and approve technologies for the first time and issue *Federal Register* notices seeking public comments, where applicable. The agencies anticipate these problems will resolve themselves as the off-cycle program reaches maturity and EPA initiates the new streamlining approaches adopted in this final rule, discussed in the previous section.

The agencies are also aware that delays exist because manufacturers frequently submit late applications, new applications, and ask for retroactive credits or FCIVs for off-cycle technologies equipped on previously-manufactured vehicles after the model year has ended. As

[3504] Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943-50; Ford, Detailed Comments, NHTSA-2018-0067-11928-15; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583-13; DENSO, Detailed Comments, NHTSA-2018-0067-11880-5; Global Automakers, Detailed Comments, NHTSA-2018-0067-12032-50; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073-120.

required under both the CO_2 and CAFE programs, manufacturers are to submit applications for off-cycle credits and FCIVs *before* the beginning of each compliance model year, to enable the agencies to make better informed final decisions before the model year ends.

To expedite the process of approvals, the agencies will enforce existing EPA and NHTSA regulations requiring manufacturers to notify and report information on the technologies before the beginning of the model year. Presently, manufacturers must notify EPA in their pre-model year reports, and in their applications for certification, of their intention to generate any A/C and off-cycle credits before the model year, regardless of the methodology for generating credits.[3505] Manufacturers choosing to generate credits using the alternative EPA-approval methodology are required to submit a detailed analytical plan to EPA *prior to a model year* in which a manufacturer intends to seek these credits. The manufacturer may seek EPA input on the proposed methodology prior to conducting testing or analytical work, and EPA will provide input on the manufacturer's analytical plan. The alternative demonstration program must be approved in advance by the Administrator. NHTSA has similar provisions for its projections reports in which detailed information on the technologies must be included in those submissions during the month of December before the model year.[3506] NHTSA's provisions also require manufacturers to submit information to NHTSA at the same time as to EPA. Consequently, the eligibility of a manufacturer to gain off-cycle CO_2 credits or CAFE adjustments for a given compliance model year requires appropriate submissions to the agencies. The agencies intend to enforce these provisions starting with the 2020 compliance model year. Manufacturers may resubmit MY 2020 information until May 1, 2020. After that time, the agencies will deny any manufacturers' late submissions requesting retroactive credits. However, manufacturers who properly submit information ahead of time will be allowed to make corrections to resolve inadvertent errors during or after the model year. The agencies believe that enforcing the existing submission requirements will be the most efficient approach to expedite approvals until new regulatory deadlines or additional requirements can be adopted.

Fiat Chrysler, Volkswagen, Global Automakers, and the Auto Alliance further suggested the EPA issue a *Federal Register* notice for submitted off-cycle applications within 30 days and issue a final decision within 90 days.[3507]

As mentioned, EPA is addressing the issues raised by commenters by streamlining its required regulatory processes to eliminate the need to submit multiple *Federal Register* notices concerning requests from different manufacturers for the same technology. Under this streamlined process, after a technology is approved for the initial manufacturer(s), EPA will approve any subsequent manufacturer requests for the same technology upon receipt of data submissions validating the benefit specific to their model types.

[3506] *See* 49 CFR Part 537.7(c)(7) and 49 CFR Part 531.6 and 533.6.
[3507] Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583; Global Automakers, Detailed Comments, NHTSA-2018-0067-12032; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

General Motors, Toyota, NCAT, Fiat Chrysler, Ford, Volkswagen, DENSO, Edison Electric Institute, Global Automakers, and the Auto Alliance further suggested that technologies approved for multiple manufacturers, to the extent additional automakers will have the same requests, be added to the menu to encourage additional implementation of the technology. Doing so would reduce duplicative efforts for the agencies, as well as manufacturers.[3508]

As mentioned previously, the agencies have decided to allow only new technologies to be added to the menu through the regular rulemaking processes including the opportunity for notice and public comment.

General Motors, DENSO, Global Automakers, and the Auto Alliance further suggested that suppliers should be allowed to request a "grams per mile" value for their off-cycle technologies. They asserted that this will provide certainty to manufacturers before they buy that technology.[3509] Toyota and the Auto Alliance suggested that the agencies could improve efficiency and reduce burdens by creating a "toolbox," methodologies that manufacturers can apply to the analysis of off-cycle credit opportunities.[3510] They stated it would additionally help manufacturers if the agency would issue guidance letters and decision documents for off-cycle credit approvals.[3511]

The agencies believe that developing a "toolbox" may not be possible due to the development of new and emerging technologies, and manufacturers' different approaches for evaluating the benefits of the technologies. The agencies may consider additional guidance, if feasible, as the programs further matures in the approval process of technologies and if the agencies can identify consistent methodologies that may help manufacturers analyze off-cycle technologies.

NCAT and General Motors requested more transparency in the A/C and off-cycle approval process. They suggested that the agencies could provide reports including off-cycle credits approved by vehicle make and model and provide further clarification of data requirements that influenced the decision process.[3512]

[3508] General Motors, Detailed Comments, NHTSA-2018-0067-11858; Toyota, Detailed Comments, NHTSA-2018-0067-12150; NCAT, Detailed Comments, NHTSA-2018-0067-11969; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943; Ford, Detailed Comments, NHTSA-2018-0067-11928; Volkswagen, Detailed Comments, NHTSA-2017-0069-0583; DENSO, Detailed Comments, NHTSA-2018-0067-11880; Edison Electric Institute, Detailed Comments, NHTSA-2018-0067-11918; Global Automakers, Detailed Comments, NHTSA-2018-0067-12032; Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

EPA and NHTSA have separate approaches for sharing information on these flexibilities, to provide public transparency. EPA already provides detailed information on manufacturers generation of A/C and off-cycle credits for each model year in its end of the year compliance report, including the magnitude of credits by manufacturer and by credit type, the credits generated by technology type, and the penetration of off-cycle technologies in each manufacturer's fleet.[3513] NHTSA plans to share similar information on its PIC and to provide projected data on the market penetration rates of the technologies as soon as it starts receiving information through its new reporting templates for the 2023 compliance model year.

(3) High Efficiency Alternators and Advanced Air Conditioning (A/C) Compressors

EPA sought comments on modifying the off-cycle menu to add certain technologies for which EPA has collected sufficient data to set an appropriate credit level. More specifically, EPA received data from multiple manufacturers on high-efficiency alternators and advanced air conditioning (A/C) compressors that could serve as the basis for new menu credits for these technologies.[3514] EPA requested comments on adding these two technologies to the menu including comments on credit level and appropriate definitions. EPA also requested comments on other off-cycle technologies that EPA could consider adding to the menu including supporting data that could serve as the basis for the credit.

EPA received only supportive comments on its specific request for comments regarding adding high efficiency alternators and advanced A/C compressors to the menu. Toyota, General Motors, BorgWarner, Fiat Chrysler, the Auto Alliance, Global Automakers, MECA, DENSO, SAFE, and Volkswagen submitted responses on the off-cycle menu. General Motors, Volkswagen, Fiat Chrysler, Global Automakers, and the Auto Alliance all supported adding high-efficiency alternators and advanced A/C compressors to the menu.[3515] They commented that these technologies have already been approved for off-cycle credits through the petition process multiple times. They contend that it would be less burdensome if the technologies would be added to the pre-approved off-cycle credit list. That said, they were concerned about being constrained by the off-cycle caps.[3516]

The agencies believe that adding high-efficiency alternators and advanced A/C compressors to the menu is a reasonable step to help streamline the program by allowing manufacturers to select the menu credit rather than continuing to seek credits through the public approval process. Therefore, EPA is revising the regulations to add these two technologies to the menus. The high-efficiency alternator is being added to the off-cycle credits menu, and the

[3516] *See, e.g.*, General Motors, Detailed Comments, NHTSA-2018-0067-11858.

advanced A/C compressor with a variable crankcase valve is being added to the menu for A/C efficiency credits. The credit levels are based on data previously submitted by multiple manufacturers through the off-cycle credits application process, and discussed in the NPRM. The high efficiency alternator credit is scalable with efficiency, providing an increasing credit value of 0.16 grams/mile CO_2 per percent improvement as the efficiency of the alternator increases above a baseline level of 67 percent efficiency. The advanced A/C compressor credit value is 1.1 grams/mile for both cars and light trucks.[3517]

EPA also received comments from the Auto Alliance, Fiat Chrysler, General Motors, Mitsubishi, Gentherm, ITB, and MEMA on a variety of individual technologies that they suggest adding to the menu.[3518] These commenters provided little data to support their recommended credit levels. The Auto Alliance and Alliance for Vehicle Efficiency further asserted that flexibility mechanisms are increasingly important and there is a need to develop unconventional and non-traditional fuel economy technologies to meet standards.[3519] They requested additional pre-defined and pre-approved technologies to be included in this regulation.[3520]

The agencies have reviewed manufacturers' requests for adding additional technologies to the picklist and concluded that there is insufficient data in the record at this time on which to base an appropriate menu credit value for the technologies. Therefore, none of these technologies are being added to the menu at this time. Given the limited data and uncertainty, EPA also does not believe it would be appropriate to add any of the technologies to the menu without an opportunity for public review and comment. Although the agencies are not adding these technologies to the menu at this time, manufacturers may seek off-cycle credits for these technologies through the other program pathways.

(4) Stop-Start Technology

In 2014, EPA approved additional credits for the Mercedes-Benz's stop-start system through the off-cycle credit process based on data submitted by Mercedes-Benz on fleet idle time and its system's real-world effectiveness (i.e., how much of the time the system turns off the engine when the vehicle is stopped).[3521] Prior to proposal, multiple auto manufacturers requested

3520 NHTSA-2018-0067-12073-48.

3521 "EPA Decision Document: Mercedes-Benz Off-cycle Credits for MY 2012-2016," EPA-420-R-14-025 (Sept. 2014).

that EPA revise the table menu value for stop-start technology based solely on one input value EPA considered, idle time, in the context of the Mercedes-Benz stop-start system. No manufacturers provided additional data on any of the other factors evaluated during consideration of a conservative credit value for stop-start systems. Stop-start systems vary significantly in hardware, design, and calibration, leading to wide variations in the amount of idle time during which the engine is actually turned off in real-world driving. EPA has learned that some stop-start systems may be less effective in the real-world than the agency estimated in its 2012 rulemaking analysis, for example, due to systems having a disable switch available to the driver, or because stop-start systems can be disabled under certain temperature conditions or auxiliary loads, which would offset the benefits of the higher idle time estimates. EPA requested additional data from manufacturers, suppliers, and other stakeholders regarding a comprehensive update to the stop-start off-cycle credit table value. EPA did not receive any additional real-world system effectiveness data from commenters on which to base an adjusted credit level. MEMA commented that EPA should base an increase in the credit on the agencies' updated estimated effectiveness of stop-start technology in the Draft Technical Assessment Report (TAR), which shows a 67 percent increase in effectiveness.[3522, 3523] However, EPA notes that this estimate is for system effectiveness over the 2-cycle test procedures and, therefore, is not an appropriate basis to adjust the off-cycle credits. The agencies are not adjusting the menu credits for stop-start systems at this time. Manufacturers may apply for additional credits if they are able to collect data demonstrating a system effectiveness that would serve as the basis for those credits.

(5) Menu Credit Cap

The off-cycle menu currently includes a fleetwide cap on credits of 10 grams/mile to address the uncertainty surrounding the data and analysis used as the basis of the menu credits.[3524] Prior to proposal, some stakeholders expressed concern that the current cap may constrain manufacturers' future ability to fully utilize the menu especially if the menu is expanded to include additional technologies, as described above. For example, Global Automakers suggested raising the cap from 10 grams/mile to 15 grams/mile.[3525] EPA requested comments on increasing the current cap, for example, from the current 10 grams/mile to 15 grams/mile to accommodate increased use of the menu. EPA also requested comment on a concept that would replace the current menu cap with an individual manufacturer cap that would scale with the manufacturer's average fleetwide target levels. The cap would be based on a percentage of the manufacturer's fleetwide 2-cycle emissions performance, for example at five to ten percent of CO_2 of a manufacturer's emissions fleet-wide target. With a cap of five percent

[3524] 40 CFR 86.1869–12(b)(2).
[3525] Global Automakers, Detailed Comments, NHTSA-2018-0067-12032.

for a manufacturer with a 2-cycle fleetwide average CO_2 level of 200 grams/mile, for example, the cap would be 10 grams/mile.

There was widespread support from automakers and suppliers for removing the cap entirely or raising the cap from 10 grams/mile to 15-20 grams/mile. Toyota, General Motors, BorgWarner, Fiat Chrysler, the Auto Alliance, Global Automakers, MECA, DENSO, SAFE, and Volkswagen submitted responses on the off-cycle cap to EPA.[3526] They argued that the 2-cycle test does not always account for all the benefits a technology provides.[3527] General Motors, Fiat Chrysler, the Auto Alliance, Global Automakers, and Volkswagen agreed that EPA should remove the 10 grams/mile cap and, if they must keep the cap, increasing it to 15 grams/mile.[3528]

Global Automakers commented that, as more technology receives off-cycle credit values, the cap will restrict innovation and therefore EPA should lift the cap now in anticipation of increased use of technologies.[3529] General Motors similarly commented that the cap was an arbitrary limit without any technical justification and that, if the agency was to add emission reduction technologies to the menu these devices could not be effectively incentivized if the 10 grams/mile cap remains in place, since there would be no room under the cap.[3530] General Motors suggested that as the program continues, manufacturers will continue to find new technologies and will be limited by the cap. They stated that the cap will stifle additional investments for technologies. MEMA commented that if EPA expands the off-cycle technologies menu and continually adds off-cycle technologies to the menu, it is critical that EPA increase or eliminate the cap on the credits gained from the off-cycle menu.[3531]

The Auto Alliance argued that putting caps on emerging new technologies will hinder further vehicle investments and improvements. The planning cycle is implemented years out and without a guarantee they will see benefits, the Auto Alliance stated that manufacturers lack incentivization to work toward large technological advances.[3532] The Auto Alliance and Alliance

[3532] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

for Vehicle Efficiency further asserted that flexibility mechanisms are increasingly important and there is a need to develop unconventional and non-traditional fuel economy technologies.[3533]

ACEEE commented that the off-cycle credit menu cap should not be increased or modified without the agency first defining any other changes it might consider making to the off-cycle credit program and this should be done through a separate NPRM and public review process.[3534] ICCT commented that if the agencies allow more use of off-cycle credits without clear validation of their real-world benefits, the regulations cannot serve their intended objectives to reduce CO_2 and fuel use.[3535]

EPA also received a few comments warning about the risks of removing the caps and over incentivizing the CAFE and CO_2 programs. ACEEE pointed out that while expanding and updating the flexibilities that incentivize innovation and research is a great method to increase fuel efficiency, it is important to put a time limit on those incentives and carefully design them so manufacturers do not take advantage. ACEEE argued that, if these flexibilities are not implemented thoughtfully, they can end up reducing the program benefits. UCS commented that, given the potential interaction from multiple incentives, it is important to consider the combined impacts of flexibilities on the overall stringency of the regulation. UCS stated that given the potential for widespread harm, credits within the program should be severely limited, and the agencies' assessment of the impacts of such incentives should be extremely conservative in order to promote increased environmental benefits of the fuel economy and carbon dioxide emissions standards.[3536]

The agencies are not increasing the 10 grams/mile menu credit cap at this time. EPA established the 10 grams/mile credit cap to address the uncertainty surrounding the data and analysis used as the basis of the menu credits, and agrees with ACEEE, ICCT, and UCS that sufficient uncertainty remains such that increasing the current cap is not justified. As noted in the 2012 final rule, EPA included the fleet-wide cap because the default credit values were based on limited data, and also because the agencies recognized that some uncertainty is introduced when credits are provided based on a general assessment of off-cycle performance as opposed to testing on the individual vehicle models.[3537] That uncertainty has not significantly diminished since the 2012 final rule. Also, over the course of implementing the program, EPA has encountered issues with the regulatory definitions currently in place for some technologies. The regulations specify that manufacturers may claim credits for technologies that meet the regulatory definitions. However, there have been instances where manufacturers have claimed credits for a technological approach that they have argued meets the regulatory definition, but EPA found that the technology was not implemented consistent with the technological approach envisioned when the off-cycle program was established. This has raised questions of whether the credits for the technological approach in question truly represent real-world reductions, and

whether the credits should ultimately be allowed. These types of issues have resulted in uncertainty, which can lead to delays in credit calculations, competitive inequities, as well as increased burden on the agency to review and resolve issues. The caps continue to serve as an important measure against the loss of emissions reductions and fuel savings given the uncertainty in the credit values as the program is implemented. Since the agencies are not expanding the menu beyond the two technologies discussed above, the agencies believe there remains enough room under the cap such that the menu may continue to serve its purpose as a source of off-cycle credits. Although a few manufacturers approached the cap limit in MY 2018, the fleet average menu credit was 4.7 grams/mile, less than half the cap value.[3538] If the agencies undertake a rulemaking in the future to modify the menu or regulatory definitions, the agencies may re-evaluate the cap levels at that time. The agencies note that the cap only applies to credits based on the menu. Under the current program, manufacturers may apply for credits beyond the cap through other available pathways based on a demonstration of off-cycle technology emission reduction data for their fleets.

As noted above, the agencies have decided to continue the option to add technologies to the menu only through the rulemaking process and, for this final rule, have decide to add two new menu items; one for high-efficiency alternators and another for advanced A/C compressors. The agencies stated that they will only add technologies when sufficient data has been collected from multiple manufacturers and vehicle models on which to base a menu credit. Accordingly, the agencies believe this approach ensures that conservative, robust and accurate credit levels are being added representing vehicles "on average" across the fleet.

Finally, NHTSA has been studying how the combination of flexibilities and incentives may adversely affect the stringency of the CAFE regulations. NHTSA is aware of an instance in which combining incentives for alternative fueled vehicles and adjustments for A/C and off-cycle technologies allowed one manufacturer to increase in CAFE fleet performance to a combined average of 516.8 mpg for MY 2017, a curious result. NHTSA iscontinuing to evaluate the issue of combining incentives and flexibilities and may address this issue further in the future.

(6) Eligibility

Though, in the NPRM, EPA did not explicitly request comment on the eligibility criteria for determining what technologies are eligible for off-cycle credits, EPA received comments on this topic. UCS commented that regulations should be clarified so that the program does not result in unwarranted credits for baseline technologies, noting that in the 2012 final rule EPA stated that technologies integral or inherent to the basic vehicle design were not eligible for credits and specifically excluded technologies identified by the agency as technologies a manufacturer may use to meet the two-cycle CO_2 standards.[3539] ACEEE commented that off-cycle credits should be limited to new and innovative technologies and, that to be eligible for

[3538] The 2018 EPA Automotive Trends Report, Greenhouse Gas Emissions, Fuel Economy, and Technology since 1975, EPA-420-R-19-002 (Mar. 2019).
[3539] UCS, Detailed Comments, NHTSA-2018-0067-12039.

credit, a technology must reduce emissions from the vehicle receiving the credit (as opposed to other vehicles on the road, for example, through system effects of technologies designed for crash avoidance or improving traffic flow).[3540] The Auto Alliance also commented in the area of eligibility, suggesting regulatory changes that would allow off-cycle credits for any technology where the manufacturer could demonstrate an off-cycle emissions benefit.[3541] The Auto Alliance commented that the program is intended to provide credit for technologies that provide more fuel economy and CO_2 emissions reduction benefit in the real-world than is realized in FTP and HFET on-cycle testing and that a baseline technology should be eligible for such credits.

Given the various public comments on eligibility of technologies for off-cycle credits, the agencies are clarifying the regulations regarding technology eligibility, consistent with the intent and EPA's interpretation of the 2012 rule, as expressed in the preamble to the proposed and final rules. The agencies believe that clarifying the regulations will reduce confusion among manufacturers as to what technologies are eligible and reduce the overall program burden associated with EPA staff giving continued guidance to manufacturers regarding eligibility, as detailed in the 2012 rule preamble. Eligibility was thoroughly addressed in the 2012 final rule preamble, but the regulations were not as clear, which has led to confusion on the part of some manufacturers and delays in reviewing credit applications.[3542] The agencies are not establishing a new policy regarding eligibility, only amending the language reflecting the existing policy in the regulations for sake of clarity.

As noted in the 2012 final rule preamble, the goal of the off-cycle credits program is to provide "an incentive for the development and use of additional technologies to achieve real-world reductions in CO_2 emissions."[3543] EPA further stated that the intent of the program is to "provide an incentive for CO_2 and fuel consumption reducing off-cycle technologies that would otherwise not be developed because they do not offer a significant 2-cycle benefit."[3544] The regulation at 40 CFR 86.1869-12(a) provides that manufacturers may generate credits for CO_2 reducing technologies "where the CO_2 reduction benefit for the technology is not adequately captured on the Federal Test Procedure and/or Highway Fuel Economy Test." The regulation continues: "[t]hese technologies must have a measurable, demonstrable, and verifiable real-world CO_2 reduction that occurs outside the conditions of the Federal Test Procedure and the Highway Fuel Economy Test."

Off-cycle credits are available for technologies that are not utilized when performing FTP and HFET tests because their operation is linked to a condition not found during the 2-cycle testing. For example, heating and cooling systems are not operated during the 2-cycle test, and therefore, efficiency improvements to these systems are not captured at all on the 2-cycle tests. As the 2012 rule's language indicates, off-cycle credits are not necessarily limited to technologies listed on the menu or off-cycle technologies with no measurable benefit on the FTP and/or HFET. Off-cycle credits may be available for some technologies whose performance is

3543 77 FR 62833.
3544 77 FR 62836.

measurable to some extent on the FTP and/or HFET but which perform measurably better off-cycle. Active aerodynamic and stop-start technologies (menu item) are examples. However, there are limits on what the agencies would consider to be an off-cycle technology eligible for credits, as discussed below.

Just as the regulations and preamble to the 2012 final rule listed technologies that the agencies considered to be off-cycle technologies, the preamble also discussed technologies that the agency would not consider off-cycle technologies—i.e., technologies the agencies consider to be "adequately captured" by the FTP and therefore not eligible for off-cycle credits. The preamble specifically noted that engine, transmission, mass reduction, passive aerodynamic design, and base tire technologies are not considered to be off-cycle technologies eligible for credits.[3545] These are technologies that are considered to be "integral or inherent to basic vehicle design."[3546] In response to comments in the final rule, the agencies further clarified that advanced combustion concepts, such as camless engines, variable compression ratio engines, micro air/hydraulic launch assist devices, would not be considered to be eligible for credits.[3547] This limitation to eligibility further extends to other engine designs, transmission designs, and electrification systems not specifically contemplated in the rulemaking, such as Atkinson combustion engines, and 9 and 10 speed transmissions, as well as to other hybrid systems such as 48 Volt technologies. Further, the 2012 final rule preamble stated that technologies included in the agencies' assessment for purposes of developing the standard would not be allowed to generate off-cycle credits and cites the technologies described in Chapter 3 of the 2012 final rule TSD.[3548] Finally, off-cycle credits are not available for technologies required to be used by Federal Law or for crash avoidance systems, safety critical systems, or technologies that may reduce the frequency of vehicle crashes.[3549]

The preamble to the 2012 final rule provides the rationale for what the agency considers an off-cycle technology and, therefore, eligible for credits. Technologies that are integral or inherent to the vehicle are, by necessity, well represented on the 2-cycle test.[3550] Examples provided in the preamble are engine, transmission, mass reduction, passive aerodynamic design, and base tire technologies. The control logic for these powertrain components, like the components themselves (i.e. engine and transmission), are constantly active, fully functioning, and operating over the entirety of the FTP and HFET. Similarly, an automatic transmission, regardless of whether it has 6-speeds or 8-speeds, would still be constantly active, fully functioning and operating over the entirety of the FTP and HFET.[3551] This would also be true for base engine technologies, advanced combustion concepts, engine components (pistons, valves,

camshafts, crankshafts, oil pumps, etc.), and driveline components (individual components of the transmission, axle, and differential).[3552]

Further, even if these technologies have greater benefits on supplemental test cycles, EPA has explained that it would be difficult to devise accurate A/B testing (i.e., with and without the technology) for these technologies.[3553] The 2012 preamble states that "EPA is limiting the off-cycle program to technologies that can be identified as add-on technologies conducive to A/B testing," partly because it would be very difficult accurately to parse out the off-cycle benefits for some integral technologies.[3554] Because the technology is integral to the vehicle, there would not be an appropriate baseline (i.e., without the technology) vehicle to use for comparison. Vehicles are not built without tires, engines, passive aerodynamics or transmissions.

Also, because these technologies are inherent to the vehicle design, their performance is already reflected in the stringency of the standard and giving credits for these inherent technologies would be a type of double-counting windfall.[3555] "[S]ince these methods are integral to basic vehicle design, there are fundamental issues as to whether they would ever warrant off-cycle credits. Being integral, there is no need to provide an incentive for their use, and (more importantly), these technologies would be incorporated regardless. Granting credits would be a windfall."[3556] As such, EPA has laid out a clear basis that technological improvements to integral and inherent components are considered to be adequately captured on the FTP and HFET test.

EPA is clarifying the regulations in a manner that is consistent with the intent and our interpretation of the 2012 rule, as expressed in the preambles to the proposed and final rules. The regulations are revised to specify that technologies used primarily to meet the 2-cycle standards are not eligible for off-cycle credits and that only technologies primarily installed for reducing off-cycle emissions would be eligible. The revised regulations specify that the technologies must not be integral or inherent to the basic vehicle design, such as, for example, engine, transmission, mass reduction, passive aerodynamic design, and tire technologies. Exceptions to these general provisions include technologies already specified on the menu, including engine idle stop-start, active aerodynamic improvements, and high-efficiency alternators. These technologies may provide some benefit on the 2-cycle test, but EPA determined in the 2012 rule that they are eligible for off-cycle credits because they are technologies that could be added to vehicles to provide discernable off-cycle reductions.

Regulatory text at 40 CFR 86.1869–12(a) states: "Manufacturers may generate credits for CO_2 reducing technologies where the CO_2 reduction benefit of the technology is not adequately captured on the Federal Test Procedure and/or the Highway Fuel Economy Test," to which EPA is adding, "such that the technology would not be otherwise installed for purposes of reducing emissions (directly or indirectly) over those test cycles (i.e., on-cycle) for compliance with the

[3556] *See also* 76 FR 75024.

[CO_2] standards." EPA is also adding text to this paragraph of the regulations specifying: "The technologies must not be integral or inherent to the basic vehicle design, such as engine, transmission, mass reduction, passive aerodynamic design, and tire technologies. Technologies installed for non-off-cycle emissions related reasons are also not eligible as they would be considered part of the baseline vehicle design. The technology must not be inherent to the design of occupant comfort and entertainment features except for technologies related to reducing passenger A/C demand and improving A/C system efficiency. Notwithstanding the provisions of this paragraph (a), off-cycle menu technologies included in paragraph (b) of this section remain eligible for credits."

The agencies believe the above regulatory changes will help reduce confusion over what technologies are eligible for off-cycle credits, refocusing the program on technologies that manufacturers would install on vehicles for purposes of reducing off-cycle emissions rather than obtaining additional credits for technologies installed primarily for 2-cycle emissions reduction or for other reasons not related to emissions. This approach is consistent with the intent of the program as stated in the 2012 final rule to provide an incentive to develop and employ off-cycle technologies not adequately captured on the 2-cycle test procedure.

Of the technologies recommended by manufacturers to be added to the menu, cooled EGR is an example of a technology that would not be eligible because it is an integral 2-cycle technology that EPA noted in its technology assessment in the MY 2012 rule. Cooled EGR is often an integral component of turbo charged gasoline direct injection engines which is a primary CO_2 reduction strategy used by manufacturers to reduce 2-cycle emissions. The technologies are calibrated to act as a system such that is not possible to separate them in a way that would allow for a clear indication of the off-cycle benefit of cooled EGR as a stand-alone technology.

EPA also received comments from the Auto Alliance regarding several technologies they believe should qualify as active warm-up off-cycle technologies. The Auto Alliance commented that systems that use waste heat from the exhaust gas stream should receive additional credits beyond the menu credits currently established for active engine and transmission warm-up.[3557] However, when EPA established the menu credits for active transmission and engine warm-up in the 2012 rule, EPA envisioned waste heat from the exhaust as the primary source of heat to quickly bring the system to operating temperature as the basis for the warm-up technology credits.[3558] Therefore, EPA does not believe additional credits, as suggested by the Auto Alliance, are warranted. EPA further notes that the definitions for active engine and transmission warm-up specify that "waste heat" be used in active warm-up technologies in order to qualify for the credits.[3559] If a system first directs heat to warm the engine oil or warm the interior cabin, and only then to the engine or transmission, thereby delaying active warm-up, EPA would not view that heat as waste heat since it is serving other purposes during initial vehicle warm-up. EPA would also not consider this approach to be warming up the engine or

[3557] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3558] *See* Joint Technical Support Document: Final Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, EPA-420-R-12-901, August 2012, p. 5-96 - 5-100.
[3559] 40 CFR 86.1869–12(b)(4)(v) and (vi).

transmission "quickly" due to the potentially significant delay in warm-up activation. In developing the active warm-up credits, EPA focused on systems using heat from the exhaust as a primary source of waste heat because that heat would be available quickly and also be exhausted by the vehicle and otherwise unused.

EPA allowed for the possible use of other sources of heat such as coolant as the basis for credits as long as those methods would "provide similar performance" as extracting the heat directly from the exhaust system.[3560] However, EPA may require manufacturers to demonstrate that the system is based on "waste heat" or heat that is not being preferentially used by the engine or other systems to warm-up other areas like engine oil or the interior cabin. Systems using waste heat from the coolant do not qualify for credits if their operation depends on, and is delayed by, engine oil temperature or interior cabin temperature. As the engine and transmission components are warming up, the engine coolant and transmission oil do not have any 'waste' heat available for warming up anything else on the vehicle. During engine and transmission warm-up, the only waste heat source in a vehicle with an internal combustion engine is the engine exhaust as the transmission and coolant have not reached warmed-up operating temperature and therefore do not have any heat to share. Conserving heat in a transmission is not a rapid transmission warm-up using waste heat. Unless the component with lubricating oil and coolant is operating at its fully warmed-up design temperature, by EPA's definition, that component does not have any waste heat available for transfer from the lubricating oil or coolant to any other device until it has reached its fully warmed-up operating temperature (i.e. the temperature when the cooling system is enabled). A qualifying system may involve a second cooling loop that operates independent of the primary coolant system and is not dependent on or otherwise delayed by, for example, cabin temperature. Evaluating whether such systems qualify for menu credits often requires additional information regarding system design to understand better how the system uses waste heat. Given the complexity of these systems and the need to sometimes consider the details of how a system operates, EPA is not making any changes to the menu regarding warm-up technologies.

The Auto Alliance further commented that active transmission bypass valves should qualify for active transmission warm-up credits.[3561] The Auto Alliance commented that traditional transmission oil coolers are always active and sized for extreme or worst-case hot ambient conditions. The coolers will, in colder ambient conditions, keep the transmission temperatures well outside of their most efficient operating range. The bypass valve circumvents the cooler when the transmission is relatively cold preserving the transmission heat, so the transmission warms more quickly. EPA disagrees that this type of approach should be eligible for active transmission warm-up because it does not use waste heat to add heat to the transmission. Instead, it prevents useful heat already present in the transmission from being unnecessarily removed. Also, EPA does not view this type of bypass valve as an off-cycle technology but rather as part of a good engineering design of a transmission cooler system. Many vehicles already are designed with transmission cooler bypass valves. EPA does not

[3560] *See* Joint Technical Support Document: Final Rulemaking for 2017-2025 Light-Duty Vehicle Greenhouse Gas Emission Standards and Corporate Average Fuel Economy Standards, p. 5-99, EPA-420-R-12-901, August 2012.
[3561] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

believe existing coolers qualify as warm-up technologies simply because they are disabled under cold conditions. This approach does not represent the addition of a new off-cycle warm-up technology but the disabling of an existing cooling technology.

Although the agencies did not consider changes to the program to allow credits for safety-related technologies and autonomous vehicle technologies in the proposal, comments were received both in favor of and not in favor of allowing such credits.[3562] The agencies note that the rationale for not allowing off-cycle credits for safety-related or crash avoidance technologies has not changed since the 2012 rule and, therefore, in the proposed rule the agencies did not consider making any changes to allow off-cycle credits for safety-related technologies.[3563] The agencies continue to believe that there is a very significant distinction between technologies providing direct and reliably quantifiable improvements to fuel economy and CO_2 emission reductions, and technologies which provide those improvements by indirect means, where the improvement is not reliably quantifiable, and may be speculative (or in many instances, non-existent), or may provide benefit to other vehicles on the road more than for themselves. The agencies also continue to believe that the advancement of crash-related and crash avoidance systems specifically is best left to NHTSA's exercise of its vehicle safety authority.

Auto manufacturers and suppliers also commented that EPA should adopt "eco-innovation" credits approved in the European Union (EU) vehicle CO_2 reduction program as part of the off-cycle credits program.[3564] No data was provided as to why the credits would be appropriate for the U.S. vehicle fleet. EPA did not consider or request comment on the EU credits program and does not believe the credit levels would necessarily be appropriate for the U.S. fleet given the very different vehicle use and driving patterns between Europe and the U.S. Thus, there is no assurance that the credits would be based on real-world emissions reductions.

EPA received comments from the Auto Alliance and Global Automakers that EPA should automatically award credits if the agency does not take final action within 90 days of receiving a request for credits.[3565] Regarding these comments, EPA does not believe such a provision is in keeping with maintaining the integrity of the off-cycle credits program. As discussed above, EPA often requires time to sort through complex issues to determine if the technologies meet the regulatory requirements for receiving credits and whether the credits have been quantified appropriately. In some instances, EPA has received public comments and manufacturer rebuttals to those comments that takes additional time to consider before making a final decision. EPA's goal continues to be to evaluate applications for credits in as timely a manner as is possible given the issues that must be addressed and within the resources available. While EPA's need carefully to consider applications may slow down the approval process or result in credits not being approved, it remains paramount to ensure credits are not provided to

[3562] *See, e.g.*, SAFE, Detailed Comments, NHTSA-2018-0067-11981; AAA, Detailed Comments, NHTSA-2018-0067-11979.

technologies that do not provide actual off-cycle benefits, and thereby do not meet the regulations. In the past, longer time frames for EPA review have not caused manufacturers to lose credits where credits are determined by EPA to be warranted under the regulations. EPA believes that the changes EPA is making to the program will help streamline the program and reduce confusion, thus helping to reduce the time necessary to evaluate applications and provide final decisions to manufacturers.

(7) Supplier Role in the Off-Cycle Credits Program

Prior to proposal, EPA heard from many suppliers and their trade associations about an interest in allowing suppliers to have a formal, regulatorily defined role in the off-cycle credits program.[3566] EPA requested comment on providing a pathway for suppliers, along with at least one auto manufacturer partner, to submit off-cycle applications for EPA approval. As described in the proposal, under such an approach, an application submitted by a supplier and vehicle manufacturer would establish a credit and/or methodology for demonstrating credits that all auto manufacturers could then use in their subsequent applications. EPA requested comment on requiring that the supplier be partnered in a substantive way with one or more auto manufacturers to ensure that there is a practical interest in the technology prior to EPA investing resources in the approval process. The supplier application would be subject to public review and comment prior to an EPA decision. However, once approved, subsequent auto manufacturer applications requesting credits based on the supplier methodology would not be subject to public review. Under this concept, the credits would be available provisionally for a limited period of time, allowing manufacturers to implement the technology and collect data on their vehicles in order to support a continuation of credits for the technology in the longer term. Also, as envisioned by EPA in its request for comment, the provisional credits could be included under the menu credit cap since they would be based on a general analysis of the technology rather than manufacturer-specific data.

Auto manufacturers' and suppliers' comments were generally supportive of an expanded role for suppliers in the off-cycle credit program. The Auto Alliance supported allowing a supplier to lead the application process but did not support the provisional credit concept since the follow-up testing conducted by manufacturers may not support the level of credits initially claimed by the supplier, resulting in a lower than anticipated credit.[3567] Instead, the Auto Alliance suggested a separate cap for supplier-based credits and noted that manufacturers could submit their own data if they wanted to pursue credits levels that exceeded the cap. General Motors similarly disagreed with the provisional credits that might be rescinded if subsequent testing does not fully validate the value of the technology.[3568] MEMA supported the request for comments regarding a supplier-led process but did not support requiring that suppliers have an auto manufacturer partner.[3569] MEMA commented that there would be no incentive for a

[3566] 83 FR 43461.
[3567] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3568] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.
[3569] MEMA, EPA-HQ-OAR-2018-0283-5692. *See* https://www.mema.org/sites/default/files/resource/MEMA%20CAFE%20and%20GHG%20Vehicle%20Comments%20FINAL%20with%20Appendices%20Oct%2026%202018.pdf.

supplier to go through the product/technology development process, collect the necessary data, and undertake the full application process for a product/technology that would not generate manufacturer interest.

At this time, EPA believes the concept of a supplier pathway would benefit from additional discussions with interested parties and an opportunity for public comment on the details of such a provision, both of which are beyond the scope of this rulemaking. EPA continues to believe such an approach could encourage the further development of off-cycle technologies, but must be done in a reasonable way that ensures the credits are based on real-world emissions reductions. EPA believes that suppliers can play an important role in providing the data and analysis needed to demonstrate the real-world emissions reduction potential of off-cycle technologies. Therefore, EPA plans to continue to engage with automotive suppliers and the manufacturers to explore the merits of a supplier pathway in the off-cycle credits program and how such a program might be designed, with the intent of EPA pursuing such a modification to the off-cycle credit program in a future regulatory action.

Under the approach suggested by the Auto Alliance, manufacturers could claim supplier-based credits indefinitely and EPA might never receive any manufacturer data substantiating the credits unless that data supported a credit that exceeded the level established through the supplier process. EPA is concerned such a one-way ratchet approach could result in the loss of emissions benefits and undermine the integrity of the off-cycle credit program. EPA also remains concerned about the potential for a significantly increased volume of credit applications, including the potential for applications for proposed technologies that manufacturers might in reality have no interest in adopting. EPA understands MEMA's perspective on the issue of requiring a manufacturer partner, but a supplier-only process would potentially open the door to many requests such that the agency would need to expend considerable additional resources. EPA notes that nothing in the current regulations prevents collaboration between manufacturers and suppliers. Suppliers can and do team with a manufacturer to support the manufacturer's application for credits including providing supporting data and analysis. Suppliers can initiate this process; manufacturer participation will be necessary to complete an application. EPA will provide additional clarity about this process through a subsequent technical amendments rulemaking.

(8) Other Considerations

Avista Oil commented that EPA should provide an opportunity for credits based on the use of recycled engine oil. Avista Oil commented that there are CO_2 emissions reductions associated with the use of recycled used engine oil and that vehicle manufacturers should be awarded credits for the use of recycled oil. Avista Oil's comment is not within the scope of the rulemaking. The off-cycle credits program focuses on providing credits for technologies that, when applied to the vehicle, the result is lower quantifiable real-world emissions from the vehicle. According to Avista Oil's comment, their recycled oil technology benefits are associated with the recycling process rather than lowering vehicle emissions on the road. Therefore, EPA would not view the technology as eligible for off-cycle credits, and EPA did not propose any other credit specific to the use of recycled engine oil.

Several commenters recommended that EPA raise the credit caps and credit values for thermal controls based on recent work by the National Renewable Energy Lab (NREL). Commenters suggested that credit values should be raised by 64 percent. In response, as discussed in the preamble, EPA is retaining the current menu credit caps and menu credit values due to uncertainties involved with the emissions projections and estimated credit values. Manufacturers may generate additional credits through the off-cycle credits program using the other two pathways by providing individual vehicle data. EPA recognizes additional modeling analysis has been performed by NREL that indicates the potential benefit of all thermal technologies including glazing. EPA designed the thermal control program and related caps based on previous NREL work and applied the thermal caps at the current levels to account for the wide range of uncertainties -- including the uncertainty of the benefit from the combination of thermal technologies and the uncertainty highlighted by the different credit levels across the NREL studies. EPA believes the separate current thermal menu program cap and AC efficiency program cap continue to be reasonable for application across the fleet given these uncertainties.

Enhanced Protective Glass Automotive Association (EPGAA) and Vitro commented that the regulations established by the 2012 rule included an oversight in defining the baseline Tts (the metric used to evaluate thermal reflectivity of glass). EPGAA commented that there was an omission in the case of trucks, where the regulations do allow the use of privacy glass in locations other than the windshield and the front doors. The commenter discussed that the reference baseline glass for trucks, SUVs, and CUVs should have already included privacy glass for some of the rearward windows. In response, EPA recognized when the thermal credit program was finalized in 2012 that some of the vehicles within the reference fleet upon which the credits were based were already composed of vehicles with this type of thermal reflective glass. However, the agency found it difficult to estimate what portion of the fleet contained privacy glass and what the Tts rating was for privacy glass across the fleet. Because of this lack of specificity in the fleet composition and glass ratings, the agencies determined that the most appropriate approach was to allow credit for any glass meeting the finalized Tts requirements, and the total thermal cap was designed to account for this and other uncertainties.

Ford and others commented that thermal control technology credit caps should be implemented on a fleet average basis rather than on a “per VIN” basis. These commenters argued that the per VIN basis creates a reporting burden that is misaligned with the current reporting structure and creates program complexity and unnecessary workload. In response, EPA continues to believe that applying the thermal control credit cap on a per vehicle (per VIN) basis is appropriate due to the synergistic effects among these technologies. The CO2 reduction potential of applying thermal control technologies is limited within any given vehicle. The program has been implemented in this manner since MY2014, and manufacturers have in fact reported the necessary information to generate thermal control credits.

Gentherm, GM, MEMA, and The ITB Group commented that cooled seats should be added to the menu based on the approved GM off-cycle credits application and NREL study. EPA and NHTSA are not adding cooled seat technology to the menu because the agencies have received data from only a single manufacturer. By contrast, for the technologies EPA and NHTSA are adding to the menu in this final rule, the agencies have assessed data from multiple manufacturers. EPA notes however that the streamlining provisions being finalized in this action should facilitate other manufacturers in being able to apply for off-cycle credits by using GM's methodology.

Finally, on October 1, 2018, EPA proposed a technical correction separate from the SAFE Vehicles rulemaking for the off-cycle credits pathway based on 5-cycle testing (83 FR 49344). This proposal would correct an error in the regulations established as part of the 2012 final rule. Some commenters expressed their support for the correction as part of their SAFE Vehicles rule comments. EPA notes that this correction continues to be part of a separate rulemaking and is not being addressed in the SAFE Vehicles final rule.

c) Final Decisions on the 2016 Alliance/Global Petition

(1) Retroactive A/C and Off-Cycle CAFE Adjustments

In 2016, the Alliance and Global submitted a petition for rulemaking, which included requests that: (1) NHTSA allow retroactive credits for A/C and off-cycle incentives for MYs 2012 to 2016; and (2) NHTSA and EPA revisit the average A/C efficiency benefit calculated by EPA applicable to MYs 2012 through 2016. The Alliance/Global argued that A/C efficiency improvements were not properly acknowledged in the CAFE program, and that manufacturers had exceeded the A/C efficiency improvements estimated by the agencies. The petitioners requested that EPA also amend its regulations such that manufacturers would be entitled to additional A/C efficiency improvement benefits retroactively. The petitioners also argued that NHTSA incorrectly stated the agency had taken off-cycle adjustments into consideration when setting standards for MYs 2017 through 2025, but not for MYs 2010-2016. The Alliance/Global further contended that because neither NHTSA nor EPA considered off-cycle adjustments in formulating the stringency of the MY 2012-2016 standards, NHTSA should retroactively grant manufacturers off-cycle adjustments for those model years as EPA did. Doing so, they said, would maintain consistency between the agencies' programs.

Of the two agencies, EPA was the first to establish an off-cycle technology program. For MYs 2012 through 2016, EPA allowed manufacturers to request off-cycle credits for "technologies that achieve [CO_2] reductions that are not reflected on current test procedures…"[3570] In the subsequent MY 2017 and later rulemaking, NHTSA joined EPA and included an off-cycle program for CAFE compliance. The Alliance/Global petition cited a statement in the MYs 2012-2016 final rule as affirmation that NHTSA took off-cycle adjustments into account in formulating the MYs 2012-2016 stringencies, and therefore should allow manufacturers to earn off-cycle benefits in model years that have already passed.

In the NPRM, NHTSA tentatively decided to retain the structure of the existing A/C efficiency program and not extend it to MYs 2010 through 2016. For the rulemaking for MYs 2012 through 2016, NHTSA determined it was unable to consider improvements manufacturers

[3570] 75 FR 25341, 25344 (May 7, 2010). EPA had also provided an option for manufacturers to claim "early" off-cycle credits in the 2009-2011 time frame.

made to passenger car A/C efficiency in calculating CAFE compliance.[3571, 3572] However, EPA did consider passenger car improvements to A/C efficiency for that timeframe. To allow manufacturers to build one fleet that complied with both EPA and NHTSA standards, the CAFE and CO_2 standards were offset to account for the differences borne out of A/C efficiency improvements. Specifically, the agencies converted EPA's grams/mile standards to NHTSA mpg (CAFE) standards. EPA then estimated the average amount of improvement manufacturers were expected to earn via improved A/C efficiency. From there, NHTSA took EPA's converted mpg standard and subtracted the average improvement attributable to improvement in A/C efficiency. NHTSA set its standard at this level to allow manufacturers to comply with both standards with similar levels of technology.[3573]

Likewise, EPA tentatively decided in the NPRM not to modify its regulations to change the way to account for A/C efficiency improvements. EPA believed this was appropriate as manufacturers decided what fuel economy-improving technologies to apply to vehicles based on the standards as finalized in 2010.[3574] This included deciding whether to apply traditional tailpipe technologies, A/C efficiency improvements, or both. Granting A/C efficiency adjustments to manufacturers retroactively could result in arbitrarily varying levels of adjustments granted to manufacturers, similar to the Alliance/Global request regarding retroactive off-cycle adjustments. Thus, the existing A/C efficiency improvement structure for MYs 2010 through 2016 would remain unchanged.

NHTSA also tentatively decided manufacturers should not be granted retroactive off-cycle adjustments for MYs 2010 through 2016, and presented a number of clarifications to justify the denial. In particular, Alliance/Global pointed to a general statement where NHTSA, while discussing consideration of "the effect of other motor vehicle standards of the Government on fuel economy," stated that that rulemaking resulted in consistent standards across the program.[3575] The Alliance/Global petition took this statement as a blanket assertion that NHTSA's consideration of all "relevant technologies" included off-cycle technologies. To the contrary, as quoted above, NHTSA explicitly stated it had not considered these off-cycle technologies.[3576]

The fact that NHTSA had not taken off-cycle adjustments into consideration in setting its MYs 2012-2016 standards makes granting the Alliance/Global request inappropriate. Doing so could result in a question as to whether the MY 2012-2016 standards were maximum feasible under 49 U.S.C. 32902(b)(2)(B). If NHTSA had considered industry's ability to earn off-cycle adjustments—an incentive that allows manufacturers to utilize technologies other than those that

[3571] At that time, NHTSA stated "[m]odernizing the passenger car test procedures, or even providing similar credits, would not be possible under EPCA as currently written." 75 FR 25557 (May 7, 2010).
[3572] 74 FR 49700 (Sept. 28, 2009).
[3573] *Id*.
[3574] In the MY 2017 and later rulemaking, NHTSA reaffirmed its position it would not extend A/C efficiency improvement benefits to earlier model years. 77 FR 62720 (Oct. 15, 2012).
[3575] *Id*.
[3576] Likewise, EPA stated it had not considered off-cycle technologies in finalizing the MYs 2012-2016 rule. "Because these technologies are not nearly so well developed and understood, EPA is not prepared to consider them in assessing the stringency of the CO_2 standards." *Id*. at 25438.

were being modeled as part of NHTSA's analysis—the agency might have concluded more stringent standards were maximum feasible. Additionally, granting off-cycle adjustments to manufacturers retroactively raises questions of equity. NHTSA issued its MYs 2012-2016 standards without an off-cycle program, and manufacturers had no reason to anticipate that NHTSA would allow the use off-cycle technologies to meet fuel economy standards. Therefore, manufacturers made fuel economy compliance decisions with the expectation that they would have to meet fuel economy standards using on-cycle technologies. Generating off-cycle adjustments retroactively would arbitrarily reward some (and potentially disadvantage other) manufacturers for compliance decisions they made without the knowledge such technologies would be eligible for NHTSA's off-cycle program. Thus, NHTSA tentatively decided to deny Alliance/Global's request for retroactive off-cycle adjustments.

It is worth noting that in the MYs 2017 and later rulemaking, NHTSA and EPA did include off-cycle technologies in establishing the stringency of the standards. As Alliance/Global noted, NHTSA and EPA limited their consideration to stop-start and active aerodynamic features because of limited technical information on these technologies.[3577] At that time, the agencies stated they "have virtually no data on the cost, development time necessary, manufacturability, etc. [sic] of these technologies. The agencies thus cannot project that some of these technologies are feasible within the 2017-2025 timeframe."[3578]

As described above, NHTSA first allowed manufacturers to generate off-cycle technology fuel consumption improvement values equivalent to CO_2 off-cycle credits in MY 2017.[3579] In finalizing the rule covering MYs 2017 and later, NHTSA declined to retroactively extend its off-cycle program to apply to model years 2012 through 2016,[3580] explaining "NHTSA did not take [off-cycle credits] into account when adopting the CAFE standards for those model years. As such, extending the credit program to the CAFE program for those model years would not be appropriate."[3581]

In the NPRM, NHTSA and EPA sought any further comments on the tentative denials of the retroactive requests in the Alliance/Global. The Auto Alliance and Fiat Chrysler provided additional comments on the tentative denial of the petition requests from the Alliance/Global. The commenters cited that the widening gap between the regulatory standards and actual industry-wide new vehicle average fuel economy that has become evident since 2016, despite the growing use of improvement "credits" from various flexibility mechanisms, such as off-cycle technology credits, mobile air conditioner efficiency credits, mobile air conditioner refrigerant leak reduction credits and credits from electrified vehicles.[3582] The commenters believe that

[3579] 77 FR 62840 (Oct. 15, 2012).
[3580] *See id*.; EPA decided to extend provisions from its MY 2017 and later off-cycle program to the 2012-2016 model years.
[3581] *Id*.
[3582] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073; Fiat Chrysler, Detailed Comments, NHTSA-2018-0067-11943.

applying retroactive credits for the new flexibilities for MYs 2012 to 2016 can address the current compliance deficiencies.

Upon consideration of the issue, NHTSA is finalizing its decision to deny any retroactive off-cycle adjustments in the CAFE program for MYs 2012-2016. As mentioned in the NPRM, NHTSA is concerned about the negative impact of allowing retroactive credits, which could undermine the stringency of the MYs 2012-2016 standards. EPA is finalizing its decision not to modify its regulations to change the benefits for A/C efficiency improvements. As mentioned by EPA, the current approach creates uniformity and objectivity in determining A/C efficiency benefits. Consequently, because EPA is maintaining the current A/C determination methodology and NHTSA already considered those A/C adjustments in its MYs 2012-2016 CAFE standards, NHTSA is also finalizing its decisions in this rule to deny any retroactive A/C adjustments in the CAFE program for MYs 2012-2016.

(2) Petition Requests on A/C Efficiency and Off-Cycle Program Administration

As discussed above, NHTSA and EPA jointly administer the off-cycle program. The 2016 Alliance/Global petition requested that EPA and NHTSA make various adjustments to the off-cycle program; specifically, the petitioners requested that the agencies should:

- re-affirm that technologies meeting the stated definitions are entitled to the off-cycle credit at the values stated in the regulation;
- re-acknowledge that technologies shown to generate more emissions reductions than the pre-approved amount are entitled to additional credit;
- confirm that technologies not in the null vehicle set but which are demonstrated to provide emissions reductions benefits constitute off-cycle credits; and
- modify the off-cycle program to account for unanticipated delays in the approval process by providing that applications based on the 5-cycle methodology are to be deemed approved if not acted upon by the agencies within a specified timeframe (for instance 90 days), subject to any subsequent review of accuracy and good faith.[3583]

With respect to Alliance/Global's request regarding off-cycle technologies that demonstrate emissions reductions greater than what is allowable from the menu, this final rule retains that capability. As was the case for MYs 2017-2021, a manufacturer may still apply for FCIVs and CO_2 credits beyond the values listed on the menu, provided the manufacturer demonstrates the CO_2 and fuel economy improvement.[3584] This includes the two-alternative processes for demonstrating CO_2 reductions and fuel economy improvement for gaining benefits using either the 5-cycle or alternative approval methodologies.[3585]

The agencies have considered Alliance/Global's requests to streamline aspects of the A/C efficiency and off-cycle programs in response to the issues outlined above. Among other things,

[3583] Alliance/Global Petition at 20.
[3584] 77 FR 62837 (Oct. 15, 2012).
[3585] 40 CFR 86.1869-12.

Alliance/Global requested that the agencies consider providing for a default acceptance of petitions for off-cycle credits after a specified period of time, provided that all required information has been provided, to accelerate the processing of off-cycle credit requests. While the agencies agree with the merits of A/C efficiency and off-cycle programmatic improvements, there are significant concerns with the concept of approving petition requests by default because such requests may not address program issues like uncertainty in quantifying program benefits, or general program administration.

Based on its consideration of the issues raised by the Alliance/Global, EPA has adopted in this final rule new processes for streamlining the compliance mechanisms for approving off-cycle and applications as discussed in the preceding section.

(3) Other EPA Responses to Alliance Requests

One issue raised in the Alliance/Global Automakers June 2016 petition (item 6 titled "Refrain from Imposing Unnecessary Restrictions on the Use of Credits") for EPA's consideration concerns how credits are managed within the CO_2 program. The Alliance and Global Automakers suggested that EPA allow more flexibility in using credits generated under the various credit programs such as air conditioning or off-cycle credits by allowing them to be carried forward or back independently. Under this approach, a manufacturer would be allowed, for example, to carry their air conditioning credits back to cover a previous deficit while running a deficit in a current model year. The Alliance referred to this petition request in their comments, noting they believe the request "remains pertinent in the context of this rulemaking."

In response, EPA did not raise this issue or any related programmatic changes in the proposal and therefore these comments are not within the scope of the rulemaking. EPA notes the GHG and CAFE programs are harmonized on the aggregation of credits.

The automakers' petition also requested that EPA correct the multiplier equation in the regulations so that manufacturers may generate the intended number of credits (item 8, "Correct the Multiplier for BEVs, PHEVs, FCVs, and CNGs"). This request concerns an error in the regulations established in the 2012 Final Rule that results in manufacturers generating fewer than intended for MY 2017-2021 vehicles in some cases. In October 2018, in response to this petition request, EPA issued a proposed rule separate from the SAFE Vehicles NPRM to correct the error in the previously established regulations. EPA will continue to address this issue and related comments in that separate rulemaking. CAFE does not include multiplier credits and therefore this is not a harmonization issue.

4. Specialty Vehicles with Low Mileage (SVLM)

In response to the NPRM, Volkswagen submitted comments seeking to adopt a new flexibility for specialty vehicles with low mileage (SVLM).[3586] The flexibility would apply to specialty vehicles produced at low volumes and produced for infrequent use. They argued these specialty vehicles do not approach the vehicle miles traveled of typical vehicles. They requested

[3586] Volkswagen, Detailed Comments, NHTSA-2017-0069-0583.

that NHTSA and EPA allow the SVLM flexibility for vehicles that demonstrate limited predicted driving use. The flexibility would allot each manufacturer a limited annual production of 5,000 SVLM vehicles. It was also proposed that, within this limited product volume, each SVLM would retain its footprint derived performance target (per model type), but would utilize a modified VMT for determining any credits or debits associated with the performance of these vehicles within the manufacturer's fleet.

The agencies have considered the request from Volkswagen for credits or debits and fuel economy adjustments for SVLM vehicles and are denying the request. NHTSA notes that Congress prescribed alternative (reduced) CAFE standards for low-volume manufacturers, codified in 49 CFR part 525. Low-volume manufacturers' vehicles are often high-end sports cars and are not typically driven by their owners for long distances. Congress limited this exemption under the CAFE program to manufacturers of fewer than 10,000 passenger automobiles.[3587] EPA has a similar program for smallvolume manufacturers which are defined as manufacturers with average sales for the three most recent consecutive model years of less than 5,000 vehicles.[3588] The flexibility proposed by Volkswagen would presumably be in addition to these existing provisions, but Volkswagen does not identify a source of authority for it. The agencies also have a number of questions about how specifically a SVLM concept might be implemented, such as whether every manufacturer would simply identify the 5,000 vehicles with the lowest projected VMT or lowest fuel economy and therefore qualify for credits for 5,000 vehicles every model year, or whether there should be additional criteria for vehicles to be included. The NPRM did not seek comment on a SVLM concept and the agencies did not receive other comments on the requested program. Therefore, the agencies are not adopting the SVLM concept suggested by Volkswagen.

E. CO_2 and CAFE Compliance Issues Not Addressed in the NPRM

1. CO_2 and CAFE Adjustments for 5-Cycle Testing

EPA and NHTSA received several comments requesting that the agencies revise current CAFE test procedures to use EPA's 5-cycle test procedures in place of the 2-cycle test procedures that have been largely unchanged since the inception of the CAFE program, or offset measured 2-cycle test fuel economy and CO_2 emissions for CO_2 and CAFE compliance. Walter Kreucher commented "some technologies (Hybrid Electric) have penalties on the road that are not reflected on the tests used to determine CAFE compliance. ...If the Agencies want to provide adjustment factors for A/C and other 'Off-Cycle' conditions it must do so in both the positive and negative direction" (sic).[3589] AVE commented that the agencies should use 5-cycle procedures rather than 2-cycle procedures, arguing that the 5-cycle model better demonstrates real-world driving conditions and would lead to a more simplified credit allocation system.[3590] BorgWarner echoed those comments, stating that the 5-cycle test is more accurate than the 2-

---

[3587] 49 U.S.C. 32902(d)(1).
[3588] 40 CFR 86.1818-12(g).
[3589] Walter Kreucher, Detailed Comments, NHTSA-2018-0067-0444.
[3590] AVE, Detailed Comments, NHTSA-2018-0067-11696.

cycle test and would reduce the need for credit adjustments.[3591] Jeremy Michalek commented that the fuel economy values the public sees reflected on vehicles for purchase (e.g., on the Monroney label or in new car advertising) is calculated from the 5-cycle test; updating the 2-cycle test to capture more of the vehicle's fuel efficiency factors would allow for better consistency and a more accurate fuel efficiency measure.[3592] The Auto Alliance proposed that the EPA revise its methodology for calculating off-cycle improvements when using the 5-cycle methodology by subtracting the 2-cycle benefit from the 5-cycle benefit to ensure credits are calculated properly.[3593]

The NPRM did not seek comment on revising compliance test procedures to use 5-cycle test procedures in place of 2-cycle test procedures, either entirely or broadly. Such a change would require extensive assessment and analysis to consider how changes could be implemented and what standards might be maximum feasible for CAFE and appropriate and reasonable for CO_2 for new test procedures. There has been no analysis conducted to estimate the impacts of such a change on the levels of the standards. Therefore, making these requested changes is outside the scope of this rulemaking.

2. National Zero Emissions Vehicle Concept

Although the agencies did not discuss or request comment on a National Zero Emissions Vehicle (NZEV) program concept, several organizations commented on that topic. Some discussed ideas from a task force that was formed by the governors of nine States who signed a memorandum of understanding (MOU) committing to undertake joint cooperative actions to build a robust market for ZEVs under their individual state programs. Collectively, these States have committed to having at least 3.3 million ZEVs operating on their roadways by 2025. ZEVs include battery-electric vehicles (BEVs), plug-in hybrid electric vehicles (PHEVs), and hydrogen fuel-cell electric vehicles (FCEVs). Comments on an NZEV concept were received from General Motors, CARB, Edison Electric Institute, Honda, NCAT, Workhorse Group, and Volvo.

General Motors offered comments supporting an NZEV program, stating that it continues to expect California to be the leader of the EV market but hopes a national effort will be put forth, making the U.S. a global leader in EV technology development and deployment.[3594] General Motors stated it believes an NZEV program would further U.S. national security interests, make the U.S. more competitive with China, which already has an NZEV program, and reduce U.S. dependence on foreign petroleum. General Motors requested that EPA incentivize EV deployment, including providing credits for autonomous EVs and EVs that are used in rideshare programs.[3595] General Motors outlined their proposed NZEV program which would include increasing ZEV requirements annually, establishing credit banks for manufacturers based on national ZEV sales, and ZEV multipliers for vehicles over 5,250 lbs., autonomous vehicles

---

[3591] BorgWarner, Detailed Comments, NHTSA-2018-0067-11895.
[3592] Jeremy Michalek, et al., Detailed Comments, NHTSA-2018-0067-11903.
[3593] Auto Alliance, Detailed Comments, NHTSA-2018-0067-12073.

[3594] General Motors, Detailed Comments, NHTSA-2018-0067-11858.
[3595] General Motors, Detailed Comments, NHTSA-2018-0067-11858.

using EV, and EVs in rideshare programs. General Motors also proposed that requirements would be revisited if EV battery cell were not available at the costs Argonne National Lab forecasts by 2025. General Motors also suggested implementing a Zero Emissions Task Force that would promote complementary policies. General Motors acknowledged that the NZEV program would have to be subject to acceleration or delay depending on how quickly technologies are incentivized like battery cost.

CARB recommended a national ZEV multiplier, stating that a national incentive would help ensure ZEVs and PHEVs were being produced for sale beyond the ten States that have ZEV programs.[3596] The Edison Electric Institute supported increasing stringency of fuel economy and CO_2 standards and incorporating policies from ZEV States to create a "One National Program."[3597] Workhorse Group commented that a national ZEV mandate, where agencies progressively increase the mandated percentage of electric vehicles in every fleet, merits serious consideration by the agencies. They contended that an NZEV would have to work with the current State ZEV mandates and not preempt the progress already made.[3598] Volvo, and Honda were proponents of incorporating ZEV standards into a national program. Volvo requested nationwide credits for ZEVs since there are 40 States without ZEV mandates.[3599] Honda mentioned that incorporating California's ZEV credits into the national program would reduce compliance costs for manufacturers while incentivizing technological development.[3600] NCAT recommended in their comment that EPA provide enhanced credits for EVs, PHEVs, and FCVs that are more stringent than California (and other States) ZEV mandates, making the national program credits "additional" to state ZEV compliance credits.[3601]

Northeast States for Coordinated Air Use Management (NESCAUM) commented that an aggressive reduction in emissions will not occur without national ZEV standards which will drive development of advanced clean vehicle technologies.[3602]

The NPRM did not propose or request comment on an NZEV concept or program, as such, and establishing such a program would be outside the scope of this rulemaking. Such a concept would require thorough assessment and full rulemaking notice and comment. There are also policy questions about what the appropriate level of potential incentives should be and whether certain technologies should receive greater incentives than other technologies, and if so, on what basis and by what amounts. Also, for the CAFE program, incentives for technologies are almost entirely prescribed by statute, and there are questions about how the CAFE program could implement an NZEV program in alignment with EPCA and EISA. Therefore, the agencies have decided not to implement an NZEV program as part of this rulemaking.

3. CO_2 In-Use Requirements

Current in-use regulations outlined in 86.1845-04 provide flexibility in determining the applicable number of test vehicles per test group. Each large volume manufacturer is provided the flexibility to employ small volume sampling allowances for a limited number of total annual production units. In response to the NPRM, Volkswagen is proposing to modify 86.1845-04 to provide a separate, additional small volume sampling allowance allocation of annual production volume for a manufacturer's plug-in hybrid vehicles. This additional allowance would only be applicable through the 2025 model year and would only be applicable to CO_2 testing requirements under the in use regulations.

The basis for this flexibility is rooted in the continuing evolution and development of traction drive battery cell chemistries and battery management systems. This ongoing development is aimed at continuously improving such features as energy density, power, cost, and durability. As such, the engineering processes for understanding and quantifying long-term performance are still developing and subject to reevaluation as new chemistries are examined. Manufacturers such as Volkswagen have allocated significant capital in battery testing to ensure that performance is maintained for consumers and are also providing longer term battery warranty provisions.

Volkswagen believes that the targeted flexibility will provide additional time to continue evaluating chemistries and reduce administrative testing burdens for a very limited production allocation per manufacturer. This provision will further support plug-in hybrid technology development and deployment. Volkswagen proposed modifying 86.1845-04 table SO4-07 footnote 2, to read as follows:

> [2] Total annual production of groups eligible for testing under small volume sampling plan is capped at a maximum of 14,999 vehicle 49 or 50 state annual sales, or a maximum of 4,500 vehicle California only sales per model year, per large volume manufacturer. Through model year 2025, a separate total annual production of plug-in hybrid electric vehicle groups shall be eligible for testing under small volume sampling plan as described above. This allocation shall only be applicable to exhaust CO_2 emission standards under this subpart.[3603]

Regarding comments from VW on CO_2 in-use requirements, EPA did not consider the change recommended by VW in the proposal and is not finalizing such a change. EPA believes the current program provides enough flexibility. EPA's general approach for this final rule is also to avoid providing incentives or other unique flexibilities to specific technologies.

[3603] *See* EPA-HQ-OAR-2018-0283-5689-A1, p.32.

F. Medium and Heavy-Duty Fuel Efficiency Technical Amendments

NHTSA proposed in the NPRM to make minor technical revisions to correct typographical mistakes and improper references adopted in the agency's 2016 Phase 2 medium- and heavy-duty fuel efficiency rule.[3604] The proposed changes were as follows:

- NHTSA heavy-duty vehicles and engine fuel consumption credit equations. In each credit equation in 49 CFR 535.7, the minus-sign in each multiplication factor was omitted in the final version of the rule sent to the *Federal Register*. For example, the credit equation in Part 535.7(b)(1) should be specified as, Total MY Fleet FCC (gallons) = (Std - Act) × (Volume) × (UL) × (10-2) instead of (102), as currently exists. NHTSA proposed to correct these omissions.
- The CO_2 to gasoline conversion factor: In 49 CFR 535.6(a)(4)(ii) and (d)(5)(ii), NHTSA provides the methodology and equations for converting the CO_2 FELs/FCLs for heavy-duty pickups and vans (gram per mile) and for engines (grams per hp-hr) to their gallon-of-gasoline equivalence. In each equation, NHTSA proposed to correct the conversion factor to 8,887 grams per gallon of gasoline fuel instead of a factor of 8,877 as currently specified.
- Curb weight definition: In 49 CFR 523.2, the reference in the definition for curb weight is incorrect. NHTSA proposed to correct the definition to incorporate a reference to 40 CFR 86.1803 instead of 49 CFR 571.3.

No public comments were received in response to NHTSA's proposed technical corrections. Therefore, NHTSA is finalizing these amendments and incorporating them into its heavy-duty regulations.

X. Regulatory Notices and Analyses

A. Executive Order 12866, Executive Order 13563

Executive Order 12866, "Regulatory Planning and Review" (58 FR 51735, Oct. 4, 1993), as amended by Executive Order 13563, "Improving Regulation and Regulatory Review" (76 FR 3821, Jan. 21, 2011), provides for making determinations whether a regulatory action is "significant" and therefore subject to the Office of Management and Budget (OMB) review and to the requirements of the Executive Order. One comment requested that the agencies provide "a far more robust cost/benefit analysis as required by Executive Order (EO) 12866 and Office of Management and Budget Circular A-4."[3605] The NPRM and this final rule satisfy the

[3604] 81 FR 73478 (Oct. 25, 2016).

[3605] *See* Anonymous Comment, Docket No. EPA-HQ-OAR-2018-0283-3896, at 4-5 (footnote and citation omitted). As an example, the comment critiqued the NPRM's discussion of the "diminishing returns" of fuel economy benefits, alleging that the discussion "is not backed by reference to data or studies regarding how this conclusion was made." *Id.* at 5. Contrary to the comment's allegation, the conclusion is supported by the analysis from U.S. Energy Information Administration's (EIA's) Annual Energy Outlook (AEO) that was cited in the discussion. *Id.* As noted in the NPRM, the EIA—the statistical and analytical agency within the U.S. Department of Energy (DOE)—is the nation's premier source of energy information, and every fuel economy rulemaking since 2002 (and requirements of Executive Order 12866, "Regulatory Planning and Review" (58 FR 51735, Oct. 4, 1993), as amended by Executive Order 13563, "Improving Regulation and Regulatory Review" (76 FR 3821, Jan. 21, 2011). Under these Executive Orders, this action is an "economically significant regulatory action" because it is likely to have an annual effect on the economy of $100 million or more. Accordingly, EPA and NHTSA submitted this action to the OMB for review and any changes made in response to OMB recommendations have been documented in the docket for this action. The benefits and costs of this proposal are described above and in the Final Regulatory Impact Analysis (FRIA), which is located in the docket and on the agencies' websites.

B. DOT Regulatory Policies and Procedures

The rule is also significant within the meaning of the Department of Transportation's Regulatory Policies and Procedures. The benefits and costs of this proposal are described above and in the FRIA, which is located in the docket and on NHTSA's website.

C. Executive Order 13771 (Reducing Regulation and Controlling Regulatory Costs)

This rule is an E.O. 13771 deregulatory action. Per OMB Memorandum M-17-21, because this rule is deregulatory, it is not required to be offset by two deregulatory actions, as one comment suggested.[3606]

D. Executive Order 13211 (Energy Effects)

Executive Order 13211 applies to any rule that: (1) is determined to be economically significant as defined under E.O. 12866, and is likely to have a significant adverse effect on the supply, distribution, or use of energy; or (2) that is designated by the Administrator of the Office of Information and Regulatory Affairs as a significant energy action. If the regulatory action meets either criterion, the agencies must evaluate the adverse energy effects of the rule and explain why the regulation is preferable to other potentially effective and reasonably feasible alternatives considered.

The rule establishes passenger car and light truck fuel economy standards and tailpipe carbon dioxide and related emissions standards. An evaluation of energy effects of the action and reasonably feasible alternatives considered is provided in NHTSA's EIS and in the FRIA. To the extent that EPA's CO_2 standards are substantially related to fuel economy and, accordingly, petroleum consumption, the EIS and FRIA analyses also provide an estimate of impacts of EPA's rule.

---

every joint CAFE and CO_2 rulemaking since 2009) has applied fuel price projections from EIA's AEO. *Id.* at 42992 n.24.

[3606] Anonymous Comment, Docket No. EPA-HQ-OAR-2018-0283-3896, at 8.

E. Environmental Considerations

1. National Environmental Policy Act (NEPA)

Concurrently with the final rule, NHTSA is releasing a Final Environmental Impact Statement (FEIS), pursuant to the National Environmental Policy Act, 42 U.S.C. 4321-4347, and implementing regulations issued by the Council on Environmental Quality (CEQ), 40 CFR part 1500, and NHTSA, 49 CFR part 520. NHTSA prepared the FEIS to analyze and disclose the potential environmental impacts of the proposed CAFE standards and a range of alternatives. The FEIS analyzes direct, indirect, and cumulative impacts and analyzes impacts in proportion to their significance. It describes potential environmental impacts to a variety of resources, including fuel and energy use, air quality, climate, land use and development, hazardous materials and regulated wastes, historical and cultural resources, noise, and environmental justice. The FEIS also describes how climate change resulting from global carbon emissions (including CO_2 emissions attributable to the U.S. light duty transportation sector under the alternatives considered) could affect certain key natural and human resources. Resource areas are assessed qualitatively and quantitatively, as appropriate, in the FEIS.

Some commenters provided feedback on the "flaws" they identified in the CAFE model, concluding that because it played a significant role in modeling for the DEIS, the DEIS itself was flawed and should be withdrawn and reissued.[3607] The agencies address the comments regarding the CAFE model above in the FRIA and in the final rule preamble. Ultimately, the findings on potential environmental impacts presented in the FEIS are of the same level of intensity and significance as those presented in the DEIS. While in some cases, the directionality of potential air quality emissions changed, the overall impact was generally small. NHTSA concludes that the CAFE model results, as used in the FEIS, do not result in the FEIS providing significant new information for the decisionmaker or the public compared to the DEIS.[3608] NHTSA therefore concludes that a supplemental DEIS is not required.

NHTSA also performed a national-scale photochemical air quality modeling and health benefit assessment for the FEIS; it is included as Appendix E. The purpose of this assessment was to use air quality modeling and health-related benefits analysis tools to examine the potential air quality-related consequences of the alternatives considered in its Draft Environmental Impact Statement (DEIS). In a comment on the DEIS, the South Coast Air Quality Management District stated that performing the photochemical modeling for the FEIS "comes too late for the public to be able to comment on that analysis," and that the EIS must be recirculated to allow such public

[3607] States of California, Connecticut, Delaware, Hawaii, Iowa, Illinois, Maine, Maryland, Minnesota, North Carolina, New Jersey, New Mexico, New York, Oregon, Rhode Island, Vermont, and Washington; the Commonwealths of Massachusetts, Pennsylvania, and Virginia; the District of Columbia; and the Cities of Los Angeles, New York, Oakland, San Francisco, and San Jose ("California *et. al.*—Detailed NEPA Comments"), Docket No. NHTSA-2017-0069-0625, at 6-11; Environmental Defense Fund, Docket No. NHTSA-2018-0067-11996, at 3-4; and Center for Biological Diversity, *et al.*, Docket No. NHTSA-2018-0067-12123, at 19.
[3608] 40 CFR 1502.9(c)(1)(ii).

comment.[3609] However, NHTSA publicly stated its intent to conduct the analysis as part of the FEIS in its scoping notice published on July 26, 2017.[3610] The agency noted that this approach was consistent with past practice and resulted from the substantial time required to complete such an analysis. NHTSA also announced that, due to the substantial lead time required, the analysis would be based on the modeling of the alternatives presented in the DEIS, not of the alternatives as presented in the FEIS. NHTSA received no public comments in response to the scoping notice addressing this analytical approach, and the agency proceeded accordingly. Furthermore, while photochemical modeling provides spatial and temporal detail for estimating changes in ambient levels of air pollutants and their associated impacts on human health and welfare, the analysis affirms the estimates that appear in the EIS and does not provide significant new information for the decisionmaker or the public. For these reasons, NHTSA concludes that inclusion of the photochemical modeling and health benefit assessment in the FEIS is appropriate, and recirculation of the EIS is not required.

NHTSA has considered the information contained in the FEIS in making the final decision described in the final rule.[3611] The preamble and final rule constitute NHTSA's Record of Decision (ROD) under 40 CFR 1505.2 for its promulgation of CAFE standards for MYs 2021-2026. NHTSA has authority to issue its FEIS and ROD simultaneously pursuant to 49 U.S.C. 304a(b) and U.S. Department of Transportation, Office of Transportation Policy, *Guidance on the Use of Combined Final Environmental Impact Statements/Records of Decision and Errata Sheets in National Environmental Policy Act Reviews* (April 25, 2019).[3612] NHTSA has determined that neither the statutory criteria nor practicability considerations preclude simultaneous issuance.

As required by the CEQ regulations,[3613] the final rule (as the ROD) sets forth the following: (1) The agency's decision (Sections V and VIII); (2) alternatives considered by NHTSA in reaching its decision, including the environmentally preferable alternative (Sections V, VII, and VIII); (3) the factors balanced by NHTSA in making its decision, including essential considerations of national policy (Section VIII.B); (4) how these factors and considerations entered into its decision (Section VIII.B); and (5) the agency's preferences among alternatives based on relevant factors, including economic and technical considerations and agency statutory missions (Section VIII.B.4 above). Section X.E.1 and this section also briefly address mitigation[3614] and whether all practicable means to avoid or minimize environmental harm from the alternative selected have been adopted.

[3613] 40 CFR 1505.2.
[3614] *See* 40 CFR 1508.20(b) ("*Mitigation* includes … (b) Minimizing impacts by limiting the degree or magnitude of the action and its implementation…")

In the DEIS and in the FEIS, the agency identified a Preferred Alternative. In the DEIS, the Preferred Alternative was identified as Alternative 1 (0.0 Percent Annual Increase in Fuel Economy, MYs 2021-2026), which were the standards the agency proposed in the NPRM. In the FEIS, the Preferred Alternative was identified as Alternative 3 (1.5 Percent Annual Increase in Fuel Economy, MYs 2021-2026). As the FEIS notes, under the Preferred Alternative, on an mpg basis, the estimated annual increases in the average required fuel economy levels between MYs 2021 and 2026 is 1.5 percent for both passenger cars and light trucks.[3615] After carefully reviewing and analyzing all of the information in the public record, the FEIS, and comments submitted on the DEIS and the NPRM, NHTSA has decided to finalize the Preferred Alternative described in the FEIS for the reasons described in the ROD.

NHTSA has considered environmental considerations as part of its balancing of the statutory factors to set maximum feasible fuel economy standards. As a result, the agency has limited the degree or magnitude of the action as appropriate in light of its statutory responsibilities. NHTSA's authority to promulgate fuel economy standards does not allow it to regulate criteria pollutants from vehicles or refineries, nor can NHTSA regulate other factors affecting those emissions, such as driving habits. Consequently, NHTSA must set CAFE standards but is unable to take further steps to mitigate the impacts of these standards. Chapter 9 of the FEIS provides a further discussion of mitigation measures in the context of NEPA.

One commenter states that NHTSA, at a minimum, "must include a thorough discussion of all reasonable mitigation measures and detail the appropriate agencies that could implement such measures."[3616] As examples, the commenter listed: "creating tax breaks for transit and biking, expanding transportation demand management programs for federal employees, implementing a social marketing campaign regarding VMT reduction, increasing dedicated funding for transit and active modes, requiring VMT as a performance measure for federal funding, and providing NEPA guidance on evaluating VMT impacts of federal projects." Each of the examples listed is beyond NHTSA's statutory authority. Furthermore, documenting the myriad measures that could reduce VMT or address criteria pollutant or carbon dioxide emissions would provide no added benefit to the decisionmaker or the public. Each of these actions requires their own extensive cost-benefit anlaysis, are beyond the purview of this action, and are beyond the legal responsibility of NHTSA. NHTSA concludes that the commenter's request is beyond the bounds of NEPA's "rule of reason."[3617]

Another commenter disputes NHTSA's conclusion that it lacks statutory authority to mitigate the impacts of its CAFE standards. Specifically, the commenter cites to its very authority to set fuel economy standards: "It is axiomatic that fuel efficiency standards set at

---

[3615] Because the standards are attribute-based, average required fuel economy levels, and therefore rates of increase in those average mpg values, depend on the future composition of the fleet, which is uncertain and subject to change. When NHTSA describes a percent increase in stringency, we mean in terms of shifts in the *footprint functions* that form the basis for the *actual* CAFE standards (as in, on a gallon per mile basis, the CAFE standards change by a given percentage from one model year to the next).
[3616] California *et. al.*—Detailed NEPA Comments, Docket No. NHTSA-2017-0069-0625, at 31.
[3617] Dep't of Transp. v. Pub. Citizen, 541 U.S. 752, 772 (2004).

levels of the No Action Alternative or at more stringent levels would eliminate the additional pollution created by the proposed freeze."[3618] This, however, mischaracterizes mitigation as nothing more than a choice among alternatives. NHTSA is already considering a range of reasonable alternatives and has concluded that alternatives more stringent than the No Action Alternative are beyond reasonable. Furthermore, NHTSA disputes that more stringent fuel economy standards will axiomatically lead to lower levels of criteria pollutant emissions. In fact, because of the rebound effect, higher levels of stringency may result in higher VMT, which may result in criteria pollutant emission increases.

The North Carolina Department of Environmental Quality commented that the proposed changes to the CAFE standards could undermine the integrity of many of the assumptions in various NEPA documents across the United States, in part because EPA required the use of the MOVES2014 model (or a subsequent revision) for transportation conformity determinations.[3619] That version of MOVES incorporates CAFE and CO_2 standards based on the agencies' actions in 2012 and does not reflect the actions being finalized in the rule. The implication of the commenter's assertion, however, is that neither NHTSA nor EPA could take any regulatory action regarding CAFE or CO_2 standards, regardless of whether such action was to increase or decrease such standards. Clearly neither agency can be paralyzed from undertaking its statutory obligations because of the independent NEPA obligations related to other ongoing Federal actions. For those actions, responsible officials may need to assess whether the final rule triggers the need for a supplemental NEPA document. However, it is not unique for Federal agencies to take actions or for new information to become available that affects the underlying inputs in models, such as EPA's MOVES model, on which NEPA and conformity analyses rely. Over time, those models will be updated to reflect these actions and information. EPA is responsible for approving the availability of models for the use in State implementation plans and transportation conformity analyses. EPA will evaluate and address, as appropriate, the impact of this action on future SIP approval actions. Currently approved emission factor models remain approved for SIPs and transportation conformity analyses, and EPA will work with DOT on the appropriate implementation of Federal requirements based on current and available information.

2. Clean Air Act (CAA) as Applied to NHTSA's Action

The CAA (42 U.S.C. 7401 et seq.) is the primary Federal legislation that addresses air quality. Under the authority of the CAA and subsequent amendments, EPA has established National Ambient Air Quality Standards (NAAQS) for six criteria pollutants, which are specifically identified pollutants that have recognized adverse effects on ambient air quality and that can accumulate in the atmosphere as a result of human activity. EPA is required to review each NAAQS every five years and to revise those standards as may be appropriate considering new scientific information.

The air quality of a geographic region is usually assessed by comparing the levels of criteria air pollutants found in the ambient air to the levels established by the NAAQS (taking

[3618] Center for Biological Diversity, *et al.*, Docket No. NHTSA-2018-0067-12123, at 55-56.
[3619] North Carolina Department of Environmental Quality, Docket No. NHTSA-2018-0067-12025, at 37. *See also* Southern Environmental Law Center, EPA-HQ-OAR-2018-0283-0887, at 2-4.

into account, as well, the other elements of a NAAQS: averaging time, form, and indicator). Concentrations of criteria pollutants within the air mass of a region are measured in parts of a pollutant per million parts (ppm) of air or in micrograms of a pollutant per cubic meter ($\mu g/m^3$) of air present in repeated air samples taken at designated monitoring locations using specified types of monitors. These ambient concentrations of each criteria pollutant are compared to the levels, averaging time, and form specified by the NAAQS in order to assess whether the region's air quality is in attainment with the NAAQS.

When the measured concentrations of a criteria pollutant within a geographic region are below those permitted by the NAAQS, EPA designates the region as an attainment area for that pollutant, while regions where concentrations of criteria pollutants exceed Federal standards are called nonattainment areas. Former nonattainment areas that are now in compliance with the NAAQS are designated as maintenance areas. Each State with a nonattainment area is required to develop and implement a State Implementation Plan (SIP) documenting how the region will reach attainment levels within time periods specified in the CAA. For maintenance areas, the SIP must document how the State intends to maintain compliance with the NAAQS. When EPA revises a NAAQS, each State must revise its SIP to address how it plans to attain the new standard.

No Federal agency may "engage in, support in any way or provide financial assistance for, license or permit, or approve" any activity that does not "conform" to a SIP or Federal Implementation Plan after EPA has approved or promulgated it.[3620] Further, no Federal agency may "approve, accept, or fund" any transportation plan, program, or project developed pursuant to title 23 or chapter 53 of title 49, U.S.C., unless the plan, program, or project has been found to "conform" to any applicable implementation plan in effect.[3621] The purpose of these conformity requirements is to ensure that Federally sponsored or conducted activities do not interfere with meeting the emissions targets in SIPs, do not cause or contribute to new violations of the NAAQS, and do not impede the ability of a State to attain or maintain the NAAQS or delay any interim milestones. EPA has issued two sets of regulations to implement the conformity requirements:

(1) The Transportation Conformity Rule[3622] applies to transportation plans, programs, and projects that are developed, funded, or approved under title 23 or chapter 53 of title 49, U.S.C.

(2) The General Conformity Rule[3623] applies to all other federal actions not covered under transportation conformity. The General Conformity Rule establishes emissions thresholds, or *de minimis* levels, for use in evaluating the conformity of an action that results in emissions increases.[3624] If the net increases of direct and indirect emissions are lower than these thresholds, then the project is presumed to conform and no further conformity evaluation is required. If the net increases of direct and indirect emissions exceed any of these thresholds, and the action is not

otherwise exempt, then a conformity determination is required. The conformity determination can entail air quality modeling studies, consultation with EPA and state air quality agencies, and commitments to revise the SIP or to implement measures to mitigate air quality impacts.

The CAFE standards and associated program activities are not developed, funded, or approved under title 23 or chapter 53 of title 49, United States Code. Accordingly, this action and associated program activities are not subject to the Transportation Conformity Rule. Under the General Conformity Rule, a conformity determination is required where a Federal action would result in total direct and indirect emissions of a criteria pollutant or precursor originating in nonattainment or maintenance areas equaling or exceeding the rates specified in 40 CFR 93.153(b)(1) and (2). As explained below, NHTSA's action results in neither direct nor indirect emissions as defined in 40 CFR 93.152.

The General Conformity Rule defines direct emissions as "those emissions of a criteria pollutant or its precursors that are caused or initiated by the Federal action and originate in a nonattainment or maintenance area and occur at the same time and place as the action and are reasonably foreseeable."[3625] Because NHTSA's action would set fuel economy standards for light duty vehicles, it would cause no direct emissions consistent with the meaning of the General Conformity Rule.[3626]

Indirect emissions under the General Conformity Rule are "those emissions of a criteria pollutant or its precursors (1) that are caused or initiated by the federal action and originate in the same nonattainment or maintenance area but occur at a different time or place as the action; (2) that are reasonably foreseeable; (3) that the agency can practically control; and (4) for which the agency has continuing program responsibility."[3627] Each element of the definition must be met to qualify as indirect emissions. NHTSA has determined that, for purposes of general conformity, emissions that may result from its final fuel economy standards would not be caused by NHTSA's action, but rather would occur because of subsequent activities the agency cannot practically control. "[E]ven if a Federal licensing, rulemaking, or other approving action is a required initial step for a subsequent activity that causes emissions, such initial steps do not mean that a Federal agency can practically control any resulting emissions."[3628]

As the CAFE program uses performance-based standards, NHTSA cannot control the technologies vehicle manufacturers use to improve the fuel economy of passenger cars and light trucks. Furthermore, NHTSA cannot control consumer purchasing (which affects average achieved fleetwide fuel economy) and driving behavior (i.e., operation of motor vehicles, as measured by VMT). It is the combination of fuel economy technologies, consumer purchasing,

---

[3625] 40 CFR 93.152.
[3626] Dep't of Transp. v. Pub. Citizen, 541 U.S. at 772 ("[T]he emissions from the Mexican trucks are not 'direct' because they will not occur at the same time or at the same place as the promulgation of the regulations."). NHTSA's action is to establish fuel economy standards for MY 2021–2026 passenger car and light trucks; any emissions increases would occur in a different place and well after promulgation of the final rule.
[3627] 40 CFR 93.152.
[3628] 40 CFR 93.152.

and driving behavior that results in criteria pollutant or precursor emissions. For purposes of analyzing the environmental impacts of the alternatives considered here and under NEPA, NHTSA has made assumptions regarding all of these factors. The agency's FEIS predicts that increases in air toxic and criteria pollutants would occur in some nonattainment areas under certain alternatives. However, the standards and alternatives do not mandate specific manufacturer decisions, consumer purchasing, or driver behavior, and NHTSA cannot practically control any of them.[3629]

In addition, NHTSA does not have the statutory authority to control the actual VMT by drivers. As the extent of emissions is directly dependent on the operation of motor vehicles, changes in any emissions that result from NHTSA's CAFE standards are not changes the agency can practically control or for which the agency has continuing program responsibility. Therefore, the final CAFE standards and alternative standards considered by NHTSA would not cause indirect emissions under the General Conformity Rule, and a general conformity determination is not required.

As this analysis was presented in the NPRM, some commenters disagreed with NHTSA's conclusion. One commenter cited two reasons for concluding that the General Conformity Rule applies to NHTSA's action.[3630] First, the commenter argues that NHTSA used "inappropriate modeling" in its analysis. However, this is irrelevant to the agency's analysis, which is based on the Federal regulations and the applicable case law. Second, the commenter asserts that NHTSA "cannot have it both ways" by alleging that it cannot control the technologies that automobile manufacturers would use or consumer purchasing behavior, yet justifies its rulemakings based on consumer purchasing and emissions implications.[3631, 3632] The rulemaking analysis presents a feasible pathway for manufacturers to comply with the rules, based on a series of assumptions about consumer behavior; it is not sufficiently foreseeable to trigger application of the General Conformity Rule. Furthermore, NHTSA cannot directly control these behaviors, and the chain of causation is too attenuated to be responsible for the resulting emissions. Another commenter stated that NHTSA has continuing program responsibility for motor vehicle criteria pollutant emissions because it "retain[s] authority to revise [its] standards in a way that affects future emission levels."[3633] However, NHTSA disagrees with this assertion. First, the agency does not have statutory authority to regulate criteria pollutant emissions from motor vehicles. Second, the fact that NHTSA could establish CAFE standards for separate, future motor vehicles does not

---

[3629] *See*, e.g., Dep't of Transp. v. Pub. Citizen, 541 U.S. 752, 772-73 (2004); S. Coast Air Quality Mgmt. Dist. v. Fed. Energy Regulatory Comm'n, 621 F.3d 1085, 1101 (9th Cir. 2010).

[3630] California *et. al.*—Detailed NEPA Comments, Docket No. NHTSA-2017-0069-0625, at 21-22.

[3631] The commenter also quotes CBD v. NHTSA, 538 F.3d at 1217, for the proposition that NHTSA's regulations are the proximate cause of the emissions because they allow particular fuel economy levels that "translate directly into particular tailpipe emissions." However, that quote was referencing carbon dioxide emissions, which are predictable based on fuel used. NHTSA can directly regulate fuel economy for passenger cars and light trucks. On the other hand, criteria pollutant emissions are more significantly impacted by VMT, technology choices, and other factors that are not directly within the control of NHTSA.

[3632] *See also* Joint Submission from the States of California *et al.* and the Cities of Oakland *et al.*, Docket No. NHTSA-2018-0067-11735, at 35.

[3633] *Id.*

establish continuing program responsibility over emissions that could result from the vehicles regulated by this action.

NHTSA and EPA further discuss their obligations under the General Conformity Rule, and further address comments received, in Section VI.D.3 above.

3. National Historic Preservation Act (NHPA)

The NHPA (54 U.S.C. 300101 *et seq.*) sets forth government policy and procedures regarding "historic properties"—that is, districts, sites, buildings, structures, and objects included on or eligible for the National Register of Historic Places. Section 106 of the NHPA requires Federal agencies to "take into account" the effects of their actions on historic properties.[3634] In the NPRM, the agencies concluded that the NHPA is not applicable to this rulemaking because the promulgation of CAFE and CO_2 emissions standards for light duty vehicles is not the type of activity that has the potential to cause effects on historic properties.

Two commenters wrote that "[c]limate change and air pollution imperil historic properties throughout the country via direct degradation, sea level rise, fire, flood, and other forms of harm." Therefore, the commenters concluded that NHTSA and EPA must consult with the relevant Federal and State authorities and fully disclose any impacts to historic properties.[3635] However, as the final rule establishes CAFE and CO_2 standards that increase each year for MYs 2021–2026, this action will result in reductions in climate change-related impacts and most air pollutants compared to the absence of regulation. Furthermore, any impacts to particular historic properties that could be related to emissions changes associated with this rulemaking are not reasonably certain to occur, would be *de minimis* in their level of impact if they did occur, and are too attenuated to be attributed directly to this action. (*See also* Section X.E.6 below.) There is no evidence that the changes in air pollution or CO_2 emissions associated with this rulemaking, in and of themselves, would alter the characteristics of a historic property qualifying it for inclusion in or eligibility for the National Register.[3636] Nevertheless, NHTSA includes a brief, qualitative discussion of the impacts of the alternatives on historical and cultural resources in Section 7.3 of the FEIS. For the foregoing reasons, the agencies continue to conclude that any potential impacts have been accounted for in the associated analyses of this rulemaking and that no consultation is required under the NHPA.

4. Fish and Wildlife Conservation Act (FWCA)

The FWCA (16 U.S.C. 2901 *et seq.*) provides financial and technical assistance to States for the development, revision, and implementation of conservation plans and programs for nongame fish and wildlife. In addition, the Act encourages all Federal departments and agencies to utilize their statutory and administrative authorities to conserve and to promote conservation

---

[3634] Section 106 is now codified at 54 U.S.C. 306108. Implementing regulations for the Section 106 process are located at 36 CFR part 800.

[3635] CARB, Docket No. NHTSA-2018-0067-11873, at 411; California *et. al.*—Detailed NEPA Comments, Docket No. NHTSA-2017-0069-0625, at 30.

[3636] 36 CFR 800.16(i).

of nongame fish and wildlife and their habitats. The agencies conclude that the FWCA is not applicable to the final rule because this rulemaking does not involve the conservation of nongame fish and wildlife and their habitats. NHTSA has, however, conducted a qualitative review in its FEIS of the related direct, indirect, and cumulative impacts, positive or negative, of the alternatives on potentially affected resources, including nongame fish and wildlife and their habitats.

5. Coastal Zone Management Act (CZMA)

The Coastal Zone Management Act (16 U.S.C. 1451 *et seq.*) provides for the preservation, protection, development, and (where possible) restoration and enhancement of the Nation's coastal zone resources. Under the statute, States are provided with funds and technical assistance in developing coastal zone management programs. Each participating State must submit its program to the Secretary of Commerce for approval. Once the program has been approved, any activity of a Federal agency, either within or outside of the coastal zone, that affects any land or water use or natural resource of the coastal zone must be carried out in a manner that is consistent, to the maximum extent practicable, with the enforceable policies of the State's program.[3637]

In the NPRM, the agencies concluded that the CZMA is not applicable to this rulemaking because this rulemaking does not involve an activity within, or outside of, the Nation's coastal zones that affects any land or water use or natural resource of the coastal zone. CARB commented that California's coast is vulnerable to sea level rise from climate change and that the proposal would exacerbate that threat. Therefore, the commenter claimed that the proposal violated California's policies and obligations in its management program to preserve, protect, and enhance its coastline.[3638] However, in its FEIS, NHTSA estimates that the sea-level rise in 2100 associated with Alternative 1 (0 percent annual average increase for both passenger cars and light trucks for MYs 2021–2026), the least stringent alternative considered, would be 0.7 mm. Such a level is too small to have any meaningful impact on land or water use or a natural resource of the coastal zone. Furthermore, as the final rule establishes CAFE and CO_2 standards that increase each year for MYs 2021–2026, this action will result in reductions in sea level rise resulting from climate change compared to the absence of regulation. Therefore, the agencies continue to conclude that the CZMA is not applicable to this rulemaking. NHTSA has, however, conducted a qualitative review in its FEIS of the related direct, indirect, and cumulative impacts, positive or negative, of the alternatives on potentially affected resources, including coastal zones.

6. Endangered Species Act (ESA)

Under Section 7(a)(2) of the Endangered Species Act (ESA), Federal agencies must ensure that actions they authorize, fund, or carry out are "not likely to jeopardize the continued existence" of any Federally listed threatened or endangered species (collectively, "listed

[3637] 16 U.S.C. 1456(c)(1)(A).
[3638] CARB, Docket No. NHTSA-2018-0067-11873, at 411.

species”) or result in the destruction or adverse modification of the designated critical habitat of these species.[3639] In general, if a Federal agency determines that an agency action may affect a listed species or designated critical habitat, it must initiate consultation with the appropriate Service—the U.S. Fish and Wildlife Service (FWS) of the Department of the Interior (DOI) and/or the National Oceanic and Atmospheric Administration’s National Marine Fisheries Service (NMFS) of the Department of Commerce (together, “the Services”), depending on the species involved—in order to ensure that the action is not likely to jeopardize the species or destroy or adversely modify designated critical habitat.[3640] Under this standard, the Federal agency taking action evaluates the possible effects of its action and determines whether to initiate consultation.[3641]

In the NPRM, the agencies noted that they had considered the effects of the proposed standards and alternatives in light of applicable ESA regulations, case law, and guidance to determine what, if any, impact there might be to listed species or designated critical habitat. The agencies also considered the discussion in the DEIS, where NHTSA incorporated by reference its response to a public comment on page 9-101 of the MY 2017–2025 CAFE Standards Final EIS.[3642] Based on that assessment, the agencies determined that the actions of setting CAFE and CO_2 emissions standards did not require consultation under Section 7(a)(2) of the ESA. Accordingly, the agencies wrote that they had concluded their review of this action under Section 7 of the ESA.

Several commenters disagreed with the agencies’ assessment. In general, commenters stated that the agencies’ proposed action would increase emissions of CO_2 and criteria air pollutants (e.g., nitrogen oxide [NO_X] and sulfur dioxide [SO_2][3643]), that these emissions would have direct or indirect (i.e., through climate change) impacts on listed species and critical habitats, that the threshold for a finding of “may affect” is extremely low, and that the agencies therefore have a duty to consult with the Services under the ESA.[3644]

3639 16 U.S.C. 1536(a)(2).
3640 *See* 50 CFR 402.14.
3641 *See* 50 CFR 402.14(a) (“Each Federal agency shall review its actions at the earliest possible time to determine whether any action may affect listed species or critical habitat.”).
3642 For the final rule for MY 2017 and beyond CAFE standards, NHTSA concluded that a Section 7(a)(2) consultation was not required because any potential for a specific impact on particular listed species and their habitats associated with emission changes achieved by that rulemaking were too uncertain and remote to trigger the threshold for such a consultation. In the Draft EIS, NHTSA wrote that this conclusion, based on the discussion and analysis cited, applied equally to the current rulemaking.
3643 In fact, in Section 4.2.1.1 of NHTSA’s FEIS, the agency reports that any of the action alternatives would result in decreased emissions of sulfur dioxide in 2025, 2035, and 2050 compared to the No Action Alternative.
3644 *See* Center for Biological Diversity, Earthjustice, Natural Resources Defense Council, and Sierra Club, Docket Nos. NHTSA-2017-0069-0605 and NHTSA-2018-0067-12127; Center for Biological Diversity, Sierra Club, and Public Citizen, Inc., Docket No. NHTSA-2018-0067-12378; Center for Biological Diversity, Earthjustice, Environmental Law and Policy Center, Natural Resources Defense Council, Public Citizen, Inc., Safe Climate Campaign, Sierra Club, Southern Environmental Law Center, and Union of Concerned Scientists, Docket No. NHTSA-2018-0067-12123, at 69; States of California, Connecticut, Delaware, Hawaii, Iowa, Illinois, Maine, Maryland, Minnesota, New Jersey, New Mexico, New York, North Carolina, Oregon, Rhode Island, Vermont, and

In light of these comments, the agencies re-evaluated their obligations under the ESA and applicable regulations, case law, and guidance. Ultimately, for the following reasons, the agencies arrive at the same conclusion. Although there is a general association between the actions undertaken in the final rule and environmental impacts, as described in this FRIA and the FEIS, the agencies' actions result in no effects on listed species or designated critical habitat and therefore do not require consultation under Section 7(a)(2) of the ESA. Furthermore, the agencies lack sufficient discretion or control to bring these actions under the consultation requirement of the ESA. The agencies' review under the ESA is concluded.

a) The Agencies' Actions Have No Effects on Listed Species or Critical Habitat and Do Not Trigger ESA Consultation

Commenters have stated that CO_2 and criteria air pollutant emissions are relevant to Section 7(a)(2) consultation because of the potential impacts of climate change or the pollutants themselves on listed species or critical habitat. The agencies have considered the potential impacts of this action to listed species or designated critical habitat of these species and conclude that any such impacts cannot be attributed to the agencies' actions (e.g., they are too uncertain and attenuated). Because the agencies conclude there are "no effects," Section 7(a)(2) consultation is not required. The agencies base this conclusion both on the language of the Section 7(a)(2) implementing regulations and on the long history of actions and guidance provided by DOI.

The Section 7(a)(2) implementing regulations require consultation if a Federal agency determines its action "may affect" listed species or critical habitat.[3645] The recently revised regulations define "effects of the action" as "all consequences to listed species or critical habitat that are caused by the proposed action, including the consequences of other activities that are caused by the proposed action. A consequence is caused by the proposed action if it would not occur *but for* the proposed action and it is *reasonably certain to occur*."[3646] The revised definition made explicit a "but for" test and the concept of "reasonably certain to occur" for all effects.[3647] However, in the preamble to the final rule, the Services emphasized that the "but for" test and "reasonably certain to occur" are not new or heightened standards.[3648] In this context,

Washington, the Commonwealths of Massachusetts, Pennsylvania, and Virginia, the District of Columbia, and the Cities of Los Angeles, New York, Oakland, San Francisco, and San Jose, Docket Nos. NHTSA-2018-0067-11735, at 47-48; and California Air Resources Board, Docket Nos. NHTSA-2018-0067-11873, at 411.

[3645] 50 CFR 402.14(a). The Services recently issued a final rule revising the regulations governing the ESA Section 7 consultation process. 84 FR 44976 (Aug. 27, 2019). The effective date of the new regulations was subsequently delayed to October 28, 2019. 84 FR 50333 (Sep. 25, 2019). As discussed in the text that follows, the agencies believe that their conclusion would be the same under both the current and prior regulations.

[3646] 50 CFR 402.02 (emphasis added), as amended by 84 FR 44976, 45016 (Aug. 27, 2019).

[3647] The Services' prior regulations defined "effects of the action" in relevant part as "the direct and indirect effects of an action on the species or critical habitat, together with the effects of other activities that are interrelated or interdependent with that action, that will be added to the environmental baseline." 50 CFR 402.02 (as in effect prior to Oct. 28, 2019). Indirect effects were defined as "those that are caused by the proposed action and are later in time, but still are reasonably certain to occur." *Id.*

[3648] 84 FR at 44977 ("As discussed in the proposed rule, the Services have applied the 'but for' test to determine causation for decades. That is, we have looked at the consequences of an action and used the causation standard of “‘but for’ causation means that the consequence in question would not occur if the proposed action did not go forward . . . . In other words, if the agency fails to take the proposed action and the activity would still occur, there is no ‘but for’ causation. In that event, the activity would not be considered an effect of the action under consultation.”[3649]

The revised ESA regulations also provide a framework for determining whether consequences are caused by a proposed action and are therefore “effects” that may trigger consultation. The regulations provide in part:

> To be considered an effect of a proposed action, a consequence must be caused by the proposed action (*i.e.*, the consequence would not occur but for the proposed action and is reasonably certain to occur). A conclusion of reasonably certain to occur must be based on clear and substantial information, using the best scientific and commercial data available. Considerations for determining that a consequence to the species or critical habitat is not caused by the proposed action include, but are not limited to:
>
> (1) The consequence is so remote in time from the action under consultation that it is not reasonably certain to occur; or
>
> (2) The consequence is so geographically remote from the immediate area involved in the action that it is not reasonably certain to occur; or
>
> (3) The consequence is only reached through a lengthy causal chain that involves so many steps as to make the consequence not reasonably certain to occur.[3650]

The regulations go on to make clear that the action agency must factor these considerations into its assessments of potential effects.[3651]

DOI, the agency charged with co-administering the ESA, previously evaluated whether CO_2 emissions associated with a specific proposed Federal action triggered ESA Section 7(a)(2) consultation. The agencies have reviewed the long history of actions and guidance provided by DOI. To that point, the agencies incorporate by reference Appendix G of the MY 2012-2016 CAFE standards EIS.[3652] That analysis relied on the significant legal and technical analysis undertaken by FWS and DOI. Specifically, NHTSA looked at the history of the Polar Bear

---

‘but for’ plus an element of foreseeability (i.e., reasonably certain to occur) to determine whether the consequence was caused by the action under consultation.”).

[3649] *Id.* We note that as the Services do not consider this to be a change in their longstanding application of the ESA, this interpretation applies equally under the prior regulations (which were effective through October 28, 2019, and the current regulations.

[3650] 50 CFR 402.17(b).

[3651] 50 CFR 402.17(c) (“*Required consideration*. The provisions in paragraphs (a) and (b) of this section must be considered by the action agency and the Services.”).

[3652] Available on NHTSA’s Corporate Average Fuel Economy website at https://one.nhtsa.gov/Laws-&-Regulations/CAFE-%E2%80%93-Fuel-Economy/Final-EIS-for-CAFE-Passenger-Cars-and-Light-Trucks,-Model-Years-2012%E2%80%932016.

Special Rule and several guidance memoranda provided by FWS and the U.S. Geological Survey. Ultimately, DOI concluded that a causal link could not be made between CO_2 emissions associated with a proposed Federal action and specific effects on listed species; therefore, no Section 7(a)(2) consultation would be required.

Subsequent to the publication of that Appendix, a court vacated the Polar Bear Special Rule on NEPA grounds, though it upheld the ESA analysis as having a rational basis.[3653] FWS then issued a revised Final Special Rule for the Polar Bear.[3654] In that final rule, FWS provided that for ESA Section 7, the determination of whether consultation is triggered is narrow and focused on the discrete effect of the proposed agency action. FWS wrote, "[T]he consultation requirement is triggered only if there is a causal connection between the proposed action and a discernible effect to the species or critical habitat that is reasonably certain to occur. One must be able to 'connect the dots' between an effect of a proposed action and an impact to the species and there must be a reasonable certainty that the effect will occur."[3655] The statement in the revised Final Special Rule is consistent with the prior guidance published by FWS and remains valid today.[3656] Likewise, the current regulations identify remoteness in time, geography, and the causal chain as factors to be considered in assessing whether a consequence is "reasonably certain to occur." If the consequence is not reasonably certain to occur, it is not an "effect of a proposed action" and does not trigger the consultation requirement.

The agencies' actions establishing CAFE and CO_2 standards for passenger cars and light trucks do not directly affect listed species or critical habitat. The regulations promulgated by the agencies are used to calculate average standards for manufacturers based on the vehicles they produce for sale in the United States. Any potential effects of this action on listed species or designated critical habitat would be a result of changes to CO_2 or air pollutant emissions that are caused by the individual choices of manufacturers in producing these vehicles and of consumers in purchasing and operating those vehicles. The agencies are not requiring, authorizing, funding, or carrying out the operation of motor vehicles (i.e., the proximate cause of downstream emissions), the production or refining of fuel (i.e., a proximate cause of upstream emissions),[3657] the use of any land that is critical habitat for any purpose, or the taking of any listed species or other activity that may affect any listed species. Ultimately, the relevant decisions that result in emissions are taken by third parties, and any on-the-ground activities to implement and carry out those decisions are undertaken by such third parties. These decisions are influenced by a complex series of market factors that, though influenced by the agencies' actions, independently

[3653] *In re: Polar Bear Endangered Species Act Listing and Section 4(D) Rule Litigation*, 818 F.Supp.2d 214 (D.D.C. Oct. 17, 2011).
[3654] 78 FR 11766 (Feb. 20, 2013).
[3655] 78 FR at 11784-11785.
[3656] *See* DOI Solicitor's Opinion No. M-37017, "Guidance on the Applicability of the Endangered Species Act Consultation Requirements to Proposed Actions Involving the Emissions of Greenhouse Gases" (Oct. 3, 2008).
[3657] The agencies note that upstream emissions sources, such as oil extraction sites and fuel refineries, remain subject to the ESA. As future non-federal activities become reasonably certain, Section 7 and/or other sections of the ESA may provide protection for listed species and designated critical habitats. For example, new oil exploration or extraction activity may result in permitting or construction activities that would trigger consultation or other activities for the protection of listed species or designated critical habitat, as impacts may be more direct and more certain to occur.

could result in the same series of decisions by consumers that commenters attribute to the agencies' actions (such as increased VMT and therefore increased emissions). This complex and lengthy chain of causality, which is highly dependent on market factors and therefore uncertain, leads the agencies to conclude that the resulting impacts of their actions to listed species or critical habitat do not satisfy the "but for" test or are "reasonably certain to occur."

With regard to climate change, EPA and NHTSA are not able to make a causal link for purposes of Section 7(a)(2) that would "connect the dots" between their actions, vehicle emissions from motor vehicles affected by their actions, climate change, and particular impacts to listed species or critical habitats. The agencies' actions are to set standards that are effectively footprint curves, which are used as part of a complex calculation based on the vehicles produced by manufacturers for sale in the United States to determine a corporate average standard for each manufacturer. This approach, dictated by the Federal statute, gives manufacturers significant discretion to design, produce, and sell motor vehicles to meet consumer demand. Because manufacturers could choose to produce more vehicles with larger footprints (and therefore less stringent standards), fleet-average CO_2 emissions could increase to some extent year-over-year independently of where the agencies set standards. Or the opposite may be true, and a shift in consumer preferences could lead to increased production of vehicles with smaller footprints (and therefore more stringent standards), resulting in overall declines in CO_2 emissions in the future compared to what the agencies are forecasting. Importantly, consumers not only choose which vehicles to purchase across a range of available fuel economies, they also choose how much to operate those vehicles (and therefore the quantity of fuel used and CO_2 emitted) independently of any action undertaken by the agencies.[3658, 3659]

Even with so many third parties in the causal chain making independent choices influenced by independent factors, the mechanics of climate change further break the chain of causality between the agencies' actions and specific effects on listed species or designated critical habitat. Climate change is a global phenomenon, impacted by greenhouse gas emissions that could occur anywhere throughout the world. As these gases accumulate in the atmosphere, radiative forcing increases, resulting in various potential impacts to the global climate system (e.g., warming temperatures, droughts, and changes in ocean pH) over long time scales. These changes could directly or indirectly impact listed species and/or designated critical habitat over time. Although this is a simplified explanation of a complex phenomenon subject to a significant degree of scientific study, it illustrates that the potential climate change-related consequences of this rulemaking on listed species and designated critical habitat are not "reasonably certain to occur" under any of the three tests in the ESA regulations and listed above. Not only are the consequences to listed species or designated critical habitat geographically and temporally remote from the emissions that result from regulated vehicles, the chain of causality is simply too lengthy and complex. Because impacts to listed species and designated critical habitat result from climate shifts that, in and of themselves, result from the accumulation over time of

[3658] While VMT is affected by the cost of driving associated with fuel economy (i.e., the rebound effect), it is also affected by several market factors, such as economic conditions, that are far beyond the agencies' control and arguably have a greater influence than this rulemaking.
[3659] The fact that overall CO_2 emissions are influenced so heavily by consumer preferences and behavior further supports the agencies' conclusion that impacts are not "reasonably certain to occur."

greenhouse gas emissions from anywhere in the world, there is simply no way to "connect the dots" between the emissions from a regulated vehicle and those impacts. While the potential impacts of climate change have been well-documented, there is no degree of certainty that this action (as distinct from any other source of CO_2 emissions) would be the cause of any particular impact to listed species or critical habitats. Because greenhouse gas emissions continue to occur from other sectors within the U.S. and from other sources globally, there is simply no scientific way to apportion any impact to a listed species or designated critical habitat to the agencies' actions.[3660]

One comment to the NPRM documented the potential impacts of climate change on Federally protected species and included a five-page table of species listed during 2006 to 2015 for which the commenters claim climate change was a listing factor.[3661] This conflates the requirements of ESA Section 4 (governing ESA listing) and ESA Section 7 (addressing the obligations of Federal agencies). Section 4 requires FWS or NMFS to assess all threats to species regardless of the origin of those threats. 16 U.S.C. 1533(a)(1). In contrast, the focus of Section 7(a)(2) is narrower and requires agencies to assess only effects on species that are attributable to the specific agency action. 16 U.S.C. 1536(a)(2). That climate change was considered as a factor in a determination to list a species does not speak to the separate inquiry of whether the specific agency action is impacting a listed species. Here, the agencies believe this comment inappropriately attributes the entire issue of climate change, including all CO_2 emissions no matter which sector generated them, to NHTSA and EPA's actions. In fact, NHTSA and EPA's actions would have only very small impacts on climate attributes, such as average temperatures, precipitation, and sea-level rise. The likelihood that these very small impacts, which are described above and in NHTSA's FEIS, would jeopardize listed species or adversely modify designated critical habitat is simply too remote to be cognizable under the ESA consultation requirements.[3662] The fact that the agencies would exacerbate the impacts of climate change to a very small degree is not enough to determine that impacts on listed species or designated critical habitat are reasonably certain to occur.[3663, 3664]

As noted above, for consultation to be required, there must exist a sufficient nexus between the agency activity and the impact on listed species that the ESA intends to avoid. The

[3661] Center for Biological Diversity, Sierra Club, and Public Citizen, Inc., Docket No. NHTSA-2018-0067-12378, at 25-30.

[3662] *Ground Zero Center for Non-Violent Action v. U.S. Dept. of Navy*, 383 F.3d 1082 (2004).

[3663] Such a broad interpretation of the ESA would ensnare every Federal action that resulted in even an additional ounce of additional carbon dioxide emissions into the Section 7(a)(2) consultation process. *See, e.g.,* 78 FR 11766, 11785 (Feb. 20, 2013) ("Without the requirement of a causal connection between the action under consultation and effects to species, literally every agency action that contributes CO_2 emissions to the atmosphere would arguably result in consultation with respect to every listed species that may be affected by climate change.").

[3664] The agencies also disagree that, for purposes of compliance with the ESA, this action would exacerbate climate change impacts on listed species or critical habitat. The final rule establishes CAFE and CO_2 standards that increase in stringency on a year-by-year basis. While these standards are less stringent than the standards considered and set forth in the 2012 rulemaking, the ESA does not serve as a one-way ratchet when agencies use their inherent authority to reconsider decisions that have not yet taken effect.

Services have defined that nexus as "but for" causation. However, there is no "but for" causation associated with the final rule as the impacts of climate change will occur regardless of this action. In fact, even if the agencies were to set CAFE and CO_2 standards at levels that would eliminate all CO_2 emissions from motor vehicles made available for sale in the United States, the impacts of climate change are still projected to occur due to emissions from other sectors in the United States and other sources globally. Changes to tailpipe greenhouse gas emissions or associated upstream emissions related to this rulemaking and the alternatives considered would be very small compared to global CO_2 emissions, which would continue. The agencies also note that because third parties (as described above) undertake most of the decisions that result in emissions, increased greenhouse gas emissions could occur regardless of the agencies' actions in the final rule. This further demonstrates the lack of "but for" causality in this case.

Criteria air pollutant emissions from passenger cars and light trucks differ from greenhouse gas emissions in many ways. Most significantly, because passenger cars and light trucks are subject to gram-per-mile emissions standards for criteria pollutants, more fuel-efficient (and, correspondingly, less CO_2-intensive) vehicles are not necessarily, from the standpoint of air quality, "cleaner" vehicles. Therefore, to the extent that CAFE and CO_2 standards lead to changes in overall quantities of vehicular emissions that impact air quality, these are dominated by induced changes in highway travel. Changes in overall fuel consumption do lead to changes in emissions from "upstream" processes involved in supplying fuel to vehicles. Depending on how total vehicular emissions and total upstream emissions change in response to less stringent standards, overall emissions could increase or decrease.

While small in magnitude, net impacts could also vary considerably among different geographic areas depending on the locations of upstream emission sources and where changes in highway travel occur. This is important because of another significant difference between criteria air pollutant emissions and greenhouse gas emissions: criteria air pollutant emissions are localized[3665] whereas CO_2 emissions contribute to global atmospheric concentrations and climate change no matter where they occur. As reported in Section 4.1.1 of the FEIS, concentrations of many air pollutants emitted from motor vehicles are elevated in ambient air within approximately 1,000 to 2,000 feet of major roadways. With meteorological conditions that tend to inhibit the dispersion of emissions, concentrations of traffic-generated air pollutants can be elevated for as much as about 8,500 feet downwind of roads.[3666, 3667] But this means that impacts of criteria pollutant emissions are dependent on where they occur, to a degree much more significant than greenhouse gas emissions. Although the agencies anticipate increased fuel use

---

3665 Criteria pollutant emissions contribute to local, regional, cross-state, and cross-national air pollution. Ultimately, however, the physical distance impacted by the pollutants is much smaller than for CO_2 emissions, which affect the global atmosphere.

3666 Hu, S., S. Fruin, K. Kozawa, S. Mara, S.E. Paulson, and A.M. Winer. *A Wide Area of Air Pollutant Impact Downwind of a Freeway during Pre-sunrise Hours*. Atmospheric Environment. 43(16):2541–49 (2009). doi:10.1016/j.atmosenv.2009.02.033.

3667 Hu, S., S.E. Paulson, S. Fruin, K. Kozawa, S. Mara, and A.M. Winer. *Observation of Elevated Air Pollutant Concentrations in a Residential Neighborhood of Los Angeles California Using a Mobile Platform*. Atmospheric Environment. 51:311–319 (2012). doi:10.1016/j.atmosenv.2011.12.055. Available at: http://europepmc.org/backend/ptpmcrender.fcgi?accid=PMC3755476&blobtype=pdf.

as a result of the final rule (compared to the standards described in the 2012 final rule),[3668] NHTSA and EPA have no way to know with reasonable certainty where additional fuel extraction and refining will occur. The agencies also cannot calculate with reasonable certainty where changes in highway travel will occur, as those impacts may not be uniform across the country. In fact, changes in land use patterns could exacerbate or reduce criteria pollutant emissions in any particular area, and such local changes are more uncertain. Therefore, even with the best scientific and commercial data available, the agencies cannot draw conclusions on impacts on particular listed species or designated critical habitat.

In short, the impacts of CAFE and CO_2 standards on criteria pollutant emissions is indirect, and the impacts on air quality at any particular location (such as where a listed species or designated critical habitat is located) are more ambiguous than for global atmospheric concentrations of CO_2 over the long term. Therefore, the agencies reach the same conclusion for criteria pollutant emissions as for CO_2 emissions and climate change. For example, the causal chain between the agencies' actions and any impacts to listed species or designated critical habitat is attenuated by the fact that independent third parties must choose not only how much to operate their motor vehicles, but where to operate those motor vehicles as well. And the agencies cannot meaningfully conclude that any impact to a listed species and designated critical habitat would be caused by criteria pollutant emissions from the vehicles regulated by the rule rather than by another source. Finally, the impacts on criteria pollutant emissions as a result of the rule, especially in light of other emissions sources besides the regulated vehicles, are small[3669] and the likelihood of jeopardy or the adverse modification of designated critical habitat is too remote. Current modeling tools available are not designed to trace fluctuations in ambient concentration levels of criteria and toxic air pollutants to potential impacts on particular endangered species. The agencies therefore cannot conclude that impacts are "reasonably certain to occur."[3670]

Finally, the agencies also note the potential uncertainty related to changes in total air pollutant and CO_2 emissions as a result of the flexibilities in the CAFE and CO_2 programs. Both programs allow manufacturers to trade and apply credits that have been earned from over-compliance in lieu of meeting the applicable standards for a particular model year, and manufacturers may have planned to rely on credits to comply with the standards for the model years regulated by this action. This could offset any changes in emissions that would result from the agencies' final decision. Furthermore, NHTSA's CAFE program allows manufacturers to pay civil penalties to cover any shortfall in compliance, further offsetting potential improvements in fuel economy (and, therefore, changes in air pollutant and CO_2 emissions) that might have occurred under the augural standards. The existence of these flexibilities further supports the agencies' conclusion that they can establish neither "but for" causation nor a reasonable certainty that impacts will occur on listed species or designated critical habitat.

[3668] Although, again, the agencies note that average fleet-wide fuel economy is projected to improve under any of the alternatives considered in this action.
[3669] For more information, see Chapter 4 of the FEIS.
[3670] *See* 50 CFR 402.17 ("A conclusion of reasonably certain to occur must be based on clear and substantial information, using the best scientific and commercial data available").

The agencies have considered this analysis and conclude that any consequence to specific listed species or designated critical habitats from climate change or other air pollutant emissions is too remote and uncertain to be attributable to the agencies' actions here. These consequences are not "effects" for purposes of consultation under Section 7(a)(2). NHTSA and EPA therefore conclude that the final rule has no effect on listed species or their critical habitats.

b) The Agencies Lack Sufficient Discretion or Control to Bring These Actions under the Consultation Requirement of the ESA

The primary purpose of EPCA, as amended by EISA, and codified at 49 U.S.C. chapter 329, is energy conservation, and NHTSA is statutorily obligated to set attribute-based CAFE standards for each model year at the levels it determines are "maximum feasible."[3671] But "maximum feasible" is a balancing of several factors, and Congress clearly did not envision that the CAFE program would "solve" energy conservation in a single rulemaking action.[3672] Fuel economy standards have the related benefit of reducing CO_2 emissions, and may also result in reduced emissions of many criteria air pollutants. Similarly, EPA has found that the elevated concentrations of greenhouse gases in the atmosphere may reasonably be anticipated to endanger public health and welfare. As a result of these findings, CAA section 202(a) requires the agency to issue standards applicable to emissions of such gases from motor vehicles. Although not a statutory requirement, EPA has given weight to the policy goal of establishing CO_2 standards that are coordinated with NHTSA's CAFE standards.[3673]

As previously indicated, commenters assert that CO_2 and criteria air pollutant emissions are relevant to Section 7(a)(2) consultation because of the potential impacts of climate change or the pollutants themselves on listed species or designated critical habitat. However, it is not clear whether their comments are based on the fact that the agencies predict increases in CO_2 emissions and most criteria pollutant emissions under all action alternatives compared to the MY 2022-2025 CO_2 and augural CAFE standards, or the fact that *any* emissions from passenger cars or light trucks will continue under any of the alternatives considered.

With regard to the latter, NHTSA does not interpret EPCA/EISA to mean that Congress expected the CAFE program to take the U.S. auto fleet off of oil entirely—indeed, EISA renders doing so impossible because it amended EPCA to prohibit NHTSA from considering the fuel economy of dedicated alternative fuel vehicles, including electric vehicles, when setting maximum feasible standards. This means that standards cannot be set that assume increased usage of full electrification for compliance. As a result, no matter the level at which NHTSA sets CAFE standards in accordance with EPCA, CO_2 and criteria pollutant emissions will continue. So long as NHTSA's obligation to set CAFE standards remains in place, it is

---

[3671] *See* 49 U.S.C. 32902(a) ("At least 18 months before the beginning of each model year, the Secretary of Transportation shall prescribe by regulation average fuel economy standards for automobiles manufactured by a manufacturer in that model year. Each standard shall be the maximum feasible average fuel economy level that the Secretary decides the manufacturers can achieve in that model year.").
[3672] *See, e.g.,* 49 U.S.C. 32902(b)(2) (setting separate requirements for CAFE standards for MYs 2011 through 2020 and MYs 2021 through 2030).
[3673] *See Mass. v. EPA*, 549 U.S. 497, 532 (2007) ("…there is no reason to think the two agencies cannot both administer their obligations and yet avoid inconsistency.")

reasonable to assume that Congress's expectation for EPA, in coordinating with NHTSA, is similar.

The purpose of Section 7(a)(2) consultation is to ensure that Federal agencies are not undertaking, funding, permitting, or authorizing actions that are likely to jeopardize the continued existence of listed species or destroy or adversely modify designated critical habitat. However, no matter what standards the agencies set under the CAFE and CO_2 programs, Americans will continue to drive. Neither NHTSA nor EPA has authority to control vehicle miles traveled. As long as there is driving, there will be emissions—whether from vehicle tailpipes or from the stationary sources that create the energy that the vehicles consume. Moreover, both agencies have concluded that significant further electrification of the fleet is not practicable at this time due to concerns about consumer acceptance in a time of foreseeably low fuel prices. The fact that CO_2 and criteria pollutant emissions will continue after NHTSA and EPA actions on standards cannot, alone, trigger Section 7(a)(2) consultation as the agencies lack the discretion or control over these emissions to simply regulate them away entirely in this action.[3674] Consultation is not required where an agency lacks discretion to take action that will inure to the benefit of listed species.[3675] Since elimination of oil from the fleet is inconsistent with the agencies' statutory authorities and the clear intent of Congress, consultation is not triggered under this scenario.

Commenters may instead be referring to the *trend* in CO_2 and criteria air pollutant emissions under the action alternatives considered in this rulemaking (e.g., whether and by how much emissions increase or decrease). To that point, all of the action alternatives considered result in increases in CO_2 and most criteria air pollutant emissions compared to the standards considered and set forth in the 2012 rulemaking. However, the agencies do not believe this is the relevant comparison for purposes of determining the applicability of Section 7 of the ESA to this action. Model years 2021 through 2026, for the most part, have not yet arrived. So it is not appropriate to compare the current action to a prior action that has not been implemented and which the agencies are reconsidering. When compared to standards through MY 2020, under any of the alternatives considered, fuel economy will improve and CO_2 and most criteria pollutant emissions will decrease over time, either as stringency increases or from the turnover in the fleet to newer, cleaner vehicles.

As detailed above, however, there is no way to meaningfully differentiate between the alternatives in terms of outcomes for listed species and designated critical habitat. The agencies cannot reasonably calculate how incrementally less emissions resulting from more stringent standards would benefit those species or habitats; rather, at most, the agencies can only posit that more stringent standards hypothetically could lead to better outcomes. But where to draw any line in terms of impacts to species and habitats is an impossible exercise. Yet, as noted above,

[3674] *National Ass'n of Home Builders v. Defenders of Wildlife*, 551 U.S. 644, 673 (2007) ("Applying *Chevron*, we defer to the Agency's reasonable interpretation of ESA [section] 7(a)(2) as applying only to 'actions in which there is discretionary Federal involvement or control.'" (quoting 50 CFR 402.03)).
[3675] *Id.*; *Sierra Club v. Babbitt*, 65 F.3d 1502, 1509 (9th Cir. 1995) (ESA Section 7(a)(2) consultation is not required where an agency lacks discretion to influence private conduct in a manner that will inure to the benefit of listed species).

NHTSA is mandated by Congress to set "maximum feasible" standards and EPA's mission is to protect public health and welfare. Under these circumstances, where the agencies must issue standards pursuant to statutory mandate that under any scenario will involve emissions, yet they lack the commensurate ability to take action that will inure to the benefit of species in any meaningful way, Section 7(a)(2) consultation is not required.

Finally, regardless of the level of stringency at which the agencies set CAFE and CO_2 standards, criteria pollutant and CO_2 emissions from motor vehicles will change to a greater or lesser degree because of several independent factors. Because of the complex relationships between fuel economy, vehicle sales, driver behavior (e.g., VMT and driving location), and technology choices by manufacturers, emissions will never uniformly increase or decrease for all future model years, across all regulated pollutants, and in all locations throughout the country. For example, increased stringency may result in greater VMT, resulting in larger downstream emissions of some criteria pollutants. On the other hand, decreased stringency may result in greater fuel refining, result in larger upstream emissions of some pollutants. Because vehicle operation and refinery activity depends upon independent market forces, impacts to particular listed species or designated critical habitat are dependent upon where vehicle operation or increased fuel refining occur, but neither agency can control such decisions. Regardless of whether NHTSA and EPA engage in Section 7(a)(2) consultation, the agencies lack the control necessary to negate all emissions increases in whatever years and locations they occur (e.g., ensure ideal technology choices by manufacturers, control consumer purchasing behavior, or regulate driving locations or VMT), or otherwise mitigate impacts associated with these particular emissions. But setting stringency is, in fact, what the agencies are statutorily obligated to do.

For the foregoing reasons, NHTSA and EPA conclude that they lack sufficient discretion or control to bring these actions under the consultation requirement of the ESA.

7. Floodplain Management (Executive Order 11988 and DOT Order 5650.2)

These Orders require Federal agencies to avoid the long- and short-term adverse impacts associated with the occupancy and modification of floodplains, and to restore and preserve the natural and beneficial values served by floodplains. Executive Order 11988 also directs agencies to minimize the impact of floods on human safety, health, and welfare, and to restore and preserve the natural and beneficial values served by floodplains through evaluating the potential effects of any actions the agency may take in a floodplain and ensuring that its program planning and budget requests reflect consideration of flood hazards and floodplain management. DOT Order 5650.2 sets forth DOT policies and procedures for implementing Executive Order 11988. The DOT Order requires that the agency determine if a proposed action is within the limits of a base floodplain, meaning it is encroaching on the floodplain, and whether this encroachment is significant. If significant, the agency is required to conduct further analysis of the proposed action and any practicable alternatives. If a practicable alternative avoids floodplain encroachment, then the agency is required to implement it.

In this rulemaking, the agencies are not occupying, modifying and/or encroaching on floodplains. The agencies, therefore, conclude that the Orders are not applicable to this action.

NHTSA has, however, conducted a review of the alternatives on potentially affected resources, including floodplains, in its FEIS.

8. Preservation of the Nation's Wetlands (Executive Order 11990 and DOT Order 5660.1a)

These Orders require Federal agencies to avoid, to the extent possible, undertaking or providing assistance for new construction located in wetlands unless the agency head finds that there is no practicable alternative to such construction and that the proposed action includes all practicable measures to minimize harm to wetlands that may result from such use. Executive Order 11990 also directs agencies to take action to minimize the destruction, loss, or degradation of wetlands in "conducting Federal activities and programs affecting land use, including but not limited to water and related land resources planning, regulating, and licensing activities." DOT Order 5660.1a sets forth DOT policy for interpreting Executive Order 11990 and requires that transportation projects "located in or having an impact on wetlands" should be conducted to assure protection of the Nation's wetlands. If a project does have a significant impact on wetlands, an EIS must be prepared.

In the NPRM, the agencies noted that they are not undertaking or providing assistance for new construction located in wetlands. The agencies, therefore, concluded that these Orders do not apply to this rulemaking. One commenter disagreed with this conclusion, noting the potential land use impacts of the rule and the agencies' obligation to consider all factors relevant to the proposal's effect on the survival and quality of wetlands.[3676] The agencies do not believe that it is feasible to establish the requisite causal chain between the impacts of this action and impacts on wetlands, nor would such impacts be reasonably foreseeable as a direct or indirect result of this rulemaking. The agencies therefore continue to conclude that these Orders do not apply to this rulemaking. Regardless, NHTSA addresses the potential effects of the alternatives on resources, including wetlands, in its FEIS.

9. Migratory Bird Treaty Act (MBTA), Bald and Golden Eagle Protection Act (BGEPA), Executive Order 13186

The MBTA (16 U.S.C. 703–712) provides for the protection of certain migratory birds by making it illegal for anyone to "pursue, hunt, take, capture, kill, attempt to take, capture, or kill, possess, offer for sale, sell, offer to barter, barter, offer to purchase, purchase, deliver for shipment, ship, export, import, cause to be shipped, exported, or imported, deliver for transportation, transport or cause to be transported, carry or cause to be carried, or receive for shipment, transportation, carriage, or export" any migratory bird covered under the statute.[3677]

The BGEPA (16 U.S.C. 668-668d) makes it illegal to "take, possess, sell, purchase, barter, offer to sell, purchase or barter, transport, export or import" any bald or golden eagles.[3678]

[3676] Joint Submission from the States of California *et al.* and the Cities of Oakland *et al.*, Docket No. NHTSA-2018-0067-11735, at 46-47.
[3677] 16 U.S.C. 703(a).
[3678] 16 U.S.C. 668(a).

Executive Order 13186, "Responsibilities of Federal Agencies to Protect Migratory Birds," helps to further the purposes of the MBTA by requiring a Federal agency to develop a Memorandum of Understanding (MOU) with the Fish and Wildlife Service when it is taking an action that has (or is likely to have) a measurable negative impact on migratory bird populations.

The agencies conclude that the MBTA, BGEPA, and Executive Order 13186 do not apply to this action because there is no disturbance, take, measurable negative impact, or other covered activity involving migratory birds or bald or golden eagles involved in this rulemaking.

10. Department of Transportation Act (Section 4(f))

Section 4(f) of the Department of Transportation Act of 1966 (49 U.S.C. 303), as amended, is designed to preserve publicly owned park and recreation lands, waterfowl and wildlife refuges, and historic sites. Specifically, Section 4(f) provides that DOT agencies cannot approve a transportation program or project that requires the use of any publicly owned land from a public park, recreation area, or wildlife or waterfowl refuge of national, State, or local significance, or any land from a historic site of national, State, or local significance, unless a determination is made that:

(1) There is no feasible and prudent alternative to the use of land, and

(2) The program or project includes all possible planning to minimize harm to the property resulting from the use.

These requirements may be satisfied if the transportation use of a Section 4(f) property results in a de minimis impact on the area.

NHTSA concludes that Section 4(f) is not applicable to this action because this rulemaking is not an approval of a transportation program or project that requires the use of any publicly owned land.

11. Executive Order 12898: "Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations"

Executive Order 12898 (59 FR 7629 (Feb. 16, 1994)) establishes Federal executive policy on environmental justice. It directs Federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority and low-income populations in the United States. DOT Order 5610.2(a)[3679] sets forth the Department of Transportation's policy to consider environmental justice principles in all its programs, policies, and activities.

Environmental justice is a principle asserting that all people deserve fair treatment and meaningful involvement with respect to environmental laws, regulations, and policies. EPA

[3679] Department of Transportation Updated Environmental Justice Order 5610.2(a), 77 FR 27534 (May 10, 2012).

seeks to provide the same degree of protection from environmental health hazards for all people. DOT shares this goal and is informed about the potential environmental impacts of its rulemakings through the NEPA process. One comment on the NPRM claimed that the agencies "failed to recognize the benefits of the existing standards" for disadvantaged communities. Specifically, the commenter claimed that the agencies did not provide an underlying analysis of environmental justice issues and thereby failed to meet the requirements of EO 12898.[3680] However, the agencies addressed their obligations under EO 12898 in the preamble to the NPRM and in Section 7.5 of the DEIS. The agencies received a number of comments regarding the analysis it presented. NHTSA responds to those comments in Section 10.7 of the FEIS, and the agencies have revised their environmental justice analysis based on the information contained in those comments. The revised analysis is presented in the fnal rule preamble, here, and in the FEIS.

There is evidence that proximity to oil refineries could be correlated with incidences of cancer and leukemia.[3681, 3682, 3683] Proximity to high-traffic roadways could result in adverse cardiovascular and respiratory impacts, among other possible impacts.[3684, 3685, 3686, 3687, 3688, 3689,

[3690] Climate change affects overall global temperatures, which could, in turn, affect the number and severity of outbreaks of vector-borne illnesses.[3691, 3692] In the context of this rulemaking, the environmental justice concern is the extent to which minority and low-income populations could be more exposed or vulnerable to such environmental and health impacts.

Numerous studies have found that some environmental hazards are more prevalent in areas where racial/ethnic minorities and people with low socioeconomic status represent a higher proportion of the population compared with the general population. In addition, compared to non-Hispanic whites, some subpopulations defined by race and ethnicity have been shown to have a greater incidence of some health conditions during certain life stages. For example, in 2014, about 13 percent of Black, non-Hispanic and 24 percent of Puerto Rican children were estimated to have asthma, compared with 8 percent of white, non-Hispanic children.[3693] The agencies have therefore considered areas nationwide that could contain minority and low-income communities who would most likely be exposed to the environmental and health impacts of oil production, distribution, and consumption or the potential impacts of climate change. These include areas where oil production and refining occur, areas near roadways, coastal flood-prone areas, and urban areas that are subject to the heat island effect.[3694]

The following discussion addresses environmental justice implications related to air quality and to climate change and carbon emissions in the context of this final rulemaking. Emissions of air pollutants may be affected by this rulemaking due to changes in fuel use and VMT, which are described above. To the degree to which minority and low-income populations may be present in proximity to the locations described in this section, they may be exposed disproportionately to these emissions changes. In addition, the following analysis also discusses other potential reasons why minority and low-income populations may be susceptible to the health impacts of air pollutants. NHTSA also discusses environmental justice in Chapter 7.5 of its FEIS.

a) Proximity to Oil Production and Refining

As stated above, numerous studies have found that some environmental hazards are more prevaluent in areas where minority and low-income populations represent a higher proportion of the population compared with the general population. For example, one study found that survey respondents who were black and, to a lesser degree, had lower income levels, were significantly

more likely to live within 1 mile of an industrial facility listed in the EPA's 1987 Toxic Release Inventory (TRI) national database.[3695]

A meta-analysis of 49 environmental equity studies concluded that evidence of race-based environmental inequities is statistically significant (although the average magnitude of these inequities is small), while evidence supporting the existence of income-based environmental inequities is substantially weaker.[3696] Considering poverty-based class effects, that meta-analysis found an inverse relationship between environmental risk and poverty, concluding that environmental risks are less likely to be located in areas of extreme poverty.[3697] However, individual studies may reach contradictory conclusions in relation to race- and income-based inequities across a range of environmental risks. Therefore, the meta-analysis also sought to examine the reasons why conclusions vary across studies of environmental inequity. Possible explanations for why studies reach contrary conclusions include variability in the source of potential environmental risk that the study considers (e.g., the type of facility or the associated level of pollution or risk); variability in the methodology applied to aggregate demographic data and to define the comparison population; and the degree to which statistical models control for other variables that may explain the distribution of potential environmental risk.

To test whether there are disparate impacts from hazardous industrial facilities on racial/ethnic minorities, the disadvantaged, the working class, and manufacturing workers, one study tested the relationship between hazard scores of Philadelphia-area facilities in EPA's Risk-Screening Environmental Indicators (RSEI) database and the demographics of populations near those facilities using multivariate regression.[3698] This study concluded that racial/ethnic minorities, the most socioeconomically disadvantaged, and those employed in manufacturing suffer a disparate impact from the highest-hazard facilities (primarily manufacturing plants).

Other commissioned reports and case studies provide additional evidence of the presence of low-income and minority populations near industrial facilities and of racial or socioeconomic

disparities in exposure to environmental risk, although these sources were not published in peer-reviewed scientific journals.[3699, 3700, 3701, 3702]

Few studies address disproportionate exposure to environmental risk associated with oil refineries specifically. One study found that the populations surrounding oil refineries are more often minorities, concluding that "56 percent of people living within three miles of [oil] refineries in the United States are minorities – almost double the national average."[3703] Another examined whether findings of environmental inequity varied between coke production plants and oil refineries, both of which are significant sources of air pollution.[3704] This study concluded that census tracts near coke plants had a disproportionate share of poor and nonwhite residents, and that existing inequities were primarily economic in nature. However, the findings for oil refineries did not strongly support an environmental inequity hypothesis. A more recent study of environmental justice in the oil refinery industry found evidence of environmental injustice as a result of unemployment levels in areas around refineries and, to a slightly lesser extent, as a result of income inequality.[3705] This study did not test for race-based environmental inequities.

Overall, the body of scientific literature points to disproportionate representation of minority and low-income populations in proximity to a range of industrial, manufacturing, and hazardous waste facilities that are stationary sources of air pollution; although results of individual studies may vary. While the scientific literature specific to oil refineries is limited, disproportionate exposure of minority and low-income populations to air pollution from oil

refineries is suggested by other broader studies of racial and socioeconomic disparities in proximity to industrial facilities generally.

The potential increase in fuel production and consumption projected as a result of this rulemaking (compared to the No Action Alternative) could lead to an increase in upstream emissions of criteria and toxic air pollutants due to increased extraction, refining, and transportation of fuel. As described in Section VII.A.4.c.3.b.i, total upstream emissions of criteria and toxic air pollutants in 2035 are projected to increase under all action alternatives compared to the No Action Alternative, with the exception that total upstream emissions of SO_2 are projected to decrease under all action alternatives under the CAFE program (but not under the CO_2 program). As noted, a correlation between proximity to oil refineries and the prevalence of minority and low-income populations is suggested in the scientific literature. To the extent that minority and low-income populations live closer to oil refining facilities, these populations may be more likely to be adversely affected by these emissions. However, the magnitude of the change in emissions relative to the baseline is minor and would not be characterized as high and adverse.

b) Proximity to High-Traffic Roadways

Studies have more consistently demonstrated a disproportionate prevalence of minority and low-income populations living near mobile sources of pollutants. In certain locations in the United States, for example, there is consistent evidence that populations or schools near roadways typically include a greater percentage of minority or low-income residents.[3706, 3707, 3708, 3709, 3710, 3711, 3712] In California, studies demonstrate that minorities and low-income populations are disproportionately likely to live near a major roadway or in areas of high traffic density

compared to the general population.[3713, 3714] A study of traffic, air pollution, and socio-economic status inside and outside the Minneapolis-St. Paul metropolitan area similarly found that populations on the lower end of the socioeconomic spectrum and minorities are disproportionately exposed to traffic and air pollution and at higher risk for adverse health outcomes.[3715] Near-road exposure to vehicle emissions can cause or exacerbate health conditions such as asthma.[3716, 3717, 3718, 3719] One study demonstrated that students at schools in Michigan closer to major highways had a higher risk of respiratory and neurological disease and were more likely to fail to meet state educational standards, after controlling for other variables.[3720] In general, studies such as these demonstrate trends in specific locations in the United States that may be indicative of broader national trends.

Fewer studies have been conducted at the national level, yet those that do exist also demonstrate a correlation between minority and low-income status and proximity to roadways.[3721, 3722] For example, one study found that greater traffic volumes and densities at the national level are associated with larger shares of minority and low-income populations living in

the vicinity.[3723] Another study found that schools with minority and underprivileged[3724] children were disproportionately located within 250 meters of a major roadway.[3725]

As detailed in Section 10.3.8 of the PRIA and Section X.E.11.a.2 of the FRIA, NHTSA and EPA analyzed two national databases that allowed evaluation of whether homes and schools were located near a major road and whether disparities in exposure may be occurring in these environments. The American Housing Survey (AHS) includes descriptive statistics of over 70,000 housing units across the nation. The study survey is conducted every two years by the U.S. Census Bureau. The second database the agencies analyzed was the U.S. Department of Education's Common Core of Data, which includes enrollment and location information for schools across the U.S.

In analyzing the 2009 AHS, the focus was on whether or not a housing unit was located within 300 feet of a "4-or-more lane highway, railroad, or airport."[3726] Whether there were differences between households in such locations compared with those in locations farther from these transportation facilities was analyzed.[3727] Other variables, such as land use category, region of country, and housing type, were included. Homes with a nonwhite householder were found to be 22 to 34 percent more likely to be located within 300 feet of these large transportation facilities than homes with white householders. Homes with a Hispanic householder were 17 to 33 percent more likely to be located within 300 feet of these large transportation facilities than homes with non-Hispanic householders. Households near large transportation facilities were, on average, lower in income and educational attainment, more likely to be a rental property, and more likely to be located in an urban area compared with households more distant from transportation facilities.

In examining schools near major roadways, the Common Core of Data (CCD) from the U.S. Department of Education, which includes information on all public elementary and secondary schools and school districts nationwide, was examined.[3728] To determine school proximities to major roadways, a geographic information system (GIS) to map each school and

---

[3723] Rowangould, G.M. *A Census of the US Near-roadway Population: Public Health and Environmental Justice Considerations*. Transportation Research Part D: Transport and Environment 25:59–67 (2013). doi:10.1016/j.trd.2013.08.003.
[3724] Public schools were determined to serve predominantly underprivileged students if they were eligible for Title I programs (federal programs that provide funds to school districts and schools with high numbers or high percentages of children who are disadvantaged) or had a majority of students who were eligible for free/reduced-price meals under the National School Lunch and Breakfast Programs.

[3726] This variable primarily represents roadway proximity. According to the Central Intelligence Agency's World Factbook, in 2010, the United States had 6,506,204 km of roadways, 224,792 km of railways, and 15,079 airports. Highways thus represent the overwhelming majority of transportation facilities described by this factor in the AHS.
[3727] Bailey, C. (2011) Demographic and Social Patterns in Housing Units Near Large Highways and other Transportation Sources. Memorandum to docket.
[3728] http://nces.ed.gov/ccd/.

roadways based on the U.S. Census's TIGER roadway file was used.[3729] Minority students were found to be overrepresented at schools within 200 meters of the largest roadways, and schools within 200 meters of the largest roadways also had higher than expected numbers of students eligible for free or reduced-price lunches. For example, Black students represent 22 percent of students at schools located within 200 meters of a primary road, whereas Black students represent 17 percent of students in all U.S. schools. Hispanic students represent 30 percent of students at schools located within 200 meters of a primary road, whereas Hispanic students represent 22 percent of students in all U.S. schools.

Overall, there is substantial evidence that the population who lives or attends school near major roadways are more likely to be minority or low income. As described in Section VII.A.4.c.3.b.i, total downstream (tailpipe) emissions of criteria and toxic air pollutants for cars and light trucks in 2035 are projected to remain relatively unchanged or decrease under all action alternatives compared to the No Action Alternative, with the following exceptions: total downstream emissions of SO_2 would increase under all action alternatives under both the CAFE and CO_2 programs; total downstream emissions of acrolein would increase under Alternatives 5, 6, and 7 under the CAFE program (but not under the CO_2 program); and total downstream emissions of acetaldehyde and butadiene would increase under Alternatives 6 and 7 under the CAFE program (but not under the CO_2 program). To the extent minority and low-income populations disproportionately live or attend schools near major roadways, these populations may be more likely to be affected by these emissions. However, because some pollutant emissions are expected to decrease and others are expected to increase, health impacts are mixed. Overall, as the magnitude of the emissions changes is anticipated to be minor compared to total tailpipe emissions for these vehicles, the impacts to minority or low-income populations are not considered high and adverse.

The agencies used the standards that were discussed in the 2012 rulemaking as the baseline for this rulemaking. Therefore, the agencies project increases in certain air pollutants for purposes of this analysis. However, as discussed above, one impact of the standards finalized in this rulemaking is to reduce the up-front cost of new and used vehicles. Low income populations may benefit most from the reduction in cost of acquiring newer vehicles, which generally are more fuel efficient and have lower air pollutant emissions than older vehicles. This cost reduction may have the effect of encouraging the quicker adoption of cleaner vehicles in low income communities, which could result in air quality and health benefits for those who live or attend school in proximity to the roadways where they are operated. To the degree to which minority populations may also live in proximity to these roadways, they would also experience benefits, thereby mitigating the disparity in racial, ethnic, and economically based exposures.

[3729] Pedde, M.; Bailey, C. Identification of Schools within 200 Meters of U.S. Primary and Secondary Roads. Memorandum to the docket (2011).

c) Other Vulnerabilities to Climate Change and Health Impacts of Air Pollutants

Some areas most vulnerable to climate change tend to have a higher concentration of minority and low-income populations, potentially putting these communities at higher risk from climate variability and climate-related extreme weather events.[3730] For example, urban areas tend to have pronounced social inequities that could result in disproportionately larger minority and low-income populations than those in the surrounding nonurban areas.[3731] Urban areas are also subject to the most substantial temperature increases from climate change because of the urban heat island effect.[3732, 3733, 3734] Taken together, these tendencies demonstrate a potential for disproportionate impacts on minority and low-income populations in urban areas. Low-income populations in coastal urban areas, which are vulnerable to increases in flooding as a result of projected sea-level rise, larger storm surges, and human settlement in floodplains, could also be disproportionately affected by climate change because they are less likely to have the means to evacuate quickly in the event of a natural disaster and, therefore, are at greater risk of injury and loss of life.[3735, 3736]

Independent of their proximity to pollution sources or climate change, locations of potentially high impact, minority and low-income populations could be more vulnerable to the health impacts of pollutants and climate change. Reports from the U.S. Department of Health and Human Services have stated that minority and low-income populations tend to have less access to health care services, and the services received are more likely to suffer with respect to quality.[3737, 3738, 3739] Other studies show that low socioeconomic position can modify the health

effects of air pollution, with higher effects observed in groups with lower socioeconomic position.[3740, 3741] Possible explanations for this observation include that low socioeconomic position groups may be differentially exposed to air pollution or may be differentially vulnerable to effects of exposure.[3742]

In terms of climate change, increases in heat-related morbidity and mortality because of higher overall and extreme temperatures are likely to affect minority and low-income populations disproportionately, partially because of limited access to air conditioning and high energy costs.[3743, 3744, 3745, 3746] Native American tribes and Alaskan Native villages are also more susceptible to the impacts of climate change, as these groups often disproportionately rely on natural resources for livelihoods, medicines, and cultural and spiritual purposes.[3747] Moreover, coastal tribal communities may have to relocate because of sea-level rise, erosion, and permafrost thaw.[3748] NHTSA's FEIS provides additional discussion of health and societal impacts of climate change on indigenous communities in Section 8.6.5.2, *Sectoral Impacts of Climate* Change, under *Human Health* and *Human Security*.

Together, this information indicates that the same set of potential environmental effects (e.g., air pollutants, heat increases, and sea-level rise) may disproportionately affect minority and low-income populations because of socioeconomic circumstances or histories of discrimination and inequity.

As described in Chapter 5 of NHTSA's FEIS, the action alternatives are projected to increase CO_2 emissions from passenger cars and light trucks by 4 to 10 percent by 2100 compared to the No Action Alternative. Impacts of climate change could disproportionately affect minority and low-income populations in urban areas that are subject to the most substantial temperature increases from climate change. These impacts are largely because of the urban heat island effect. Additionally, minority and low-income populations that live in flood-prone coastal areas could be disproportionately affected. However, the contribution of the action alternatives to climate change impacts would be very minor rather than high and adverse. Compared to the annual U.S. CO_2 emissions of 7,193 $MMTCO_2e$ from all sources by the end of the century projected by the GCAM Reference scenario, the action alternatives are projected to increase annual U.S. CO_2 emissions by 0.4 to 1.2 percent in 2100. Compared to annual global CO_2 emissions, the action alternatives would represent an even smaller percentage increase and ultimately, by 2100, are projected to result in percentage increases in global mean surface temperature, atmospheric CO_2 concentrations, and sea level, and decreases in ocean pH, ranging from 0.09 percent to less than 0.01 percent. Any impacts of this rulemaking on low-income and minority communities would be attenuated by a lengthy causal chain; but if one could attempt to draw those links, the changes to climate values would be very small and incremental compared to the expected changes associated with the emissions trajectories in the GCAM Reference scenario.

As reported in Section VII.A.4.c.3.c above, adverse health impacts over the lifetimes of vehicles through MY 2029 are projected to increase nationwide under each of the action alternatives (except Alternative 6 and Alternative 7 under the CAFE program, which show decreases) compared to the No Action Alternative. Increases in these pollutant emissions, however, would be primarily the result of increases in upstream emissions (emissions near refineries, power plants, and extraction sites), while downstream emissions (tailpipe emissions near roadways) are anticipated to decrease or increase by smaller amounts. The health impacts reported in that section occur over a long period of time, would be incremental in magnitude, and would not be characterized as high. Those impacts would also be borne nationwide, so impacts to minority and low-income populations would be smaller.

d) Conclusion

Based on the foregoing, the agencies have determined that this rulemaking (and alternatives considered) would not result in disproportionately high and adverse human health or environmental effects on minority or low-income populations. This rulemaking would set standards nationwide, and although minority and low-income populations may experience some disproportionate effects, in particular locations, the overall impacts on human health and the environment would not be "high and adverse" under EO 12898.

Furthermore, the agencies note that there are no mitigation measures or alternatives available as part of this action that could fulfill the respective statutory missions of the agencies and that would address the considerations discussed in Section VIII (e.g., economic practicability) or avoid or reduce any disproportionate effects in particular locations experienced by minority and low-income populations. The impacts described in this analysis would result from air pollutant and CO_2 emissions that may occur from the levels of stringency selected by the agencies. However, for the reasons described in Section VIII, the agencies cannot select a higher level of stringency. While the agencies have considered the potential impacts described in this analysis, there is a substantial need, based on the overall public interest, to address the costs associated with the standards discussed in the 2012 rulemaking. More stringent alternatives would have severe adverse social and economic costs, as described in Section VIII, and necessitate the level of standards finalized in this rulemaking.

12. Executive Order 13045: "Protection of Children from Environmental Health Risks and Safety Risks"

This action is subject to EO 13045 (62 FR 19885, April 23, 1997) because it is an economically significant regulatory action as defined by EO 12866, and the agencies have reason to believe that the environmental health or safety risks related to this action may have a disproportionate effect on children. Specifically, children are more vulnerable to adverse health effects related to mobile source emissions, as well as to the potential long-term impacts of climate change. Pursuant to EO 13045, NHTSA and EPA must prepare an evaluation of the environmental health or safety effects of the planned regulation on children and an explanation of why the planned regulation is preferable to other potentially effective and reasonably feasible alternatives considered by the agencies. Further, this analysis may be included as part of any other required analysis.

The final rule preamble and NHTSA's Final EIS discuss air quality, climate change, and their related environmental and health effects, noting where these would disproportionately affect children. The EPA Administrator has also discussed the impact of climate-related health effects on children in the Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act (74 FR 66496, December 15, 2009). In addition, the the preamble and this FRIA explain why the agencies' final standards are preferable to other alternatives considered. Together, the preamble and NHTSA's Final EIS satisfy the agencies' responsibilities under EO 13045.

F. Regulatory Flexibility Act

Pursuant to the Regulatory Flexibility Act (5 U.S.C. 601 *et seq.,* as amended by the Small Business Regulatory Enforcement Fairness Act (SBREFA) of 1996), whenever an agency is required to publish a notice of proposed rulemaking or final rule, it must prepare and make available for public comment a regulatory flexibility analysis that describes the effect of the rule on small entities (*i.e.*, small businesses, small organizations, and small governmental jurisdictions). No regulatory flexibility analysis is required if the head of an agency certifies the rule will not have a significant economic impact on a substantial number of small entities. SBREFA amended the Regulatory Flexibility Act to require Federal agencies to provide a statement of the factual basis for certifying that a rule will not have a significant economic impact on a substantial number of small entities.

Two comments argued that the agencies should prepare a regulatory flexibility analysis and convene a small business review panel to assess the impacts in accordance with the

Regulatory Flexibility Act, 5 U.S.C. 601 *et seq.*, as amended by SBREFA.[3749] The agencies considered these comments and the impacts of this rule under the Regulatory Flexibility Act and certify that this rule will not have a significant economic impact on a substantial number of small entities. The following is the agencies' statement providing the factual basis for this certification pursuant to 5 U.S.C. 605(b).

Small businesses are defined based on the North American Industry Classification System (NAICS) code.[3750] One of the criteria for determining size is the number of employees in the firm. For establishments primarily engaged in manufacturing or assembling automobiles, as well as light duty trucks, the firm must have less than 1,500 employees to be classified as a small business. This rule would affect motor vehicle manufacturers. As shown in Table X-1, the agencies have identified 15 small manufacturers of passenger cars, light trucks, and SUVs of electric, hybrid, and internal combustion engines.[3751] The agencies acknowledge that some newer manufacturers may not be listed. However, those new manufacturers tend to have transportation products that are not part of the light-duty vehicle fleet and have yet to start production of light-duty vehicles. Moreover, NHTSA does not believe that there are a "substantial number" of these newer companies.[3752]

[3749] *See* National Coalition for Advanced Transportation (NCAT) Comment, Docket No. NHTSA-2018-0067-11969, at 64-65; Workhorse Group, Inc. Comment, Docket No. NHTSA-2018-0067-12215, at 1-2.

[3750] Classified in NAICS under Subsector 336—Transportation Equipment Manufacturing for Automobile Manufacturing (336111), Light Truck (336112), and Heavy Duty Truck Manufacturing (336120). https://www.sba.gov/document/support-table-size-standards.

[3751] Two comments pointed out that Workhorse Group Inc. was not listed as a small domestic vehicle manufacturer in Table XII-1 of the proposal. *See* National Coalition for Advanced Transportation (NCAT) Comment, Docket No. NHTSA-2018-0067-11969, at 64-65; Workhorse Group, Inc. Comment, Docket No. NHTSA-2018-0067-12215, at 1-2. Workhorse Group has been added to the table here, but neither its addition nor the existence of a small number of other new small manufacturers does not alter the conclusion that this rule will not have a significant economic impact on a substantial number of small entities.

[3752] 5 U.S.C. 605(b).

Table X-1 – Small Domestic Vehicle Manufacturers

Manufacturers	**Founded**	**Employees**[3753]	**Estimated Annual Production**[3754]	**Sale Price per Unit**
Karma Automotive	2014	625	900	$130,000
BXR Motors	2008	< 10	< 100	$155,000 to $185,000
Falcon Motorsports	2009	5	< 100	$300,000 to $400,000
Lucra Cars	2005	8	< 100	$100,000
Lyons Motor Car	2012	< 10	< 100	$1,400,000
Rezvani Motors	2014	6	< 100	$95,000 to $270,000
Rossion Automotive	2007	6	< 100	$90,000
Saleen	1984	51	< 100	$100,000
Shelby American	1962	61	< 100	$60,000 to $250,000
Panoz	1988	20	< 100	$155,000 to $175,000
Faraday Future	2014	790	0	$200,000 to $300,000
Lucid Motor Car	2007	269	0	$60,000
Rivian Automotive	2009	208	0	N/A
SF Motors	2016	204	0	N/A
Workhorse Group	2007	125	0	$52,000

NHTSA believes that the rulemaking would not have a significant economic impact on the small vehicle manufacturers because under 49 CFR part 525, passenger car manufacturers making less than 10,000 vehicles per year can petition NHTSA to have alternative standards set for those manufacturers. These manufacturers do not currently meet the 27.5 mpg standard and must already petition the agency for relief. If the standard is raised, it has no meaningful impact on these manufacturers—they still must go through the same process and petition for relief. Given there already is a mechanism for relieving burden on small businesses, which is the purpose of the Regulatory Flexibility Act, a regulatory flexibility analysis was not prepared.

Two comments argued that small manufacturers of electric vehicles would face a significant economic impact because their ability to earn credits would be "substantially diminished."[3755] The method for earning credits applies equally across manufacturers and does not place small entities at a significant competitive disadvantage. In any event, even if the rule had a "significant economic impact" on these small EV manufacturers, the amount of these companies is not "a substantial number."[3756] For these reasons, their existence does not alter the agencies' analysis of the applicability of the Regulatory Flexibility Act. EPA believes this rulemaking would not have a significant economic impact on a substantial number of small

entities under the Regulatory Flexibility Act, as amended by the Small Business Regulatory Enforcement Fairness Act. EPA is exempting from the CO_2 standards any manufacturer, domestic or foreign, meeting SBA's size definitions of small business as described in 13 CFR 121.201. EPA adopted the same type of exemption for small businesses in the 2017 and later rulemaking. EPA estimates that small entities comprise less than 0.1 percent of total annual vehicle sales and exempting them will have a negligible impact on the CO_2 emissions reductions from the standards. Because EPA is exempting small businesses from the CO_2 standards, the agency certifies that the rule will not have a significant economic impact on a substantial number of small entities. Therefore, EPA has not conducted a Regulatory Flexibility Analysis or a SBREFA SBAR Panel for the rule.

EPA regulations allow small businesses voluntarily to waive their small business exemption and optionally to certify to the CO_2 standards. This option allows small entity manufacturers to earn CO_2 credits under the CO_2 program, if their actual fleetwide CO_2 performance is better than their fleetwide CO_2 target standard. However, the exemption waiver is optional for small entities and thus the agency believes that manufacturers opt into the CO_2 program if it is economically advantageous for them to do so, for example in order to generate and sell CO_2 credits. Therefore, EPA believes this voluntary option does not affect EPA's determination that the standards will impose no significant adverse impact on small entities.

G. Executive Order 13132 (Federalism)

Executive Order 13132 requires Federal agencies to develop an accountable process to ensure "meaningful and timely input by State and local officials in the development of regulatory policies that have federalism implications." The Order defines the term "[p]olicies that have federalism implications" to include regulations that have "substantial direct effects on the States, on the relationship between the national government and the States, or on the distribution of power and responsibilities among the various levels of government." Under the Order, agencies may not issue a regulation that has federalism implications, that imposes substantial direct compliance costs, unless the Federal government provides the funds necessary to pay the direct compliance costs incurred by State and local governments, or the agencies consult with State and local officials early in the process of developing the proposed regulation. The agencies complied with the Order's requirements.

NHTSA also addressed the federalism implications of its proposal in The Safer Affordable Fuel-Efficient Vehicles Rule Part One: One National Program final rulemaking.[3757]

H. Executive Order 12988 (Civil Justice Reform)

Pursuant to Executive Order 12988, "Civil Justice Reform,"[3758] NHTSA has considered whether this rulemaking would have any retroactive effect. This proposed rule does not have any retroactive effect.

[3757] 84 FR 51310 (Sep. 27, 2019).
[3758] 61 FR 4729 (Feb. 7, 1996).

I. Executive Order 13175 (Consultation and Coordination With Indian Tribal Governments)

This final rule does not have tribal implications, as specified in Executive Order 13175 (65 FR 67249, November 9, 2000). This rule will be implemented at the Federal level and impose compliance costs only on vehicle manufacturers. Thus, Executive Order 13175 does not apply to this rule. Some comments complained that the agencies have not consulted or coordinated with Native American communities and Indian Tribes in promulgating this rule.[3759] Executive Order 13175 requires consultation with Tribal officials when agencies are developing policies that have "substantial direct effects" on Tribes and Tribal interests.[3760] Even accepting the comments' description of the effects of the rule, they have identified only indirect effects of the standards on Tribal interests.[3761]

J. Unfunded Mandates Reform Act

Section 202 of the Unfunded Mandates Reform Act of 1995 (UMRA) requires Federal agencies to prepare a written assessment of the costs, benefits, and other effects of a proposed or final rule that includes a Federal mandate likely to result in the expenditure by State, local, or Tribal governments, in the aggregate, or by the private sector, of more than $100 million in any one year (adjusted for inflation with base year of 1995). Adjusting this amount by the implicit gross domestic product price deflator for 2016 results in $148 million (111.416/75.324 = 1.48).[3762] Before promulgating a rule for which a written statement is needed, section 205 of UMRA generally requires NHTSA and EPA to identify and consider a reasonable number of regulatory alternatives and adopt the least costly, most cost-effective, or least burdensome alternative that achieves the objective of the rule. The provisions of section 205 do not apply when they are inconsistent with applicable law. Moreover, section 205 allows NHTSA and EPA to adopt an alternative other than the least costly, most cost-effective, or least burdensome alternative if the agency publishes with the rule an explanation of why that alternative was not adopted.

This rule will not result in the expenditure by State, local, or Tribal governments, in the aggregate, of more than $148 million annually, but it will result in the expenditure of that magnitude by vehicle manufacturers and/or their suppliers. In developing this rule, NHTSA and EPA considered a variety of alternative average fuel economy standards lower and higher than those previously proposed. The fuel economy standards for MYs 2021-2026 are the least costly, most cost-effective, and least burdensome alternative that achieve the objectives of the rule.

K. Regulation Identifier Number

The Department of Transportation assigns a regulation identifier number (RIN) to each regulatory action listed in the Unified Agenda of Federal Regulations. The Regulatory Information Service Center publishes the Unified Agenda in April and October of each year. The RIN contained in the heading at the beginning of this document may be used to find this action in the Unified Agenda.

L. National Technology Transfer and Advancement Act

Section 12(d) of the National Technology Transfer and Advancement Act (NTTAA) requires NHTSA and EPA to evaluate and use existing voluntary consensus standards in its regulatory activities unless doing so would be inconsistent with applicable law (*e.g.*, the statutory provisions regarding NHTSA's vehicle safety authority, or EPA's testing authority) or otherwise impractical.[3763]

Voluntary consensus standards are technical standards developed or adopted by voluntary consensus standards bodies. Technical standards are defined by the NTTAA as "performance-based or design-specific technical specification and related management systems practices." They pertain to "products and processes, such as size, strength, or technical performance of a product, process or material."

Examples of organizations generally regarded as voluntary consensus standards bodies include the American Society for Testing and Materials (ASTM), the Society of Automotive Engineers (SAE), and the American National Standards Institute (ANSI). If the agencies do not use available and potentially applicable voluntary consensus standards, they are required by the Act to provide Congress, through OMB, an explanation of the reasons for not using such standards.

For CO_2 emissions, EPA will collect data over the same tests that are used for the MY 2012-2016 CO_2 standards and for the CAFE program. This unified data collection will minimize the amount of testing done by manufacturers because manufacturers are already required to run these tests. For A/C credits, EPA will use a consensus methodology developed by the Society of Automotive Engineers (SAE) and also a new A/C test. EPA knows of no consensus standard available for the A/C test.

There are currently no voluntary consensus standards that NHTSA administers relevant to today's CAFE standards.

[3763] 15 U.S.C. 272.

M. Department of Energy Review

In accordance with 49 U.S.C. 32902(j)(2), NHTSA submitted this rule to the Department of Energy for review.

N. Paperwork Reduction Act

The Paperwork Reduction Act (PRA) of 1995, Public Law 104-13,[3764] gives OMB authority to regulate matters regarding the collection, management, storage, and dissemination of certain information by and for the Federal government. It seeks to reduce the total amount of paperwork handled by the government and the public. NHTSA strives to reduce the public's information collection burden hours each fiscal year by streamlining external and internal processes.

To this end, NHTSA will continue to collect information to ensure compliance with its CAFE program. NHTSA will reinstate its previously-approved collection of information for Corporate Average Fuel Economy (CAFE) reports specified in 49 CFR part 537 (OMB control number 2127-0019), add the additional burden for reporting changes adopted in the October 15, 2012 final rule that recently came into effect (*see* 77 FR 62623), and account for the change in burden in this rule as well as for other CAFE reporting provisions required by Congress and NHTSA. NHTSA is also changing the name of this collection to represent more accurately the breadth of all CAFE regulatory reporting. Although NHTSA is adding additional burden hours to its CAFE report requirement in 49 CFR 537, the agency believes there will be a reduction in the overall paperwork burden due to the standardization of data and the streamlined process.

In compliance with the PRA, the information collection request (ICR) abstracted below was forwarded to OMB for review and comment. The ICR describes the nature of the information collection and its expected burden.

Title: Corporate Average Fuel Economy.

Type of Request: Reinstatement and amendment of a previously approved collection.

OMB Control Number: 2127-0019.

Form Numbers: NHTSA Form 1474 (CAFE Projections Reporting Template) and NHTSA Form 1475 (CAFE Credit Template).

Requested Expiration Date of Approval: Three years from date of approval.

Summary of the collection of information: As part of this rulemaking, NHTSA is reinstating and modifying its previously-approved collection for CAFE-related collections of information. NHTSA and EPA have coordinated their compliance and reporting requirements in

---

[3764] Codified at 44 U.S.C. 3501 *et seq*.

an effort not to impose duplicative burdens on regulated entities. This information collection contains three different components: burden related to NHTSA's CAFE reporting requirements; burden related to CAFE compliance, but not via reporting requirements; and information gathered by NHTSA to help inform CAFE analyses. All templates referenced in this section will be available in the rulemaking docket and the NHTSA public information center[3765].

1. CAFE Compliance Reports

NHTSA is reinstating[3766] its collection related to the reporting requirements in 49 U.S.C. 32907, "Reports and tests of manufacturers." In that section, manufacturers are statutorily required to submit CAFE compliance reports to the Secretary of Transportation.[3767] The reports must state if a manufacturer will comply with its applicable fuel economy standard(s), describe what actions the manufacturer intends to take to comply with the standard(s), and include other information as required by NHTSA. Manufacturers are required to submit two CAFE compliance reports—a pre-model year report (PMY) and a mid-model year (MMY) report—each year. In the event a manufacturer needs to correct previously-submitted information, a manufacturer may need to file additional reports.[3768]

To implement this statute, NHTSA issued 49 CFR part 537, "Automotive Fuel Economy Reports," which adds additional definition to the terms of section 32907. The first report, the PMY report must be submitted to NHTSA before December 31 of the calendar year prior to the corresponding model year and contain manufacturers' projected information for that upcoming model year. The second report, the MMY report must be submitted by July 31 of the given model year and contain updated information from manufacturers based on actual and projected information known midway through the model year. Finally, the last report, a supplementary report, is required to be submitted anytime a manufacturer needs to correct information previously submitted to NHTSA.

Compliance reports must include information on passenger and non-passenger automobiles (trucks) describing the projected and actual fuel economy standards, fuel economy performance values, production sales volumes and information on vehicle design features (*e.g.,* engine displacement and transmission class) and other vehicle attribute characteristics (*e.g.,* track width, wheel base, and other light truck off-road features). Manufacturers submit confidential and non-confidential versions of these reports to NHTSA. Confidential reports differ by including estimated or actual production sales information, which is withheld from public

[3766] This collection expired on April 30, 2016.

[3767] 49 U.S.C. 32907 (delegated to the NHTSA Administrator at 49 CFR 1.95). Because of this delegation, for purposes of discussion, statutory references to the Secretary of Transportation in this section will be discussed in terms of NHTSA or the NHTSA Administrator.

[3768] Specifically, a manufacturer shall submit a report containing the information during the 30 days before the beginning of each model year, and during the 30 days beginning the 180th day of the model year. When a manufacturer decides that actions reported are not sufficient to ensure compliance with that standard, the manufacturer shall report additional actions it intends to take to comply with the standard and include a statement about whether those actions are sufficient to ensure compliance.

disclosure to protect each manufacturer's competitive sales strategies. NHTSA uses the reports as the basis for vehicle auditing and testing, which helps manufacturers correct reporting errors prior to the end of the model year and facilitate acceptance of their final CAFE report by the Environmental Protection Agency (EPA). The reports also help the agency, as well as the manufacturers who prepare them, anticipate potential compliance issues as early as possible, and help manufacturers plan their compliance strategies.

Further, NHTSA is modifying this collection to account for additional information manufacturers are required to include in their reports. In the CAFE standards previously promulgated for MY 2017 and beyond,[3769] NHTSA allowed for manufacturers to gain additional fuel economy benefits by installing certain technologies on their vehicles beginning with MY 2017.[3770] These technologies include air-conditioning systems with increased efficiency, off-cycle technologies whose benefits are not adequately captured on the Federal Test Procedure and/or the Highway Fuel Economy Test,[3771] and hybrid electric technologies installed on full-size pickup trucks. Prior to MY 2017, manufacturers were unable to earn a fuel economy benefit for these technologies, so NHTSA's reporting requirements did not include an opportunity to report them. Now, manufacturers must provide information on these technologies in their CAFE reports. NHTSA requires manufacturers to provide detailed information on the model types using these technologies to gain fuel economy benefits. These details are necessary to facilitate NHTSA's technical analyses and to ensure the agency can perform random enforcement audits when necessary.

In addition to a list of all fuel consumption improvement technologies utilized in their fleet, 49 CFR 537 requires manufacturers to report the make, model type, compliance category, and production volume of each vehicle equipped with each technology and the associated fuel consumption improvement value (FCIV). NHTSA is adding the reporting and enforcement burden hours and cost for these new incentives to this collection. Manufacturers can also petition the EPA and NHTSA, in accordance with 40 CFR 86.1868-12 or 40 CFR 86.1869-12, to gain additional credits based upon the improved performance of any of the new incentivized technologies allowed starting in model year 2017. EPA approves these petitions in collaboration with NHTSA and any adjustments are taken into account for both programs. As a part the agencies' coordination, NHTSA provides EPA with an evaluation of each new technology to ensure its direct impact on fuel economy and an assessment on the suitability of each technology for use in increasing a manufacturer's fuel economy performance. Furthermore, at times, NHTSA may independently request additional information from a manufacturer to support its evaluations. This information along with any research conclusions shared with EPA and NHTSA in the petitions is required to be submitted in manufacturer's CAFE reports.

NHTSA is also changing the burden hours for its CAFE reporting requirements in 49 CFR part 537 by adjusting the total amount of time spent collecting the required reporting information through the use of a standardized reporting template to streamline the collection

---

[3769] 77 FR 62623 (Oct. 15, 2012).

[3770] These technologies were not included in the burden for part 537 at the time as the additional reporting requirements would not take effect until years later.

[3771] *E.g.*, engine idle stop-start systems, active transmission warmup systems, etc.

process. The standardized template will be used by manufacturers to collect all the required CAFE information under 49 CFR 537.7(b) and (c) and provides a format which ensures accuracy, completeness, and better alignment with the final data provided to EPA.

2. Other CAFE Compliance Collections

NHTSA is adopting a new standardized template for manufacturers buying CAFE credits and for manufacturers submitting credit transactions in accordance with 49 CFR part 536. In 49 CFR part 536.5(d), NHTSA is required to assess compliance with fuel economy standards each year, utilizing the certified and reported CAFE data provided by the EPA for enforcement of the CAFE program pursuant to 49 U.S.C. 32904(e). Credit values are calculated based on the CAFE data from the EPA. If a manufacturer’s vehicles in a particular compliance category performs better than its required fuel economy standard, NHTSA adds credits to the manufacturer's account for that compliance category. If a manufacturer’s vehicles in a particular compliance category perform worse than the required fuel economy standard, NHTSA will add a credit deficit to the manufacturer’s account and will provide written notification to the manufacturer concerning its failure to comply. The manufacturer will be required to confirm the shortfall and must either: submit a plan indicating how it will allocate existing credits or earn, transfer, and/or acquire credits or pay the equivalent civil penalty. The manufacturer must submit a plan or payment within 60 days of receiving notification from NHTSA.

Manufacturers should use the credit transaction template any time a credit transaction request is sent to NHTSA. For example, manufacturers that purchase credits and want to apply them to their credit accounts will use the credit transaction template. The template NHTSA is adopting is a simple spreadsheet that credit entities fill out. When completed, credit entities will have an organized list of credit transactions and will be able to click a button on the spreadsheet to generate a joint transaction letter for trading parties to sign and submit to NHTSA, along with the spreadsheet. Entities trading credits are also required to provide to NHTSA all the confidential information associated with the monetary and non-monetary price of credit trades. NHTSA believes these changes will significantly reduce the burden on manufacturers in managing their CAFE credit accounts and provide better oversight of the CAFE credit program for NHTSA.

Finally, NHTSA is accounting for the additional burden due to existing CAFE program elements. In 49 CFR part 525, small volume manufacturers submit petitions to NHTSA for exemption from an applicable average fuel economy standard and to request to comply with a less stringent alternative average fuel economy standard. In 49 CFR part 534, manufacturers are required to submit information to NHTSA when establishing a corporate controlled relationship with another manufacturer. A controlled relationship exists between manufacturers that control, are controlled by, or are under common control with, one or more other manufacturers. Accordingly, manufacturers that have entered into written contracts transferring rights and responsibilities to other manufacturers in controlled relationships for CAFE purposes are required to provide reports to NHTSA. There are additional reporting requirements for manufacturers submitting carry back plans and when manufacturers split apart from controlled relationships and must designate how credits are to be allocated between the parties.[3772] Manufacturers with credit deficits at the end of the model year, can carry back future earned credits up to three model years in advance of the deficit to resolve a current shortfall. The carryback plan proving the existence of a manufacturer's future earned credits must be submitted and approved by NHTSA, pursuant to 49 U.S.C. 32903(b).

3. Analysis Fleet Composition

As discussed in Section VI.B, in setting CAFE standards, NHTSA creates an analysis fleet from which to model potential future economy improvements. To compose this fleet, the agency uses a mixture of compliance data and information from other sources to replicate more closely the fleet from a recent model year. While refining the analysis fleet, NHTSA occasionally asks manufacturers for information that is similar to information submitted as part of EPA's final model year report (*e.g.*, final model year vehicle volumes). Periodically, NHTSA may ask manufacturers for more detailed information than what is required for compliance (*e.g.*, what engines are shared across vehicle models). Often, NHTSA requests this information from manufacturers after manufacturers have submitted their final model year reports to EPA, but before EPA processes and releases final model year reports.

Information like this, which is used to verify and supplement the data used to create the analysis fleet, is tremendously valuable to generating an accurate analysis fleet, and setting maximum feasible standards. The more accurate the analysis fleet is, the more accurate the modeling of what technologies could be applied will be. Therefore, NHTSA is accounting for the burden on manufacturers to provide the agency with this additional information. In almost all instances, manufacturers already have the information NHTSA seeks, but it might need to be reformatted or recompiled. Because of this, NHTSA believes the burden to provide this information will often be minimal.

Affected Public: Respondents are manufacturers of engines and vehicles within the North American Industry Classification System (NAICS) and use the coding structure as defined by NAICS including codes 33611, 336111, 336112, 33631, 33631, 33632, 336320, 33635, and 336350 for motor vehicle and parts manufacturing.

Respondent's obligation to respond: Regulated entities are required to respond to inquiries covered by this collection. 49 U.S.C. 32907. 49 CFR part 525, 534, 536, and 537.

Frequency of response: Variable, based on compliance obligation. Please see PRA supporting documentation in the docket for more detailed information.

Average burden time per response: Variable, based on compliance obligation. Please see PRA supporting documentation in the docket for more detailed information.

Number of respondents: 23.

[3772] *See* 49 CFR part 536.

4. Estimated Total Annual Burden Hours and Costs:

Table X-2 – Estimated Burden for Reporting Requirements

	Manufacturer		**Government**	
Applies to:	**Hours**	**Cost**	**Hours**	**Cost**
Prior Collection	3,189.00	$24,573.50	975.00	$31,529.00
Current Collection	4,018.73	$198,885.02	3,038.00	$141,246.78
Difference	829.73	$174,311.52	2,063.00	$109,717.78

O. Privacy Act

In accordance with 5 U.S.C. 553(c), the agencies solicited comments from the public to inform the rulemaking process better. These comments are posted, without edit, to www.regulations.gov, as described in DOT's system of records notice, DOT/ALL-14 FDMS, accessible through www.transportation.gov/privacy. In order to facilitate comment tracking and response, the agencies encouraged commenters to provide their names, or the names of their organizations; however, submission of names is completely optional.
